Edge detection unit - Time difference

Name:
EdgeDetect01Difference
EdgeDetect02Difference

The difference between the master edge and the slave edge of the respective unit is saved to these registers. If multiple measurement periods are completed within a single cycle (task class), then the time difference from the last period is shown.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Time difference between master edge and slave edge [µs]

4.12.2.28.2.3 Counter functions

Fast digital inputs 11 to 14 can be used for counter functions. This function does not use the digital input filter. The following functions are available. Only one of these basic configurations can be enabled at a time:

- 2x event counter with latch function
- 2x AB incremental counter without latch function
- DF counter function
- ABR counter function

Configuring the counter function

The following counter functions can be configured:

Counter function	Description
2x event counter with latch function	Input 11 for event counter 1 and input 13 for event counter 2 can be used simultaneously as event counters. Both rising and falling edges are counted. The latch function of all 4 inputs can be used.
2x AB incremental counter without latch function	Inputs 11 and 12 as AB counter 1 and inputs 13 and 14 as AB counter 2. Since no more fast inputs are available, the latch function is not available.
DF counter: Direction/Frequency with latch function	The D, F and R signals are linked to inputs 11, 12 and 13. Signal D defines the positive (Level = 0) or negative (Level = 1) counting direction. The latch function of all 4 inputs can be used.
ABR counter with latch function	The A, B and R signals are linked to inputs 11, 12 and 13. The latch function of all 4 inputs can be used.

Name:
X2CfO_CounterMode

This register configures the counter function:

Data type	Value	Information
USINT	0	2x event counter with latch function
	1	2x AB incremental counter without latch function
	2	DF counter with latch function
	3	ABR counter with latch function

Configuring the mode of the latch function

Name:
X2CfO_Latch01Mode
X2CfO_Latch02Mode

This register sets the mode of the latch function. The following latch functions can be configured:

Latch function	Description
Single shot latch mode	The latch function must be enabled/set. After a successful latch procedure the function must first be reset. Then it can be enabled again.
Continuous latch mode	The latch function only has to be enabled/set as long as latching is desired.

A changed counter value on "LatchCount" indicates that the latch procedure has been performed (see "Counter value of latch events"). The counter value is stored in the latch register (see "Latched counter value").

Data type	Value	Information
USINT	0	Single shot latch mode
	1	Continuous latch mode

Configuring the latch signals

Name:
X2CfO_Latch01Comparator
X2CfO_Latch02Comparator

This register defines the inputs and their level for triggering the latch procedure.

- This defines which inputs are linked to generate the latch event. All 4 digital input signals can be used for an "AND" connection.
- The "active voltage level" needed for the latch procedure can be defined to adjust for the physical signals. It is not possible to configure a high and low level at the same time.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Value	Information
0	0	Input 11 high level disabled
	1	Input 11 high level enabled for comparator
1	0	Input 12 high level disabled
	1	Input 12 high level enabled for comparator
2	0	Input 13 high level disabled
	1	Input 13 high level enabled for comparator
3	0	Input 14 high level disabled
	1	Input 14 high level enabled for comparator
4	0	Input 11 low level disabled
	1	Input 11 low level enabled for comparator
5	0	Input 12 low level disabled
	1	Input 12 low level enabled for comparator
6	0	Input 13 low level disabled
	1	Input 13 low level enabled for comparator
7	0	Input 14 low level disabled
	1	Input 14 low level enabled for comparator

Clear counter value and enable/disable latch function

Name:
Counter01Reset
Counter02Reset
Latch01Enable
Latch02Enable

The respective bits in these registers clear the counter value or start the latch procedure.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Counter0xReset	0	Do not reset the counter
		1	Reset the counter
1	Latch0xEnable	0	Do not latch the counter
		1	Latch the counter
2 - 7	Reserved	0	

Counter value

Name:
Counter01Value
Counter02Value

The current counter values are saved in these registers.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Current counter value

Latched counter value

Name:
Counter01Latch
Counter02Latch

As soon as the latch conditions have been met, the value of the respective counter is copied to these registers.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Latched counter value

Counter value of latch events

Name:
Latch01Count
Latch02Count

These registers hold the counter values of the latch events. This allows detection of whether a new latched counter value has been saved.

Data type	Value	Information
DINT	-128 to 127	Running counter: Number of detected latch events

Timestamp of last counter change

Name:
Counter01TimeChanged
Counter02TimeChanged

The CPU system time at the time of the last change to the counter value is saved in these registers.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	The CPU system time at the time of the last change to the counter value

Timestamp of last valid counter value

Name:
Counter01TimeValid
Counter02TimeValid

The CPU system time at the time of the last valid counter value is saved in these registers.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	CPU system time of current counter value

4.12.2.28.3.1 Physical configuration of I/O channels

These registers are used to define the functionality of the channels. Depending on the desired configuration, the following assignments can be made with respect to the existing software and hardware:

- A physical configuration as input or output for mixed channels
- An explicit assignment as direct I/O channel: i.e. digital input or digital output
- An explicit assignment as PWM output
- An explicit assignment as D or F movement output

Physical configuration

Name:
X3CfO_PhyIOConfigCh01 to X3CfO_PhyIOConfigCh12

These registers are used to configure the functionality of the channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Name:
X3CfO_PhyIOConfigCh01 to X3CfO_PhyIOConfigCh04

Channels 1 to 4 are digital outputs and can only be used as direct I/O channel.

Bit	Description	Value	Information
0 - 7		0	Direct I/O operation of output

Name:
X3CfO_PhyIOConfigCh05 to X3CfO_PhyIOConfigCh08

Channels 5 to 8 are digital mixed channels and can be configured as either input or output.

Bit	Description	Value	Information
0 - 1		00	Configured as digital output
		01	Reserved
		10	Reserved
		11	Configured as digital input
2 - 7		0	Direct I/O operation of output

Name:
X3CfO_PhyIOConfigCh09 to X3CfO_PhyIOConfigCh12

Channels 9 to 12 are fast digital outputs and can be configured as direct I/O, PWM or movement channels.

Bit	Description	Value	Information
0 - 3	Reserved	0	
4 - 5		00	Direct I/O operation of output
		01	Output operated as PWM
		10	Reserved
		11	Output operated as D/F movement
6 - 7	Reserved	0	

4.12.2.28.3.2 Monitoring of the I/O supply voltage

Name:
StatusInput01

The status of the I/O supply voltage is shown in this register.

Data type	Value	Information
USINT	0	I/O supply voltage within permitted range
	1	I/O supply voltage not connected or outside of the permitted range

4.12.2.28.3.3 Digital inputs

Unfiltered

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:
X3CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

Data type	Value	Filter
USINT	0	No SW filter
	1	0.1 ms
	...	...
	250	25 ms - Higher values are limited to this value

Input state of digital inputs 5 to 8

Name:
DigitalInput05 to DigitalInput08

This register is used to indicate the input state of digital inputs 5 to 8.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput05	0 or 1	Input status of digital input 5
...		...	
3	DigitalInput08	0 or 1	Input status of digital input 8

4.12.2.28.3.4 Digital outputs

The output status is processed in a 100 µs cycle.

Switching state of digital outputs 1 to 12

Name:
DigitalOutput01 to DigitalOutput12

These registers are used to store the switching state of digital outputs 1 to 12.

Data type	Value
USINT	See bit structure.

Bit structure:

Register 8208:

Bit	Description	Value	Information
0	DigitalOutput01	0	Digital output 1 reset
		1	Digital output 1 set
...		...	
7	DigitalOutput08	0	Digital output 8 reset
		1	Digital output 8 set

Register 8209:

Bit	Description	Value	Information
0	DigitalOutput09	0	Digital output 9 reset
		1	Digital output 9 set
...		...	
3	DigitalOutput12	0	Digital output 12 reset
		1	Digital output 12 set

4.12.2.28.3.5 Monitoring status of the digital outputs

The error states of the outputs must be programmed in the application. The status information that is read is the actual voltage state on the channel (set or reset). The error state is therefore determined by a difference between the data points "DigitalOutputxx" and the corresponding "StatusDigitalOutputxx".

At least 3 system ticks are needed internally to read the output status. This is the reason for the delay after which the earliest possible comparison can be made after a change in the status of the output.

The digital input filter is not applied to this status information.

Status of digital outputs 1 to 12

Name:
StatusDigitalOutput01 to StatusDigitalOutput12

These registers are used to indicate the status of digital outputs 1 to 12.

Data type	Value
USINT	See bit structure.

Bit structure:

Register 8193:

Bit	Description	Value	Information
0	StatusDigitalOutput01	0	Channel 1: Digital output reset or short circuit
		1	Channel 1: Digital output set or voltage feedback
...		...	
7	StatusDigitalOutput08	0	Channel 8: Digital output reset or short circuit
		1	Channel 8: Digital output set or voltage feedback

Register 8194:

Bit	Description	Value	Information
0	StatusDigitalOutput09	0	Channel 9: Digital output reset or short circuit
		1	Channel 9: Digital output set or voltage feedback
...		...	
3	StatusDigitalOutput12	0	Channel 12: Digital output reset or short circuit
		1	Channel 12: Digital output set or voltage feedback

4.12.2.28.3.6 Pulse width modulation (PWM) function

Digital inputs 9 to 12 can be configured as PWM outputs. Two data points are available per channel for controlling the PWM signal.

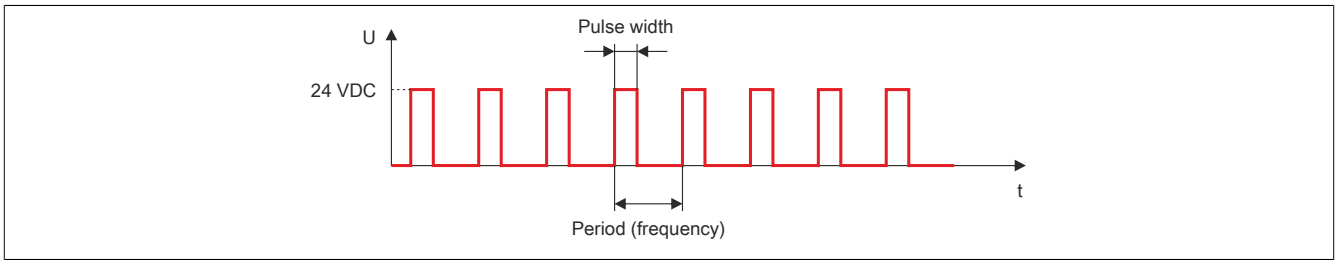

Figure 227: The PWM signal is controlled by setting the pulse width and the duration of the period

Period duration of the PWM outputs

Name:
PWMPeriod09 to PWMPeriod12

These registers are used to define the duration of the period, i.e. the time base for the respective PWM output. This time represents the 100% value, which can be resolved to 0.1% through the duty cycle.

Data type	Value	Information
UINT	5 to 65,535	Duration of period, between 5 and 65535 µs: Corresponds to a frequency of 200 kHz to ≈15 Hz

Duty cycle of the PWM outputs

Name:
PWMOutput09 to PWMOutput12

These registers output the duty cycle of the respective PWM output in a resolution of 0.1% of the period.

Data type	Value	Information
INT	0 to 1000	Duty cycle of the output in 0 to 100.0%

Example: Period duration T [µs] with a duty cycle of 25% equals a duty time of t_1 [µs].

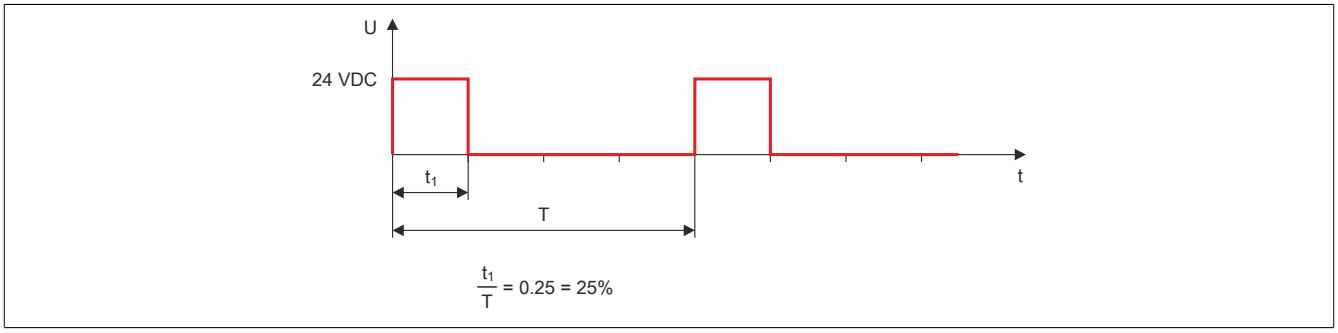

Figure 228: Duty time as a function of the period and the duty cycle

4.12.2.28.3.7 DF movement generator function

Digital output channels 9 to 12 can be configured as 2 independently functioning movement generators (Direction/Frequency) for stepper motor control. The movement generators are assigned to the following channels:

Movement generator	Channel	Function
1	DO 9	D: Direction
	DO 10	F: Frequency
2	DO 11	D: Direction
	DO 12	F: Frequency

The frequency is output via the respective F channel, and the direction is output via the respective D channel. The switchover between directions (movement/counter) takes place via the sign of the speed setpoint.

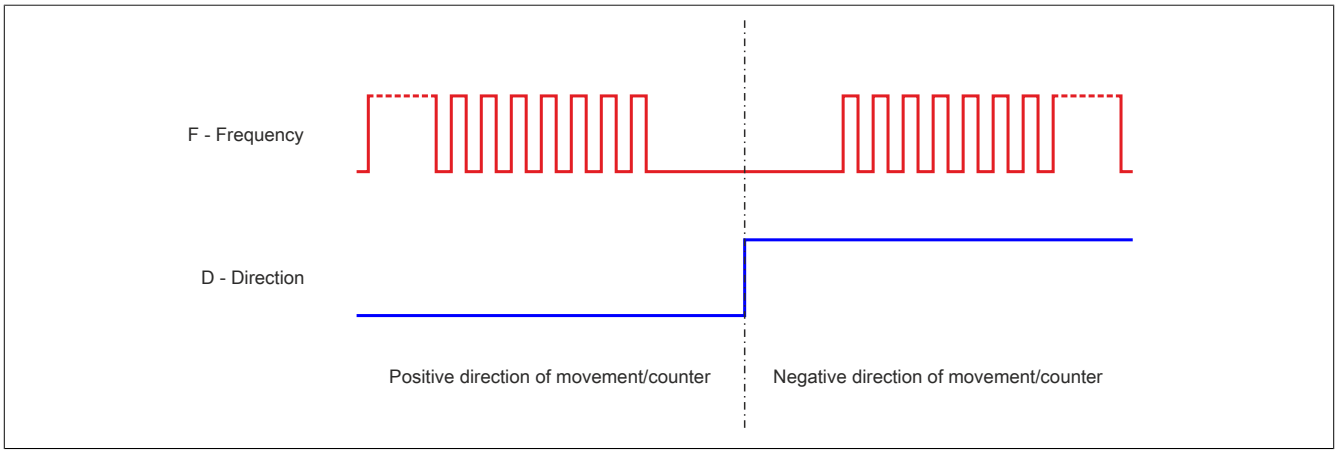

Figure 229: Frequency output via F channel, direction output via D channel

The respective output must be configured correctly in order to completely process the movement function (see "Physical configuration").

The data points described below are available for configuring and controlling the respective movements.

Configuring the movement mode

Name:
X3Cfo_Mov01Mode
X3Cfo_Mov02Mode

These registers are used to configure how the speed setpoint is interpreted. The difference between the two modes is whether edges or periods are output for each increment of the setpoint.

Data type	Value	Information
USINT	0	Edge mode: Each increment generates an edge on the output
	1	Pulse mode: Each increment generates a period on the output

Edge mode

4 increments of the speed setpoint correspond to 2 periods on the output:

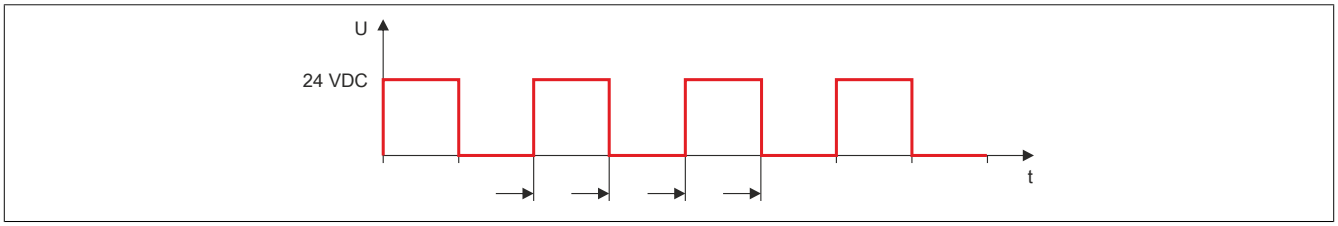

Figure 230: Interpretation of the speed setpoint with edge output for each increment

Pulse mode

2 increments of the speed setpoint correspond to 2 periods on the output:

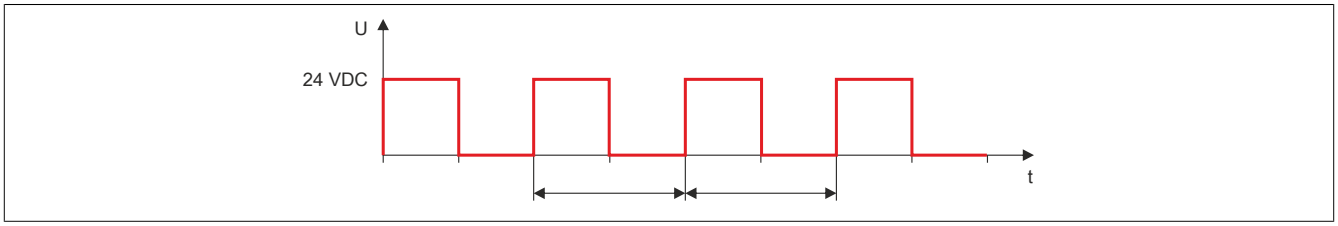

Figure 231: Interpretation of the speed setpoint with period output for each increment

Configuring the maximum speed of the movement

The maximum speed or output frequency of the movement is configured in order to protect the digital output, the actuator/drive being controlled and/or the mechanical system.

Name:
X3Cfo_Mov01SpeedLimit
X3Cfo_Mov02SpeedLimit

These registers are used to configure the maximum speed / output frequency permitted in the system. It is important that the limit values for edge and pulse mode are different.

Edge mode

Data type	Value	Information
UDINT	10 to 400,000	Speed [increments per second]

Pulse mode

Data type	Value	Information
UDINT	5 to 200,000	Speed [increments per second]

Activates the movement

When a movement is active, the two channels are operated according to the preset values.

Name:
Mov01Enable
Mov02Enable

These registers are used to enable or disable the movement function.

Mov01Enable

Data type	Value	Information
USINT	0	Movement 1 disabled
	2	Movement 1 enabled: The speed setpoint is evaluated

Mov02Enable

Data type	Value	Information
USINT	0	Movement 2 disabled
	4	Movement 2 enabled: The speed setpoint is evaluated

Speed and direction control of the movement

The following parameters are important for speed and direction control of the movement:

Characteristic value	Description
Speed control	The joint axes receive this speed setpoint from the standard application. 0 to ±32767 correspond to 0 to ±100% of the configured maximum speed
Direction control	The direction of movement is defined by the sign of the speed setpoint: 0 to +32767 correspond to 0 to the maximum speed in the positive direction of movement 0 to -32767 correspond to 0 to the maximum speed in the negative direction of movement
Resolution of the speed setpoint	The resolution of the speed setpoint is: Maximum speed / 32767
Relationship: Speed / Frequency	The relationship between speed and output frequency is: (Speed setpoint / Maximum speed) * 32767 
Table 224: Parameters for speed and direction control of the movement

Name:
Mov01Speed
Mov02Speed

These registers are used to set the speed of the movement.

Data type	Value	Information
INT	0 to 32,767	Speed setpoint 0 to 100%: Movement output F = 0 to maximum speed
		Positive direction of movement: Movement output D = 0
	0 to -32,767	Speed setpoint 0 to 100%: Movement output F = 0 to maximum speed
		Negative direction of movement: Movement output D = 1

Position feedback for movement

The position feedback is represented by a fixed point value [16.16]:

- HighWord = whole number increments
- LowWord = positions after the decimal of the increments

Name:
Mov01Position
Mov02Position

These registers show the current position of the movement.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Position value in fixed point format [16.16]

4.12.3 X20CP1483 and X20CP1483-1

4.12.3.1 General information

The x86 100 MHz-compatible X20CP1483 is the entry-level X20 CPU. With an optimal price/performance ratio, it has the same basic features as the larger CPUs and offers sufficient performance for most standard applications.

USB and Ethernet are included in every CPU. In addition, every CPU has a POWERLINK connection for real-time communication.
In addition, a multi-purpose slot is provided for an additional interface module.

- Intel x86 100 MHz-compatible with additional I/O processor
- Ethernet, POWERLINK V1/V2 and USB onboard
- Modular expansion of interfaces
- CompactFlash as removable application memory
- Fanless
- Extremely compact

4.12.3.2 Order data - X20CP148x

Model number	Short description
	X20 CPUs
X20CP1483	X20 CPU, x86 100 MHz Intel compatible, 32 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1483-1	X20 CPU, x86 100 MHz Intel compatible, 64 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
	Required accessories
	CompactFlash cards
0CFCRD.0128E.01	CompactFlash 128 MB WD extended temp.
0CFCRD.0512E.01	CompactFlash 512 MB WD extended temp.
5CFCRD.016G-06	CompactFlash 16 GB B&R (SLC)
5CFCRD.0512-06	CompactFlash 512 MB B&R (SLC)
5CFCRD.1024-06	CompactFlash 1 GB B&R (SLC)
5CFCRD.2048-06	CompactFlash 2 GB B&R (SLC)

Note	Order application memory (CompactFlash) separately Backup battery included in delivery X20 locking plate (right) included in delivery X20 terminal block (12-pin) included in delivery Interface module slot covers included in delivery	
Dimensions		
Width	150 mm	
Height	99 mm	
Depth	85 mm	
Weight	300 g	

Table 227: X20CP1483, X20CP1483-1 - Technical data

1) The specified values are maximum values. The exact calculation is included as a data sheet in the module documentation and can be downloaded from the B&R website.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) When operated at temperatures above 55°C, a derating of the nominal output power to 5 W for the X2X Link supply must be taken into consideration.
4) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.
5) Can be configured in Automation Studio.
6) Minus configured remanent variables.
7) See the POWERLINK help system under "General information, Hardware - IF/LS".

4.12.3.4 X20 CPUs - Status LEDs

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
			Blinking	Boot mode system start: CPU initializing the application, all bus systems and I/O modules[1)]
		Red	On	SERVICE mode
			Blinking	The "R/E" LED blinks red and the "RDY/F" LED blinks yellow when there is a license violation.
			Double flash	BOOT mode (during firmware update)[1)]
	RDY/F	Yellow	On	SERVICE or BOOT mode
			Blinking	The "RDY/F" LED blinks yellow and the "R/E" LED blinks red when there is a license violation.
	S/E	Green/Red		Status/Error LED. The statuses of this LED are described in section 4.12.3.4.1 ""S/E" LED".
	PLK	Green	On	A link to the POWERLINK peer station has been established.
			Blinking	A link to the POWERLINK peer station has been established. The LED blinks when Ethernet activity is taking place on the bus.
	ETH	Green	On	A link to the peer station has been established.
			Blinking	A link to the peer station has been established. Indicates Ethernet activity is taking place on the bus.
	CF	Green	On	CompactFlash inserted and detected
		Yellow	On	CompactFlash read/write access
	DC	Yellow	On	CPU power supply OK
		Red	On	Backup battery empty

1) The process can take several minutes depending on the configuration.

4.12.3.4.1 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.12.3.4.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 228: Status/Error LED - Ethernet operating mode

4.12.3.4.1.2 POWERLINK V1

Status LED		Status of the POWERLINK node
Green	Red	
On	Off	The POWERLINK node is running with no errors.
Off	On	A system error has occurred. The error type can be read using the PLC logbook. An irreparable problem has occurred. The system cannot properly carry out its tasks. This state can only be changed by resetting the module.
Blinking alternately		The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the configured node number lies within the range 0x01 - 0xFD.
Off	Blinking	System failure. The red blinking LED signals an error code (see section 4.12.2.4.2 "System failure error codes").
Off	Off	Module is: • Off • Starting up • Not configured correctly in Automation Studio • Defective

Table 229: Status/Error LED - POWERLINK V1 operating mode

4.12.3.4.1.3 POWERLINK V2

Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 230: Status/Error LED as Error LED - POWERLINK operating mode

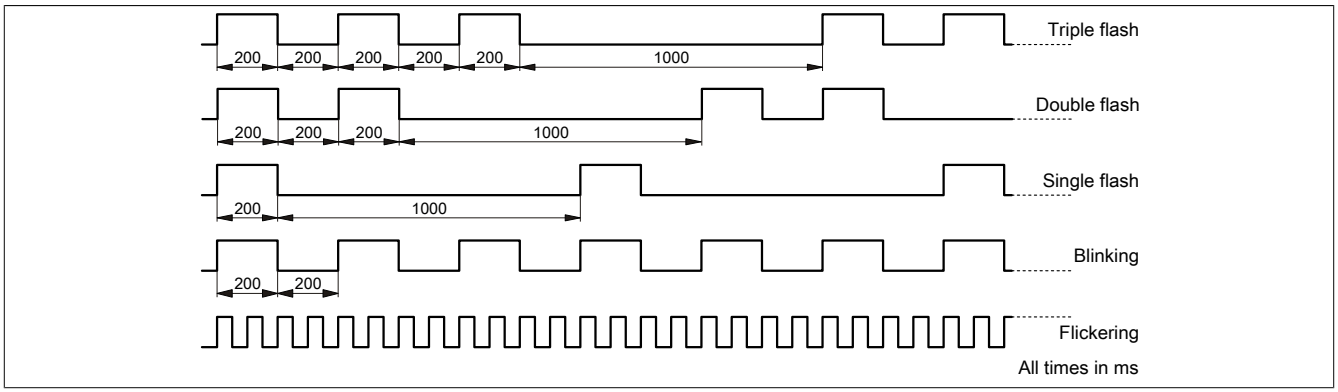
Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.

Table 231: Status/Error LED as Status LED - POWERLINK operating mode

Green - Status	Description
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 231: Status/Error LED as Status LED - POWERLINK operating mode

Status LEDs - Blinking patterns



4.12.3.4.2 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	●	●	●	-	Pause	●	●	●	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	●	●	-	Pause	-	●	●	-	Pause

Table 232: Status/Error ("S/E") LED - System failure error codes

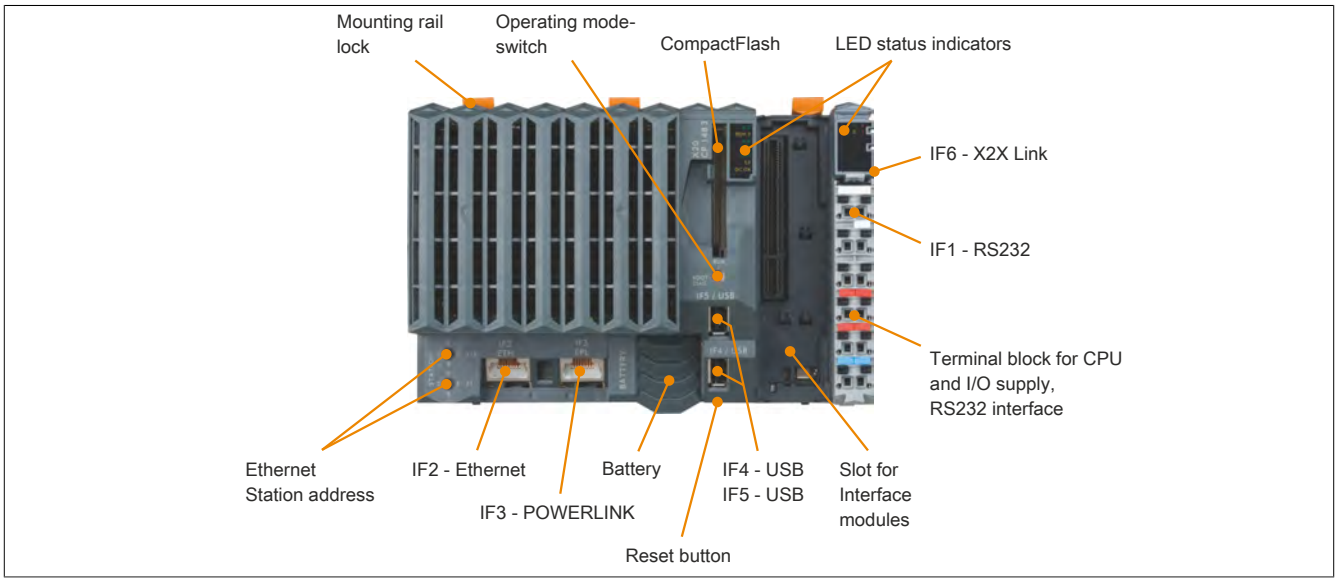
Key:
- ● ... 150 ms
- \- ... 600 ms
- Pause ... 2 second delay

4.12.3.5 LED status indicators for the integrated power supply

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	S	Yellow	Off	No RS232 activity
			On	The LED lights up when data is being sent or received via the RS232 interface.
	I	Red	Off	The X2X Link supply is within the valid limits
			On	The X2X Link supply for the power supply is overloaded

4.12.3.6 Operating and connection elements



4.12.3.7 Slot for application memory

These CPUs require application memory in order to operate. The application memory is provided in the form of a CompactFlash card. It is not included with the CPUs, but must be ordered separately as an accessory.

Information:

The CompactFlash card must not be removed during operation.

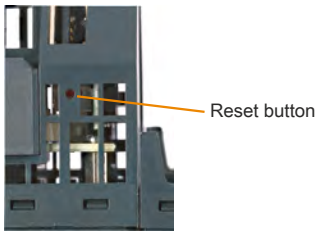
4.12.3.8 Operating mode switch

The operating mode switch is used to set the operating mode.

Switch position	Operating mode	Description
BOOT	BOOT	When the switch is in this position, the default B&R Automation Runtime (AR) system is started and the runtime system can be installed via the online interface (B&R Automation Studio). User flash memory is deleted only after the download begins.
RUN	RUN	RUN mode
DIAG	DIAGNOSE	Boots the CPU in diagnostic mode. Program sections in User RAM and User FlashPROM are not initialized. After diagnostic mode, the CPU always boots with a cold restart.

Table 233: X20 CPUs - Operating modes

4.12.3.9 Reset button



The reset button is located below the USB interfaces on the bottom of the housing. It can be pressed with any small pointed object (e.g. paper clip). Pressing the reset button triggers a hardware reset, which means:

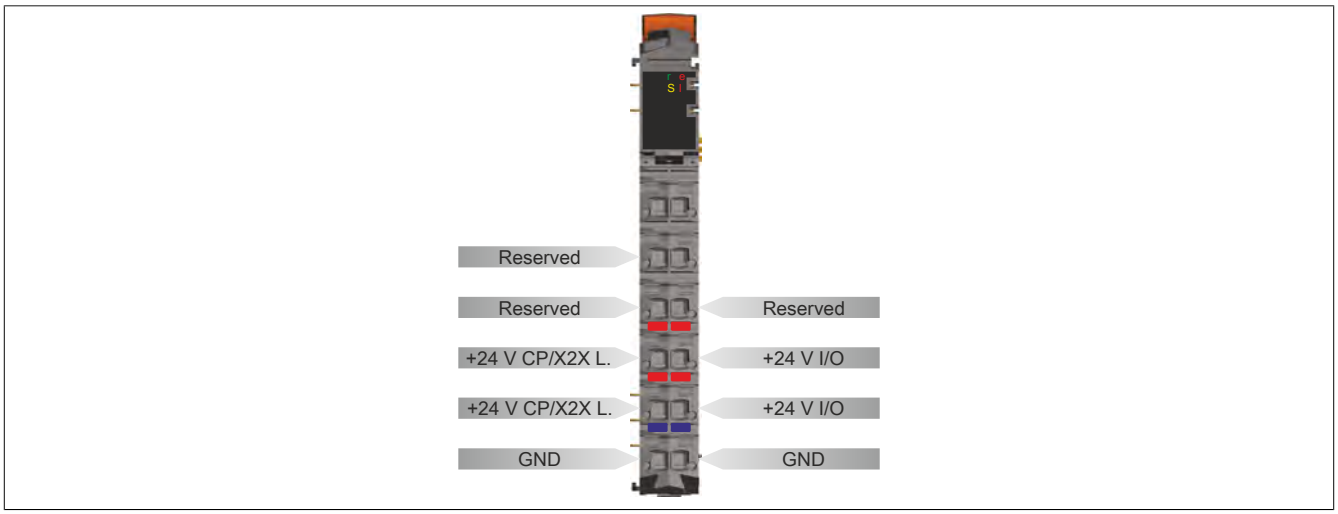
- All application programs are stopped.
- All outputs are set to zero.

The PLC then boots into Service mode by default. The boot mode that follows after pressing the reset button can be defined in Automation Studio.

4.12.3.10 CPU supply

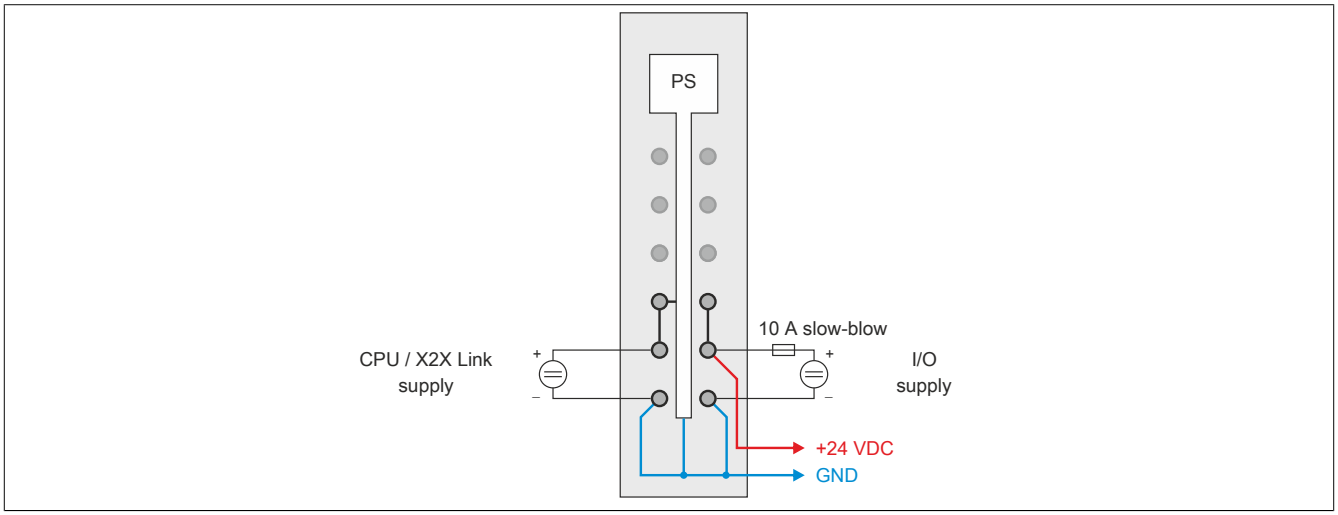
A power supply is integrated in the X20 CPUs. It has a feed for the CPU, the X2X Link and the internal I/O supply. Supply for the CPU and X2X Link is electrically isolated.

Pinout of the integrated power supply

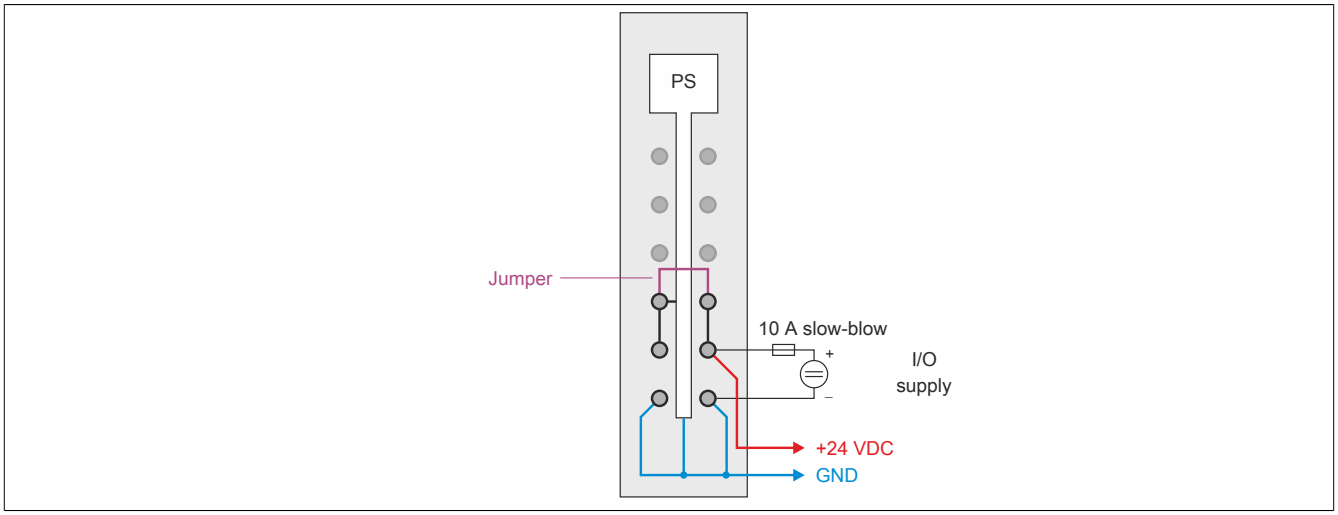


Connection examples

Connection example with 2 separate supplies

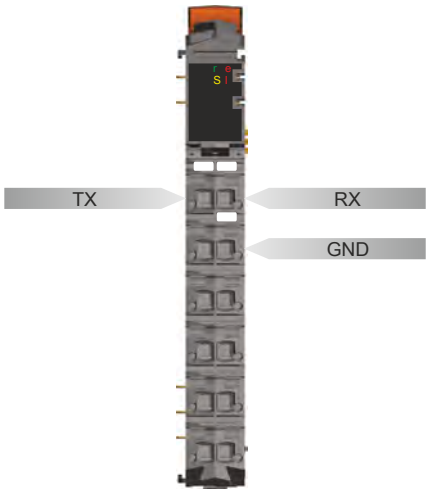


Connection example with a supply and jumper



4.12.3.11 RS232 interface (IF1)

The non-electrically isolated RS232 interface is primarily intended to serve as an online interface for communication with the programming device.



4.12.3.12 Ethernet interface (IF2)

The IF2 is executed as the10 BASE-T / 100 BASE-TX interface.

The INA2000 station number of the Ethernet interface is set using the two hex switches.

Information about cabling X20 modules with an Ethernet interface can be found on the B&R website in the module's download section at www.br-automation.com.

Information:

The Ethernet interface (IF2) is not suited for POWERLINK (see 4.12.3.13 "POWERLINK interface (IF3)").

Pinout

Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	TXD	Transmit data
	2	TXD\	Transmit data\
	3	RXD	Receive data
	4	Termination	
	5	Termination	
	6	RXD\	Receive data\
	7	Termination	
	8	Termination	

4.12.3.13 POWERLINK interface (IF3)

POWERLINK V1

Switch position	Description
0x00	Operation as managing node.
0x01 - 0xFD	Node number of the POWERLINK node. Operation as controlled node.
0xFE - 0xFF	Reserved, switch position not permitted

Table 234: POWERLINK V1 - Node numbers

POWERLINK V2

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as a controlled node.
0xF0	Operation as a managing node.
0xF1 - 0xFF	Reserved, switch position not permitted

Table 235: POWERLINK node number

Ethernet mode

Starting with Automation Studio Version V2.5.3 and with Automation Runtime V2.90, the interface can be operated as an Ethernet interface.

The INA2000 station number can be set using the B&R Automation Studio software.

Pinout

Information about cabling X20 modules with an Ethernet interface can be found on the B&R website in the module's download section at www.br-automation.com.

Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.12.3.14 USB interfaces (IF4 and IF5)

IF4 and IF5 are USB interfaces. The connection is made using a USB 1.1 interface.

The USB interfaces can only be used for devices approved by B&R (e.g. floppy disk drive, DiskOnKey or dongle).

Information:

USB interfaces cannot be used for online communication with a programming device.

4.12.3.15 Slots for interface modules

The CPUs have one or three slots for interface modules.

Various bus and network systems can easily be integrated into the X20 system by selecting the corresponding interface module.

4.12.3.16 Overtemperature cutoff

To prevent damage, a shut-off/reset is triggered on the CPU when the processor reaches 100°C.

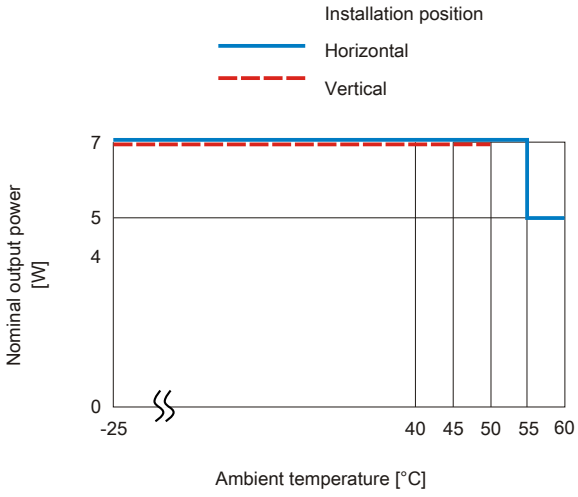
The following errors are entered in the logbook:

Error number	Error description
9204	WARNING: System halted because of temperature check
9210	WARNING: Boot by watchdog or manual reset

Table 236: X20 CPUs - Logbook entries after overtemperature cutoff

4.12.3.17 Derating

There is no derating when operated below 55°C. Above 55°C, the nominal output power for the X2X Link supply must be reduced to 5 W.



4.12.3.18 Data / Real-time clock buffering

The CPUs are buffered by a backup battery. The following areas are buffered:

- Remanent variables
- User RAM
- System RAM
- Real-time clock

Battery monitoring

The battery voltage is checked cyclically. The cyclic load test of the battery does not considerably shorten the battery life, instead it gives an early warning of weakened buffer capacity.

The status information "Battery OK" is available from the system library function "BatteryInfo" and the CPU's I/O mapping.

Replacement interval for battery

The battery should be replaced every 4 years. The replacement intervals recommended by B&R reflect the batteries' average service life and operating conditions. It does not represent the maximum buffer duration.

4.12.3.19 Exchanging the lithium battery

The CPUs have a lithium battery. The lithium battery is found in a separate compartment on the bottom of the module and protected by a cover.

Backup battery data

Model number 4A0006.00-000 0AC201.91	 1 pcs. 4 pcs.
Short description	Lithium battery, 3 V / 950 mAh, button cell
Storage temperature	-20 to 60°C
Storage time	Max. 3 years at 30°C
Relative humidity	0 to 95%, non-condensing

Table 237: X20 CPUs - Backup battery data

Important information about the battery exchange

The product design allows the battery to be changed with the PLC switched either on or off. In some countries, safety regulations do not allow batteries to be changed while the module is switched on. To prevent data loss, the battery must be changed within 1 min. with the power off.

Warning!

The battery must be replaced by a Typ CR2477N Renata battery only. The use of another battery may present a risk of fire or explosion.

The battery may explode if handled improperly. Do not recharge, disassemble or dispose of in fire.

Procedure for exreplacing the battery

1. Touch the mounting rail or ground connection (not the power supply!) in order to discharge any electrostatic charge from your body.
2. Remove the cover for the lithium battery. Do this by sliding it down and away from the CPU.

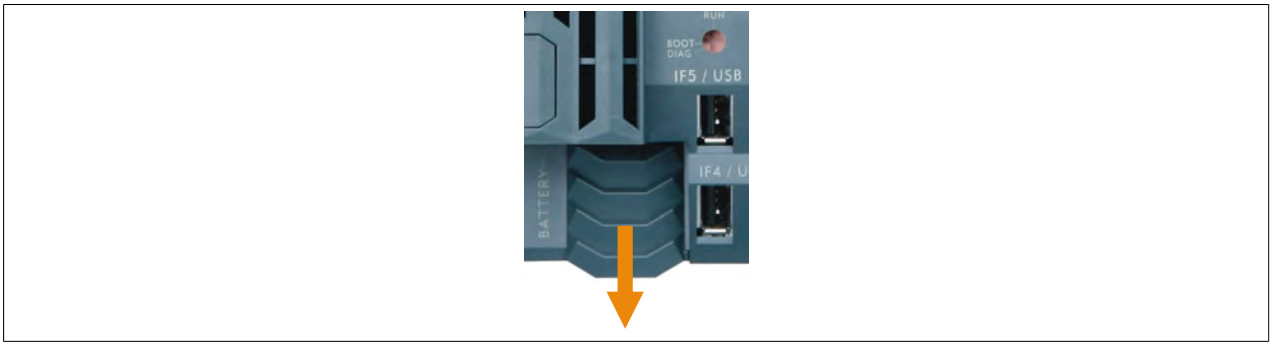


Figure 232: X20 CPUs - Remove lithium battery cover

3. Remove the battery from the holder (do not use pliers or uninsulated tweezers -> risk of short circuiting). The battery should not be held by its edges. **Insulated** tweezers may also be used to remove the battery.

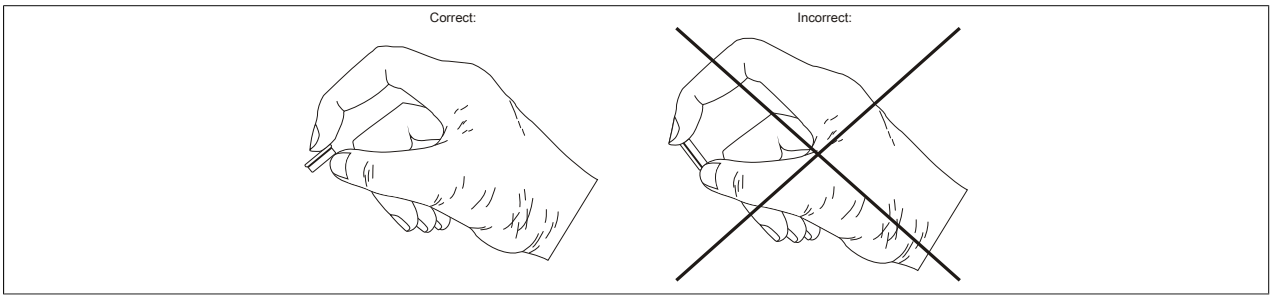

Figure 233: X20 CPUs - Correct grip for the battery

4. Insert the new battery with the correct polarity. To do this, lay the battery with the "+" side up on the right part of the battery holder under the USB interface IF4. Then secure the battery in the holder by pressing above the left part of the battery holder.
5. Replace the cover.

Information:

Lithium batteries are considered hazardous waste. Used batteries should be disposed of in accordance with applicable local regulations.

4.12.3.20 Programming the system flash memory

General information

In order for the application project to be executed on the CPU, the Automation Runtime operating system, the system components and the application project must be installed on the CompactFlash card.

Creating a CompactFlash using a USB card reader

The easiest way to perform an initial installation is by creating a fully programmed CompactFlash card using a USB card reader.

1. Creating and configuring a project in Automation Studio
2. In Automation Studio, select **Tools / Create CompactFlash**
3. In the dialog box that opens, select a CompactFlash card and then generate it
4. Insert the finished CompactFlash into the CPU and turn on the CPU's supply voltage
5. CPU booting

For details about commissioning: See help system under "Automation Software / Getting Started"

Installation over an online connection

The CPUs are delivered with a default B&R Automation Runtime system (with limited functions) already installed. This runtime system is started in Boot mode (operating mode switch in the BOOT position or no CompactFlash / invalid CompactFlash inserted). It initializes the Ethernet interface and onboard serial RS232 interface, making it possible to download a new runtime system.

1. Insert the CompactFlash card and switch on the power to the CPU. When the switch is in the BOOT position, a new or invalid CompactFlash card starts the CPU with the default B&R Automation Runtime system.
2. Establish a physical online connection between the programming device (PC or industrial PC) and the CPU (e.g. over an Ethernet network or the RS232 interface).
3. Before you can establish an online connection via Ethernet, the CPU must be assigned an IP address. In Automation Studio, select **Settings** from the Online menu and then click on the **Browse targets** button to search for B&R target systems on the local network. The CPU should appear in the list. If the CPU has not already received an IP address from a DHCP server, right-click on it and select **Set IP parameters** from the shortcut menu. All necessary network configurations can be made on a temporary basis in this dialog box (should be identical to the settings defined in the project).
4. Configure online connection in B&R Automation Studio. For details about the configuration: See help system under "Automation Software / Communication / Online communication"
5. Start the download procedure by selecting the **Services** command from the **Project** menu. Then select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions provided by B&R Automation Studio.

4.12.4 X20(c)CP158x and X20(c)CP358x

4.12.4.1 General information

Based on state-of-the-art Intel® ATOM™ processor technology, X20 CPUs cover a wide spectrum of requirements. They can be implemented in solutions ranging from standard applications to those requiring the highest levels of performance.

The series starts with Intel® ATOM™ processor 333 MHz compatible models – X20CP1583 and X20CP3583. With an optimum price/performance ratio, it has the same basic features as all of the larger CPUs.

The basic model includes USB, Ethernet, POWERLINK V1/V2 and replaceable CompactFlash card. The standard Ethernet interface is capable of handling communication in the gigabit range. For improved real-time network performance, the onboard POWERLINK interface supports poll response chaining mode (PRC).
In addition, there are up to three multi-purpose slots for additional interface modules.

- Intel® ATOM™ 1600/1000/600 Performance with integrated I/O processor
- Entry-level CPU is Intel® ATOM™ 333 MHz-compatible with integrated I/O processor
- Ethernet, POWERLINK V1/V2 with poll response chaining and onboard USB
- 1 or 3 slots for modular interface expansion
- CompactFlash as removable application memory
- Up to 512 MB DDR2-SRAM according to performance requirements
- CPU redundancy possible
- Fanless
- Extremely compact

4.12.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.12.4.3 Order data - X20CP158x

Model number	Short description
	X20 CPUs
X20CP1583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1584	X20 CPU, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP1584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1585	X20 CPU, ATOM 1.0 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP1586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
	Required accessories
	CompactFlash cards
0CFCRD.0128E.01	CompactFlash 128 MB WD extended temp.
0CFCRD.0512E.01	CompactFlash 512 MB WD extended temp.
5CFCRD.016G-06	CompactFlash 16 GB B&R (SLC)
5CFCRD.0512-06	CompactFlash 512 MB B&R (SLC)
5CFCRD.1024-06	CompactFlash 1 GB B&R (SLC)
5CFCRD.2048-06	CompactFlash 2 GB B&R (SLC)

Table 240: X20CP1583, X20CP1584, X20cCP1584, X20CP1585, X20CP1586, X20cCP1586 - Technical data

1) The specified values are maximum values. The exact calculation is included as a data sheet in the module documentation and can be downloaded from the B&R website.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) When operated at temperatures above 55°C, a derating of the rated output current to 5 W for the X2X Link supply must be taken into consideration.
4) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operating in parallel are switched on and off at the same time.
5) Can be configured in Automation Studio.
6) 1 MB SRAM minus the configured remanent variables.
7) See the POWERLINK online help documentation under "Communication, POWERLINK, General information, Hardware - IF/LS".

4.12.4.5 Order data - X20CP358x

Model number	Short description
	X20 CPUs
X20CP3583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3584	X20 CPU, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20cCP3584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3585	X20 CPU, ATOM 1.0 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CP3586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20cCP3586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.

4.12.4.7 X20 CPUs - Status LEDs

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
			Blinking	Boot mode system start: CPU initializing the application, all bus systems and I/O modules[1)]
		Red	On	SERVICE mode
			Blinking	The "R/E" LED blinks red and the "RDY/F" LED blinks yellow when there is a license violation.
			Double flash	BOOT mode (during firmware update)[1)]
	RDY/F	Yellow	On	SERVICE or BOOT mode
			Blinking	The "RDY/F" LED blinks yellow and the "R/E" LED blinks red when there is a license violation.
	S/E	Green/Red		Status/Error LED. The statuses of this LED are described in section 4.12.3.4.1 ""S/E" LED".
	PLK	Green	On	A link to the POWERLINK peer station has been established.
			Blinking	A link to the POWERLINK peer station has been established. The LED blinks when Ethernet activity is taking place on the bus.
	ETH	Green	On	A link to the peer station has been established.
			Blinking	A link to the peer station has been established. Indicates Ethernet activity is taking place on the bus.
	CF	Green	On	CompactFlash inserted and detected
		Yellow	On	CompactFlash read/write access
	DC	Yellow	On	CPU power supply OK
		Red	On	Backup battery empty

1) The process can take several minutes depending on the configuration.

4.12.4.7.1 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.12.4.7.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 244: Status/Error LED - Ethernet operating mode

4.12.4.7.1.2 POWERLINK V1

Status LED		Status of the POWERLINK node
Green	Red	
On	Off	The POWERLINK node is running with no errors.
Off	On	A system error has occurred. The error type can be read using the PLC logbook. An irreparable problem has occurred. The system cannot properly carry out its tasks. This state can only be changed by resetting the module.
Blinking alternately		The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the configured node number lies within the range 0x01 - 0xFD.
Off	Blinking	System failure. The red blinking LED signals an error code (see section 4.12.2.4.2 "System failure error codes").
Off	Off	Module is: • Off • Starting up • Not configured correctly in Automation Studio • Defective

Table 245: Status/Error LED - POWERLINK V1 operating mode

4.12.4.7.1.3 POWERLINK V2

Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 246: Status/Error LED as Error LED - POWERLINK operating mode

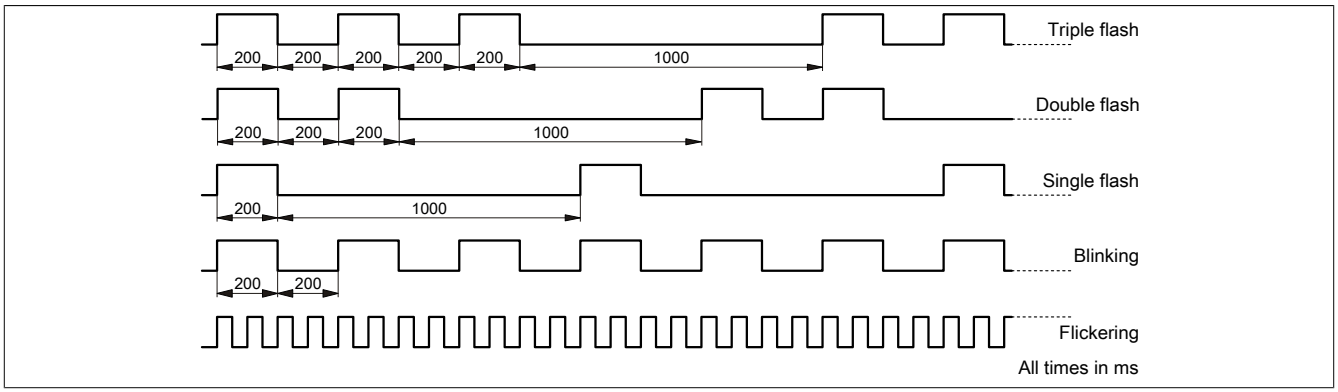
Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.

Table 247: Status/Error LED as Status LED - POWERLINK operating mode

Green - Status	Description
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 247: Status/Error LED as Status LED - POWERLINK operating mode

Status LEDs - Blinking patterns



4.12.4.7.2 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	●	●	●	-	Pause	●	●	●	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	●	●	-	Pause	-	●	●	-	Pause

Table 248: Status/Error ("S/E") LED - System failure error codes

Key:
- ● ... 150 ms
- \- ... 600 ms
- Pause ... 2 second delay

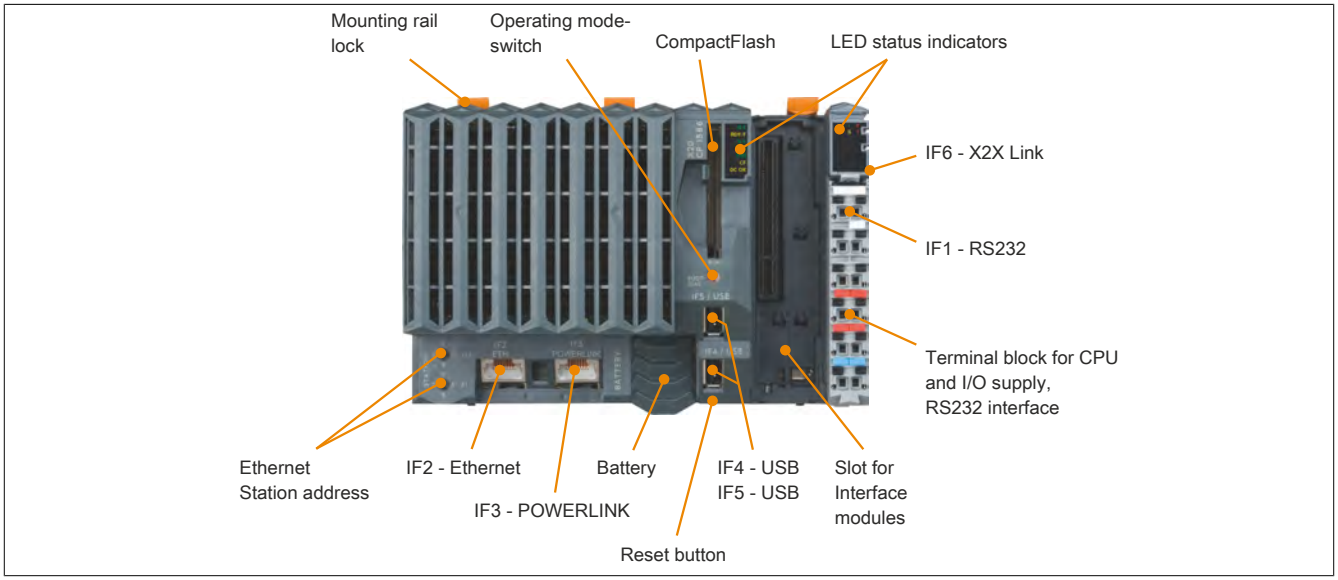
4.12.4.8 LED status indicators for the integrated power supply

For a description of the various operating modes, see section 2.11.1 "re LEDs".

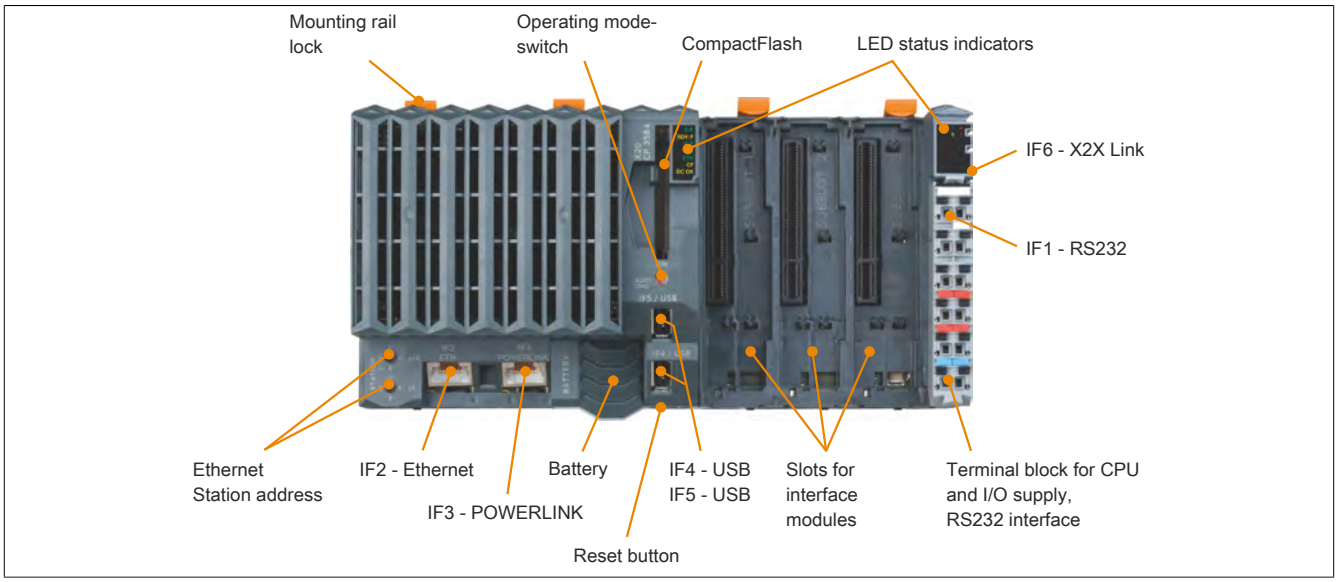
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	S	Yellow	Off	No RS232 activity
			On	The LED lights up when data is being sent or received via the RS232 interface.
	I	Red	Off	The X2X Link supply is within the valid limits
			On	The X2X Link supply for the power supply is overloaded

4.12.4.9 Operating and connection elements

X20CP158x



X20CP358x



4.12.4.10 Slot for application memory

These CPUs require application memory in order to operate. The application memory is provided in the form of a CompactFlash card. It is not included with the CPUs, but must be ordered separately as an accessory.

Information:

The CompactFlash card must not be removed during operation.

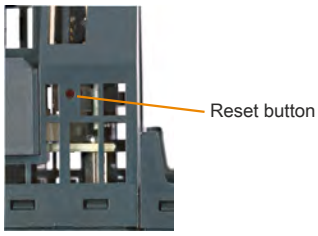
4.12.4.11 Operating mode switch

The operating mode switch is used to set the operating mode.

Switch position	Operating mode	Description
BOOT	BOOT	When the switch is in this position, the default B&R Automation Runtime (AR) system is started and the runtime system can be installed via the online interface (B&R Automation Studio). User flash memory is deleted only after the download begins.
RUN	RUN	RUN mode
DIAG	DIAGNOSE	Boots the CPU in diagnostic mode. Program sections in User RAM and User FlashPROM are not initialized. After diagnostic mode, the CPU always boots with a cold restart.

Table 249: X20 CPUs - Operating modes

4.12.4.12 Reset button



The reset button is located below the USB interfaces on the bottom of the housing. It can be pressed with any small pointed object (e.g. paper clip). Pressing the reset button triggers a hardware reset, which means:

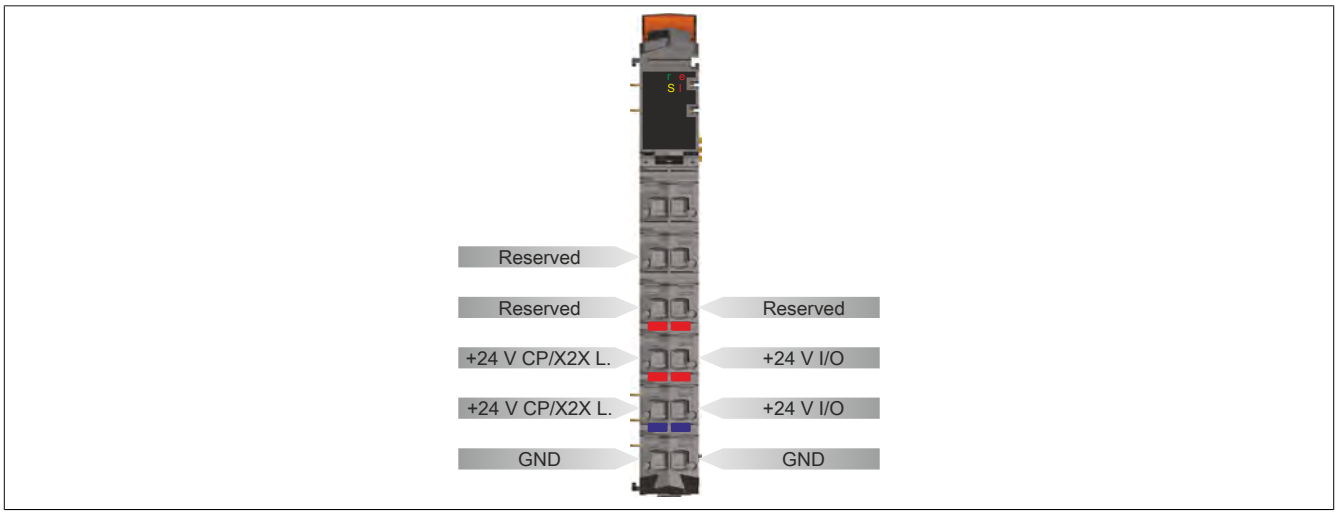
- All application programs are stopped.
- All outputs are set to zero.

The PLC then boots into Service mode by default. The boot mode that follows after pressing the reset button can be defined in Automation Studio.

4.12.4.13 CPU supply

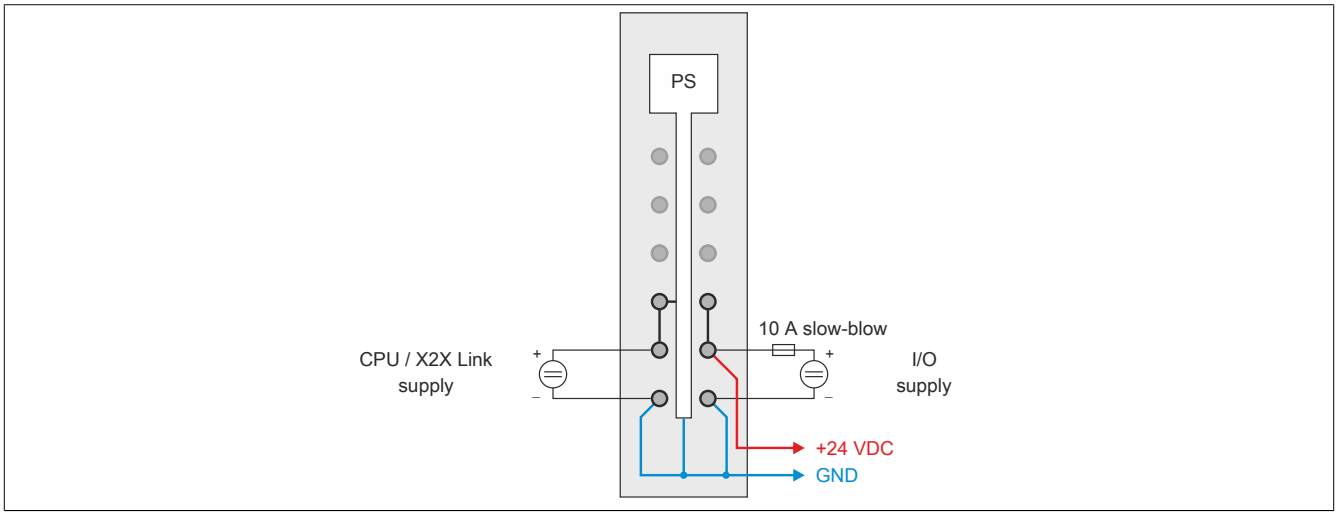
A power supply is integrated in the X20 CPUs. It has a feed for the CPU, the X2X Link and the internal I/O supply. Supply for the CPU and X2X Link is electrically isolated.

Pinout of the integrated power supply

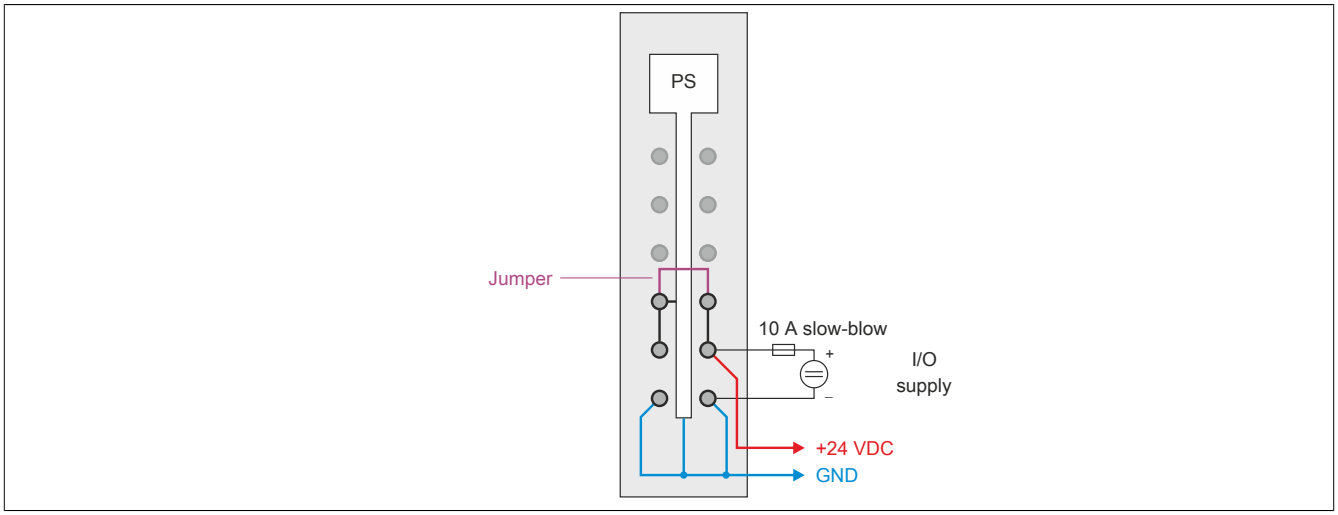


Connection examples

Connection example with 2 separate supplies

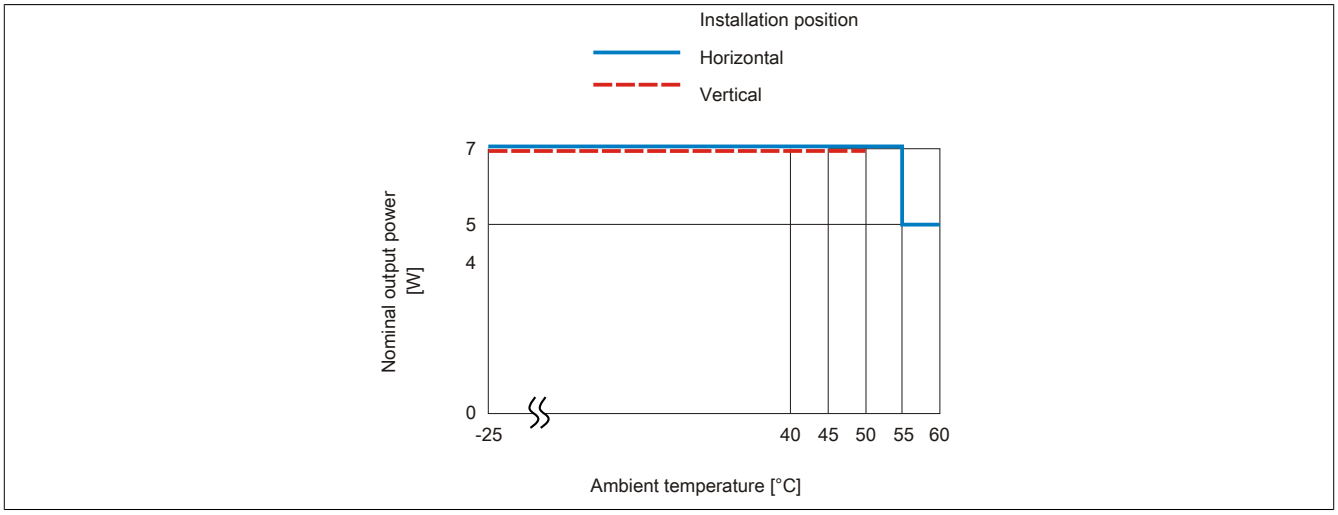


Connection example with a supply and jumper



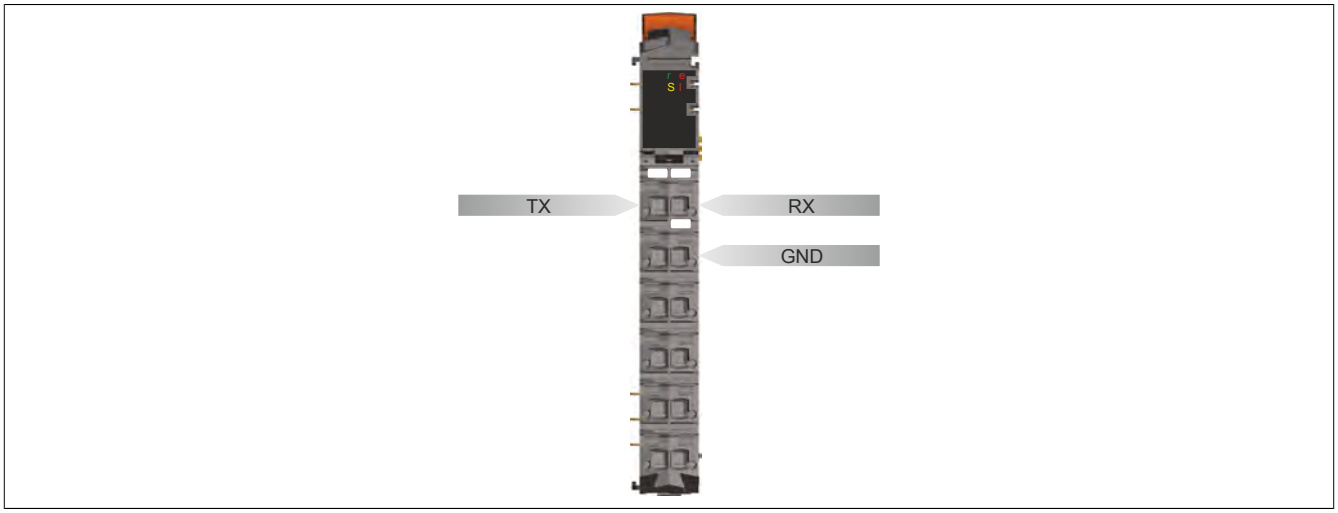
4.12.4.14 Derating

There is no derating when operated below 55°C. Above 55°C, the nominal output power for the X2X Link supply must be reduced to 5 W.



4.12.4.15 RS232 interface (IF1)

The non-electrically isolated RS232 interface is primarily intended to serve as an online interface for communication with the programming device.



4.12.4.16 Ethernet interface (IF2)

The IF2 is executed as the10 BASE-T / 100 BASE-TX / 1000 BASE-T gigabit Ethernet interface.

The INA2000 station number of the Ethernet interface is set using the two hex switches.

Information about cabling X20 modules with an Ethernet interface can be found on the B&R website in the module's download section at www.br-automation.com.

Information:

The Ethernet interface (IF2) is not suitable for POWERLINK (see 4.12.4.17 "POWERLINK interface (IF3)").

Pinout

Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45 port	1	D1+	Data 1+
	2	D1-	Data 1-
	3	D2+	Data 2+
	4	D3+	Data 3+
	5	D3-	Data 3-
	6	D2-	Data 2-
	7	D4+	Data 4+
	8	D4-	Data 4-

4.12.4.17 POWERLINK interface (IF3)

POWERLINK V1

Switch position	Description
0x00	Operation as managing node.
0x01 - 0xFD	Node number of the POWERLINK node. Operation as controlled node.
0xFE - 0xFF	Reserved, switch position not permitted

Table 250: POWERLINK V1 - Node numbers

POWERLINK V2

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as a controlled node.
0xF0	Operation as a managing node.
0xF1 - 0xFF	Reserved, switch position not permitted

Table 251: POWERLINK node number

Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number can be set using the B&R Automation Studio software.

Pinout

Information about cabling X20 modules with an Ethernet interface can be found on the B&R website in the module's download section at www.br-automation.com.

Pin	Assignment	
1	RxD	Receive data
2	RxD\	Receive data\
3	TxD	Transmit data
4	Termination	
5	Termination	
6	TxD\	Transmit data\
7	Termination	
8	Termination	

Table 252: X20 CPUs - Pinout for POWERLINK interface (IF3)

4.12.4.18 USB interfaces (IF4 and IF5)

IF4 and IF5 are USB interfaces. The connection is made using a USB 1.1/2.0 interface.

The USB interfaces can only be used for devices approved by B&R (e.g. floppy disk drive, DiskOnKey or dongle).

Information:

USB interfaces cannot be used for online communication with a programming device.

Only devices isolated from GND can be connected to the USB interfaces.

4.12.4.19 Slots for interface modules

The CPUs have one or three slots for interface modules.

Various bus and network systems can easily be integrated into the X20 system by selecting the corresponding interface module.

4.12.4.20 Overtemperature cutoff

To prevent damage, the CPU is cut off and reset when the processor reaches 110°C or the circuit board reaches 95°C.

The following errors are entered in the logbook:

Error number	Error description
9204	WARNING: System halted because of temperature check
9210	WARNING: Boot by watchdog or manual reset

Table 253: X20 CPUs - Logbook entries after overtemperature cutoff

4.12.4.21 Data / Real-time clock buffering

The CPUs are buffered by a backup battery. The following areas are buffered:

- Remanent variables
- User RAM
- System RAM
- Real-time clock

Battery monitoring

The battery voltage is checked cyclically. The cyclic load test of the battery does not considerably shorten the battery life, instead it gives an early warning of weakened buffer capacity.

The status information "Battery OK" is available from the system library function "BatteryInfo" and the CPU's I/O mapping.

Replacement interval for battery

The battery should be replaced every 4 years. The replacement intervals recommended by B&R reflect the batteries' average service life and operating conditions. It does not represent the maximum buffer duration.

4.12.4.22 Exchanging the lithium battery

The CPUs have a lithium battery. The lithium battery is found in a separate compartment on the bottom of the module and protected by a cover.

Backup battery data

Model number 4A0006.00-000 0AC201.91	 1 pcs. 4 pcs.
Short description	Lithium battery, 3 V / 950 mAh, button cell
Storage temperature	-20 to 60°C
Storage time	Max. 3 years at 30°C
Relative humidity	0 to 95%, non-condensing

Table 254: X20 CPUs - Backup battery data

Important information about the battery exchange

The product design allows the battery to be changed with the PLC switched either on or off. In some countries, safety regulations do not allow batteries to be changed while the module is switched on. To prevent data loss, the battery must be changed within 1 min. with the power off.

Warning!

The battery must be replaced by a Typ CR2477N Renata battery only. The use of another battery may present a risk of fire or explosion.

The battery may explode if handled improperly. Do not recharge, disassemble or dispose of in fire.

Procedure for exreplacing the battery

1. Touch the mounting rail or ground connection (not the power supply!) in order to discharge any electrostatic charge from your body.
2. Remove the cover for the lithium battery. Do this by sliding it down and away from the CPU.

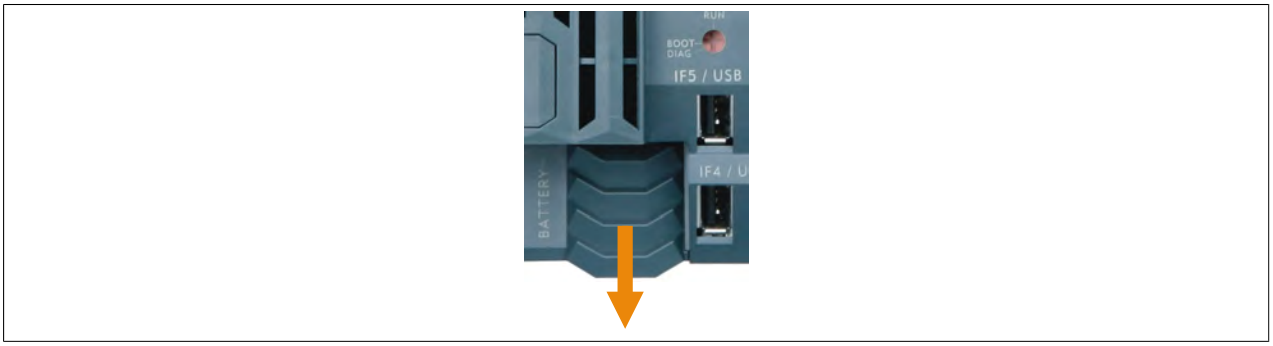


Figure 234: X20 CPUs - Remove lithium battery cover

3. Remove the battery from the holder (do not use pliers or uninsulated tweezers -> risk of short circuiting). The battery should not be held by its edges. **Insulated** tweezers may also be used to remove the battery.

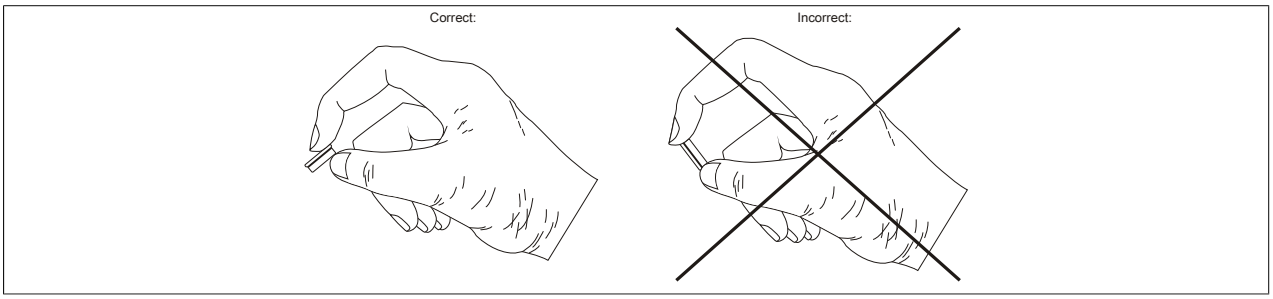

Figure 235: X20 CPUs - Correct grip for the battery

4. Insert the new battery with the correct polarity. To do this, lay the battery with the "+" side up on the right part of the battery holder under the USB interface IF4. Then secure the battery in the holder by pressing above the left part of the battery holder.
5. Replace the cover.

Information:

Lithium batteries are considered hazardous waste. Used batteries should be disposed of in accordance with applicable local regulations.

4.12.4.23 Programming the system flash memory

General information

In order for the application project to be executed on the CPU, the Automation Runtime operating system, the system components and the application project must be installed on the CompactFlash card.

Creating a CompactFlash using a USB card reader

The easiest way to perform an initial installation is by creating a fully programmed CompactFlash card using a USB card reader.

1. Creating and configuring a project in Automation Studio
2. In Automation Studio, select **Tools / Create CompactFlash**
3. In the dialog box that opens, select a CompactFlash card and then generate it
4. Insert the finished CompactFlash into the CPU and turn on the CPU's supply voltage
5. CPU booting

For details about commissioning: See help system under "Automation Software / Getting Started"

Installation over an online connection

The CPUs are delivered with a default B&R Automation Runtime system (with limited functions) already installed. This runtime system is started in Boot mode (operating mode switch in the BOOT position or no CompactFlash / invalid CompactFlash inserted). It initializes the Ethernet interface and onboard serial RS232 interface, making it possible to download a new runtime system.

1. Insert the CompactFlash card and switch on the power to the CPU. When the switch is in the BOOT position, a new or invalid CompactFlash card starts the CPU with the default B&R Automation Runtime system.
2. Establish a physical online connection between the programming device (PC or industrial PC) and the CPU (e.g. over an Ethernet network or the RS232 interface).
3. Before you can establish an online connection via Ethernet, the CPU must be assigned an IP address. In Automation Studio, select **Settings** from the Online menu and then click on the **Browse targets** button to search for B&R target systems on the local network. The CPU should appear in the list. If the CPU has not already received an IP address from a DHCP server, right-click on it and select **Set IP parameters** from the shortcut menu. All necessary network configurations can be made on a temporary basis in this dialog box (should be identical to the settings defined in the project).
4. Configure online connection in B&R Automation Studio. For details about the configuration: See help system under "Automation Software / Communication / Online communication"
5. Start the download procedure by selecting the **Services** command from the **Project** menu. Then select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions provided by B&R Automation Studio.

4.12.4.24 Information regarding switching from X20CPx48x to X20CPx58x

- A hardware upgrade is required for some X20 IFxxxx interface modules. This can be installed from Automation Studio by selecting **Tools/Upgrades** from the menu.
  In addition, some modules specify a specific hardware revision. The following table provides an overview:

Model number	Minimum upgrade version	Minimum hardware revision
X20IF1020	1.1.5.1	H0
X20IF1030	1.1.5.1	I0
X20IF1041-1	-	-
X20IF1043-1	-	-
X20IF1051-1	-	-
X20IF1053-1	-	-
X20IF1061	-	E0
X20IF1061-1	-	-
X20IF1063	1.1.5.0	-
X20IF1063-1	-	-
X20IF1065	-	-
X20IF1072	1.0.5.1	-
X20IF1082	1.2.2.0	-
X20IF1082-2	1.2.1.0	-
X20IF1086-2	1.1.1.0	-
X20IF1091	1.0.5.1	-
X20IF10A1-1	-	-
X20IF10D1-1	-	-
X20IF10D3-1	-	-
X20IF10E1-1	-	-
X20IF10E3-1	-	-
X20IF10G3-1	-	-
X20IF10H3-1	-	-
X20IF2772	1.0.6.1	-
X20IF2792	1.0.5.1	-

Table 255: X20 CPUs - Minimum upgrade version and minimum hardware revision for X20 IFxxxx interface modules

- The X20CPx58x CPUs are supported by B&R Automation Studio V3.0.90.20 and higher.
- If an X20CPx48x is to be replaced by an X20CPx58x in an existing Automation Studio configuration, the X20CPx58x may not be listed as one of the available options even though the upgrade for the CPU has already been installed. If this is the case, it is necessary to upgrade the X20CPx48x.
- Starting with Automation Runtime 4.x, USB devices are integrated in Automation Runtime dynamically so that they no longer need to be configured in Automation Studio. In order to use a USB device, its internal device name needs to be obtained at runtime. For an example, see the Automation Studio help system for the library "AsUSB / Examples".

4.13 Digital input modules

Digital input modules convert binary process signals into the internal signal level required by the PLC. The states of the digital inputs are indicated with status LEDs.

4.13.1 Brief information

Product ID	Short description	on page
X20DI0471	X20 digital input module, 10 inputs, 48 VDC, sink, configurable input filter, 1-wire connections	1208
X20DI2371	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 3-wire connections	1215
X20DI2372	X20 digital input module, 2 inputs, 24 VDC, source, configurable input filter, 3-wire connections	1221
X20DI2377	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 2 event counters 50 kHz, 3-wire connections	1227
X20DI2653	X20 digital input module, 2 inputs, 100 to 240 VAC, 240 V keyed, 3-wire connections	1235
X20DI4371	X20 digital input module, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections	1241
X20DI4372	X20 digital input module, 4 inputs, 24 VDC, source, configurable input filter, 3-wire connections	1248

X20DI4760	X20 digital input module, 4 NAMUR inputs, 8.05 V	1271
X20DI6371	X20 digital input module, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections	1280
X20DI6372	X20 digital input module, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections	1286
X20DI6373	X20 digital input module, 6 inputs, 24 VDC, sink/source, all inputs floating, configurable input filter, 2-wire connections	1292
X20DI6553	X20 digital input module, 6 inputs, 100 to 120 VAC, 240 V keyed, 1-wire connections	1298
X20DI8371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 1-wire connections	1304
X20DI9371	X20 digital input module, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections	1310
X20DI9372	X20 digital input module, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections	1317
X20DID371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 2-wire connections	1324
X20DIF371	X20 digital input module, 16 inputs, 24 VDC, sink, configurable input filter, 1-wire connections	1330
X20cDI4371	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections	1241
X20cDI4375	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, open line and short circuit detection, 3-wire connections	1254
X20cDI4760	X20 digital input module, coated, 4 NAMUR inputs, 8.05 V	1271
X20cDI6371	X20 digital input module, coated, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections	1280
X20cDI6372	X20 digital input module, coated, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections	1286
X20cDI9371	X20 digital input module, coated, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections	1310
X20cDI9372	X20 digital input module, coated, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections	1317

4.13.2 X20DI0471

4.13.2.1 General information

The module is equipped with 10 inputs for 1-wire connections. It is designed for a nominal voltage 4.75 to 60 VDC.

- 10 digital inputs
- 4.75 to 60 VDC inputs
- Sink circuit
- 1-wire connections
- Configurable software input filter for entire module

4.13.2.2 Order data

Model number	Short description	Figure
	Digital inputs	
X20DI0471	X20 digital input module, 10 inputs, 48 VDC, sink, configurable input filter, 1-wire connections	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 256: X20DI0471 - Order data

4.13.2.3 Technical data

Product ID	X20DI0471
Short description	
I/O module	10 digital inputs 4.75 to 60 VDC for 1-wire connections
General information	
B&R ID code	0xE7CE
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	TBD
Internal I/O	TBD
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
GOST-R	Yes
Digital inputs	
Nominal voltage	4.75 to 60 VDC
Input voltage	0 to 60 VDC
Reference voltage	4.75 to 60 VDC
Input current	0.5 to 1 mA
Input filter	
Hardware	≤100 µs
Software	Default 1 ms, configurable between 0 and 25 ms in 0.2 ms intervals
Connection type	1-wire connections
Input circuit	Sink
Reference voltage input resistance	20 kΩ
Switching threshold	
Low	≤0.2 x U_{ref}
High	≥0.6 x U_{ref}
Reference voltage monitoring	Yes
Isolation voltage between channel and bus	TBD V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5 $^{+0.2}$ mm

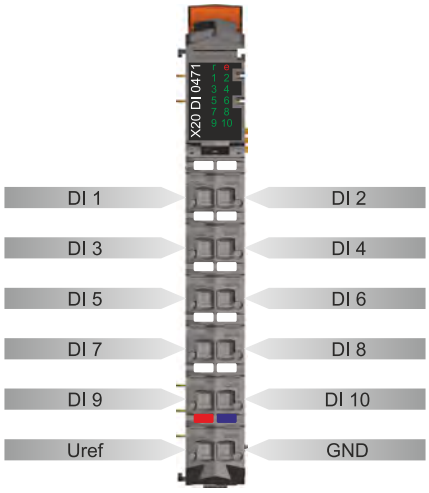
Table 257: X20DI0471 - Technical data

4.13.2.4 LED status indicators

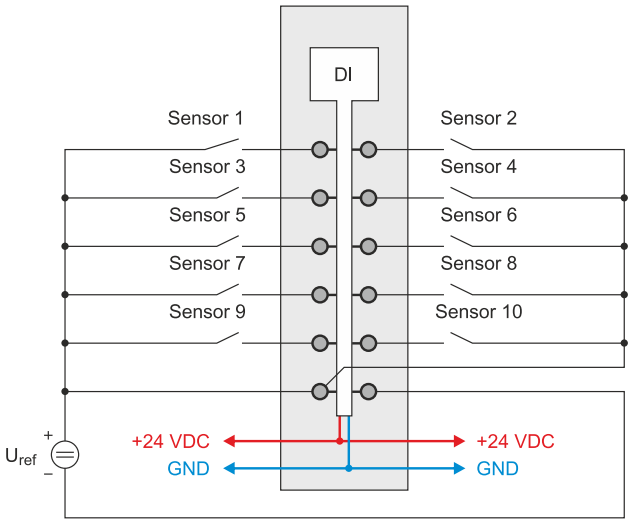
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 10	Green		Input state of the corresponding digital input

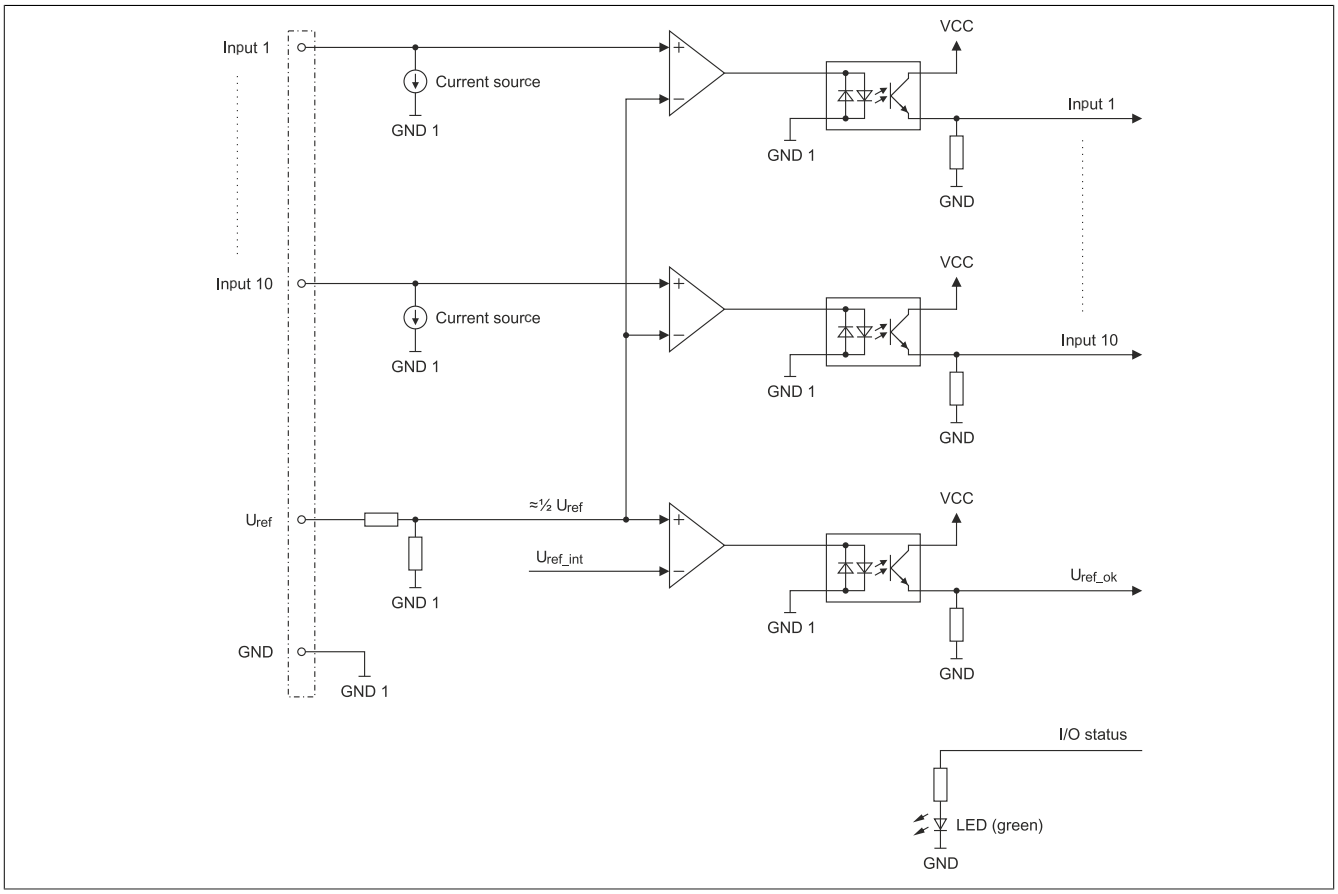
4.13.2.5 Pinout



4.13.2.6 Connection example

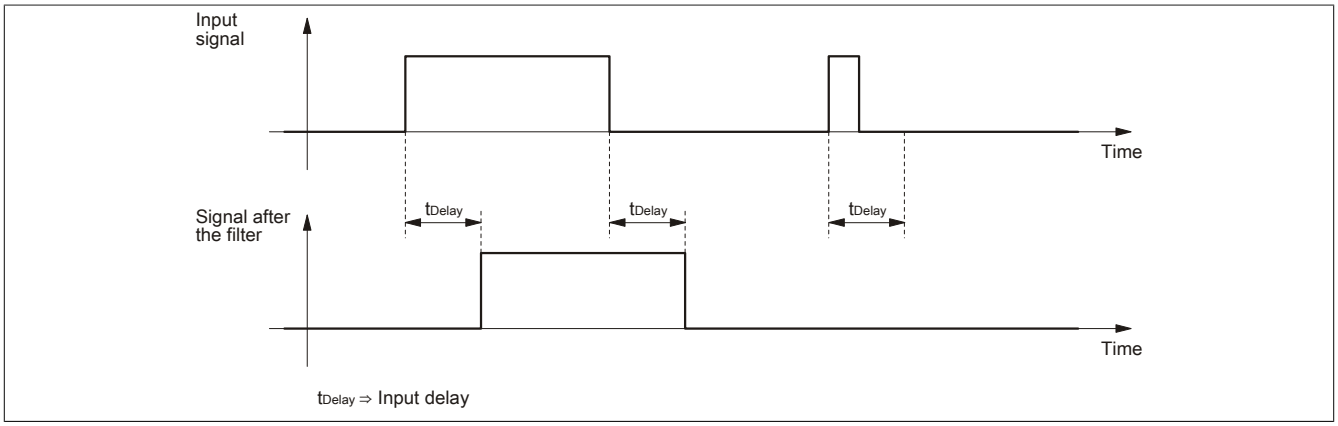


4.13.2.7 Input circuit diagram



4.13.2.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.2.9 Register description

4.13.2.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.2.9.2 Function model 0 - default

Register	Fixed offset	Register name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
-	1	DigitalInput	UINT	•			
0	1	Input state of digital inputs 1 to 8	USINT				
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	2	Input state of digital inputs 9 to 10	USINT	•			
		DigitalInput09	Bit 0				
		DigitalInput10	Bit 1				
		ReferenceStatus	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.2.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Register name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input state of digital inputs 1 to 8	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	1	Input state of digital inputs 9 to 10	USINT	•			
		DigitalInput09	Bit 0				
		DigitalInput10	Bit 1				
		ReferenceStatus	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies the position of the register within the CAN object.

4.13.2.9.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.13.2.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.2.9.5 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.2.9.5.1 Details related to use

The table shows how the register must be defined in relation to the function model and which parameter is available for this in the Automation Studio configuration.

Function model	Value or path for the configuration parameter
All	General / Input filter [0.1 ms]

4.13.2.9.6 Input state of digital inputs 1 to 10

Register name:
DigitalInput or
DigitalInput01 to DigitalInput10

This register indicates the input state of digital inputs 1 to 10 and the status of the reference voltage.

The reference voltage is monitored. The status is output in bit 7. The nominal voltage is 4.75 to 60 VDC.

Reference voltage	Status of the digital inputs in relation to the input voltage	
U_{ref} < 4.75 V	All digital inputs are in a low state regardless of the voltage on the inputs.	
U_{ref} ≥ 4.75 V	$U_{In} \leq 0.2 * U_{ref}$	The digital input is low
	$U_{In} \geq 0.6 * U_{ref}$	The digital input is high
	$0.2 * U_{ref} < U_{In} < 0.6 * U_{ref}$	This area is inconclusive. The digital input is either low or high.

Example

The reference voltage U_{ref} = 48 VDC

Calculation of the switching threshold:

Switching threshold low = 48 * 0.2 = 9.6 VDC

Switching threshold high = 48 * 0.6 = 28.8 VDC

Status of the digital inputs in relation to the input voltage:

Input voltage	State of the digital input
$U_{In} \leq 9.6$ VDC	The digital input is low
9.6 VDC < U_{In} < 28.8 VDC	The digital input is either low or high (inconclusive).
$U_{In} \geq 28.8$ VDC	The digital input is high

Only function model 0 - Standard

The "Packed inputs" setting in the Automation Studio I/O configuration is used to determine whether all of the bits from this register should be set up individually as data points in the Automation Studio I/O mapping ("DigitalInput01" to "DigitalInput10") or whether this register should be displayed as an individual UINT data point ("DigitalInput").

Data type	Value	Information	
UINT	0x0000 to 0x83FF	Packed inputs = On	
		0xy000 to 0xy3FF	Status of digital inputs 1 to 10
		0x0yyy	Reference voltage U_{ref} < 4.75 V
		0x8yyy	Reference voltage U_{ref} ≥ 4.75 V
USINT	See bit structure.	Packed inputs = Off or Function model <> 0 - Standard	

Bit structure:

Register 0

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input state - Digital input 8

Register 1

Bit	Name	Value	Information
0	DigitalInput09	0 or 1	Input state - Digital input 9
1	DigitalInput10	0 or 1	Input state - Digital input 10
2 - 6	Reserved		
7	ReferenceStatus	0	Reference voltage U_{ref} < 4.75 V
		1	Reference voltage U_{ref} ≥ 4.75 V

4.13.2.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.2.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.3 X20DI2371

4.13.3.1 General Information

The module is equipped with 2 inputs for 3-wire connections.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 digital inputs
- Sink connection
- 3-wire connections
- 24 VDC and GND for sensor supply
- Software input filter can be configured for entire module

4.13.3.3 Technical data

Product ID	X20DI2371
Short description	
I/O module	2 digital inputs 24 VDC for 3-wire connections
General information	
B&R ID code	0x1B8D
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.12 W
Internal I/O	0.29 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Nominal voltage	24 VDC
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Typ. 3.75 mA
Input filter	
Hardware	≤100 µs
Software	Default 1 ms, configurable between 0 and 25 ms in 0.2 ms intervals
Connection type	3-wire connections
Input circuit	Sink
Input resistance	Typ. 6.4 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
Sensor supply	
Power consumption	Max. 12.0 W 2)
Voltage	Module supply minus voltage drop for short circuit protection
Voltage drop for short circuit protection at 500 mA	Max. 2 VDC
Summation current	0.5 A
Short circuit protection	Yes
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB06 or X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 259: X20DI2371 - Technical data

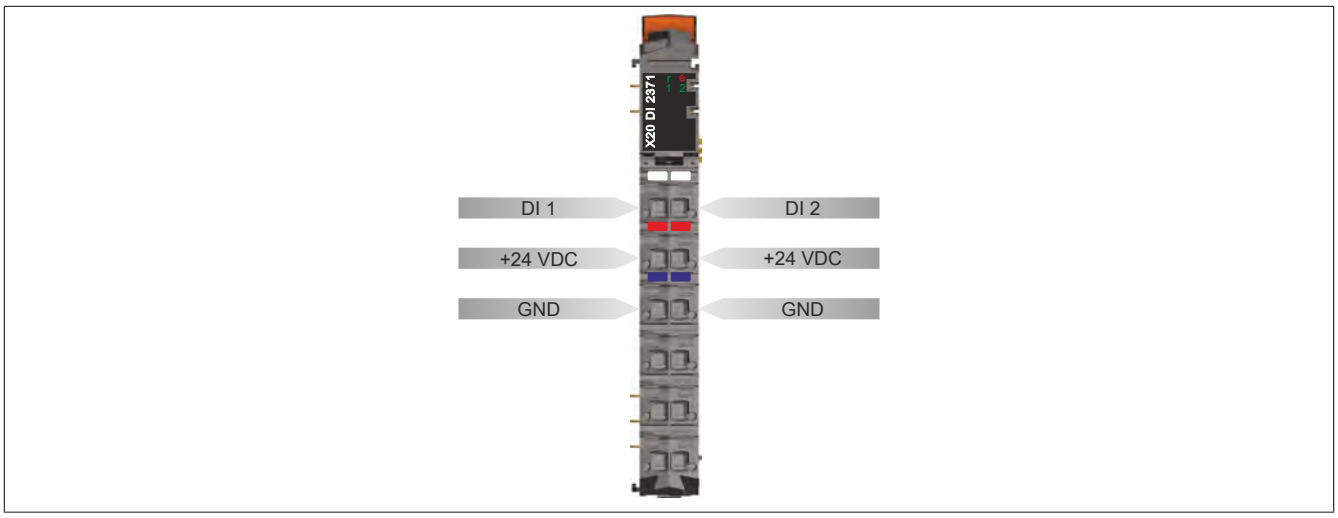
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.13.3.4 Status LEDs

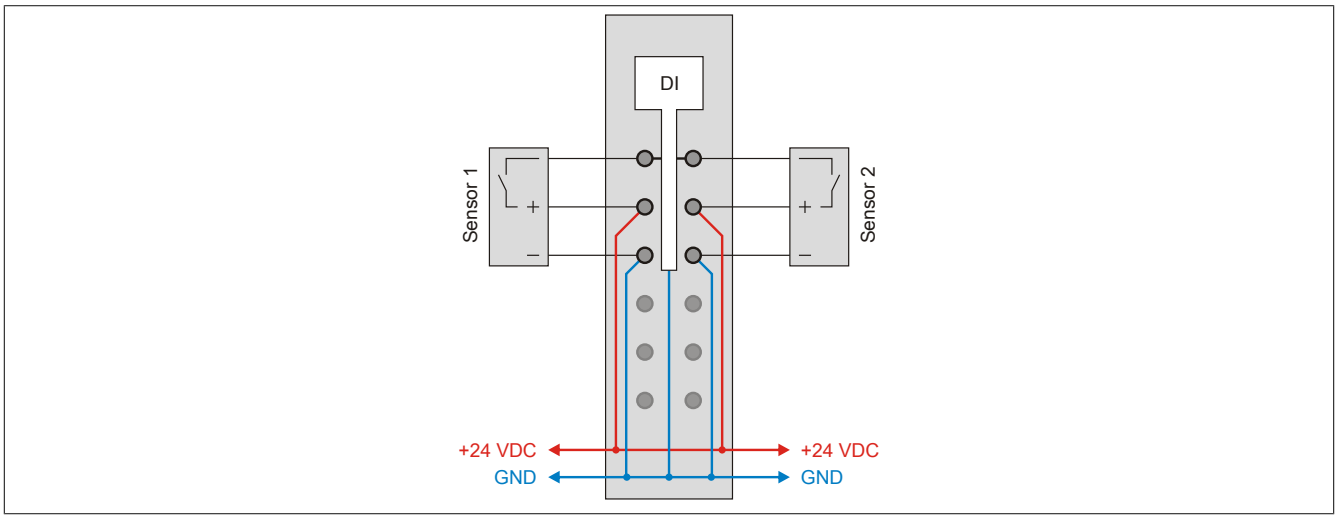
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green		Input status of the corresponding digital input

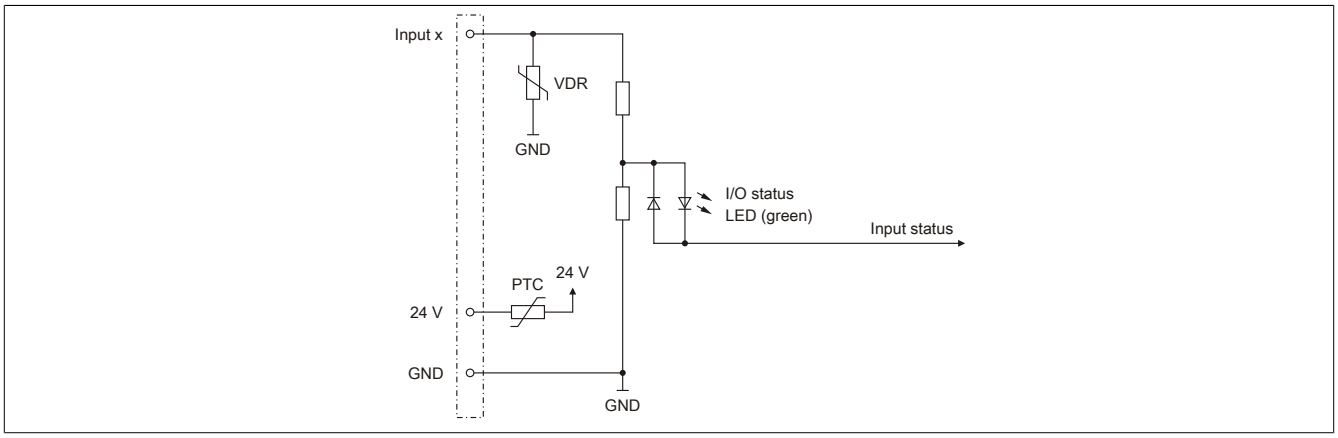
4.13.3.5 Pinout



4.13.3.6 Connection example

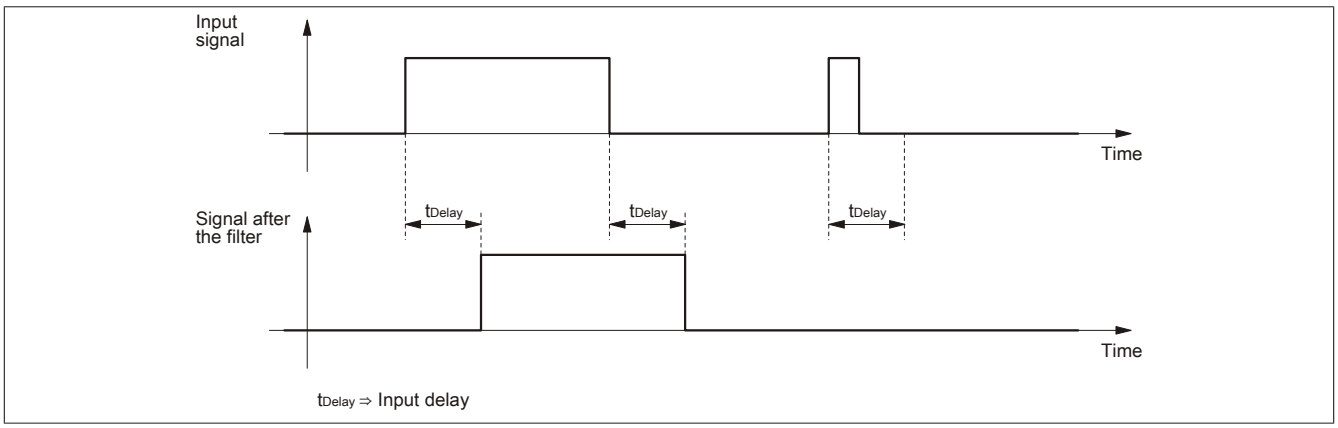


4.13.3.7 Input circuit diagram



4.13.3.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.3.9 Register description

4.13.3.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.3.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.3.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	Input status of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.3.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.3.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.3.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.3.9.4.2 Input status of digital inputs 1 to 2

Name:
DigitalInput or
DigitalInput01 to DigitalInput02

The input status of digital inputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 3	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
1	DigitalInput02	0 or 1	Input status - Digital input 2

4.13.3.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.3.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.4 X20DI2372

4.13.4.1 General Information

The module is equipped with 2 inputs for 3-wire connections.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 digital inputs
- Source connection
- 3-wire connections
- 24 VDC and GND for sensor supply
- Software input filter can be configured for entire module

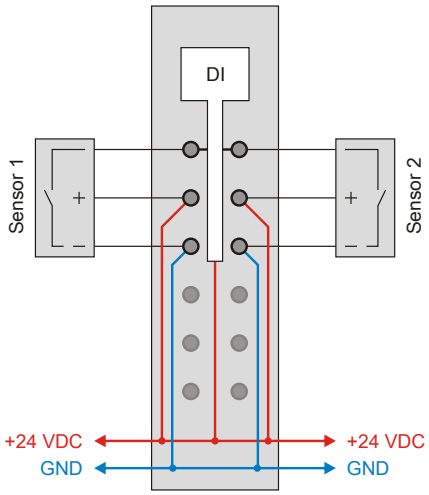
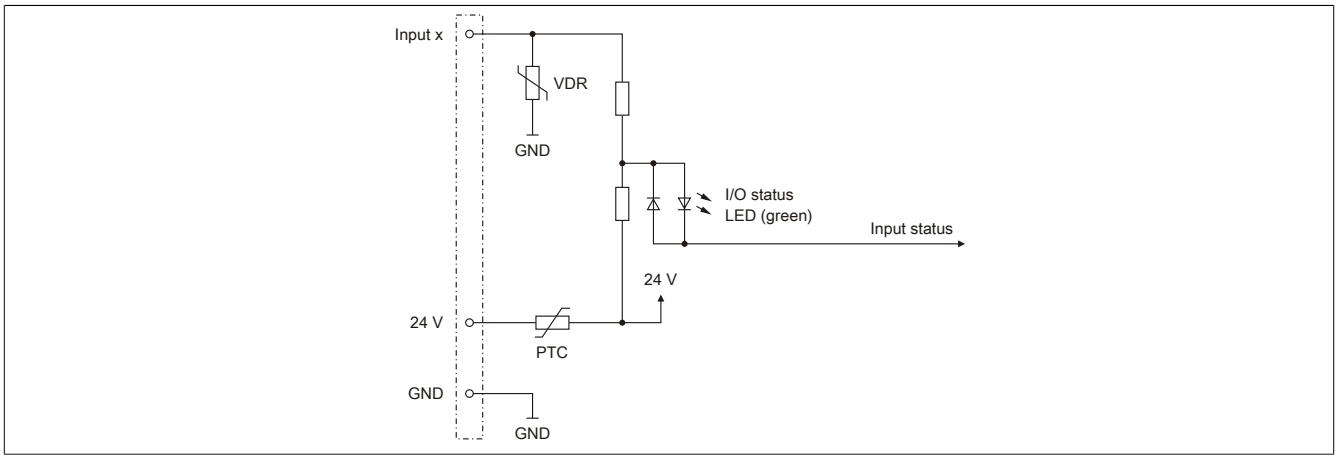
4.13.4.6 Connection example

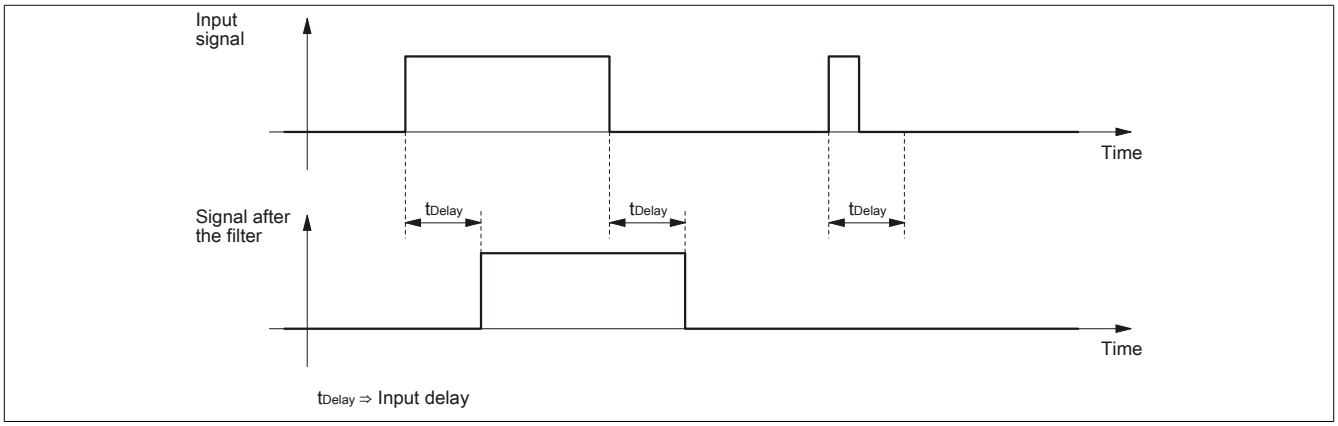


4.13.4.7 Input circuit diagram



4.13.4.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.4.9 Register description

4.13.4.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.4.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.4.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	Input status of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.4.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.4.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.4.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.4.9.4.2 Input status of digital inputs 1 to 2

Name:
DigitalInput or
DigitalInput01 to DigitalInput02

The input status of digital inputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 3	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
1	DigitalInput02	0 or 1	Input status - Digital input 2

4.13.4.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.4.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.5 X20DI2377

4.13.5.1 General Information

The module is equipped with two inputs for 3-wire connections. Both inputs can be configured as event counters. Gate measurement is only ever possible on one channel.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 digital inputs
- Sink connection
- 3-wire connections
- 2 counter inputs with 50 kHz counter frequency
- Gate measurement
- 24 VDC and GND for sensor supply
- Software input filter can be configured for entire module

1) The offset specifies where the register is within the CAN object.

4.13.5.9.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.13.5.9.5 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.5.9.5.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.5.9.5.2 Input status of digital inputs 1 to 2

Name:
DigitalInput or
DigitalInput01 to DigitalInput02

The input status of digital inputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 3	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
1	DigitalInput02	0 or 1	Input status - Digital input 2

4.13.5.9.5.3 Input status of digital latch inputs 1 - 2

Name:
DigitalInputLatch01 to DigitalInputLatch02

The input status of digital inputs 1 to 2 after expiration of the input filter time is mapped in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInputLatch01	0 or 1	Input status of digital input 1 after expiration of the delay time
1	DigitalInputLatch02	0 or 1	Input status of digital input 2 after expiration of the delay time

4.13.5.9.6 Counter operation

The following operation modes can be selected:

- Event counter mode
- Event counter mode with software (processed after the input filter)
- Gate measurement

Event counter mode

The rising (positive) edges are registered on the counter input.

The counter state is registered with a fixed offset with respect to the network cycle and transferred in the same cycle.

Event counter mode with software

The rising (positive) edges are registered on the counter input. But the edges are first processed through the configured software filter.

The counter state is registered with a fixed offset with respect to the network cycle and transferred in the same cycle.

Gate measurement

The time of rising to falling edges for the gate input is registered using an internal frequency. The result is checked for overflow (0xFFFF) and corrected with the adjustable prescaler.

The recovery time between measurements must be >100 µs.

The measurement result is transferred with the falling edge to the result memory.

Information:

Only one of the counter channels at a time can be used for gate measurement.

4.13.5.9.6.1 Event or gate counter

Name:
Counter01 to Counter02

This register displays the results of the individual counters.

Event counter or gate measurement (16-bit counter value) depending on operating mode.

Data type	Value
USINT	Counter value

4.13.5.9.6.2 Counter configuration

Name:
ConfigOutput02 to ConfigOutput03

This register can be used to configure the individual counters.

Data type	Value
USINT	See bit structure.

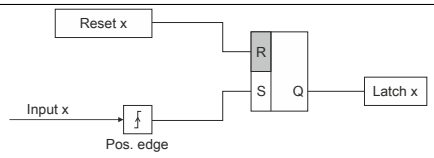
Bit structure:

Bit	Name	Value	Information
0 - 3	Counter frequency	0	48 MHz (only with gate measurement)
		1	3 MHz (only with gate measurement)
		1	**Event counter** via software (only in event counter operation)
		2	187.5 kHz (only with gate measurement)
		3	24 MHz (only with gate measurement)
		4	12 MHz (only with gate measurement)
		5	6 MHz (only with gate measurement)
		6	1.5 MHz (only with gate measurement)
		7	750 kHz (only with gate measurement)
		8	375 kHz (only with gate measurement)
4	Reserved	0	
5	ResetCounter01 or ResetCounter02	0	No influence on the counter
		1	Clear counter (at rising edge)
6 - 7		0	Event counter measurement
		1	Gate measurement

4.13.5.9.7 Rising edge input latch

Using this function, the rising edges of the input signal can be latched with a resolution of 200 µs. With the "Acknowledge - input latch" function, the input latch is either reset or prevented from latching.

It works in the same way as a dominant reset RS flip-flop.



R	S	Q	Status
0	0	x	Do not change
0	1	1	Set
1	0	0	Reset
1	1	0	Reset

4.13.5.9.7.1 Acknowledge digital inputs

Name:
DigitalInput01LatchQuitt to DigitalInput02LatchQuitt

This register is used to reset the input latches channel by channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01LatchQuitt	0	No influence on the latch status
		1	Resets the latch status
1	DigitalInput02LatchQuitt	0	No influence on the latch status
		1	Resets the latch status
2 - 7	Reserved	-	

4.13.5.9.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.5.9.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.13.6 X20DI2653

4.13.6.1 General Information

The module is equipped with 2 inputs for 3-wire connections. It is designed for an input voltage of 100 to 240 VAC.

- 2 digital inputs
- 100 to 240 VAC inputs
- 50 Hz or 60 Hz
- 3-wire connections
- 240 V coded

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.13.6.2 Order data

Product ID	X20DI2653
Short description	
I/O module	2 digital inputs 100 to 240 VAC for 3-wire connections
General information	
B&R ID code	0x2544
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
External I/O supply	Yes, using software (typical threshold 85 VAC)
Power consumption	
Bus	0.14 W
Internal I/O	-
External I/O	0.55 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Digital inputs	
Nominal voltage	100 to 240 VAC
Input filter	
Software	Default 1 ms, configurable between 0 and 25 ms in 0.2 ms intervals
Hardware	
1 -> 0	≤30 ms
0 -> 1	≤40 ms
Connection type	3-wire connections
Rated frequency	47 to 63 Hz
Switching threshold	
Low	<40 VAC
High	>79 VAC
Isolation voltage between channel and bus	1 minute 2500 VAC
Input voltage	
Maximum	264 VAC
Input current	
100 VAC / 60 Hz	4 mA (Rev. ≥ E0), 5 mA (Rev. < E0)
240 VAC / 50 Hz	8.5 mA (Rev. ≥ E0), 11 mA (Rev. < E0)
Sensor supply	
Voltage	Equal to the module supply
Summation current	2 A_{eff}
Short circuit protection	No
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB32 terminal block separately Order 1x X20BM12 bus module separately
Spacing	12.5 $^{+0.2}$ mm

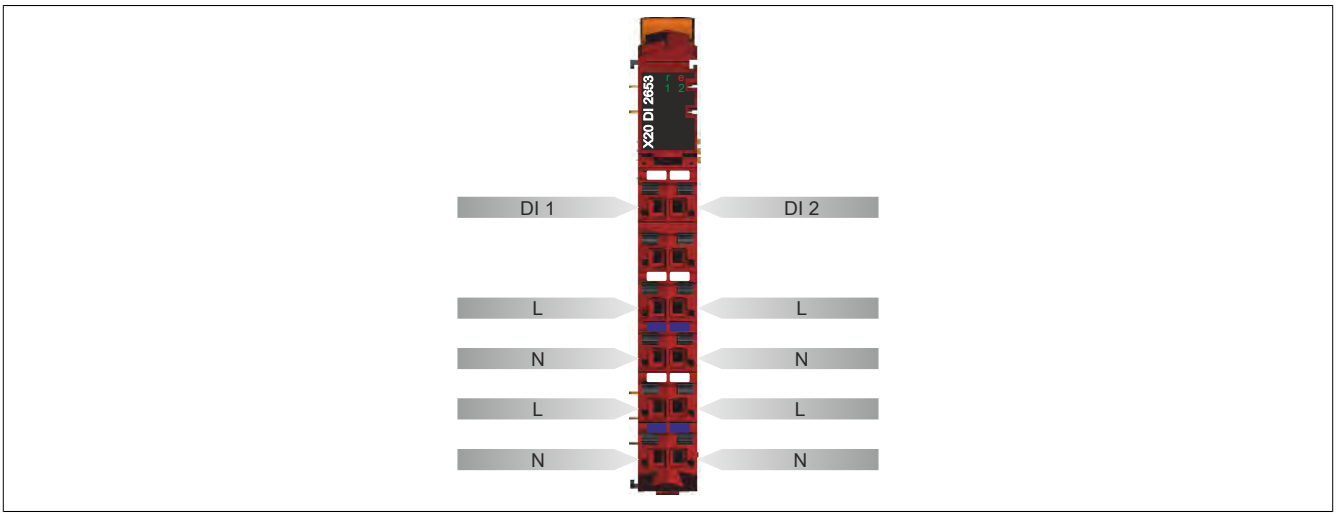
Ta max.: See environmental conditions

4.13.6.4 Status LEDs

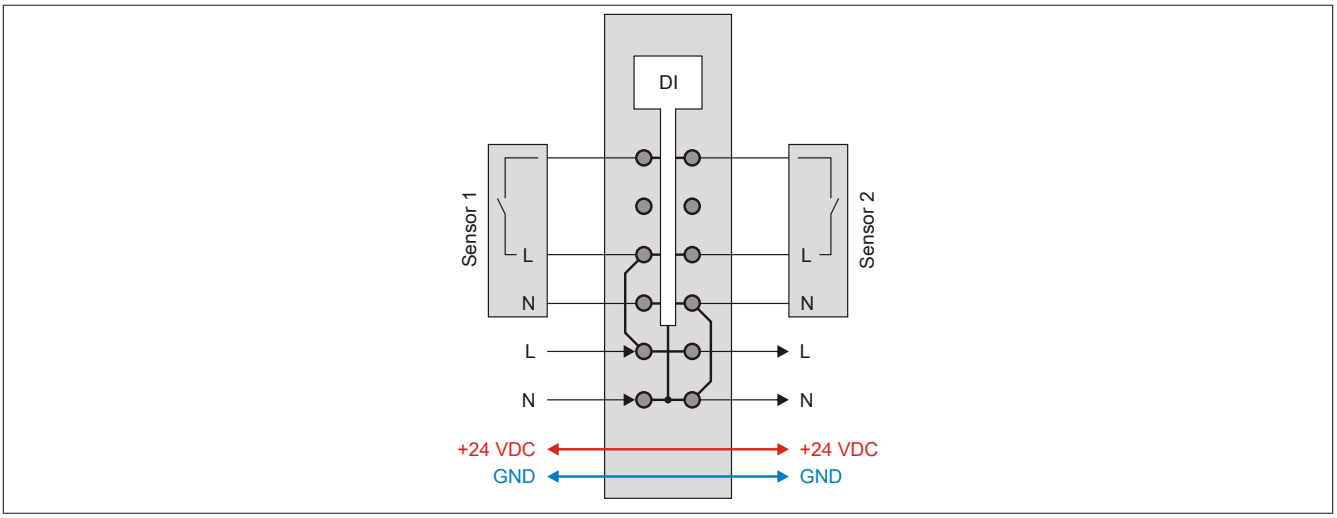
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Double flash	External supply is too low or not connected
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green		Input status of the corresponding digital input

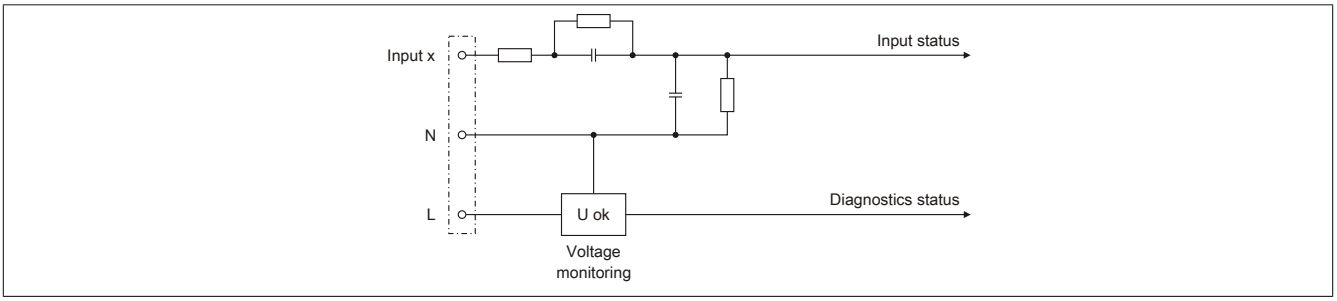
4.13.6.5 Pinout



4.13.6.6 Connection example

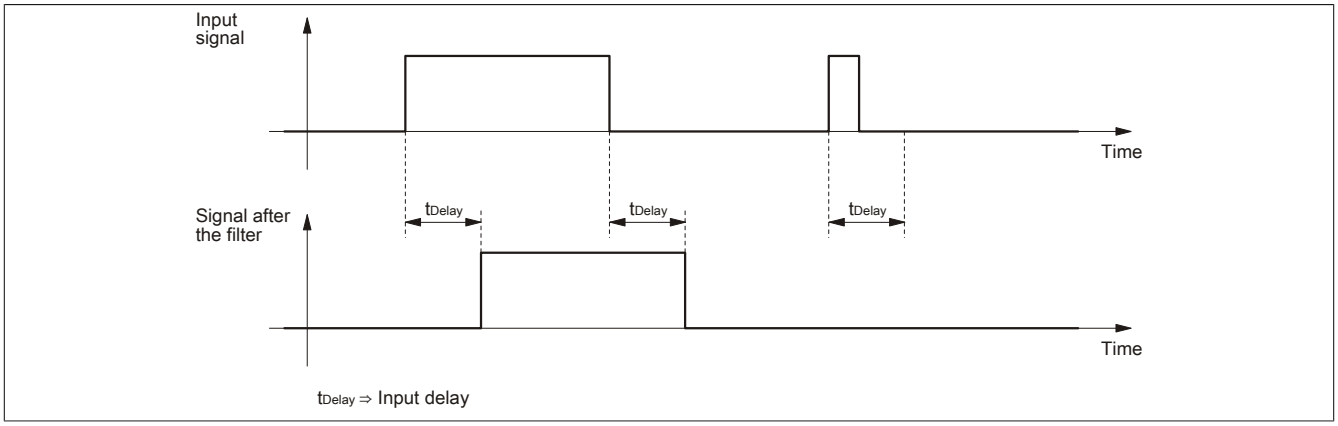


4.13.6.7 Input circuit diagram



4.13.6.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.6.9 Register description

4.13.6.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.6.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.6.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 0				
		DigitalInput02	Bit 1				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.6.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.6.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.6.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.6.9.4.2 Input status of digital inputs 1 to 2

Name:
DigitalInput or
DigitalInput01 to DigitalInput02
PowerSupply

The input status of digital inputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01", "DigitalInput02" and "PowerSupply") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
1	DigitalInput02	0 or 1	Input status - Digital input 2
2 - 6	Reserved	0	
7	PowerSupply	0	Supply voltage too low
		1	Supply voltage >80 VAC

4.13.6.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.6.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.7 X20(c)DI4371

4.13.7.1 General Information

The module is equipped with four inputs for 3-wire connections.

- 4 digital inputs
- Sink connection
- 3-wire connections
- 4 counter inputs with 1 kHz counter frequency
- 24 VDC and GND for sensor supply
- Software input filter can be configured for entire module

4.13.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.13.7.3 Order data

Model number	Short description	Figure

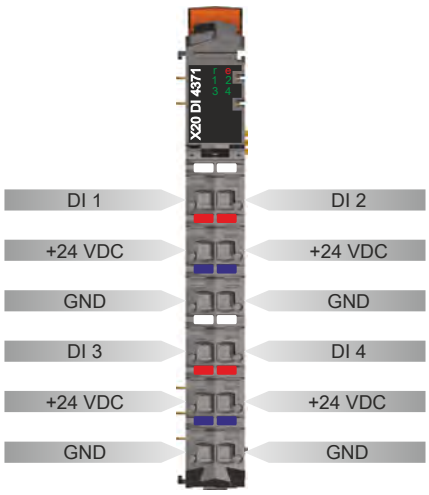
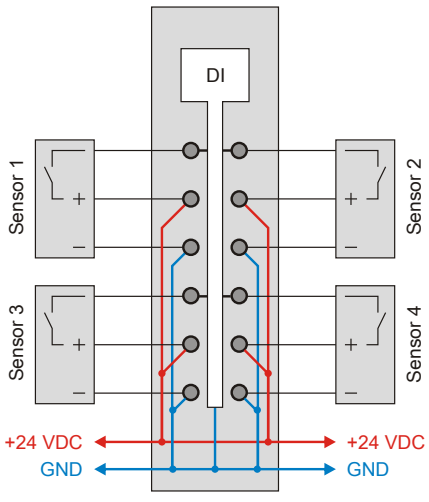
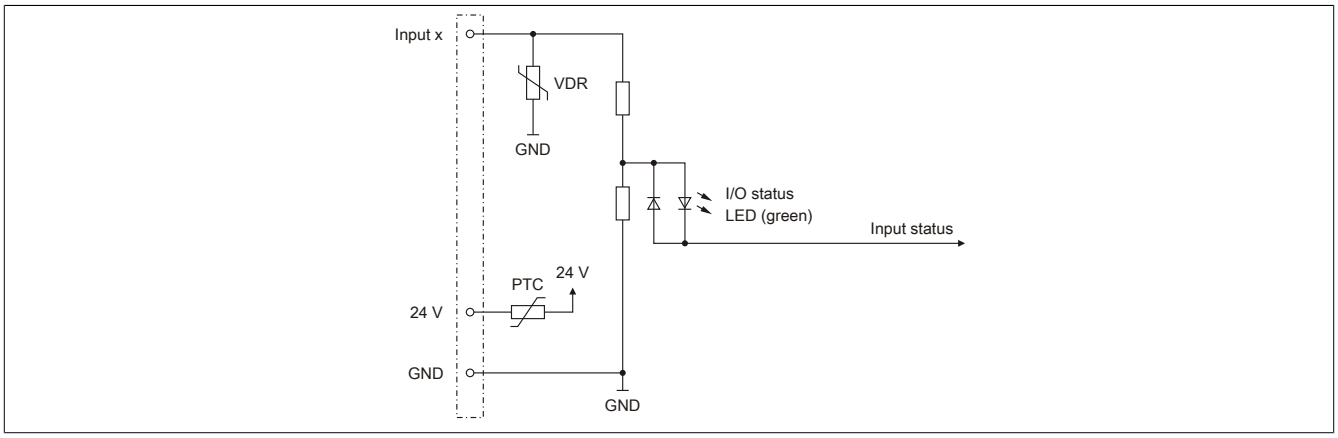
4.13.7.6 Pinout



4.13.7.7 Connection example

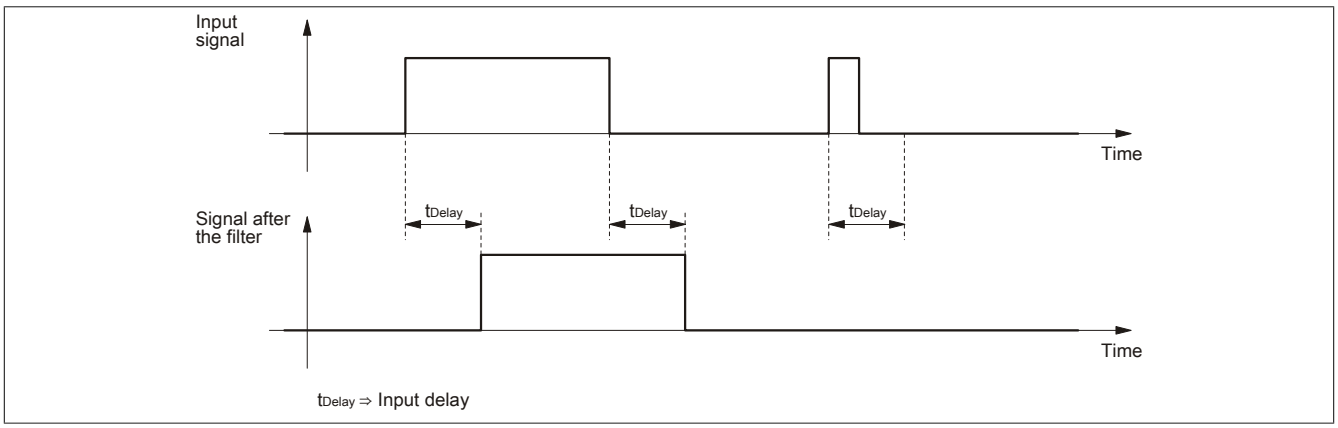


4.13.7.8 Input circuit diagram



4.13.7.9 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.7.10 Register description

4.13.7.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.7.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.7.10.3 Function model 1 - Event counter

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	Input status of digital inputs 1 to 4	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
4	2	Counter01	UINT	•			
6	4	Counter02	UINT	•			
8	6	Counter03	UINT	•			
10	8	Counter04	UINT	•			
12	0	Resets the counter registers	USINT			•	
		ResetCounter01	Bit 0				
		...	...				
		ResetCounter04	Bit 3				
18	-	ConfigOutput01	USINT				•
14	-	ConfigOutput02	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.7.10.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 4	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.7.10.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.7.10.5 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.7.10.5.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.7.10.5.2 Input status of digital inputs 1 to 4

Name:
DigitalInput or
DigitalInput01 to DigitalInput04

The input status of digital inputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput04") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status - Digital input 4

4.13.7.10.6 The event counter function model

Starting with hardware variant F0 and firmware version 801, the module has four software counters for signal edges. Each counter register can be configured individually for falling, rising or both edges.

4.13.7.10.6.1 Counter register

Name:
Counter01 to Counter04

These registers provide the current counter value for the configured events.

Data type	Value
UINT	0 to 65535

4.13.7.10.6.2 Resets the counter registers

Name:
ResetCounter01 to ResetCounter04

Using these data points, the corresponding counter registers can be reset to 0.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	ResetCounter01	0	No change
		1	Counter register 1 is reset
...		...	
3	ResetCounter04	0	No change
		1	Counter register 4 is reset

Information:

A counter is only reset if a positive edge is detected on the reset bit.

A continually set reset bit does not prevent counting in the counter register.

4.13.7.10.6.3 Configuration of the edges

Name:
ConfigOutput02

This register is used to configure which event will be assessed on the channel input for the respective counter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Rising edge on input 1	0	Event is not counted
		1	Event increments Counter01
...		...	
3	Rising edge on input 4	0	Event is not counted
		1	Event increments Counter04
4	Falling edge on input 1	0	Event is not counted
		1	Event increments Counter01
...		...	
7	Falling edge on input 4	0	Event is not counted
		1	Event increments Counter04

4.13.7.10.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.7.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.8 X20DI4372

4.13.8.1 General Information

The module is equipped with 4 inputs for 3-wire connections.

- 4 digital inputs
- Source connection
- 3-wire connections
- 24 VDC and GND for sensor supply
- Software input filter can be configured for entire module

4.13.8.2 Order data

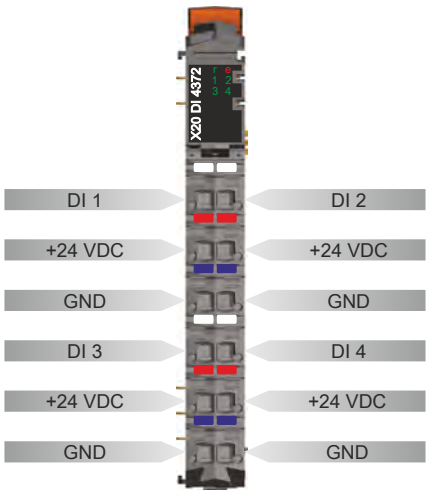
4.13.8.4 Status LEDs

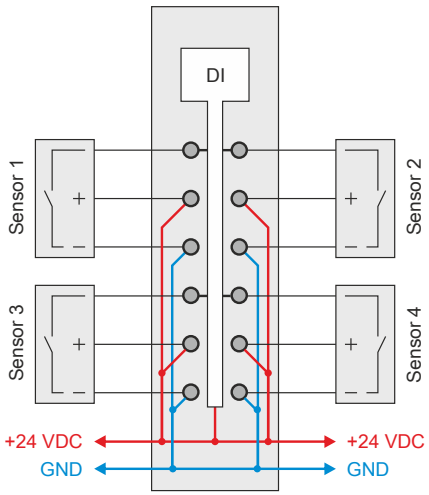
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input status of the corresponding digital input

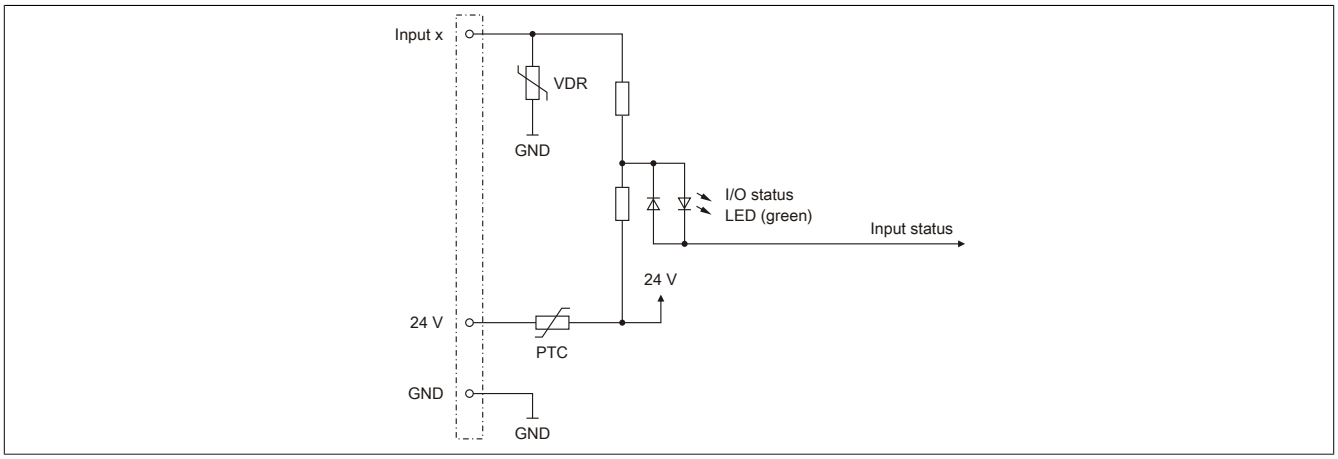
4.13.8.5 Pinout



4.13.8.6 Connection example

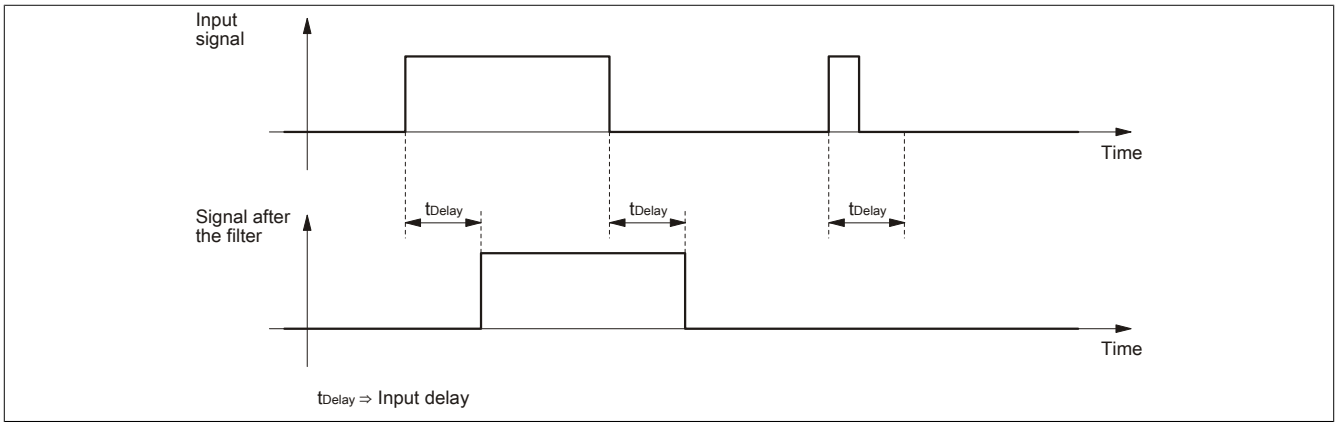


4.13.8.7 Input circuit diagram



4.13.8.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.8.9 Register description

4.13.8.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.8.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.8.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 4	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.8.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.8.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.8.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.8.9.4.2 Input status of digital inputs 1 to 4

Name:
DigitalInput or
DigitalInput01 to DigitalInput04

The input status of digital inputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput04") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status - Digital input 4

4.13.8.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.8.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.9 X20(c)DI4375

4.13.9.1 General Information

The module is equipped with 4 inputs for 3-wire connections. It has open circuit and short circuit detection. This detection can be switched off individually for each channel.

- 4 digital inputs
- Sink connection
- 3-wire connections
- 24 VDC and GND for sensor supply
- Open circuit and short circuit detection, can be switched off individually for each channel
- Software input filter can be configured for entire module

4.13.9.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.13.9.5 Status LEDs

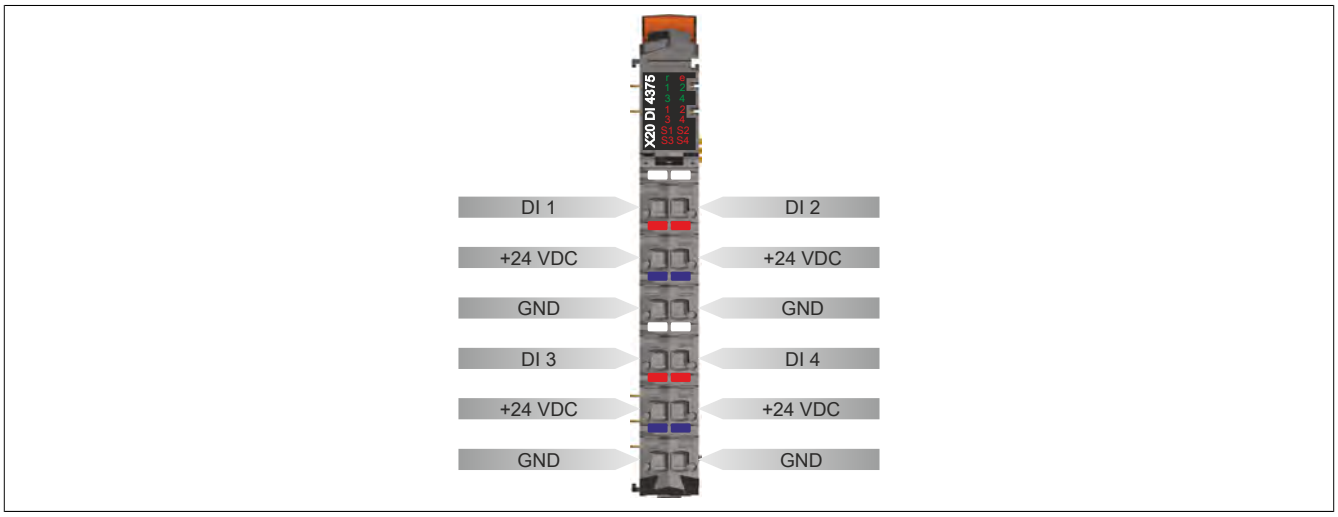
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Summary status for channel error → Check the red channel LEDs 1 - 4
			Double flash	Module supply below lower limit
			Triple flash	Converter error (or transition between single and double flash)
	1 - 4	Green		Input status of the corresponding digital input
	1 - 4	Red	Off	No error detected
			Single flash	Short circuit of respective digital input with +24 VDC
			Blinking	Open circuit or the measured value is below the lower switch off threshold
			Single flash, inverse	Other channel error
	S1 - S4	Red	Off	Sensor supply OK
			On	Sensor supply monitor has detected something

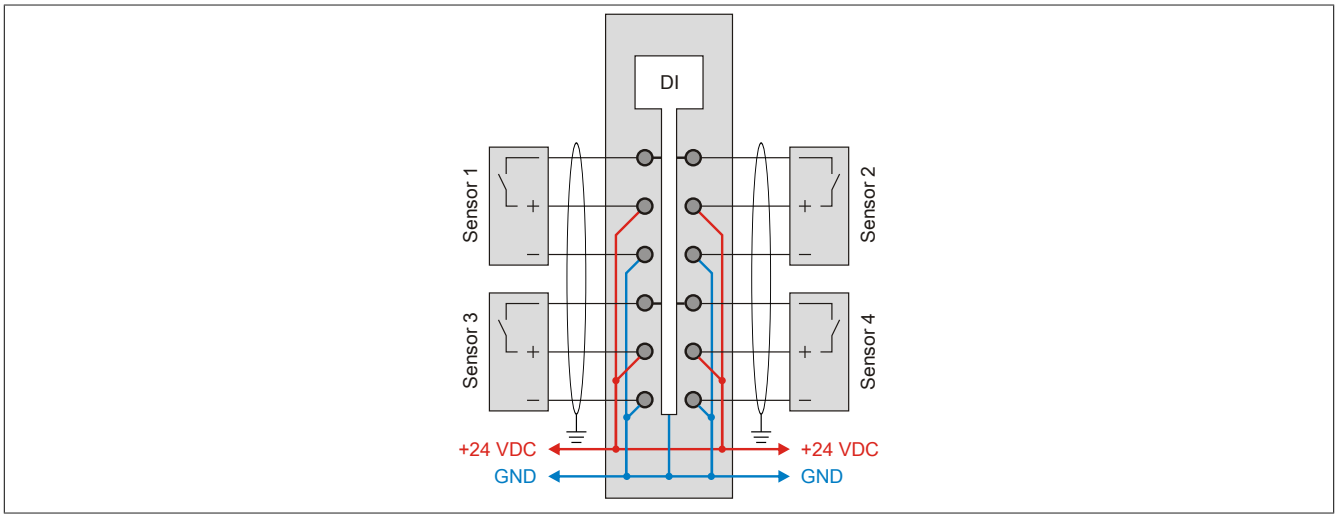
1) Depending on the configuration, a firmware update can take up to several minutes.

4.13.9.6 Pinout

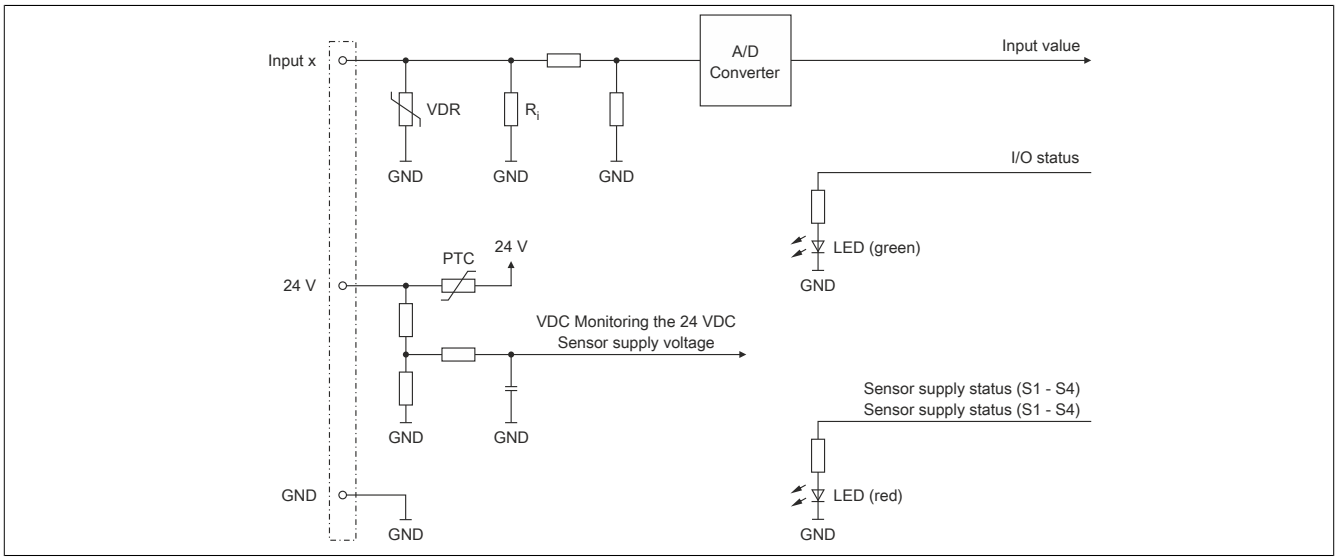
Shielded cables should be used for all connections.



4.13.9.7 Connection example

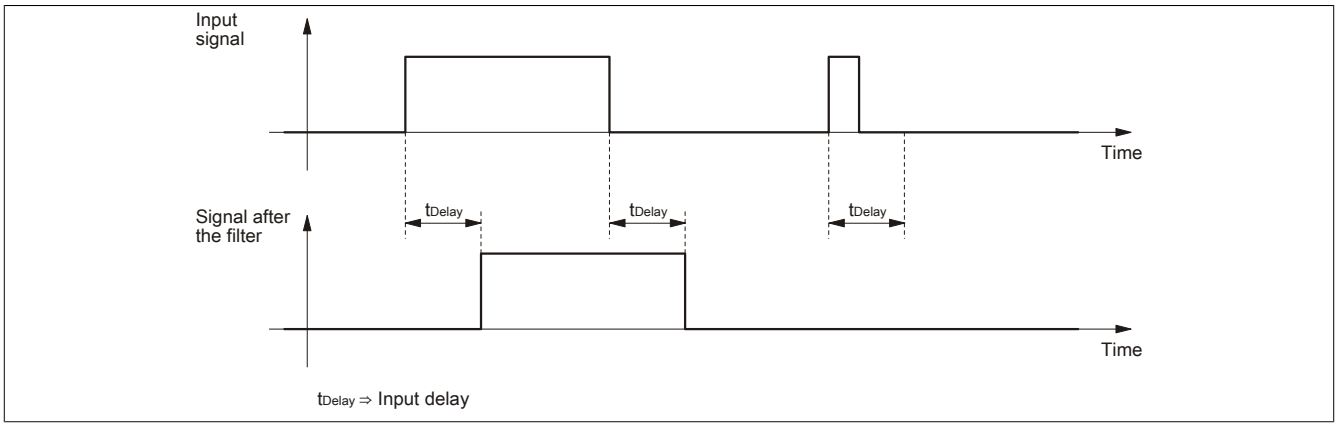


4.13.9.8 Input circuit diagram



4.13.9.9 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.9.14.4.1 "ConfigOutput02" on page 1260. Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.9.10 Open circuit and short circuit detection

General Information

The X20DI4375 digital input module is equipped with open line and short circuit detection. To do this the sensor needs to be connected to the necessary resistances.

Sensor connections

The resistances are connected to the sensor parallel or in series. The following values are defined for the resistances:

Resistance	Range
Serial	1 - 2 kΩ (10%)
Parallel	10 - 20 kΩ (10%)

Connection options

To guarantee error-free functionality of the open circuit and short circuit detection, the +24 VDC sensor supply from the module must absolutely be used.

Sensor connections	Description	Detection	Setting in configuration register
	Standard connection	-	0
	Series and parallel resistance	Open circuit and short circuit	1
	Parallel and series resistor	Open circuit and short circuit	2
	Parallel resistance	Open line	3
	Series resistor	Short circuit	4

4.13.9.11 Error status

The following errors are detected by the module and can be evaluated separately for each channel:

- Sensor line short circuit
- Sensor line open circuit
- Sensor supply
- Other channel error

4.13.9.12 Timestamp

Each converted value is given a timestamp. The time of the last conversion can be read.

4.13.9.13 Configuration

The sensor connections and therefore the sensor monitoring are set in the configuration register. Sensor monitoring and the settings in the configuration register are described in section 4.13.9.10 "Open circuit and short circuit detection" on page 1257.

4.13.9.14 Register description

4.13.9.14.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.9.14.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
2305	DigitalInput	USINT	•

2050	-	ConfigOutput01	UINT				•
2053	-	ConfigOutput02	USINT				•

1) The offset specifies the position of the register within the CAN object.

4.13.9.14.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.9.14.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.9.14.4.1 Digital input filter

Name:
ConfigOutput02

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.9.14.4.2 Input status of digital inputs 1 to 4

Name:
DigitalInput or
DigitalInput01 to DigitalInput04
StateDigitalInput01 to StateDigitalInput04

The input status and status of digital inputs 1 to 4 are mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput04" and "StateDigitalInput01" through "StateDigitalInput04") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status - Digital input 4
4	StateDigitalInput01	0	No error
		1	Short-circuit, open line, sensor monitoring error or other channel error
...		...	
7	StateDigitalInput04	0	No error
		1	Short-circuit, open line, sensor monitoring error or other channel error

4.13.9.14.5 Short circuit monitoring of channels 1 to 4

Name:
StatusInput01 or
SC_DigitalInput01 to SC_DigitalInput04

This register indicates whether a short circuit has occurred on the individual channels.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("SC_DigitalInput01" through "SC_DigitalInput04") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	SC_DigitalInput01	0	No error
		1	Short circuit on channel 1
...		...	
3	SC_DigitalInput04	0	No error
		1	Short circuit on channel 4
4 - 7	Reserved		

4.13.9.14.6 Open line monitoring on channels 1 to 4

Name:
StatusInput02 or
WB_DigitalInput01 to WB_DigitalInput04

This register indicates whether an open line has occurred on the individual channels.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("WB_DigitalInput01" through "WB_DigitalInput04") or whether this register should be displayed as an individual USINT data point ("StatusInput02").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	WB_DigitalInput01	0	No error
		1	Open line on channel 1
...		...	
3	WB_DigitalInput04	0	No error
		1	Open line on channel 4
4 - 7	Reserved	-	

4.13.9.14.7 Voltage monitoring on channels 1 to 4

Name:
StatusInput03 or
SM_DigitalInput01 to SM_DigitalInput04

This register monitors the voltage supply on the individual channels.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("SM_DigitalInput01" through "SM_DigitalInput04") or whether this register should be displayed as an individual USINT data point ("StatusInput03").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	SM_DigitalInput01	0	No error
		1	Sensor supply error on channel 1
...		...	
3	SM_DigitalInput04	0	No error
		1	Sensor supply error on channel 4
4 - 7	Reserved	-	

4.13.9.14.8 Error monitoring on channels 1 to 4

Name:
StatusInput04 or
IE_DigitalInput01 to IE_DigitalInput04

This register indicates whether any other errors have occurred on the individual channels.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("IE_DigitalInput01" through "IE_DigitalInput04") or whether this register should be displayed as an individual USINT data point ("StatusInput04").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	IE_DigitalInput01	0	No error
		1	Other error on channel 1
...		...	
3	IE_DigitalInput04	0	No error
		1	Other error on channel 4
4 - 7	Reserved	-	

4.13.9.14.9 Timestamp of last conversion

Name:
SampleTimeStamp

This register shows the timestamp of the last conversion in µs.

Data type	Value
UDINT	Timestamp of the last conversion in µs

4.13.9.14.10 Configuration of line status monitoring

Name:
ConfigOutput01

This register is used to configure short circuit monitoring and line status monitoring on the inputs.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 3	Channel configuration - Channel 1	0	Standard
		1	Serial/Parallel: R-1k in series with (R-10k parallel to the switch)
		2	Parallel/Serial: R-10k parallel to (R-1k in series with switch)
		3	Parallel: R-10k parallel to switch
		4	Serial: R-1k in series with switch
		5 to 15	Inactive
4 - 7	Channel configuration - Channel 2	0 to 15	See Channel configuration - Channel 1
8 - 11	Channel configuration - Channel 3	0 to 15	See Channel configuration - Channel 1
12 - 15	Channel configuration - Channel 4	0 to 15	See Channel configuration - Channel 1

The name R-1k indicates a resistance in the permitted range of 1000 Ohm to 2000 Ohm with an accuracy of 10%.

The name R-10k indicates a resistance in the permitted range of 10000 Ohm to 20000 Ohm with an accuracy of 10%.

Information:

Inputs that are not being used should be set to the type "Standard" or "Serial" to prevent mistakes.

Configuration Possibilities:

Value	Configuration	Diagram	Information
0	**Standard**		Short-circuit detection and line break monitoring is not possible when using this configuration.
1	**Serial/parallel**		Short-circuit detection and line break monitoring is possible with this configuration.
2	**Parallel/serial**		Short-circuit detection and line break monitoring is possible with this configuration.
3	**Parallel**		This configuration allows line break monitoring. Short-circuit detection is not possible when using this configuration.
4	**Serial**		This configuration allows short circuit detection. Line break monitoring is not possible when using this configuration.

4.13.9.14.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
All channels	150 µs

4.13.9.14.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
All channels	150 µs

4.13.10 X20DI4653

4.13.10.1 General Information

The module is equipped with 4 inputs for 2-wire connections. It is designed for an input voltage of 100 to 240 VAC.

- 4 digital inputs
- 100 to 240 VAC inputs
- 50 Hz or 60 Hz
- 2-wire connections
- 240 V coded

> **Danger!**
>
> **Risk of electric shock!**
>
> **The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.**

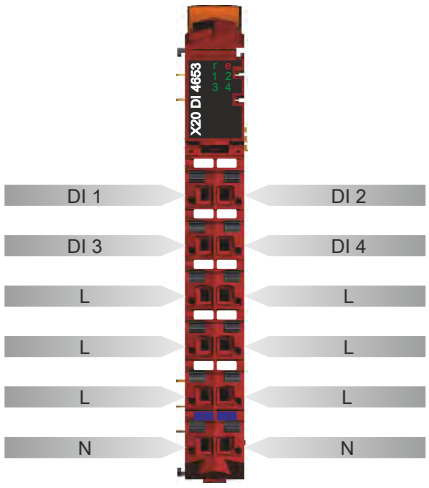
4.13.10.4 Status LEDs

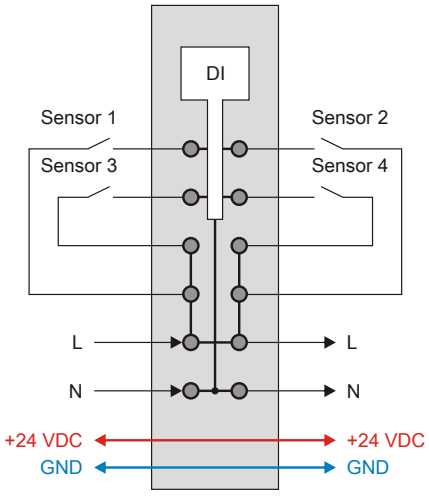
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Double flash	External supply is too low or not connected
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input status of the corresponding digital input

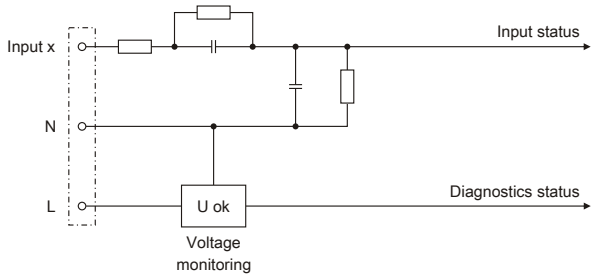
4.13.10.5 Pinout



4.13.10.6 Connection example

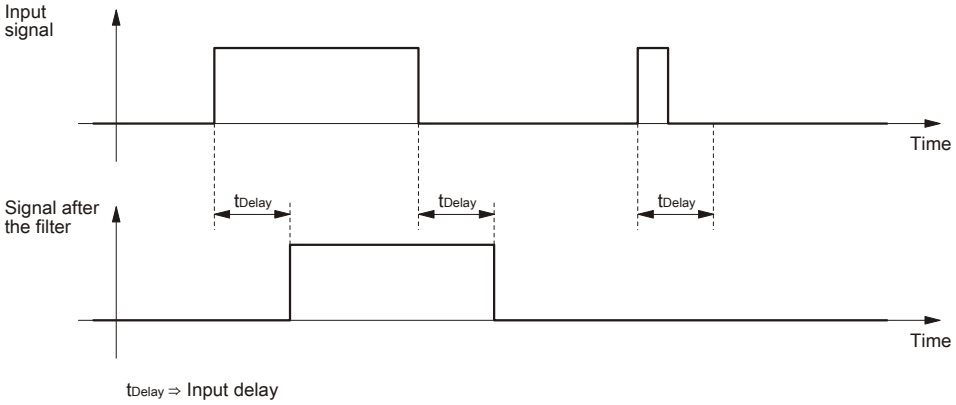


4.13.10.7 Input circuit diagram



4.13.10.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.10.9 Register description

4.13.10.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.10.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.10.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 4	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.10.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.10.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.10.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.10.9.4.2 Input status of digital inputs 1 to 4

Name:
DigitalInput or
DigitalInput01 to DigitalInput04
PowerSupply

The input status of digital inputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02" and "PowerSupply") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status - Digital input 4
4 - 6	Reserved	0	
7	PowerSupply	0	Supply voltage too low
		1	Supply voltage >80 VAC

4.13.10.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.10.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.11 X20(c)DI4760

4.13.11.1 General Information

The module is used to transfer digital signals from NAMUR encoders according to EN 60947-5-6. In addition to NAMUR encoders, normal switches can also be used.

- 4 digital inputs
- Input module for NAMUR encoders
- Open line and short circuit detection
- Each input can be used as a counter input

4.13.11.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.13.11.3 Order data

Model number	Short description	Figure
	Digital inputs	
X20DI4760	X20 digital input module, 4 NAMUR inputs, 8.05 V	
X20cDI4760	X20 digital input module, coated, 4 NAMUR inputs, 8.05 V

4.13.11.4 Technical data

Product ID	X20DI4760	X20cDI4760
Short description		
I/O module	4 NAMUR inputs, special function	
General information		
B&R ID code	0x2105	0xE221
Status indicators	I/O function by channel, open line and short circuit detection by channel, operating status, module status	
Diagnostics		
Module run/error	Yes, using status LED and software	
Short circuit	Yes, using status LED and software	
Open line	Yes, using status LED and software	
Power consumption		
Bus	0.01 W	
Internal I/O	1.5 W	
Additional power dissipation caused by the actuators (resistive) [W]	-	
Electrical isolation		
Channel - Bus	Yes	
Channel - Channel	No	
Certification		
CE	Yes	
cULus	Yes	
cCSAus HazLoc Class 1 Division 2	Yes	-
ATEX Zone 2 [1]	Yes	
KC	Yes	-
GL	Yes	
GOST-R	Yes	
Event counter		
Quantity	4	
Signal form	Symmetrical square wave pulse or corresponding minimum pulse duration [2]	
Evaluation	Every rising edge, cyclic counter	
Counter size	8-bit	
Input frequency		
1 input active	Max. 1600 Hz	
2 inputs active	Max. 1100 Hz	
3 inputs active	Max. 870 Hz	
4 inputs active	Max. 680 Hz	
NAMUR inputs		
Open line detection	<350 µA	
Input circuit	For NAMUR encoders in accordance with EN 60947-5-6	
Isolation voltage between channel and bus	500 V_{eff}	
Short circuit detection	>7 mA	
No load voltage	8.05 V ±0.33%	
Switching amplifier internal resistance	1 kΩ ±1%	
Max. short circuit current	8.2 mA	
Input delay		
1 input active	≤310 µs	
2 inputs active	≤450 µs	
3 inputs active	≤570 µs	
4 inputs active	≤735 µs	
Switching threshold		
Area	1.2 mA to 2.1 mA	
Switching hysteresis	Typ. 300 µA	
Operating conditions		
Mounting orientation		
Horizontal	Yes	
Vertical	Yes	
Installation at elevations above sea level		
0 to 2000 m	No limitations	
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m	
EN 60529 protection	IP20

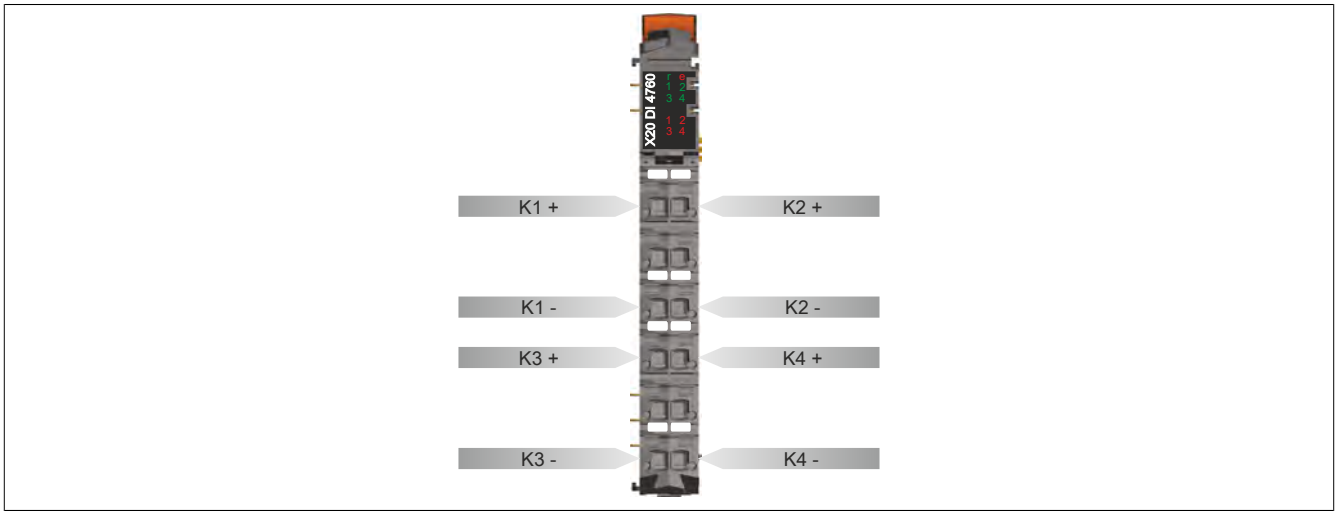
   Ta max.: See environmental conditions
2) Minimum pulse duration: t[s] ≥ 1/(2 x f_{max}[Hz])

4.13.11.5 Status LEDs

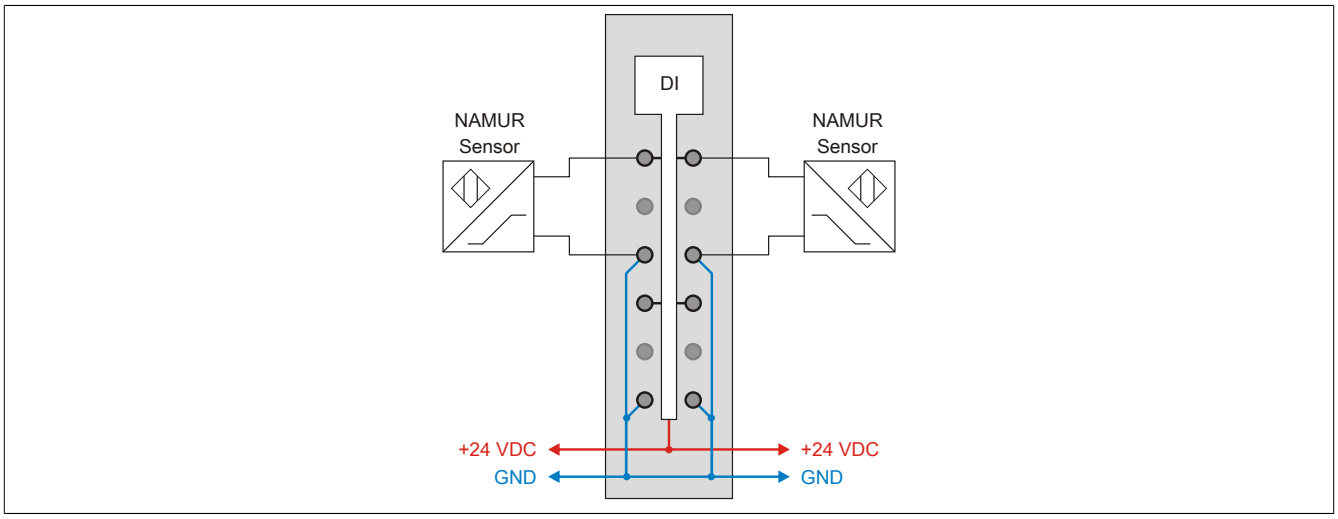
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Error on at least one channel
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green	Off	Open line or input status log. 0
			On	Short circuit or input status log. 1
	1 - 4	Red	Off	The sensor is ready for operation
			Blinking 1Hz	Open line on corresponding channel
			On	Short circuit on corresponding channel

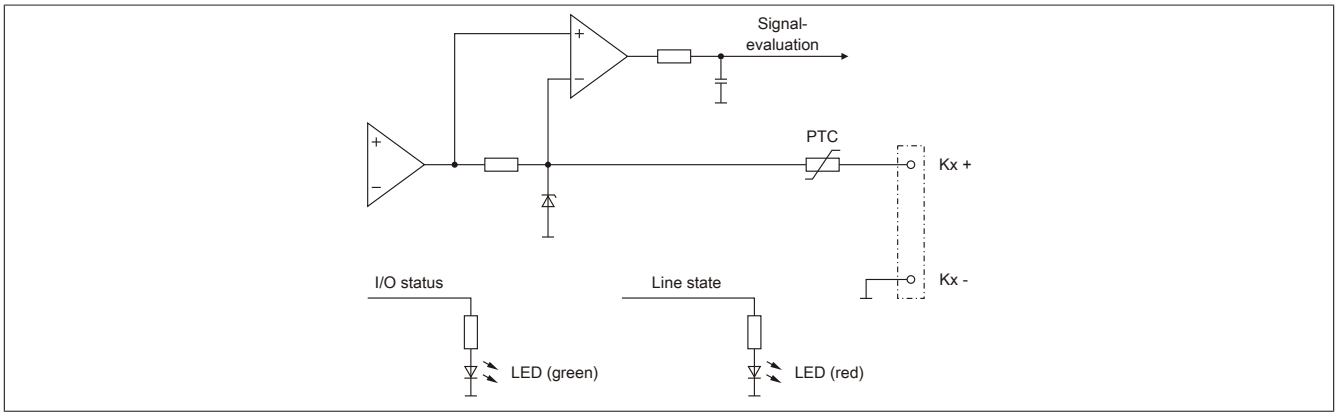
4.13.11.6 Pinout



4.13.11.7 Connection example

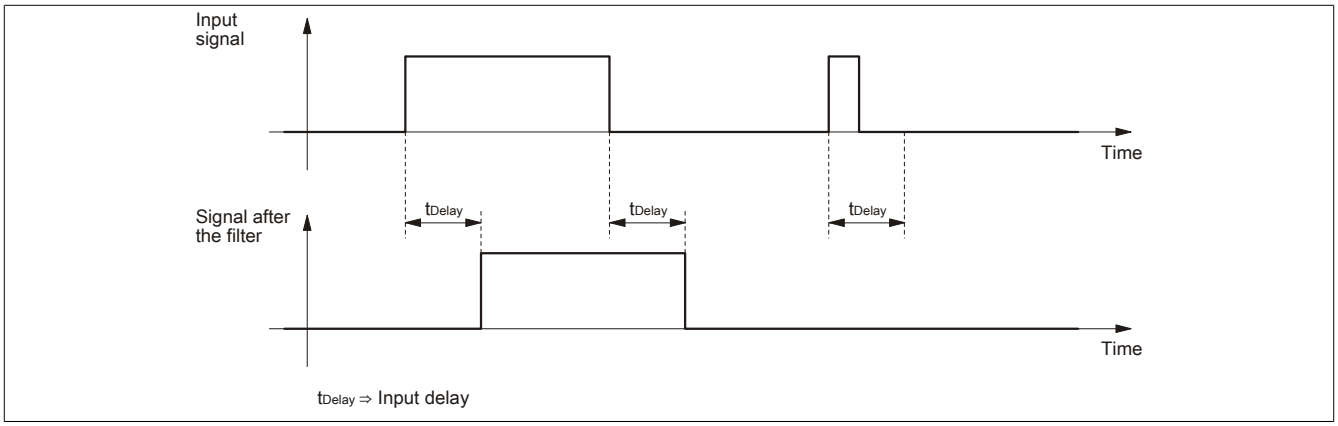


4.13.11.8 Input circuit diagram



4.13.11.9 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.11.12.4.1 "ConfigOutput03" on page 1277. Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.11.10 Examples of possible signal generators

Proximity switch	
Switch in accordance with EN 60947-5-6 (NAMUR)	Mechanical contacts (instead of NAMUR encoders)	
Without open line detection and without short circuit detection	Without open line detection and with short circuit detection	With open line detection and without short circuit detection	With open line detection and with short circuit detection	
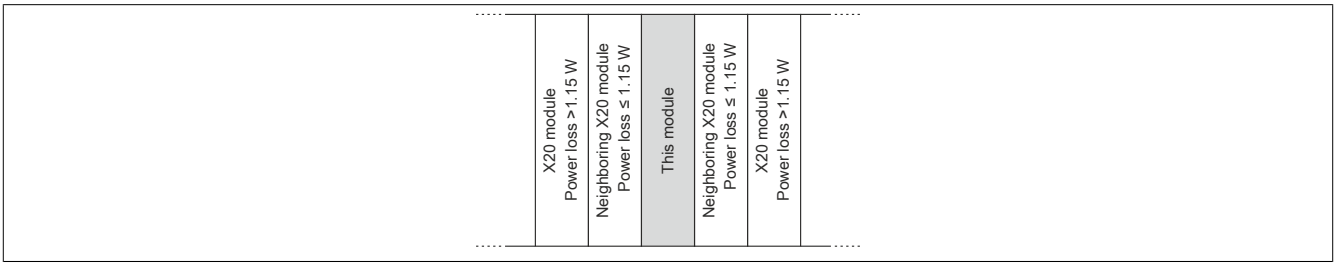
4.13.11.11 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.13.11.12 Register description

4.13.11.12.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.11.12.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
0	DigitalInput	USINT	•			
	DigitalInput01	Bit 0				
	...	...				
	DigitalInput04	Bit 3				
4	Counter01	USINT	•			
6	Counter02	USINT	•			
8	Counter03	USINT	•			
10	Counter04	USINT	•			
30	StatusInput	USINT	•			
	ShortCircuit01	Bit 0				
	...	...				
	ShortCircuit04	Bit 3				
	OpenLine01	Bit 4				
	...	...				
	OpenLine04	Bit 7				
16	OutputConfig01	USINT				•
18	OutputConfig02	USINT				•
20	OutputConfig03	USINT				•

4.13.11.12.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 4	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput04	Bit 3				
4	-	Counter01	USINT		•		
6	-	Counter02	USINT		•		
8	-	Counter03	USINT		•		
10	-	Counter04	USINT		•		
30	-	Status of channels 1 to 4	USINT		•		
		ShortCircuit01	Bit 0				
		...	...				
		ShortCircuit04	Bit 3				
		OpenLine01	Bit 4				
		...	...				
		OpenLine04	Bit 7				
16	-	ConfigOutput01	USINT				•
18	-	ConfigOutput02	USINT				•
20	-	ConfigOutput03	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.11.12.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.11.12.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.11.12.4.1 Digital input filter

Name:
ConfigOutput03

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.11.12.4.2 Input status of digital inputs 1 to 4

Name:
DigitalInput or
DigitalInput01 to DigitalInput04
PowerSupply

The input status of digital inputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02" and "PowerSupply") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 15	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status - Digital input 4
4 - 6	Reserved	0	
7	PowerSupply	0	Supply voltage too low
		1	Supply voltage >80 VAC

4.13.11.12.5 Positive edge counter on digital inputs

Name:
Counter01 to Counter04

These registers cyclically count the positive edges on the individual channels.

Data type	Value
USINT	Positive edge counter on channel, cyclic

4.13.11.12.6 Status of channels 1 to 4

Name:
StatusInput01 and
ShortCircuit01 to ShortCircuit04
OpenLine01 to OpenLine04

This register indicates whether an open line or overflow has occurred on the individual channels.

Only function model 0 - Standard:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("ShortCircuit01" to "ShortCircuit04" and "OpenLine01" to "OpenLine04") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Values	Information
USINT	0 to 255	Packed inputs = On
	See bit structure.	Packed inputs = Off or Function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	ShortCircuit01	0	No error
		1	Overload on channel 1
...		...	
3	ShortCircuit04	0	No error
		1	Overload on channel 4
4	OpenLine01	0	No error
		1	Open line on channel 1
...		...	
7	OpenLine04	0	No error
		1	Open line on channel 4

4.13.11.12.7 Function expansion

Firmware version 802 is offered for hardware variant 7 or higher of the module. This and subsequent firmware versions provide the user with new configuration possibilities.

4.13.11.12.7.1 Disabling channels and status messages

Name:
OutputConfig01

This register can be used to (de)activate individual channels or just their status responses.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1	0	Channel enabled
		1	Channel disabled
...		...	
3	Channel 4	0	Channel enabled
		1	Channel disabled
4	Status message - Channel 1	0	Status message activated
		1	Status message deactivated
...		...	
7	Status message - Channel 4	0	Status message activated
		1	Status message deactivated

4.13.11.12.7.2 Replacement values during overload

Name:
OutputConfig02

This register can be used to specify defined replacement values for the individual channels according to the error situation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Overload - Channel 1	0	Replacement value when overload is FALSE
		1	Replacement value when overload is TRUE
...		...	
3	Overload - Channel 4	0	Replacement value when overload is FALSE
		1	Replacement value when overload is TRUE
4	Open line - Channel 1	0	Replacement value when open line is FALSE
		1	Replacement value when open line is TRUE
...		...	
7	Open line - Channel 4	0	Replacement value when open line is FALSE
		1	Replacement value when open line is TRUE

4.13.11.12.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.11.12.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.12 X20(c)DI6371

4.13.12.1 General Information

The module is equipped with six inputs for 1 or 2-wire connections. The X20 6-pin terminal block can be used for universal 1-line wiring. Two-line wiring can be implemented using the 12-pin terminal block. The inputs on the module are designed for sink connections.

- 6 digital inputs
- Sink connection
- 2-wire connections
- 24 VDC for sensor supply
- Software input filter can be configured for entire module
- 1-wire connection type with 6-pin terminal block

4.13.12.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.13.12.3 Order data

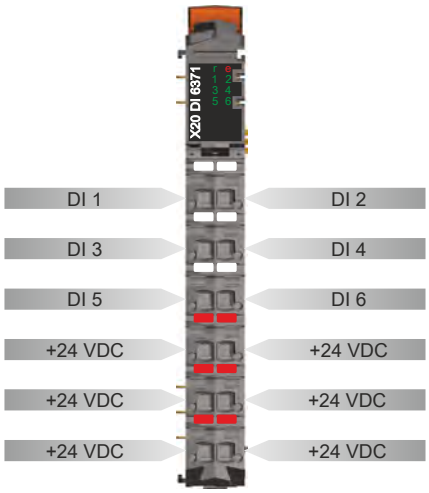
4.13.12.5 Status LEDs

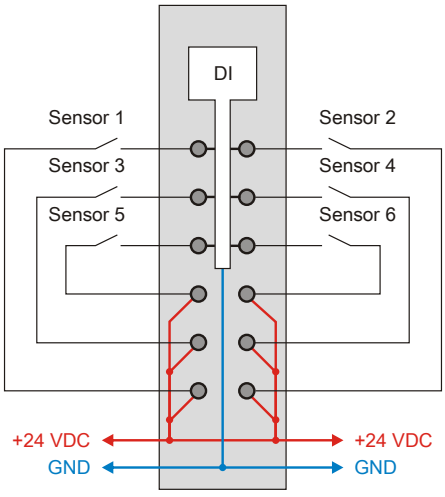
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Green		Input status of the corresponding digital input

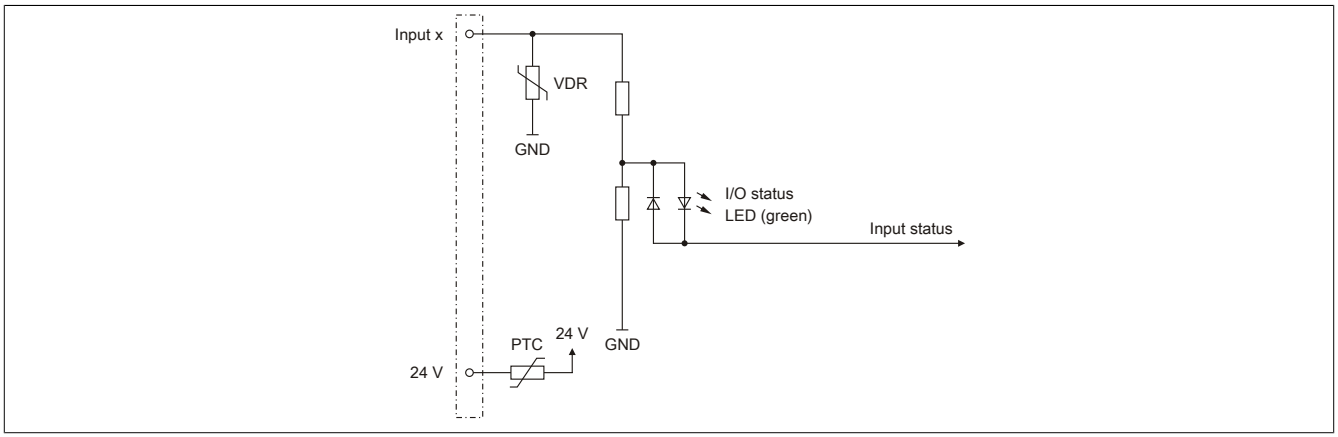
4.13.12.6 Pinout



4.13.12.7 Connection example

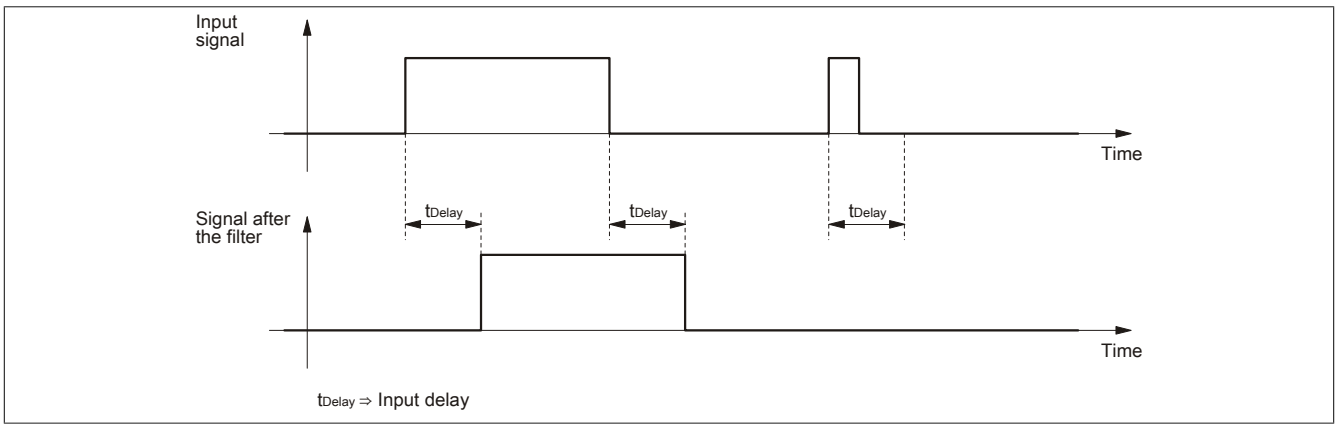


4.13.12.8 Input circuit diagram



4.13.12.9 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.12.10 Register description

4.13.12.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.12.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.12.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 6	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.12.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.12.10.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.12.10.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.12.10.4.2 Input status of digital inputs 1 to 6

Name:
DigitalInput or
DigitalInput01 to DigitalInput06

The input status of digital inputs 1 to 6 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput06") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 63	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
5	DigitalInput06	0 or 1	Input status - Digital input 6

4.13.12.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.12.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.13 X20(c)DI6372

4.13.13.1 General Information

The module is equipped with six inputs for 1 or 2-wire connections. The X20 6-pin terminal block can be used for universal 1-line wiring. Two-line wiring can be implemented using the 12-pin terminal block. The inputs on the module are designed for source connections.

- 6 digital inputs
- Source connection
- 2-wire connections
- 24 VDC for sensor supply
- Software input filter can be configured for entire module
- 1-wire connection type with 6-pin terminal block

4.13.13.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

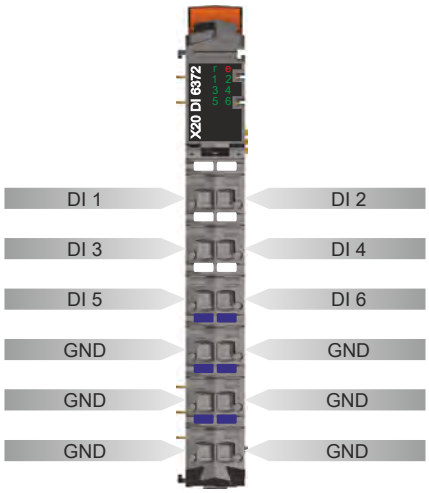
4.13.13.5 Status LEDs

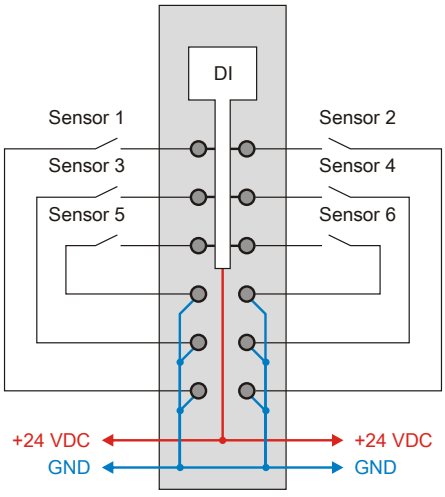
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Green		Input status of the corresponding digital input

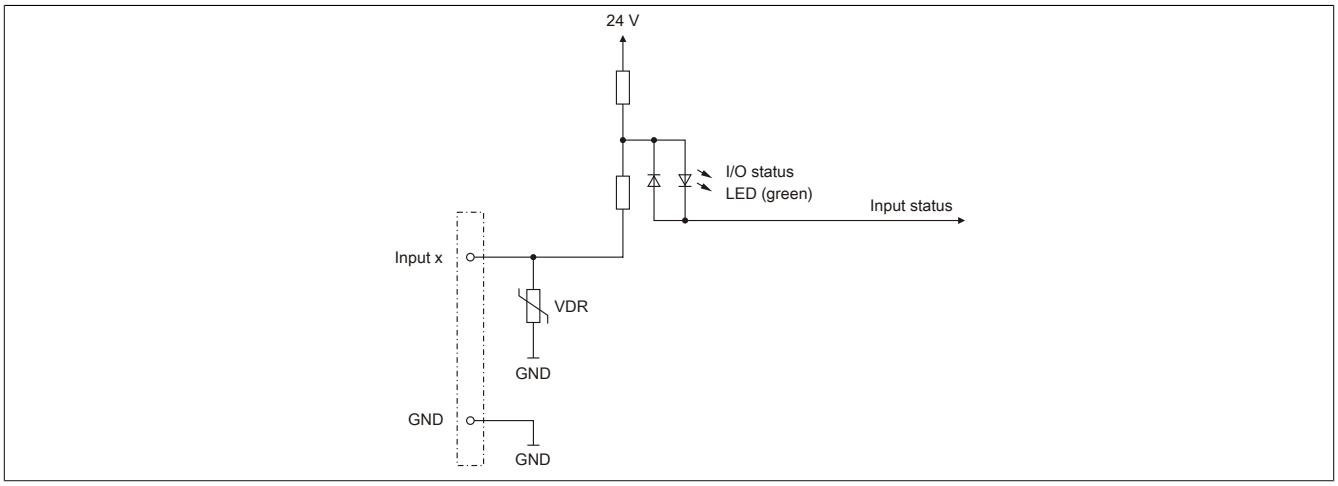
4.13.13.6 Pinout



4.13.13.7 Connection example

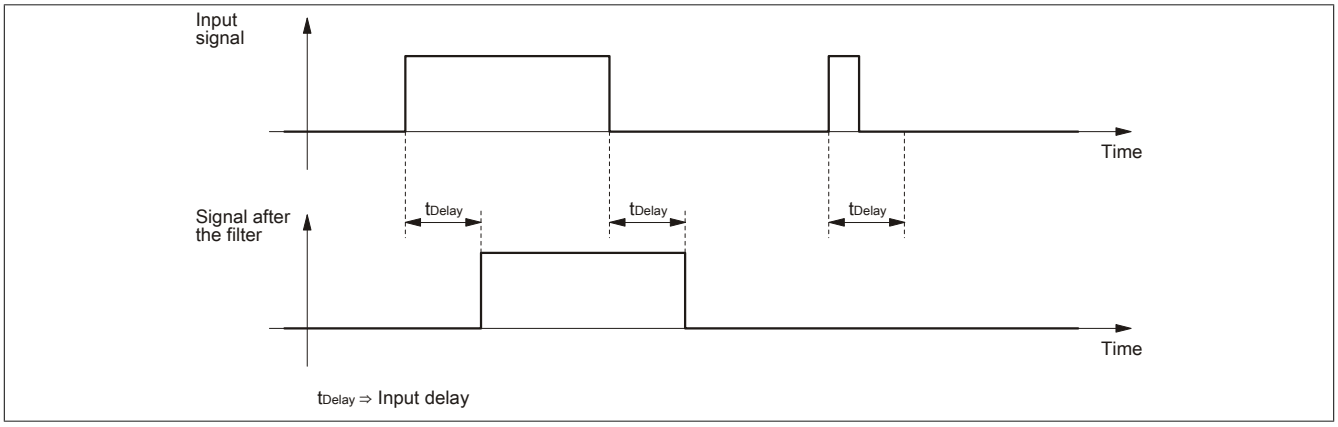


4.13.13.8 Input circuit diagram



4.13.13.9 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.13.10 Register description

4.13.13.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.13.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.13.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 6	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.13.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.13.10.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.13.10.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.13.10.4.2 Input status of digital inputs 1 to 6

Name:
DigitalInput or
DigitalInput01 to DigitalInput06

The input status of digital inputs 1 to 6 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput06") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 63	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
5	DigitalInput06	0 or 1	Input status - Digital input 6

4.13.13.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.13.13.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.13.14 X20DI6373

4.13.14.1 General Information

The module has 6 inputs. The input circuit can be sink or source thanks to the potential-free design of the inputs.

- 6 digital inputs
- Sink/Source connection
- Software input filter can be configured for entire module

4.13.14.2 Order data

Model number	Short description	Figure

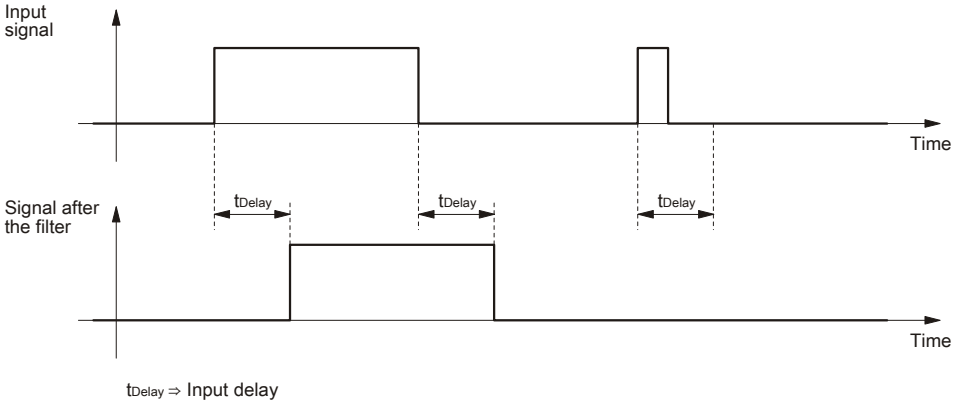
4.13.15.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.15.9 Register description

4.13.15.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.15.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.15.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 6	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput06	Bit 5				
		PowerSupply	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.15.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.15.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.15.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.15.9.4.2 Input status of digital inputs 1 to 6

Name:
DigitalInput or
DigitalInput01 to DigitalInput06
PowerSupply

The input status of digital inputs 1 to 6 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput02" and "PowerSupply") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 63	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
5	DigitalInput04	0 or 1	Input status - Digital input 6
6	Reserved	0	
7	PowerSupply	0	Supply voltage too low
		1	Supply voltage >80 VAC

4.13.15.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.15.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.13.16 X20DI8371

4.13.16.1 General Information

The module is equipped with eight inputs for 1-wire connections. The module is designed for sink input wiring.

- 8 digital inputs
- Sink connection
- 1-wire connections
- Software input filter can be configured for entire module

4.13.16.2 Order data

X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 284: X20DI8371 - Order data

4.13.16.3 Technical data

Product ID	X20DI8371
Short description	
I/O module	8 digital inputs 24 VDC for 1-wire connections
General information	
B&R ID code	0xA4AB
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.18 W
Internal I/O	-
External I/O	1.2 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Nominal voltage	24 VDC
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Typ. 3.75 mA
Input filter	
Hardware	≤100 µs
Software	Default 1 ms, configurable between 0 and 25 ms in 0.2 ms intervals
Connection type	1-wire connections
Input circuit	Sink
Input resistance	Typ. 6.4 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 285: X20DI8371 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

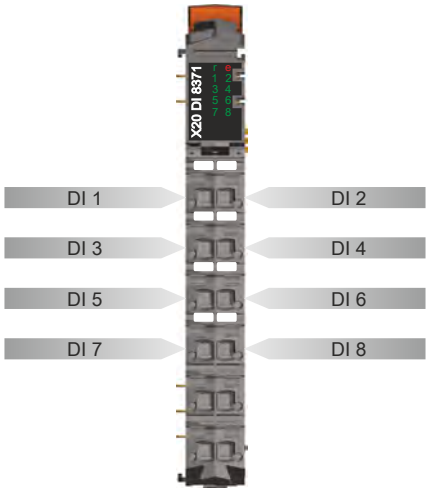
4.13.16.4 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

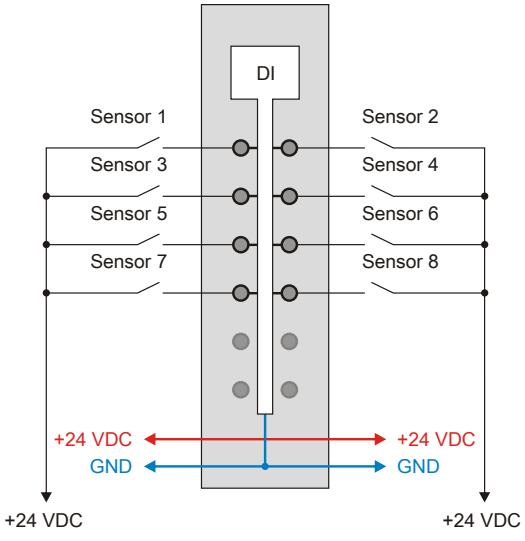
Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			Double flash	BOOT mode (during firmware update)[1)]
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Green		Input status of the corresponding digital input

1) Depending on the configuration, a firmware update can take up to several minutes.

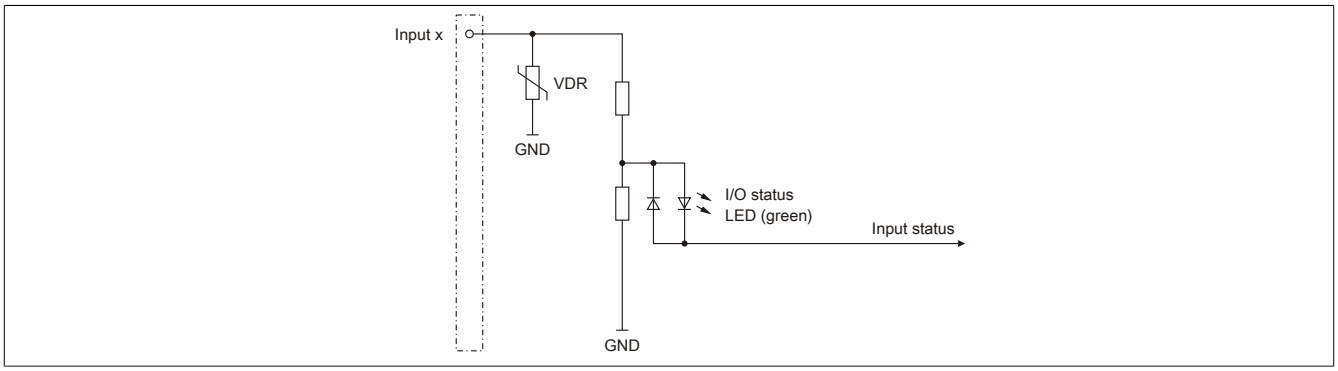
4.13.16.5 Pinout



4.13.16.6 Connection example

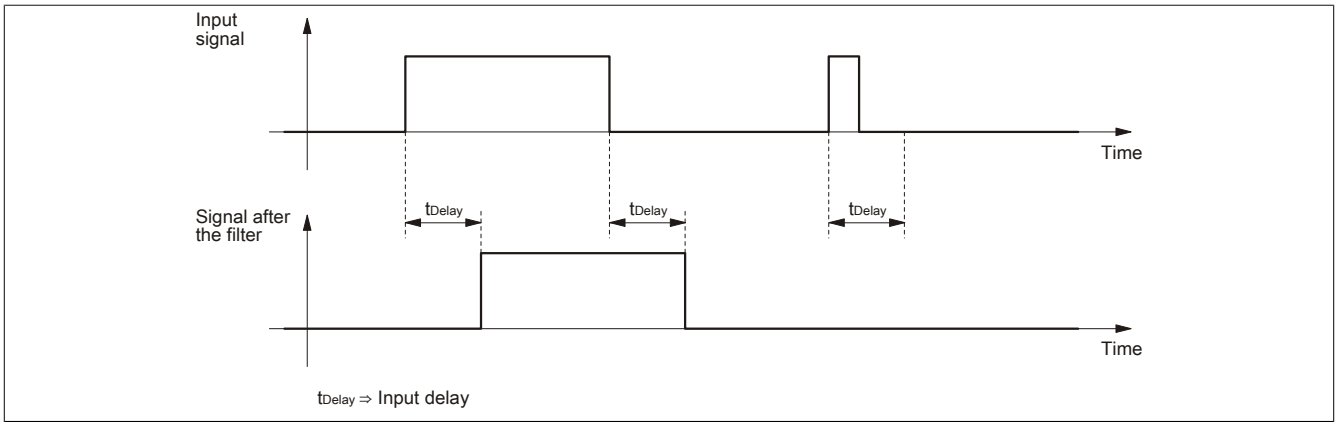


4.13.16.7 Input circuit diagram



4.13.16.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.16.9 Register description

4.13.16.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.16.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.16.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.16.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.16.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.16.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.16.9.4.2 Input state of digital inputs 1 to 8

Name:
DigitalInput or
DigitalInput01 to DigitalInput08

This register is used to indicate the input state of digital inputs 1 to 8.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput08") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input state - Digital input 8

4.13.16.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.16.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.13.17 X20(c)DI9371

4.13.17.1 General Information

The module is equipped with 12 inputs for 1-wire connections. The module is designed for sink input wiring.

- 12 digital inputs
- Sink connection
- 1-wire connections
- Software input filter can be configured for entire module

4.13.17.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

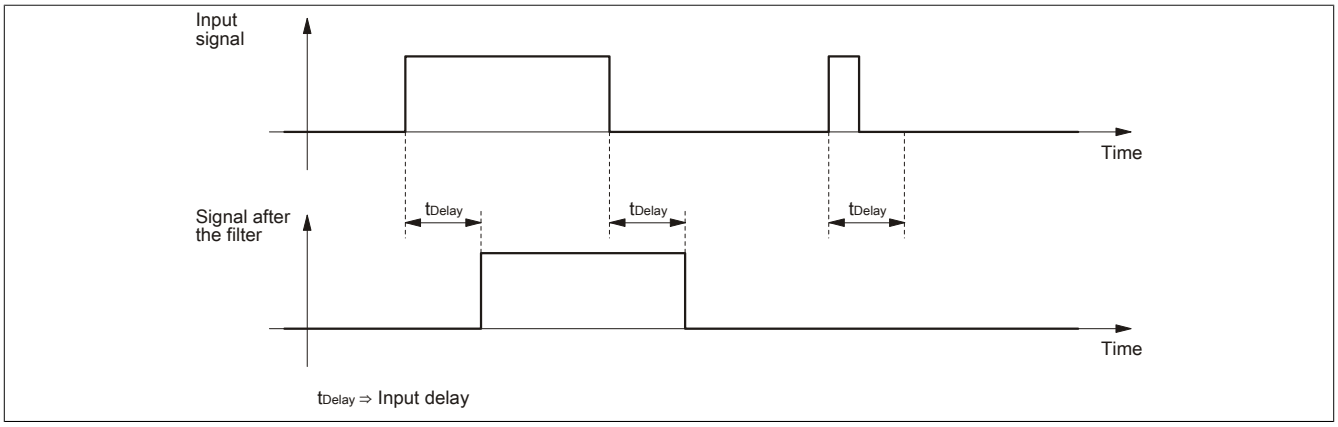
4.13.17.9 Input filter

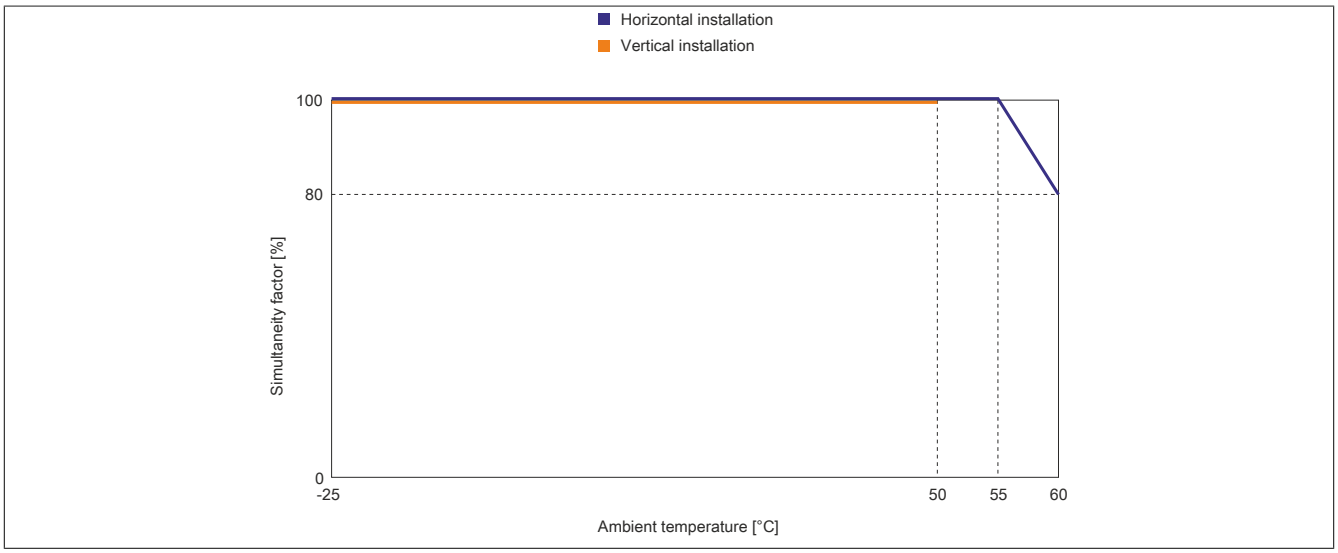
An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



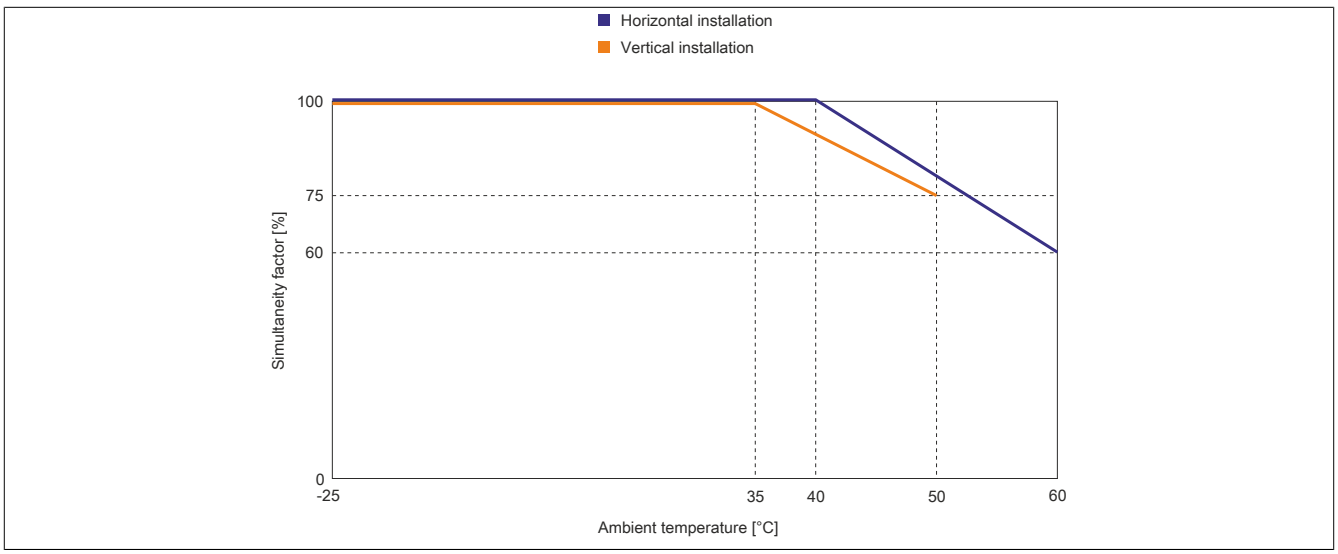
4.13.17.10 Derating

Be aware of the derating values below for the simultaneity factor.

Derating of simultaneity factor at 24 VDC input voltage



Derating of simultaneity factor at 28.8 VDC input voltage



4.13.17.11 Register description

4.13.17.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.17.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
-	1	DigitalInput	UINT	•			
0	1	Input status of digital inputs 1 to 8	USINT				
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	2	Input status of digital inputs 9 to 12	USINT	•			
		DigitalInput09	Bit 0				
		...	...				
		DigitalInput12	Bit 3				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.17.11.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 8	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	1	Input status of digital inputs 9 to 12	USINT	•			
		DigitalInput09	Bit 0				
		...	...				
		DigitalInput12	Bit 3				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.17.11.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.13.17.11.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.17.11.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.17.11.4.2 Input state of digital inputs 1 to 12

Name:
DigitalInput or
DigitalInput01 to DigitalInput12

This register indicates the input state of digital inputs 1 to 12.

Only function model 0 - Standard

The "Packed inputs" setting in the Automation Studio I/O configuration is used to determine whether all of the bits from these registers should be set up individually as data points in the Automation Studio I/O mapping ("DigitalInput01" to "DigitalInput12") or whether this register should be displayed as an individual UINT data point ("DigitalInput").

Data type	Values	Information
UINT	0 to 4095	Packed inputs = On
USINT	See bit structure.	Packed inputs = Off or Function model <> 0 - Standard

Bit structure:

Register 0

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input state - Digital input 8

Register 1

Bit	Name	Value	Information
0	DigitalInput09	0 or 1	Input state - Digital input 9
...		...	
3	DigitalInput12	0 or 1	Input state - Digital input 12

4.13.17.11.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.17.11.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.13.18 X20(c)DI9372

4.13.18.1 General Information

The module is equipped with 12 inputs for 1-wire connections. The module is designed for source input wiring.

- 12 digital inputs
- Source connection
- 1-wire connections
- Software input filter can be configured for entire module

4.13.18.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.13.19.3 Technical data

Product ID	X20DID371
Short description	
I/O module	8 digital inputs 24 VDC for 1- or 2-wire connections
General information	
B&R ID code	0xC0E7
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.13 W
Internal I/O	1.2 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Nominal voltage	24 VDC
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Typ. 3.75 mA
Input filter	
Hardware	≤100 µs
Software	Default 1 ms, configurable between 0 and 25 ms in 0.2 ms intervals
Connection type	1- or 2-wire connections
Input circuit	Sink
Input resistance	Typ. 6.4 kΩ
Sensor supply	0.5 A summation current
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB1F terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

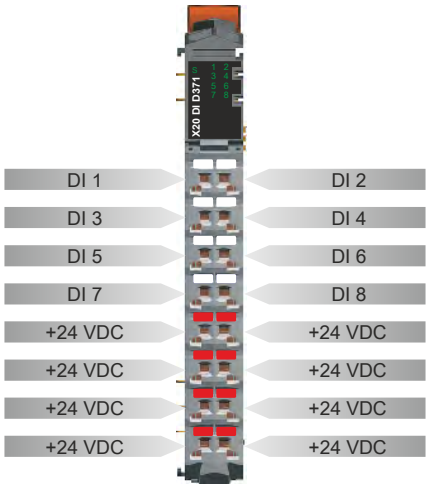
4.13.19.4 Status LEDs

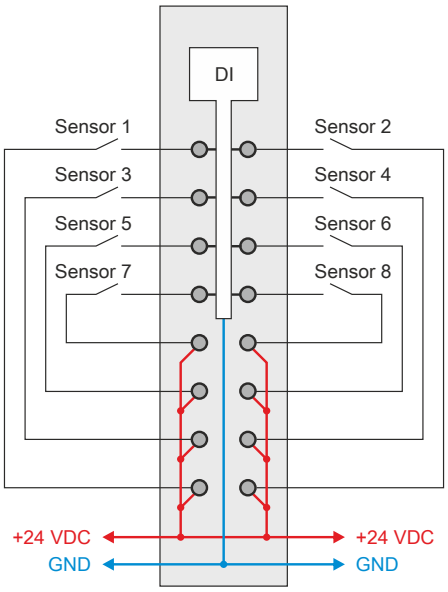
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	S	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	Module supply not connected or everything OK
		Red on / Green single flash		Invalid firmware
	1 - 8	Green		Input status of the corresponding digital input

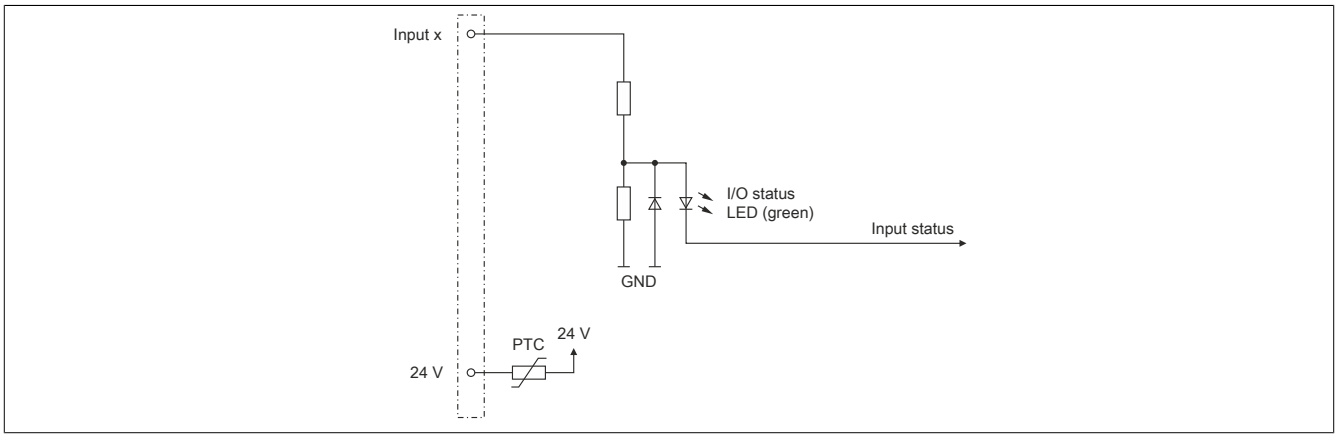
4.13.19.5 Pinout



4.13.19.6 Connection example

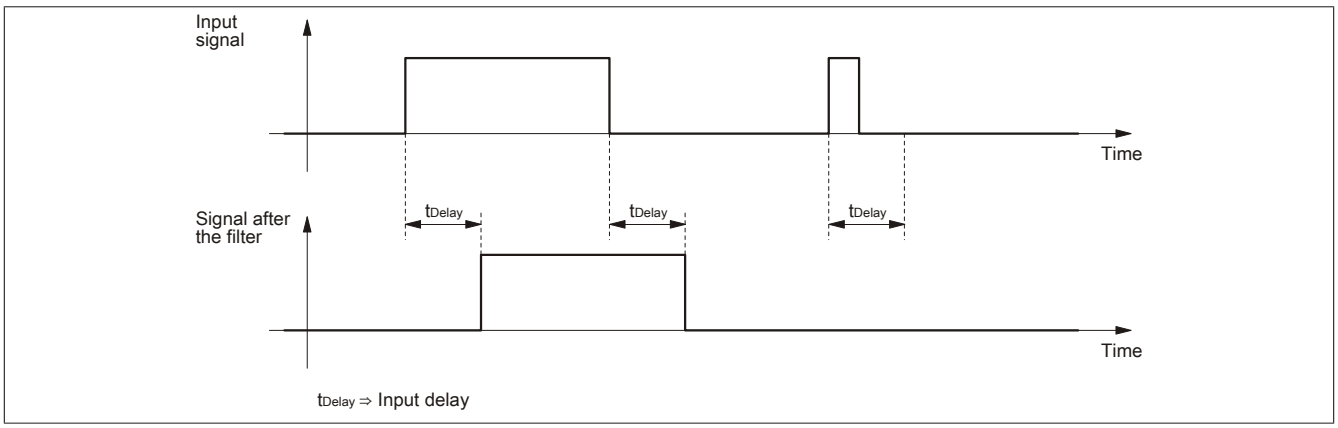


4.13.19.7 Input circuit diagram



4.13.19.8 Input filter

An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



4.13.19.9 Register description

4.13.19.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.19.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	1	DigitalInput	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.19.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input state of digital inputs 1 to 8	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.19.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.13.19.9.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.19.9.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.19.9.4.2 Input state of digital inputs 1 to 8

Name:
DigitalInput or
DigitalInput01 to DigitalInput08

This register is used to indicate the input state of digital inputs 1 to 8.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput08") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input state - Digital input 8

4.13.19.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.19.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.13.20 X20DIF371

4.13.20.1 General Information

The module is equipped with 16 inputs for 1-wire connections. The module is designed for sink input wiring.

- 16 digital inputs
- Sink connection
- 1-wire connections
- Software input filter can be configured for entire module

4.13.20.2 Order data

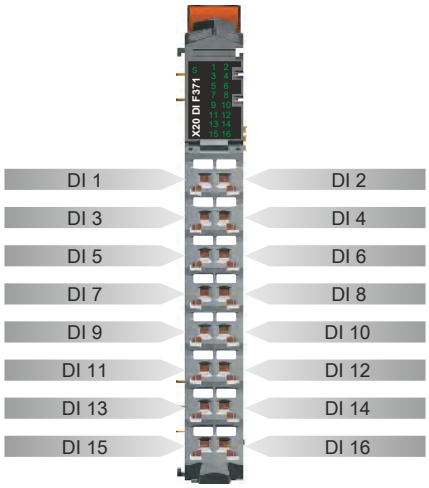
2) Derating must be taken into consideration.

4.13.20.4 Status LEDs

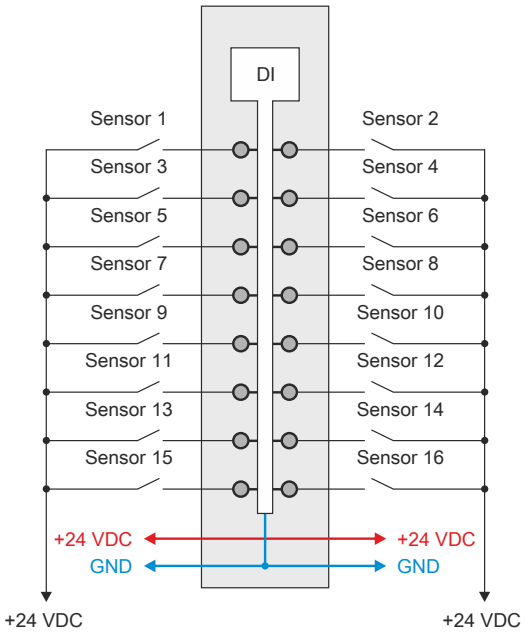
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	S	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	Module supply not connected or everything OK
		Red on / Green single flash		Invalid firmware
	1 - 16	Green		Input status of the corresponding digital input

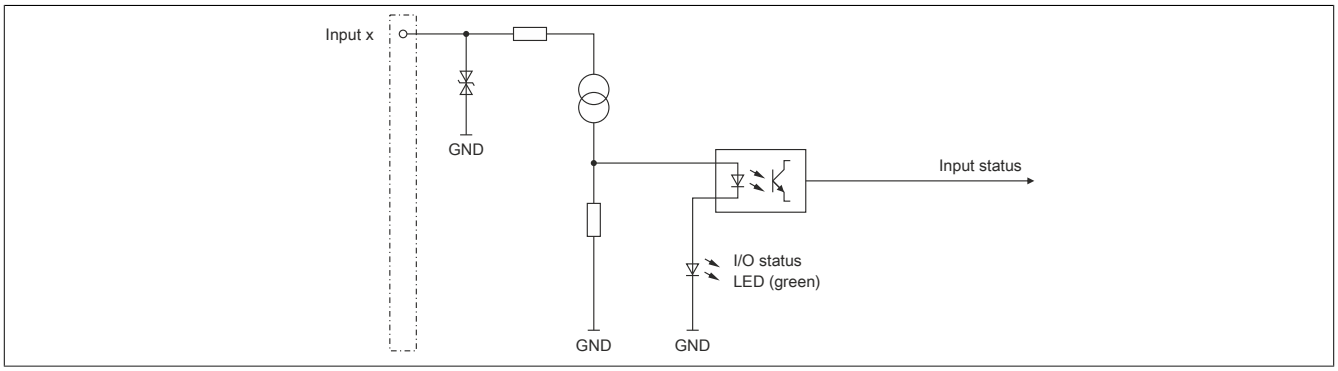
4.13.20.5 Pinout



4.13.20.6 Connection example

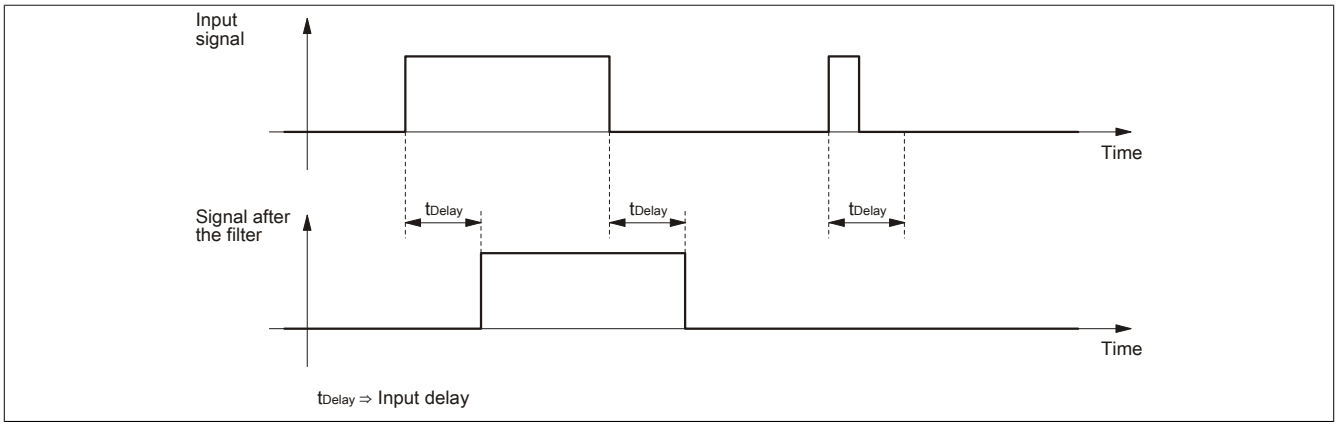


4.13.20.7 Input circuit diagram



4.13.20.8 Input filter

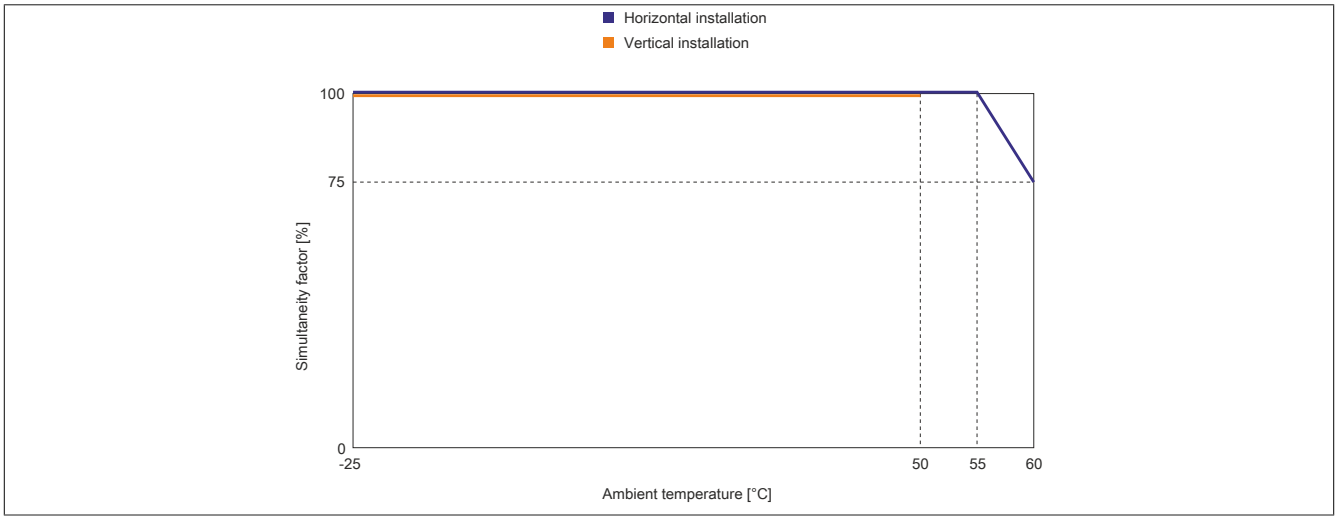
An input filter is available for each input. The input delay can be set using register 4.13.2.9.5 "ConfigOutput01". Disturbance pulses which are shorter than the input delay are suppressed by the input filter.



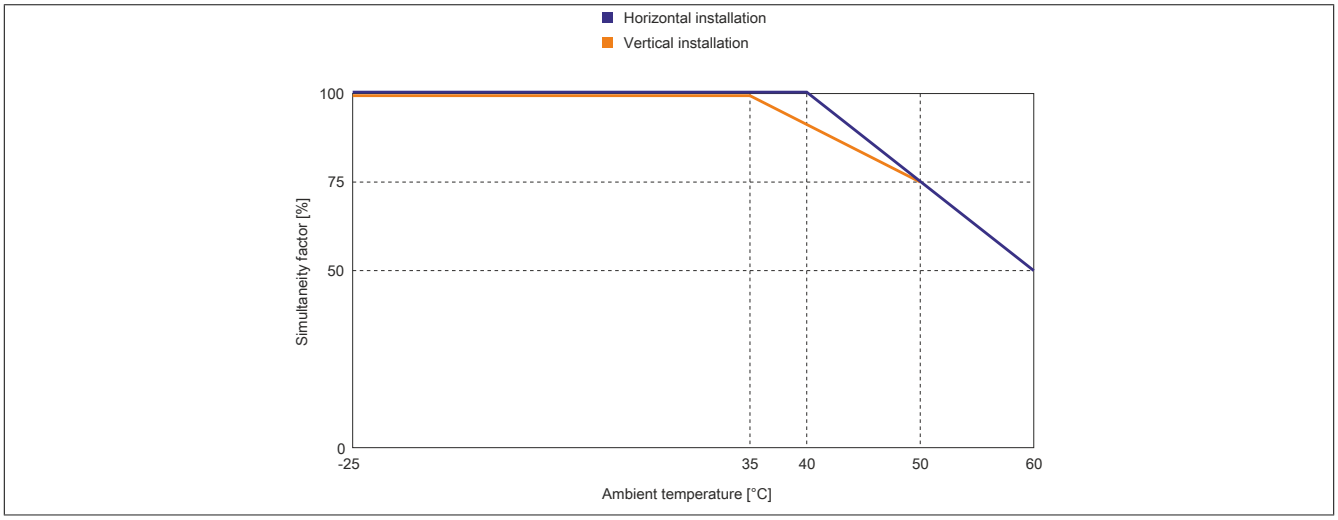
4.13.20.9 Derating

Be aware of the derating values below for the simultaneity factor.

Derating of simultaneity factor at 24 VDC input voltage



Derating of simultaneity factor at 28.8 VDC input voltage



4.13.20.10 Register description

4.13.20.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.13.20.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
-	1	DigitalInput	UINT	•			
0	1	Input status of digital inputs 1 to 8	USINT				
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	2	Input status of digital inputs 9 to 16	USINT	•			
		DigitalInput09	Bit 0				
		...	...				
		DigitalInput16	Bit 7				
18	-	ConfigOutput01	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.13.20.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Input status of digital inputs 1 to 8	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
1	1	Input status of digital inputs 9 to 16	USINT	•			
		DigitalInput09	Bit 0				
		...	...				
		DigitalInput16	Bit 7				
18	-	ConfigOutput01	USINT				•

1) The offset specifies where the register is within the CAN object.

4.13.20.10.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.13.20.10.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.13.20.10.4.1 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.13.20.10.4.2 Input status of digital inputs 1 to 16

Name:
DigitalInput or
DigitalInput01 to DigitalInput16

The input status of digital inputs 9 to 16 is mapped in this register.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput16") or whether this register should be displayed as an individual UINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 65535	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Register 0:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input status - Digital input 8

Register 1:

Bit	Name	Value	Information
0	DigitalInput09	0 or 1	Input status - Digital input 9
...		...	
7	DigitalInput16	0 or 1	Input status - Digital input 16

4.13.20.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Without filtering	100 µs
With filtering	150 µs

4.13.20.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Without filtering	100 µs
With filtering	200 µs

4.14 Digital mixed modules

Digital mixed modules are a combination of digital input and output modules. The states of the digital inputs or outputs are shown by the status LEDs.

4.14.1 Brief information

Product ID	Short description	on page
X20DM9324	X20 digital mixed module, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source 1-wire connections	1338
X20cDM9324	X20 digital mixed module, coated, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source, 1-wire connections	1338

4.14.2 X20(c)DM9324

4.14.2.1 General information

This module is equipped with 8 inputs and 4 outputs for 1-wire connections. The inputs are designed for sink connections, the outputs for source connections.

- 8 digital inputs, sink connections
- 4 digital outputs, source connections
- 1-wire connections
- Configurable software input filter for entire module
- Integrated output protection

4.14.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

		DigitalOutput04	Bit 3				
18	-	ConfigOutput01	USINT				•
30	-	Status of digital outputs 1 to 4	USINT		•		
		StatusDigitalOutput01	Bit 0				
			...				
		StatusDigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.14.2.11.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.14.2.11.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.14.2.11.4.1 Input state of digital inputs 1 to 8

Name:
DigitalInput or
DigitalInput01 to DigitalInput08

This register is used to indicate the input state of digital inputs 1 to 8.

Function model 0 - Standard only:

The "packed inputs" setting in the AS I/O configuration is used to determine whether all of this register's bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput08") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed inputs = on
	See bit structure	Packed inputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input state - Digital input 8

4.14.2.11.4.2 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.14.2.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.14.2.11.5.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.14.2.11.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.14.2.11.6.1 Status of digital outputs 1 to 4

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput04

The status of digital outputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit		Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
3	StatusDigitalOutput04	0	Channel 04: No error
		1	Channel 04: Short circuit or overload

4.14.2.11.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.14.2.11.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without filtering	100 µs
With filtering	200 µs

4.15 Digital output modules

Digital output modules are used to control external loads (relays, motors, solenoids). The states of the digital outputs are indicated by status LEDs.

4.15.1 Brief information

Product ID	Short description	on page
X20DO2321	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, sink, 3-wire connections	1349
X20DO2322	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, source, 3-wire connections	1357
X20DO2623	X20 digital output module, 2 outputs, 100-240 VAC, 1 A, source, 240 V keyed, 3-wire connections	1365
X20DO2633	X20 digital output module, 2 triac outputs, 12 to 240 VAC, 2 A, L switching, phase angle control, 240 V keyed	1374
X20DO2649	X20 digital output module, 2 relays, changeover contacts, 240 VAC / 5 A, 24 VDC / 5 A	1390
X20DO4321	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, sink, 3-wire connections	1396
X20DO4322	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections	1404
X20DO4331	X20 digital output module, 4 outputs, 24 VDC, 2 A, sink, 3-wire connections	1413
X20DO4332	X20 digital output module, 4 outputs, 24 VDC, 2 A, source, 3-wire connections	1423
X20DO4529	X20 digital output module, 4 relays, changeover contacts, 115 VAC / 0.5 A, 24 VDC / 1 A	1433
X20DO4613	X20 digital output module, 4 triac coupler outputs, 12 to 240 VAC, 50 mA, zero-crossing detection, 240 V keyed,...	1439
X20DO4623	X20 digital output module, 4 outputs, 100-240 VAC, 0.5 A, source, 240 V keyed, 2-wire connections	1452
X20DO4633	X20 digital output module, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed	1461
X20DO4649	X20 digital output module, 4 relays, N.O. contacts, 240 VAC / 5 A	1477
X20DO6321	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections	1483
X20DO6322	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections	1490
X20DO6325	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, open line and overload detection, 2-wire connections	1498
X20DO6529	X20 digital output module, 6 relays, normally open contacts, 115 VAC / 0.5 A, 30 VDC / 1 A	1509
X20DO6639	X20 digital output module, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A	1515
X20DO8232	X20 digital output module, 8 outputs, 12 VDC, 2 A, source, supply directly on module, 1-wire connections	1521
X20DO8322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 1-wire connections	1532
X20DO8323	X20 digital output module, 8 outputs, 12 to 24 V, 0.5 A, sink/source, 1-wire connections, full bridge, half bridge, thermal overload protection	1539
X20DO8331	X20 digital output module, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections	1548
X20DO8332	X20 digital output module, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections	1560
X20DO9321	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections	1572
X20DO9322	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections	1580
X20DOD322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 2-wire connections	1588
X20DOF322	X20 digital output module, 16 outputs, 24 VDC, 0.5 A, source, 1-wire connections	1594
X20cDO2633	X20 digital output module, coated, 2 triac outputs, 12 to 240 VAC, 2 A, L switching, phase angle control, 240 V keyed	1374
X20cDO4322	X20 digital output module, coated, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections	1404
X20cDO4332	X20 digital output module, coated, 4 outputs, 24 VDC, 2 A, source, 3-wire connections	1423
X20cDO4633	X20 digital output module, coated, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed	1461
X20cDO4649	X20 digital output module, coated, 4 relays, N.O. contacts, 240 VAC / 5 A	1477
X20cDO6321	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections	1483
X20cDO6322	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections	1490
X20cDO6639	X20 digital output module, coated, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A	1515
X20cDO8331	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections	1548
X20cDO8332	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections	1560
X20cDO9321	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections	1572
X20cDO9322	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections	1580

4.15.2 Calculation of the additional power dissipation resulting from actuators

Calculation of power dissipation when specifying $R_{DS(on)}$

Explaining output load with an X20DO4332 example

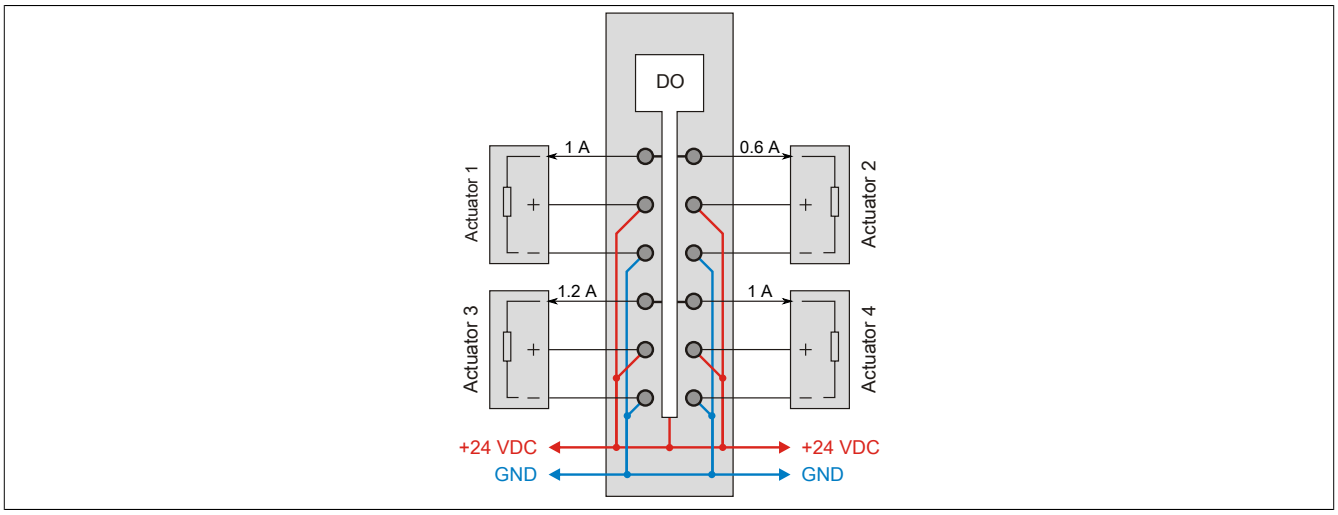

Figure 236: Calculation of power dissipation when specifying $R_{DS(on)}$

Theoretically highest power dissipation resulting from actuators:

Number of outputs * RDS_{on} * nominal output current² = power dissipation

4 * 140 mΩ * 2 A^2 = 2.24 W

Power dissipation resulting from actuators in this example:

140 mΩ * (1 A^2 + 0.6 A^2 + 1.2 A^2 + 1 A^2) = 0.532 W

Power dissipation calculation when specifying the residual voltage

Explaining output load with an X20DO4623 example

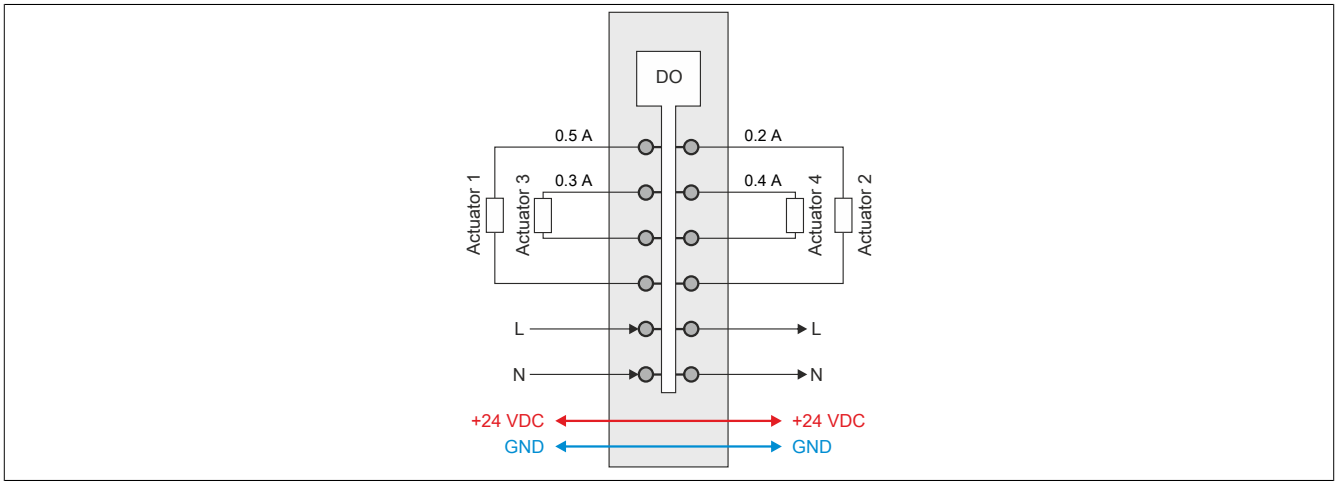

Figure 237: Power dissipation calculation when specifying the residual voltage

Theoretically highest power dissipation resulting from actuators:

Number of outputs * residual voltage * nominal output current = power dissipation

4 * 1.6 V * 0.5 A = 3.2 W

Power dissipation resulting from actuators in this example:

1.6 V * (0.5 A + 0.2 A + 0.3 A + 0.4 A) = 2.24 W

Power dissipation calculation when specifying the contact resistance

Explaining output load with an X20DO4649 example

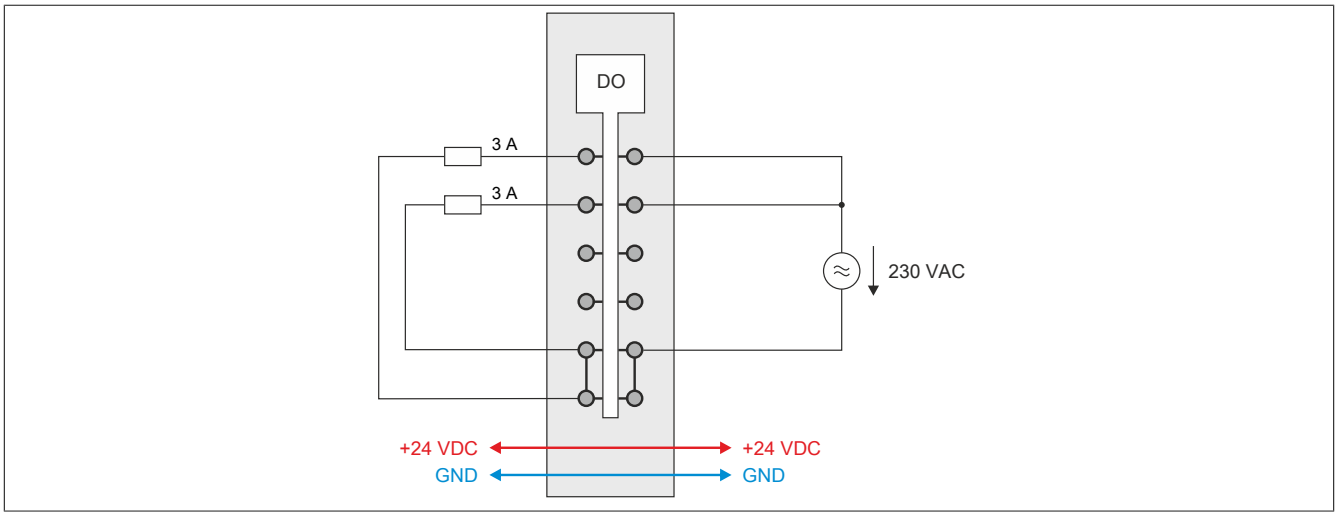

Figure 238: Power dissipation calculation when specifying the contact resistance

Theoretically highest power dissipation resulting from actuators:

Number of outputs * contact resistance * nominal output current^2 = power dissipation

4 * 15 mΩ * 5 A^2 = 1.5 W

Power dissipation resulting from actuators in this example:

15 mΩ * (3 A^2 + 3 A^2) = 0.27 W

4.15.3 X20DO2321

4.15.3.1 General information

The module is equipped with 2 outputs for 3-wire connections. It is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 digital outputs
- Sink connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

Design	FET negative switching
Nominal voltage	24 VDC
Switching voltage	24 VDC -15 % / +20 %
Nominal output current	0.5 A
Total nominal current	1 A
Connection type	3-wire connections
Output circuit	Sink

Table 297: X20DO2321 - Technical data

Product ID	X20DO2321
Output protection	Thermal cutoff if overcurrent or short circuit occurs (see value "Peak short circuit current") Internal inverse diode for switching inductive loads (see section "Switching inductive loads")
Actuator supply	0.5 A in total for output-independent actuator supply
Diagnostic status	Output monitoring with 10 ms delay
Leakage current when switched off	75 µA
$R_{DS(on)}$	120 mΩ
Peak short circuit current	<7 A
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Switching delay	
0 -> 1	<300 µs
1 -> 0	<300 µs
Switching frequency	
Resistive load	Max. 500 Hz
Inductive load	See section "Switching inductive loads"
Braking voltage when switching off inductive loads	Typ. 50 VDC
Isolation voltage between channel and bus	500 V_{eff}
Actuator supply	
Voltage	Module supply minus voltage drop for short circuit protection
Voltage drop for short circuit protection at 500 mA	Max. 2 V
Short circuit protection	Yes
Power consumption	
Actuator supply	Max. 12 W [3]
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB06 or X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 297: X20DO2321 - Technical data

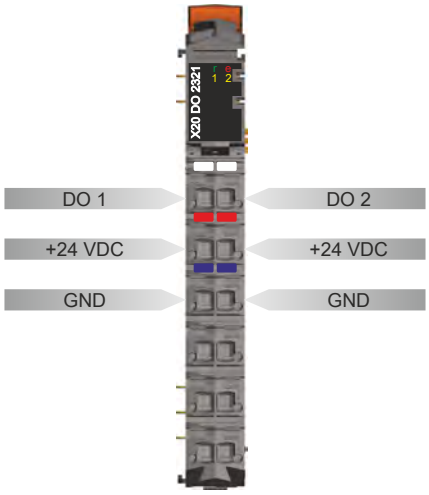
1) Number of outputs x $R_{DS(on)}$ x Nominal output current² (A calculation example can be found on the B&R website in the download area for the module.)
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.15.3.4 Status LEDs

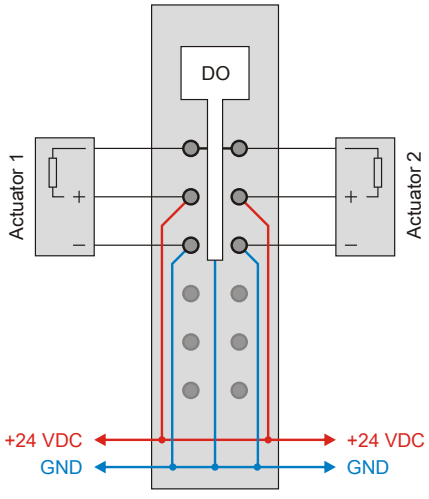
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	Reset mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Orange		Output status of the corresponding digital output

4.15.3.5 Pinout



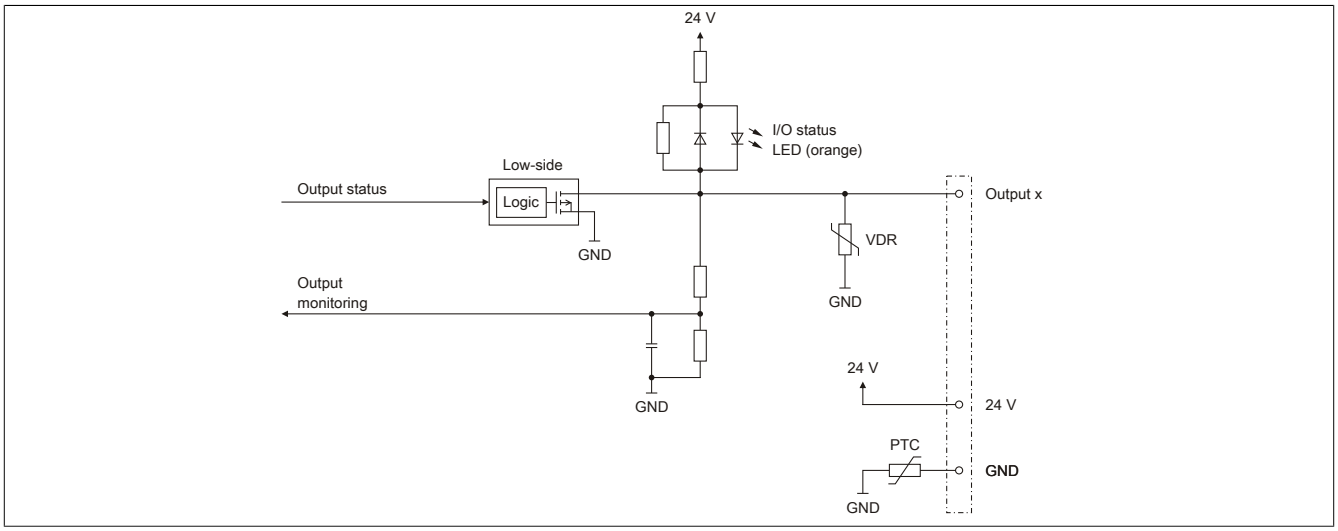
4.15.3.6 Connection example



4.15.3.7 OSP hardware requirements

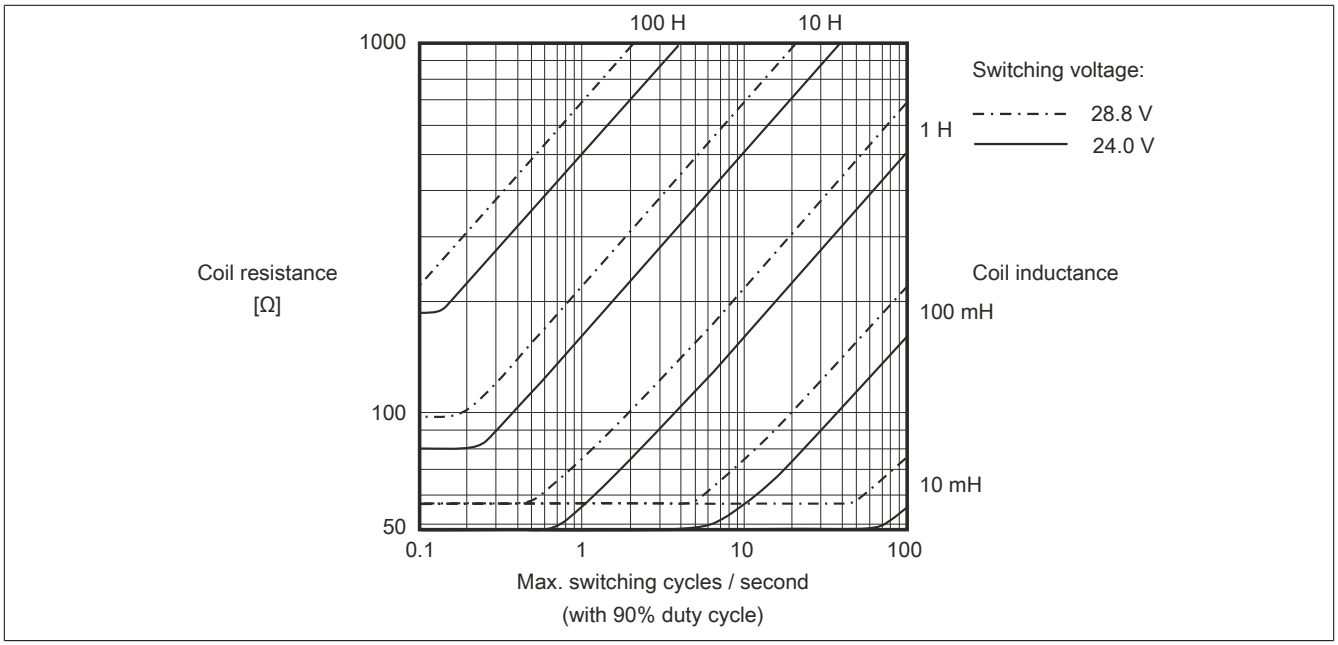
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.3.8 Output circuit diagram



4.15.3.9 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.3.10 Register description

4.15.3.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.3.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.3.10.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 2	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	1	Status of digital outputs 1 to 2	USINT	•			
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.3.10.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 2	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	-	Status of digital outputs 1 to 2	USINT		•		
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				

1) The offset specifies where the register is within the CAN object.

4.15.3.10.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.3.10.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.3.10.5.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

4.15.3.10.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.3.10.6.1 Status of digital outputs 1 to 2

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput02

The status of digital outputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
1	StatusDigitalOutput02	0	Channel 02: No error
		1	Channel 02: Short circuit or overload

4.15.3.10.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.3.10.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.3.10.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.3.10.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.3.10.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.3.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.4 X20DO2322

4.15.4.1 General information

The module is equipped with 2 outputs for 3-wire connections. It is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 digital outputs
- Source connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

Spacing	$12.5^{+0.2}$ mm

Table 299: X20DO2322 - Technical data

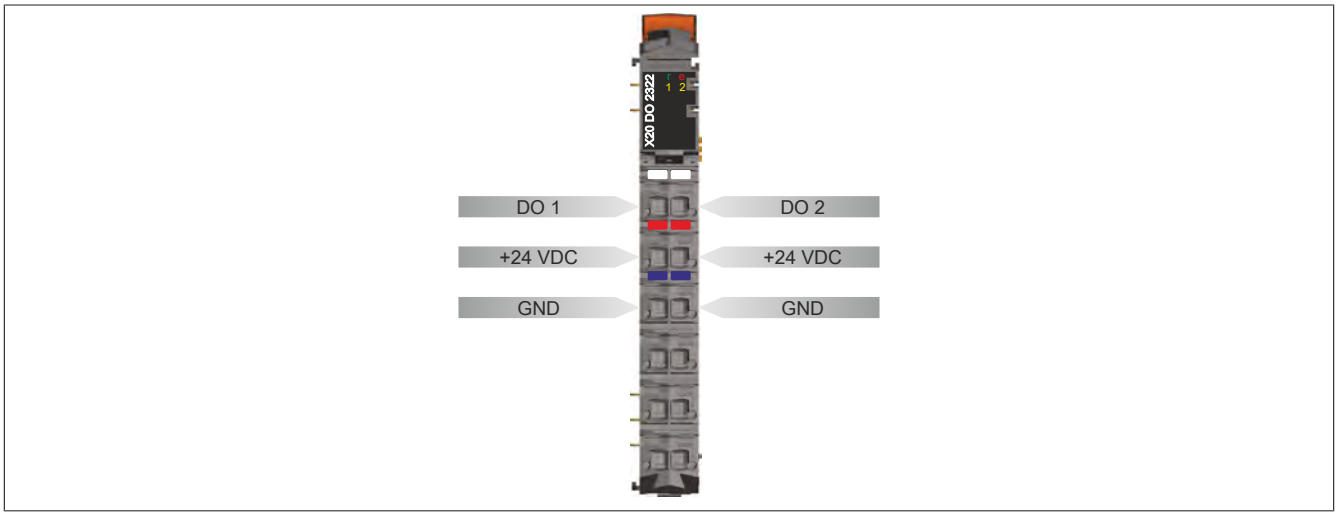
1) Number of outputs x $R_{DS(on)}$ x Nominal output current^2 (A calculation example can be found on the B&R website in the download area for the module.)
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) At loads ≤ 1 kΩ
4) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.15.4.4 Status LEDs

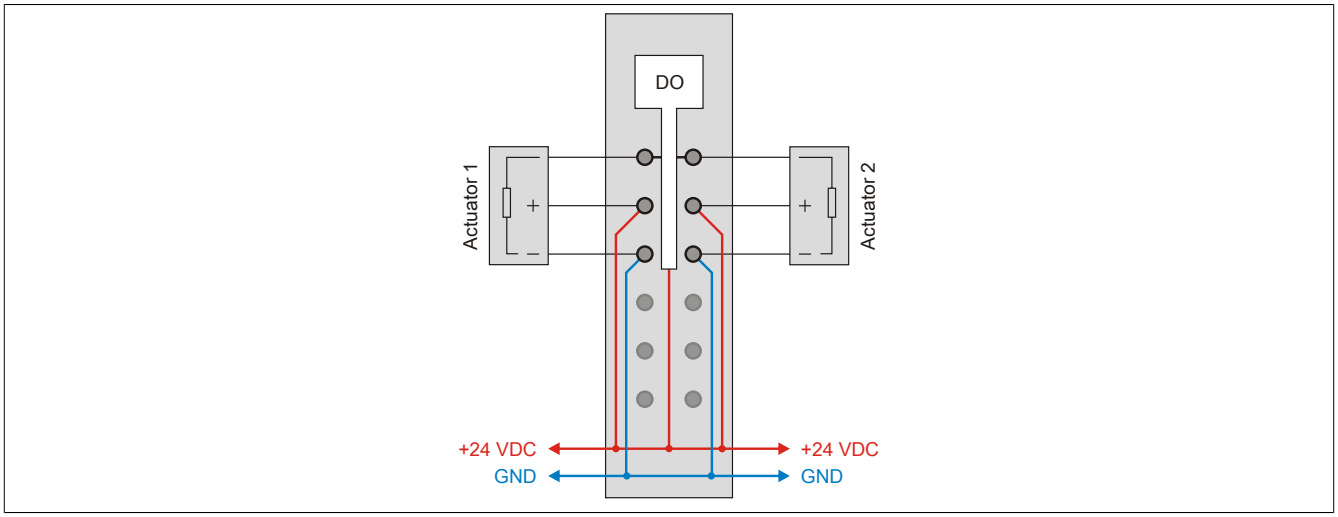
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Orange		Output status of the corresponding digital output

4.15.4.5 Pinout



4.15.4.6 Connection example



Caution!

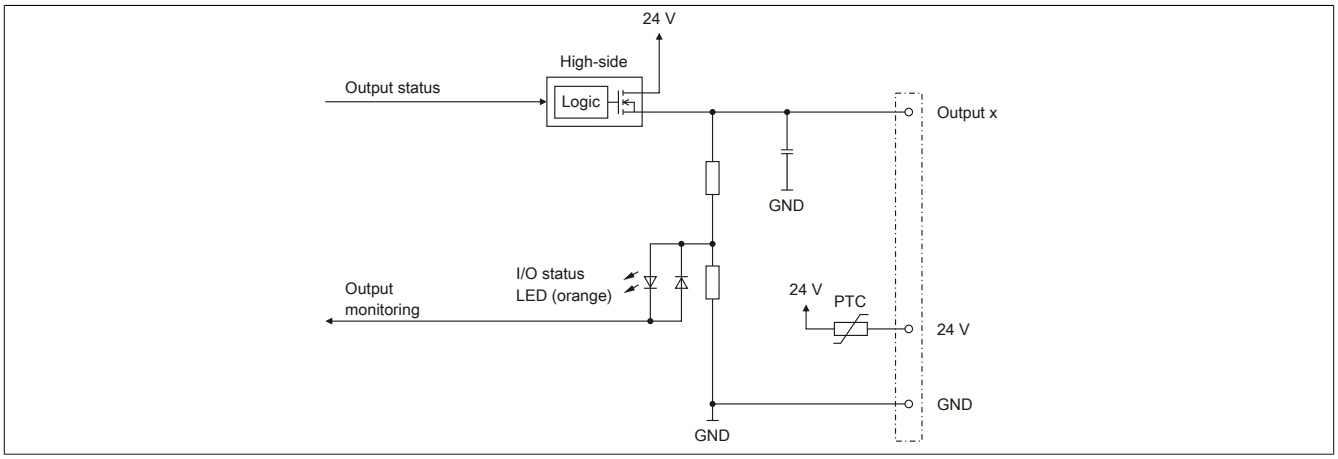
If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.4.7 OSP hardware requirements

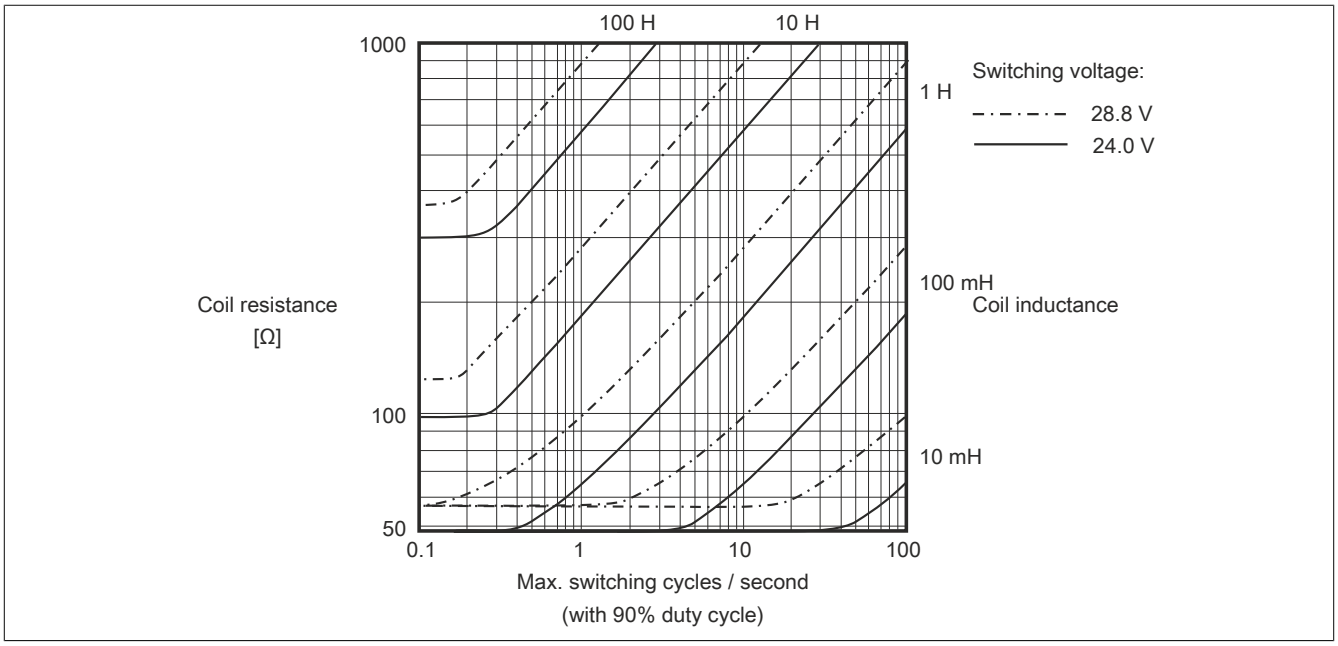
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.4.8 Output circuit diagram



4.15.4.9 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.4.10 Register description

4.15.4.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.4.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.4.10.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 2	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	1	Status of digital outputs 1 to 2	USINT	•			
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.4.10.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 2	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
30	-	Status of digital outputs 1 to 2	USINT		•		
		StatusDigitalOutput01	Bit 0				
		StatusDigitalOutput02	Bit 1				

1) The offset specifies where the register is within the CAN object.

4.15.4.10.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.4.10.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.4.10.5.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

4.15.4.10.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.4.10.6.1 Status of digital outputs 1 to 2

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput02

The status of digital outputs 1 to 2 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
1	StatusDigitalOutput02	0	Channel 02: No error
		1	Channel 02: Short circuit or overload

4.15.4.10.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.4.10.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.4.10.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.4.10.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.4.10.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.4.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.5 X20DO2623

4.15.5.1 General information

The module is a digital output module that is equipped with 2 SSR outputs with zero cross-over switches and uses 3-line connections. The module is also equipped with integrated full-wave control. The supply (L and N) is fed directly to the module.

- 2 digital outputs
- Outputs with integrated snubber circuit
- Outputs with 100 to 240 VAC
- L switching
- 50 Hz or 60 Hz
- 3-wire connections
- Integrated full-wave control
- 240 V coding

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.15.5.2 Order data

Model number	Short description	Figure

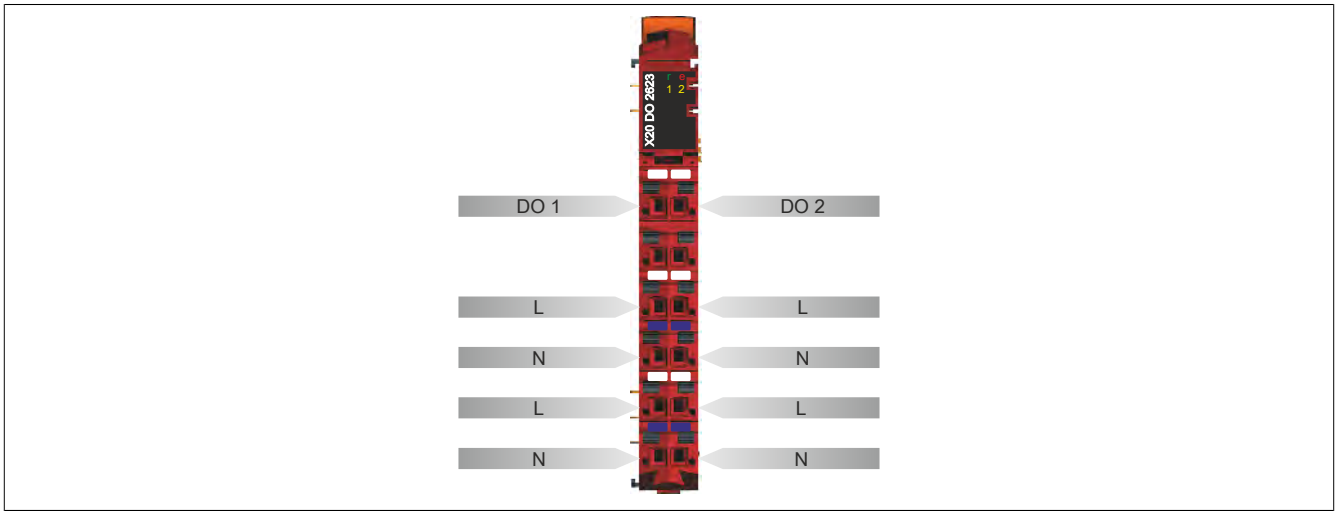
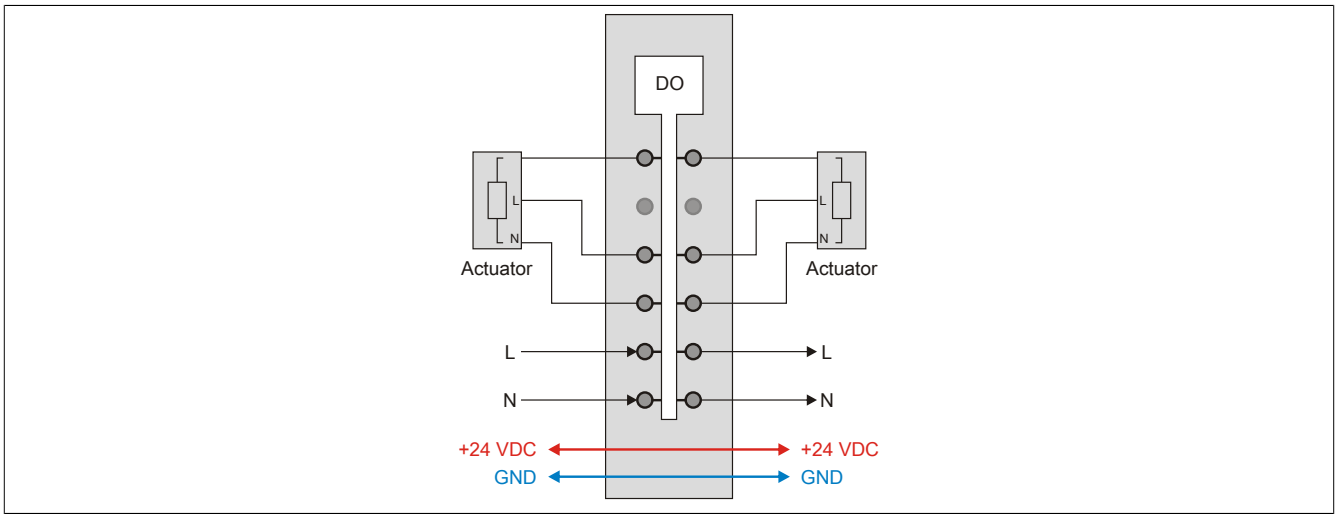
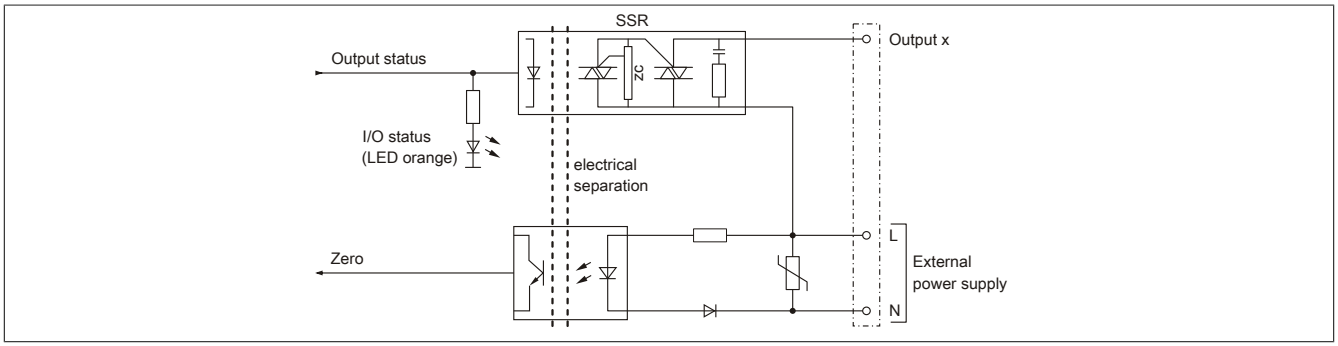
4.15.5.5 Pinout



4.15.5.6 Connection example



4.15.5.7 Output circuit diagram



4.15.5.8 Integrated full-wave control

Full-wave control is used to control power for electrical power consumers that are operated with AC voltage. Temperature control is a typical application

Unlike phase-angle control, the sine wave oscillation form of the mains voltage is not changed during full-wave control. This significantly reduces system perturbation.

The output voltage (channel) is switched on and off at a certain ratio. This switches the multi-cycle packets. A multi-cycle packet consists of a number of complete sine waves throughout a cycle. The relationship between the power-on duration and the cycle duration results in the desired effect of reduced power consumption by the connected power consumer.

With the full-wave control that is integrated in the module, a maximum of 24 full waves can be provided on the outputs per cycle. Control takes place in 4% steps.

Settings		Full waves

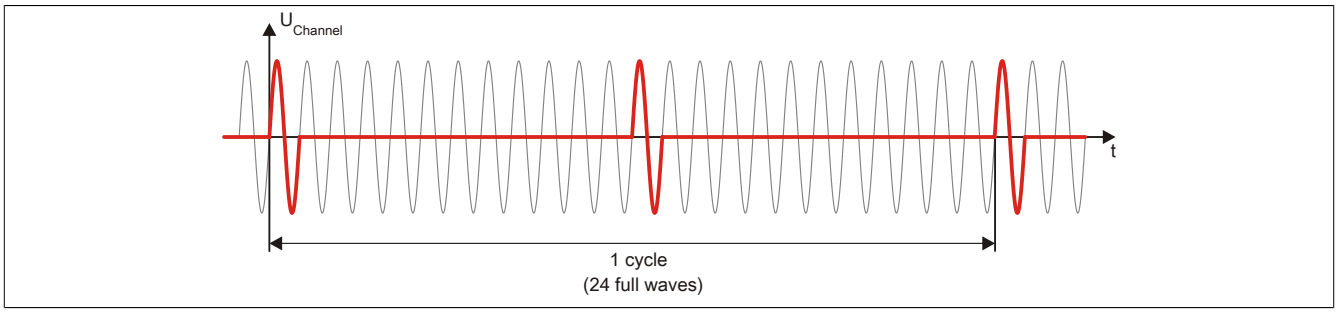
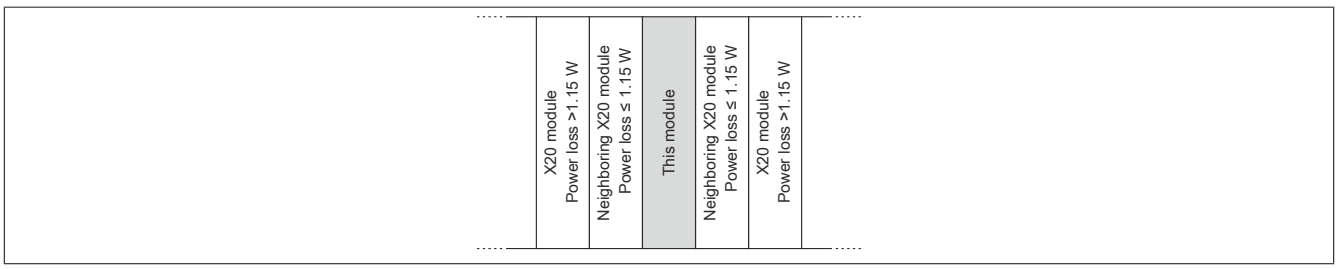
Example of full-wave control (8%):



4.15.5.9 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.15.5.10 Register description

4.15.5.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.5.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				
4	1	AnalogOutput01	USINT			•	
6	2	AnalogOutput02	USINT			•	
12	3	ShiftOutput01[1)]	USINT			•	
14	4	ShiftOutput02[1)]	USINT			•	
28	-	Output configuration 1 - 2 ConfigOutput01	USINT				•
30	1	StatusInput01	USINT	•			
		ZeroCrossingInput	Bit 0				
		ZeroCrossingStatus	Bit 4				

1) Firmware version 816 and up.

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.5.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
4	0	AnalogOutput01	USINT			•	
6	2	AnalogOutput02	USINT			•	
12	-	ShiftOutput01[2)]	USINT				•
14	-	ShiftOutput02[2)]	USINT				•
30	0	Zero crossing status	USINT	•			
		ZeroCrossingInput	Bit 0				
		ZeroCrossingStatus	Bit 4				

1) The offset specifies where the register is within the CAN object.
2) Firmware version 816 and up.

4.15.5.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.15.5.10.4 Digital outputs

The output status is transferred to the control switch asynchronously to the connected network. The outputs switch on when the voltage crosses zero and switch off when the current crosses zero.

4.15.5.10.4.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

Information:

The states in this register are only applied when the channels are set to DIGITAL in "Setting the output configuration ".

When using the setting "packed outputs" ALL channels must be set to DIGITAL. Mixed operation is not possible.

4.15.5.10.5 Analog outputs

The output value is transferred to the control circuit in sync with the connected power mains according to the firing pattern table (see "Integrated full-wave control"). The analog value is output with a resolution of ~4% over a duration of 24 complete waves. Values > 96% result in full control. Changes to the output value within an interval are applied after the next zero crossover.

4.15.5.10.5.1 Setting the output value from the firing pattern table

Name:
AnalogOutput01 to AnalogOutput02

These registers are used to set the output value from the firing pattern table.

Values between 0 and 100 correspond to the output value for the respective channel in percent. Values above 100 correspond to 100%.

Data type	Value
USINT	0 to 100

Information:

The states in these registers are only applied when the channels are set to ANALOG in Setting the output configuration .

4.15.5.10.5.2 Setting the output configuration

Name:
Output configuration 1 - 2 ConfigOutput01

Each channel can be configured for either "digital" or "analog" operation in this register. The corresponding DigitalOutput or AnalogOutput registers must be written depending on the setting.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1	0	Digital register is used
		1	Analog register is used
1	Channel 2	0	Digital register is used
		1	Analog register is used
2 - 7	Reserved	0	

4.15.5.10.5.3 Shift switching pattern

Name:
ShiftOutput01 to ShiftOutput02

To prevent load peaks due to simultaneous switching of outputs, this register can be used to shift the switching pattern by a number of full waves. Due to the hardware used, it is not possible to shift by less than a full wave.

Values higher than 23 are limited to 23.

Data type	Value	Information
USINT	0	No shift
	1 to 23	Size of the shift in number of full waves

Example

Set 0 on Channel 1 and 1 on Channel 2. With the same control value (see "Integrated full-wave control") this delays the switching pattern of Channel 2 by one full wave.

4.15.5.10.6 Zero crossing status

Name:
ZeroCrossingInput
ZeroCrossingStatus
StatusInput01

Zero crossing detection uses a fixed filter time of 1 ms and a scanning frequency of 10 kHz. When a missing or too short period is detected, control is switched off until at least 2 periods are detected correctly, and the status flag is set accordingly. Control is offset by 2 ms from the negative half-wave until the next zero crossover is detected correctly or another error occurs. This is normally at least one complete wave.

Monitoring is activated at the first zero crossover after being switched on.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("ZeroCrossingInput" through "ZeroCrossingStatus") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 17	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	ZeroCrossingInput[1)]	0	Signal during the negative half-wave
		1	Signal during the positive half-wave
1 - 3	Reserved	0	
4	ZeroCrossingStatus	0	No error
		1	Zero crossover failed
5 - 7	Reserved	0	

1) Value is valid if no error has occurred (ZeroCrossingStatus= 0)

4.15.5.10.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Digital mode	100 µs
Digital and analog mode	150 µs

4.15.5.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Digital mode	100 µs
Digital and analog mode	150 µs

4.15.6 X20(c)DO2633

4.15.6.1 General information

The module is a digital output module with phase-angle control that is equipped with 2 Triac outputs using 3-line connections. The supply (L and N) is fed directly to the module.

- 2 digital outputs
- Outputs with integrated snubber circuit
- Outputs with 12 to 240 VAC
- L switching
- Zero-crossing detection
- Phase-angle control
- Open-circuit detection for each channel
- Negative half-waves can be switched off
- 50 Hz or 60 Hz
- 3-wire connections
- 240 V coding
- OSP mode
- Frequency mode

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.15.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.15.6.3 Order data

Model number	Short description	Figure

4.15.6.5 Status LEDs

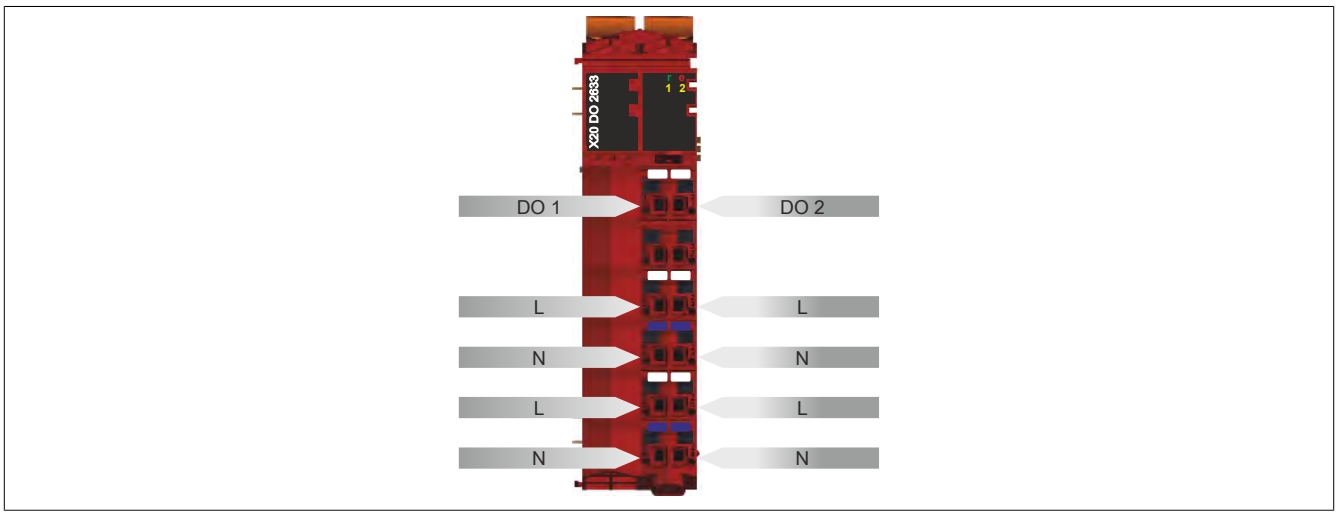
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Zero cross-over signal has dropped out
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Orange		Control status of the corresponding digital output

4.15.6.6 Pinout

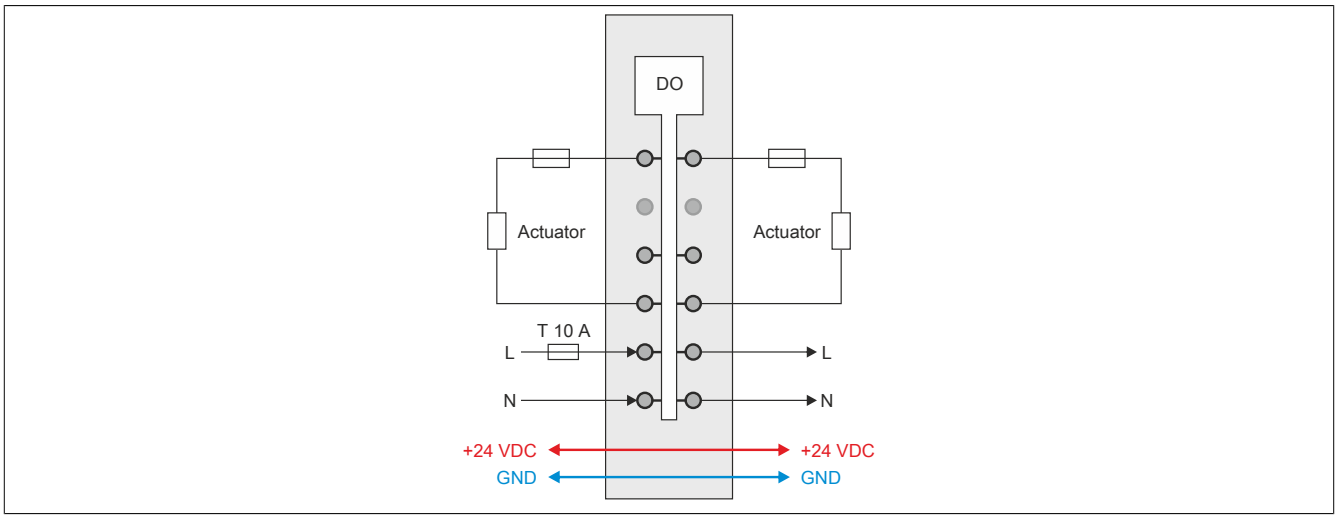
The following points must be taken into consideration when wiring the module:

- For thermal reasons, wires with a cross-section ≥1.5 mm² must be used to wire the module.
- The neutral return lines for the outputs must be wired to the terminal block separately for each channel and must not be bypassed in the field.
- A line filter must be used for the 240 V supply that provides ≥40 dB attenuation at 150 kHz and works up to 5 MHz.

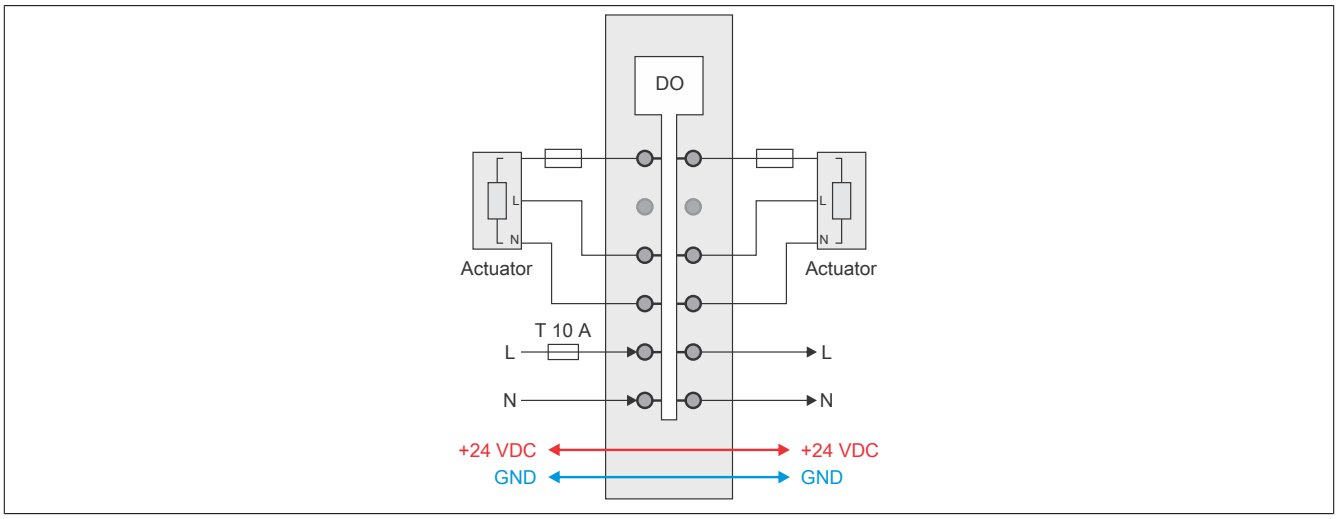


4.15.6.7 Connection example

2-wire connections



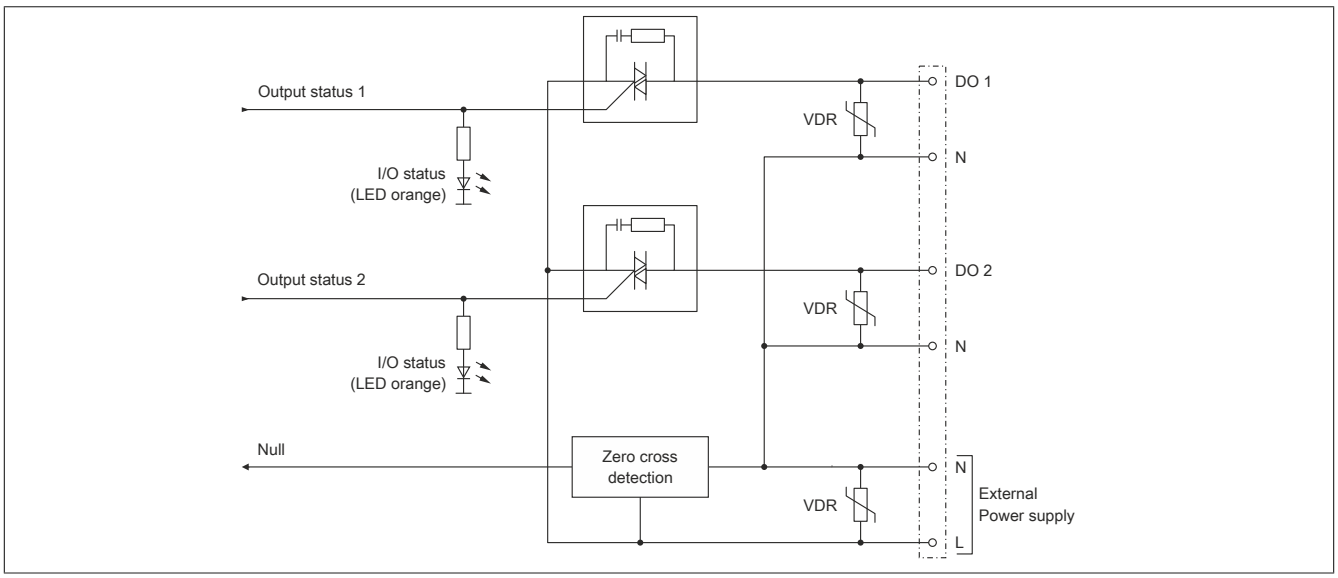
3-wire connections



4.15.6.8 OSP hardware requirements

In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.6.9 Output circuit diagram



4.15.6.10 External fuses

The following protective circuit must be used for safe operation:

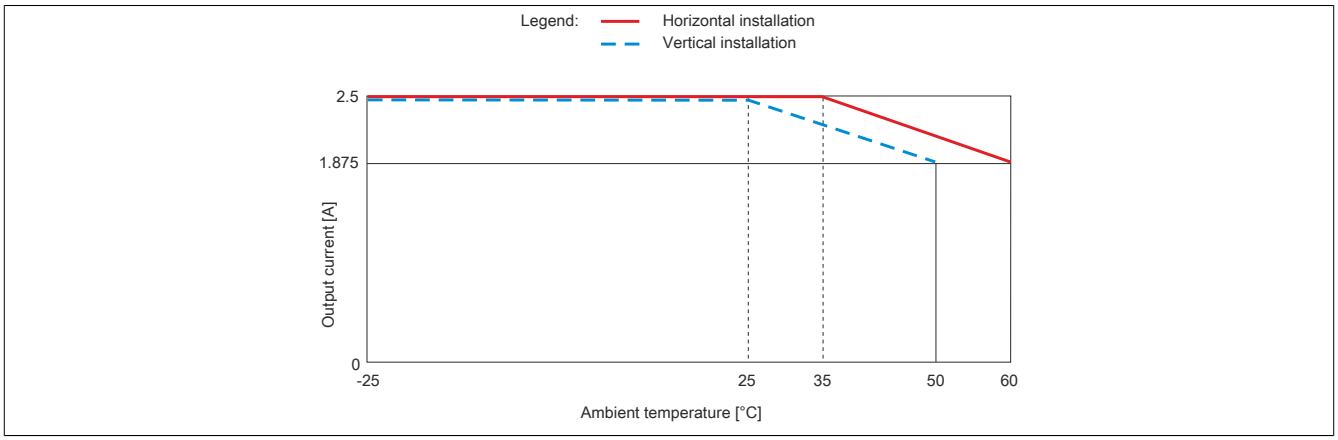
	Protective circuit	Value
For the supply lines	Fuse	T 10 A
For the outputs	Fuse	Melting integral $I^2t \leq 78\ A^2s$ when tp = 10 ms
With an inductive load	Varistor[1)]	e.g. varistor with 275 V_{RMS} at 240 VAC
For the supply voltage	Line filter[2)]	Attenuation ≥40 dB at 150 kHz, effective range up to 5 MHz

1) See also section 4.15.6.14 "Operation with inductive loads" on page 1379

2) Meeting the limit values specified in the standards EN 61131, EN 55011 and EN 55022 (each Class A) requires installation of a line filter in the 240 V supply line. Line filters such as the Schaffner FN 2412-8-44 can be used.
If periodic ground transients occur on the supply lines (as can occur with upstream inverters), it is necessary to use an asymmetric filter that keeps these types of changes in potential below a few volts (e.g. "Sinus Plus" from Schaffner) in addition to the symmetric filter.

4.15.6.11 Derating

The derating listed below must be applied for the current:



4.15.6.12 Operating principle

The digital output module was designed for phase control of resistive and and inductive loads. The triac outputs do not have short circuit protection. The integrated open-circuit detection makes it possible to recognize defects on the load or the cabling (see 4.15.6.13 "Open line detection" on page 1378).

The module is equipped with internal zero-crossing detection. Zero-crossing detection is the basis for a software PLL that generates 200 times the zero-crossing frequency. The output signal of the PLL is the base timer for the PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control to the outputs is cut until the PLL is tuned correctly. The tuning procedure can take several seconds. In addition, the "ZeroCrossingStatus" bit is set and the error LED enabled (valid frequency range for the supply is 45 to 65 Hz).

Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.6.13 Open line detection

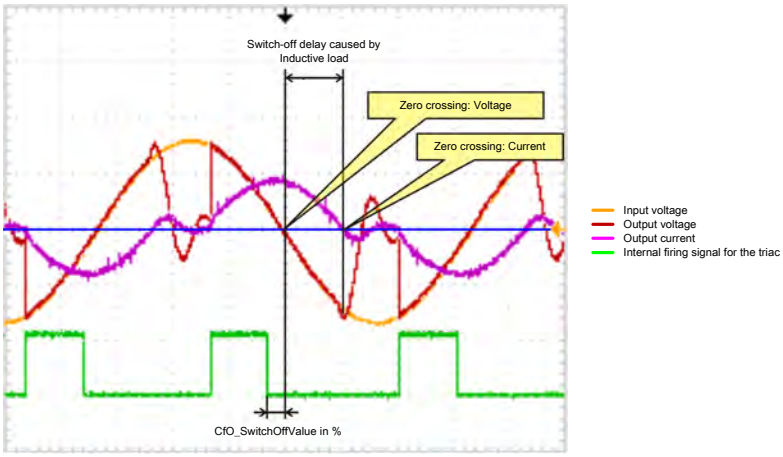
The module is equipped with open-circuit detection. Note that open-circuit detection only works when the output is enabled. An open-circuit will not be detected if the output is turned off.

In addition, open-circuit detection is restricted or doesn't work at all for inductive loads. This depends on the inductance of the load and should be determined beforehand, if necessary.

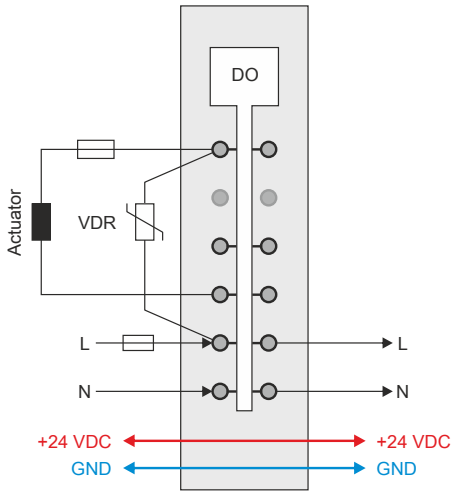
4.15.6.14 Operation with inductive loads

As inherent to its functional principal, the triac output is cleared when the current crosses zero. Because zero crossing for current is delayed with inductive loads, it is possible that the triac will be fired again even though it is not completely cleared at higher output values (between 50 and 100% depending on the inductance of the load). In this case, a full-wave is output. This causes the available control range (0 to 95%) to be changed.

For open line detection (LowCurrentStatus), a pause in control is required where the triac is not permitted to be fired. The full wave that is created with inductive loads causes open line detection to be triggered even though the load on the output is sufficient.
This behavior can be used to detect the full wave and properly adjust the control range (Example: If open line detection is triggered at a control value of 70%, that means that 0 to **70%** corresponds to 0 to **100%** output).



With inductive loads, a suitable varistor must be provided between the output DO x and the phase L (e.g. a varistor with 275 V_{RMS} at 240 VAC).



4.15.6.15 Register description

4.15.6.15.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.6.15.2 Function model 0 - Standard and Function model 2 - Frequency mode

The only difference between function model 2 and function model 0 is the possibility of generating half-wave patterns in various frequencies. Register 18 "CfO_Frequency" is an additional register for this.

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
4	AnalogOutput01	USINT			•	
6	AnalogOutput02	USINT			•	
18	CfO-Frequency	UINT				•
20	CfO_SwitchOffValue1	USINT				•
22	CfO_SwitchOffValue2	USINT				•
28	CfO_OutputConfig	USINT				•
29	CfO_OutputTolerance	USINT				•
Communication						
2	DigitalOutput	USINT			•	
	DigitalOutput01	Bit 0				
	DigitalOutput02	Bit 2				
30	StatusInput01	USINT	•			
	LowCurrentStatus1	Bit 0				
	LowCurrentStatus2	Bit 1				
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.6.15.3 Function model 1 - OSP

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
4	AnalogOutput01	USINT			•	
6	AnalogOutput02	USINT			•	
20	CfO_SwitchOffValue1	USINT				•
22	CfO_SwitchOffValue2	USINT				•
28	CfO_OutputConfig	USINT				•
29	CfO_OutputTolerance	USINT				•
Configuration - OSP						
34	Activating the OSP output in the module	USINT			•	
	OSPValid	Bit 0				
32	CfgOSPMode	USINT				•
36	CfgOSPValue	USINT				•
38	CfgOSPValue01	USINT				•
40	CfgOSPValue02	USINT				•
Communication						
2	Switching state of digital outputs 1 to 2	USINT			•	
	DigitalOutput01	Bit 0				
	DigitalOutput02	Bit 1				
30	Status of the outputs	USINT	•			
	LowCurrentStatus1	Bit 0				
	LowCurrentStatus2	Bit 1				
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.6.15.4 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General							
4	0	AnalogOutput01	USINT			•	
6	2	AnalogOutput02	USINT			•	
20	-	CfO_SwitchOffValue1	USINT				•
22	-	CfO_SwitchOffValue2	USINT				•
28	-	CfO_OutputConfig	USINT				•
29	-	CfO_OutputTolerance	USINT				•
Communication							
30	0	Status of the outputs	USINT	•			
		LowCurrentStatus1	Bit 0				
		LowCurrentStatus2	Bit 1				
		ZeroCrossingInput	Bit 4				
		ZeroCrossingStatus	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.15.6.15.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.15.6.15.5 General information

The digital output module was designed for phase control of resistive and inductive loads. The triac outputs do not have short circuit protection, but have open line detection that can be used to find defects in the consumer or the wiring.

The module is equipped with internal zero-crossing detection. Zero crossing detection is the basis for a software PLL that generates 200 times the zero crossing frequency. The output signal of the PLL is the base timer for the 2 PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control of the outputs is cut until the PLL is tuned correctly (can take several seconds). In addition, the "ZeroCrossingStatus" bit is set and the Error LED is enabled (valid frequency range for the supply is 45 to 65 Hz).

Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.6.15.6 Digital outputs

The output state of the outputs defined as digital is transferred to the output ports of the control switch in sync with the connected power mains. The switch-on state is applied when the voltage crosses zero on the positive half-wave and the switch-off state at the zero crossing for current in each half wave.

4.15.6.15.6.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

Information:

The states in these registers are only applied when the channels are set to DIGITAL in "Configuration of the output channels".

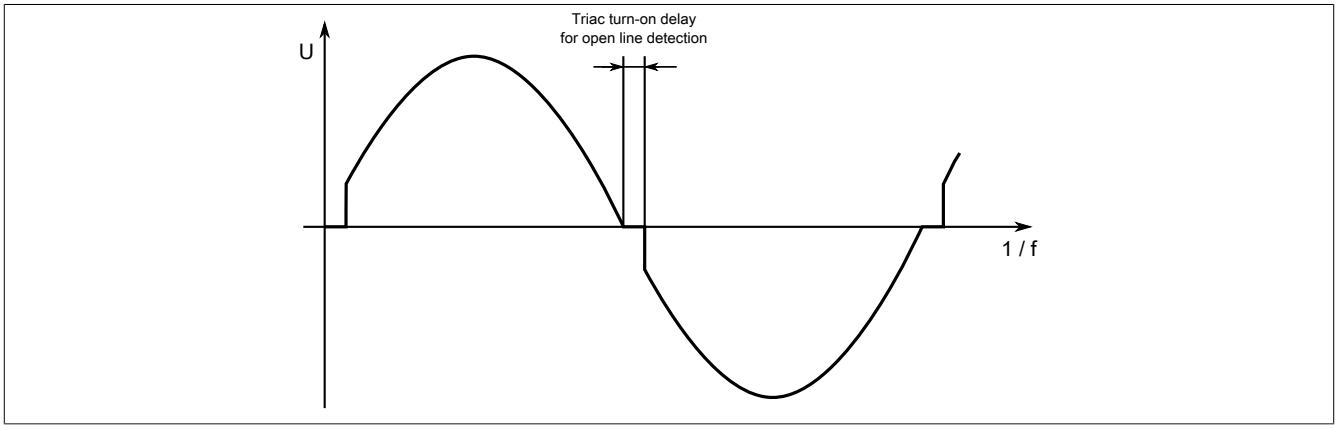
When using the setting "packed outputs" ALL channels must be set to DIGITAL. Mixed operation is not possible.

4.15.6.15.7 Analog outputs

The output value of the outputs defined as analog outputs (unit percent) is switched through to the control ports in sync with power mains. The analog value is output to the TRIAC control port in the range between (output value > SwitchOffValue) and (output value <= 95%) with a resolution of 1%.

A short triac turn-on delay is required for open line detection. Therefore even with output values >= 96%, there is a small pause in control.

Changes to the output value are applied at the next positive half-wave



4.15.6.15.7.1 Commutation angle for analog outputs 1 - 2

Name:
AnalogOutput01 to AnalogOutput02

These registers are used to set the commutation angle for phase angle control.

Values between 0 and 100 correspond to the output value for the respective channel in percent. Values above 100 correspond to 100%.

Data type	Value
USINT	0 to 100

Information:

The commutation angle for phase angle control set in these registers are only applied when the channels are set to ANALOG in "Configuration of the output channels".

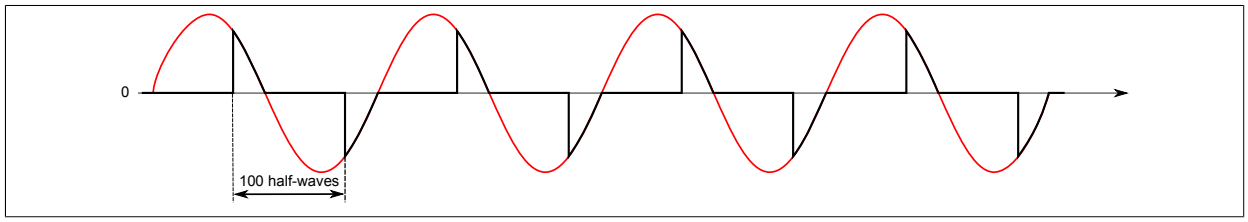
4.15.6.15.8 Output configuration

4.15.6.15.8.1 Configuring the half-wave pattern

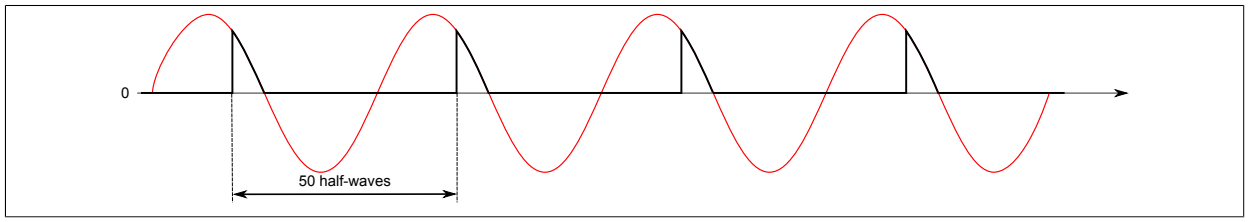
Name:
CfO_Frequency

This register can only be used in function model 2 - Frequency mode and makes it possible to configure the output of half-wave patterns in various frequencies. The commutation angle of the outputs is not affected by this. The following frequency patterns can be configured:

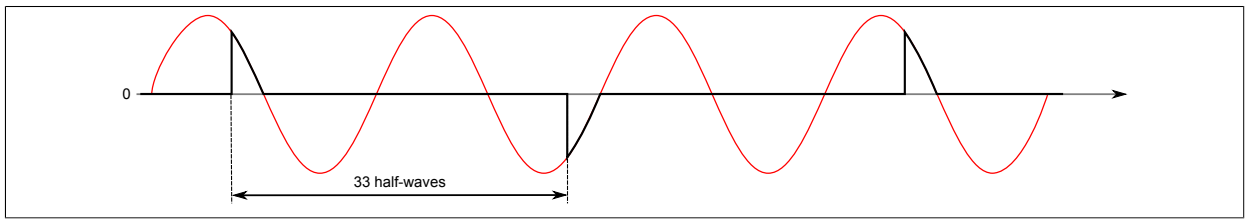
- 100 half-waves



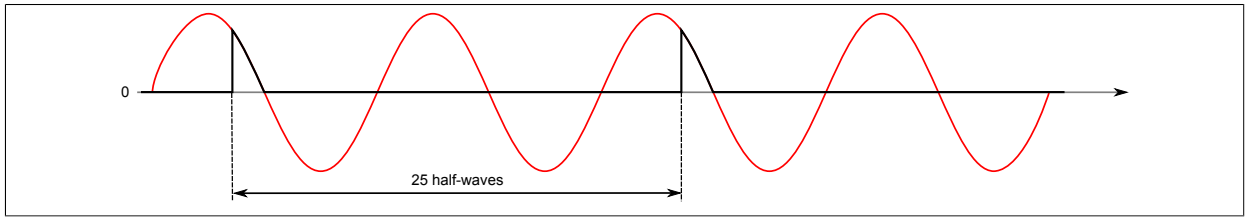
- 50 half-waves



- 33 half-waves



- 25 half-waves



With multichannel operation, the second channels should be operated with delayed half-waves in order to ensure that the load is placed evenly on the module.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Channel 1	0000	100 half-waves/second
		0001	50 half-waves/second
		0010	25 half-waves/second
		0011	33 half-waves/second
		0101	50 half-waves/second delayed by 1 half-wave
		0110	25 half-waves/second delayed by 2 half-waves
		0111	33 half-waves/second delayed by 1 half-wave
4 - 7	Channel 2	0000 to 0111	See channel 1
8 - 15	Reserved	-	

Information:

This function is available beginning with firmware version 940. This can be included beginning with hardware variant 8.

4.15.6.15.8.2 Setting the switch-off time

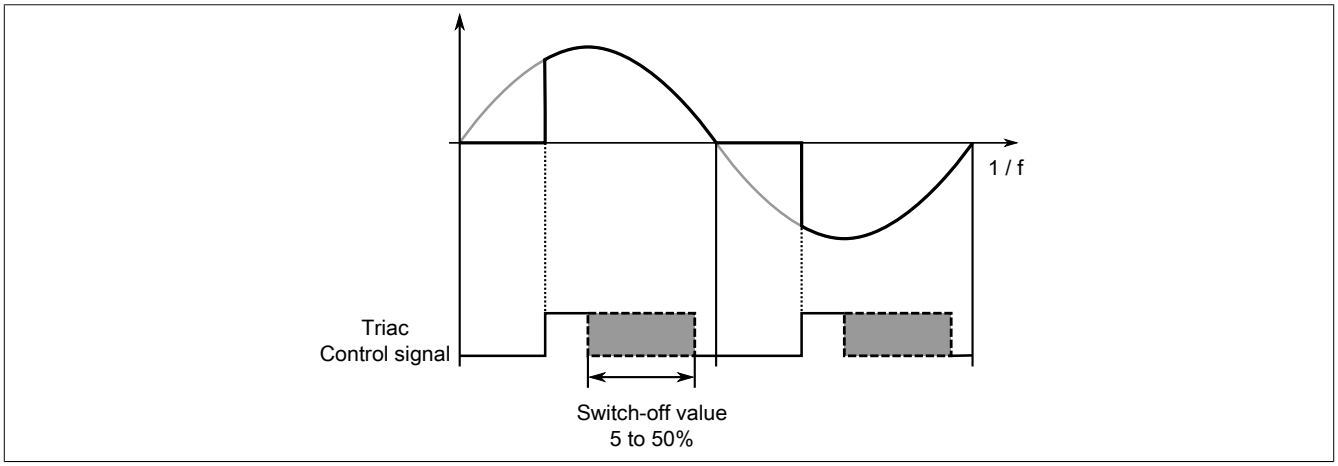
Name:
CfO_SwitchOffValue1 and CfO_SwitchOffValue2

This register defines how far in front of the zero cross-over the internal control signal for the TRIAC is switched off. Increasing this value may be necessary in order to prevent unwanted firing of the TRIAC in the event of a slight disturbance in the mains frequency.

With smaller loads, it is important to ensure that this switch off value is not set to large (too early) to prevent switching off prematurely.

The triac can of course only be fired before the set switch-off time.

"SwitchOffValue" in the AS I/O configuration.



Data type	Value	Description
USINT	5 to 50	Switch-off time in %

4.15.6.15.8.3 Configuration of the output channels

Name:
CfO_OutputConfig

The configuration of the output channels are stored in this register.

"Output type digital/analog" and "Output type full/half wave" in the AS I/O configuration

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1: Digital / Analog output	0	Output channel 1 is defined as a digital output. The output status is defined using bit 0 in the DigitalOutput 1 - 2 register.
		1	Output channel 1 is defined as an analog output. The output status is defined using the AnalogOutput01 register.
1	Channel 2: Digital / Analog output	0	Output channel 2 is defined as a digital output. The output status is defined using bit 0 in the DigitalOutput 1 - 2 register.
		1	Output channel 2 is defined as an analog output. The output status is defined using the AnalogOutput02 register.
2 - 3	Reserved	-	
4	Channel 1: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 1
		1	Negative half-wave on output channel 1 is suppressed.
5	Channel 2: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 2
		1	Negative half-wave on output channel 2 is suppressed.
6 - 7	Reserved	-	

1) Not available in function model 2 - Frequency mode.

4.15.6.15.8.4 Switching behavior for zero-crossing errors

Name:
CfO_OutputTolerance

This register can be used to set the switching behavior of the trigger. After the number of zero-crossing errors configured in Bit 0 to 4, the output is switched off for at least 3 periods. This is followed by synchronization with the zero signal according to Bit 7.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Trigger for Resync	0 to 30	Number of zero-crossover errors
5 - 6	Reserved	-	
7	Fast settling	0	Fast synchronization
		1	PLL synchronization

Fast synchronization

With this option, the trigger point is closed-loop controlled after each individual zero-crossover and input jitter.

- **Advantage:** Increased tolerance and faster response to deviations in mains frequency
- **Disadvantage:** Increased switch-on jitter for firing signal by zero cross signal ±100 µSec

PLL synchronization

With this option the intervals between zero cross-overs are measured and the PLL frequency is updated accordingly.

- **Advantage:** Jitter-free firing signal
- **Disadvantage:** When the output is switched off, additional measurement phases are required before it can be switched back on.

Information:

This function is available starting with Firmware version 928. This can be installed with hardware version 8 and hardware revision B4 or higher.

4.15.6.15.9 Status of the outputs

Name:
LowCurrentStatus1 through LowCurrentStatus2
ZeroCrossingInput
ZeroCrossingStatus
StatusInput01

The operating status of the outputs is mapped in this register.

In order to do determine the "LowCurrentStatus", the system checks if there is a neutral connection from the output via the consumer shortly before each triac firing.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("LowCurrentStatus1" through "ZeroCrossingStatus") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	LowCurrentStatus1	0	Current flow on activated output 1
		1	No current flow on activated output 1
1	LowCurrentStatus2	0	Current flow on activated output 2
		1	No current flow on activated output 2
2 - 3	Reserved	-	
4	ZeroCrossingInput	0	Zero cross signal during the negative half-wave
		1	Zero cross signal during the positive half-wave
5 - 6	Reserved	-	
7	ZeroCrossingStatus	0	Zero cross signal OK
		1	Zero cross signal has dropped out

4.15.6.15.10 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.6.15.10.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.6.15.10.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.6.15.10.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.6.15.10.4 Define the OSP analog output value

Name:
CfgOSPValue01 to CfgOSPValue02

This register contains the analog output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	0 to 100

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.6.15.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
All channels	250 µs

4.15.6.15.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
All channels	150 µs

4.15.7 X20DO2649

4.15.7.1 General information

The module has 2 relay outputs.

- 2 digital outputs
- Relay module for 240 VAC / 30 VDC
- 2 change over contacts
- Single-channel isolated outputs

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.15.7.2 Order data

Product ID	X20DO2649
Digital outputs	
Design	Relay / Changeover contact Channels are single-channel isolated
Nominal voltage	30 VDC / 240 VAC
Max. voltage	264 VAC
Switching voltage	Max. 110 VDC / 264 VAC
Rated frequency	DC / 45 to 63 Hz
Nominal output current	5 A at 30 VDC / 5 A at 240 VAC
Total nominal current	10 A at 30 VDC / 10 A at 240 VAC
Actuator supply	External
Starting current	Max. 6 A (per channel)
Contact resistance	50 mΩ
Switching delay	
0 -> 1	≤10 ms
1 -> 0	≤10 ms
Isolation voltage	
Contact - Contact	Tested at 1000 VAC
Contact - Coil	Tested at 4000 VAC
Service life	
Electrical [3]	Min. 60 x 10^3 ops. (NC) at 6 A Min. 30 x 30^3 ops. (NO) at 6 A
Mechanical	Min. 10 x 10^6 ops.
Switching capacity	
Minimum	10 mA / 5 VDC
Maximum	180 W / 1500 VA
Protective circuit	
Internal	None
External	
AC	RC combination or VDR
DC	Inverse diode, RC combination or VDR
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

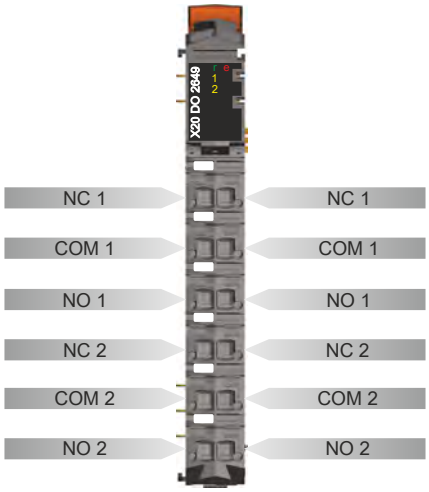
4.15.7.4 Status LEDs

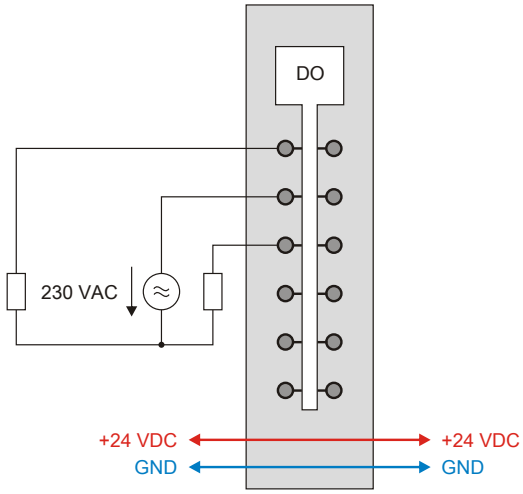
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Orange		Output status of the corresponding digital output

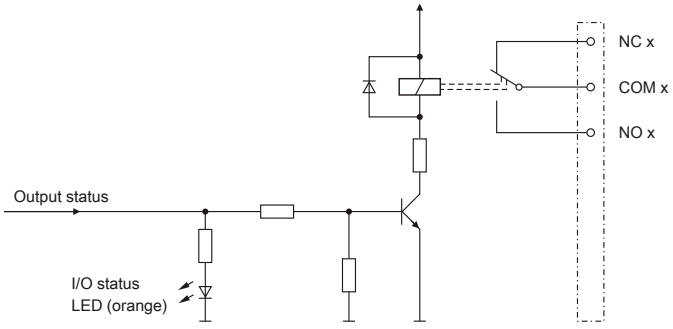
4.15.7.5 Pinout



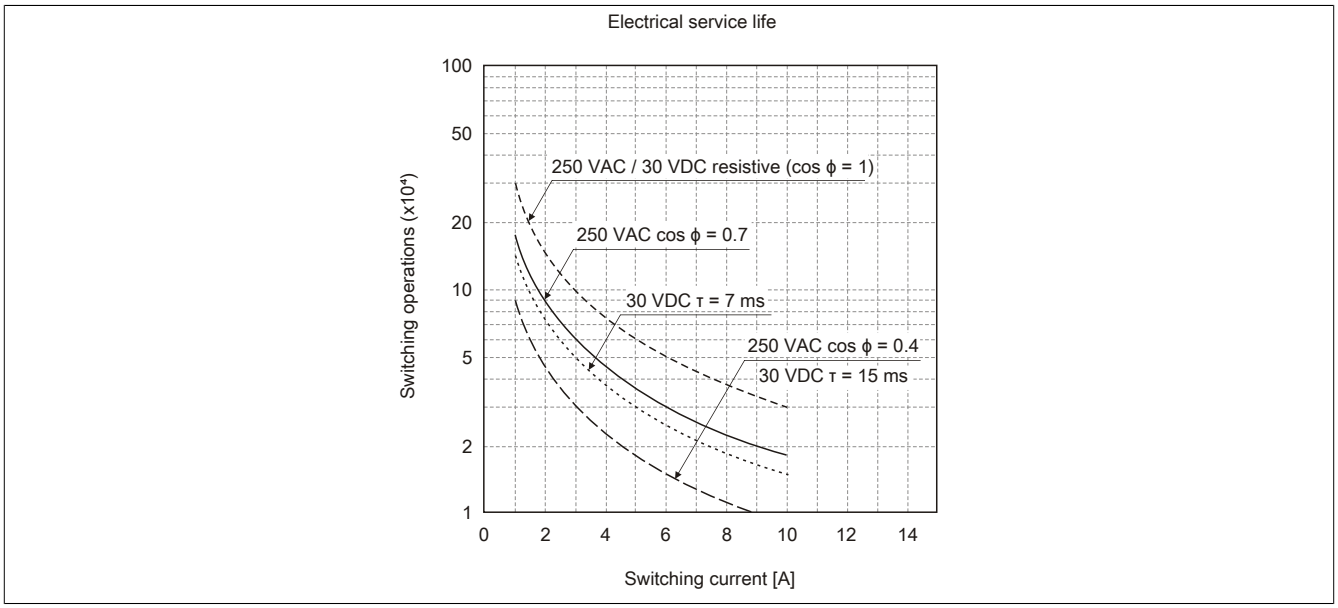
4.15.7.6 Connection example



4.15.7.7 Output circuit diagram



4.15.7.8 Electrical service life



4.15.7.9 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the maximal current per channel is limited to 4 A and maximal total current is limited to 8 A.

4.15.7.10 Register description

4.15.7.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.7.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.7.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 2	USINT			•	
		DigitalOutput01	Bit 0				
		DigitalOutput02	Bit 1				

1) The offset specifies where the register is within the CAN object.

4.15.7.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.7.10.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.7.10.4.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 3	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

4.15.7.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.7.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.8 X20DO4321

4.15.8.1 General information

The module is equipped with 4 outputs for 3-wire connections.

- 4 digital outputs
- Sink connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

4.15.8.2 Order data

Model number	Short description	Figure

Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 307: X20DO4321 - Technical data

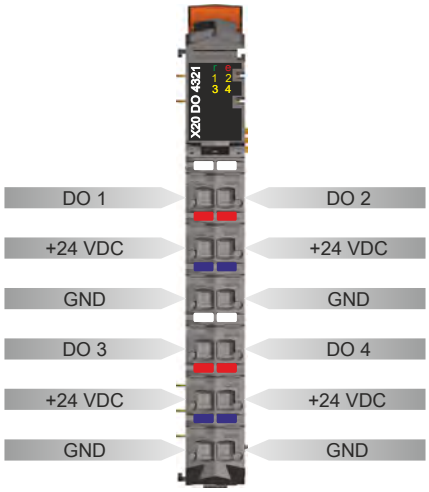
1) Number of outputs x $R_{DS(on)}$ x Nominal output current² (A calculation example can be found on the B&R website in the download area for the module.)
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.15.8.4 Status LEDs

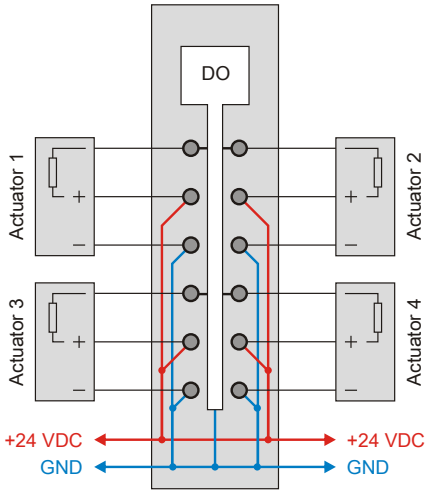
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	Reset mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Output status of the corresponding digital output

4.15.8.5 Pinout



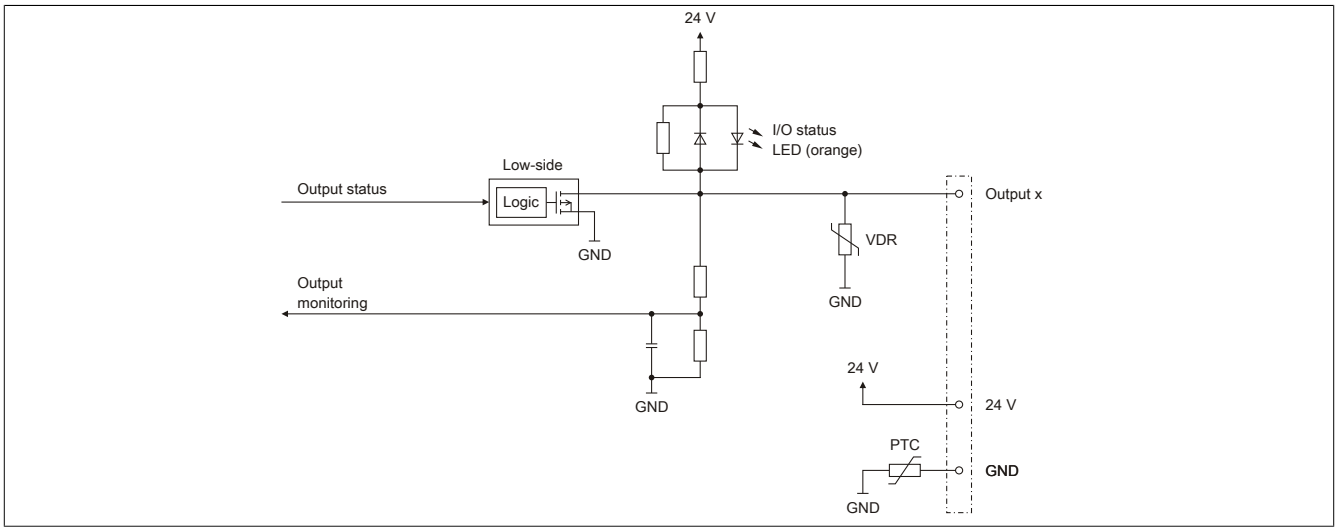
4.15.8.6 Connection example



4.15.8.7 OSP hardware requirements

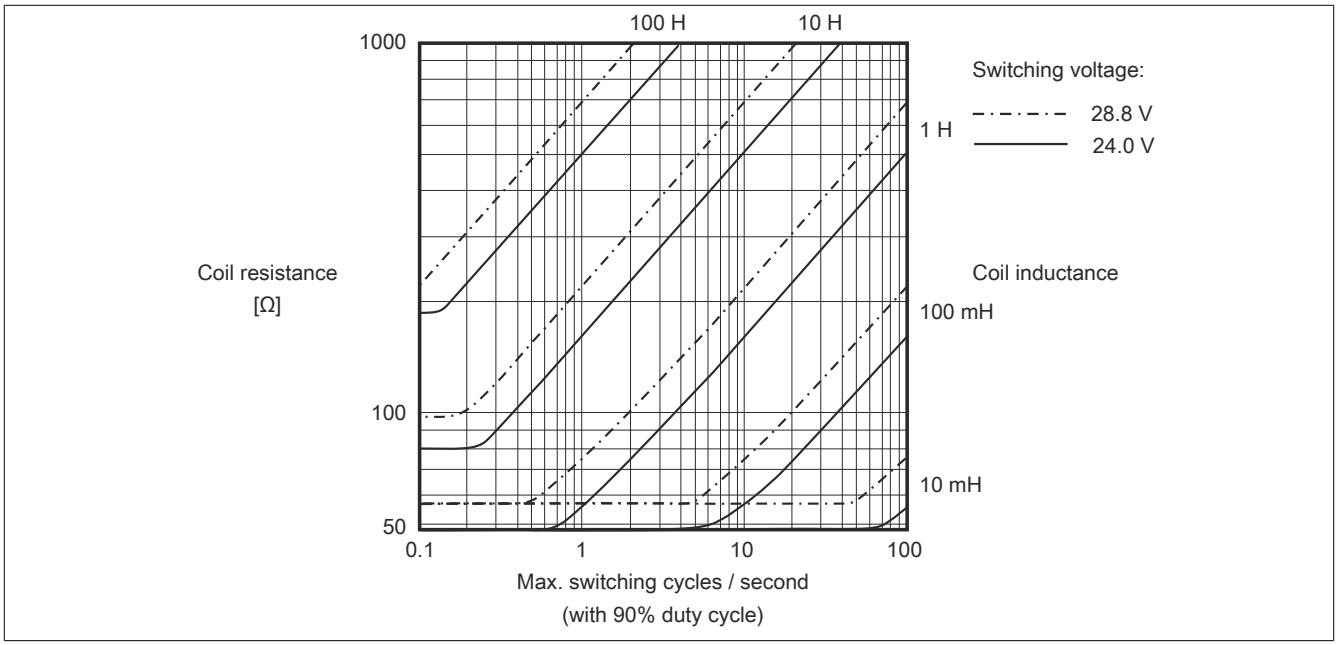
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.8.8 Output circuit diagram



4.15.8.9 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.8.10 Register description

4.15.8.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.8.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.8.10.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	Status of digital outputs 1 to 4	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.8.10.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	-	Status of digital outputs 1 to 4	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.8.10.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.8.10.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.8.10.5.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.15.8.10.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.8.10.6.1 Status of digital outputs 1 to 4

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput04

The status of digital outputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit		Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
3	StatusDigitalOutput04	0	Channel 04: No error
		1	Channel 04: Short circuit or overload

4.15.8.10.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.8.10.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.8.10.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.8.10.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.8.10.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.8.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.9 X20(c)DO4322

4.15.9.1 General information

The module is equipped with 4 outputs for 3-wire connections.

- 4 digital outputs
- Source connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

4.15.9.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.15.9.3 Order data

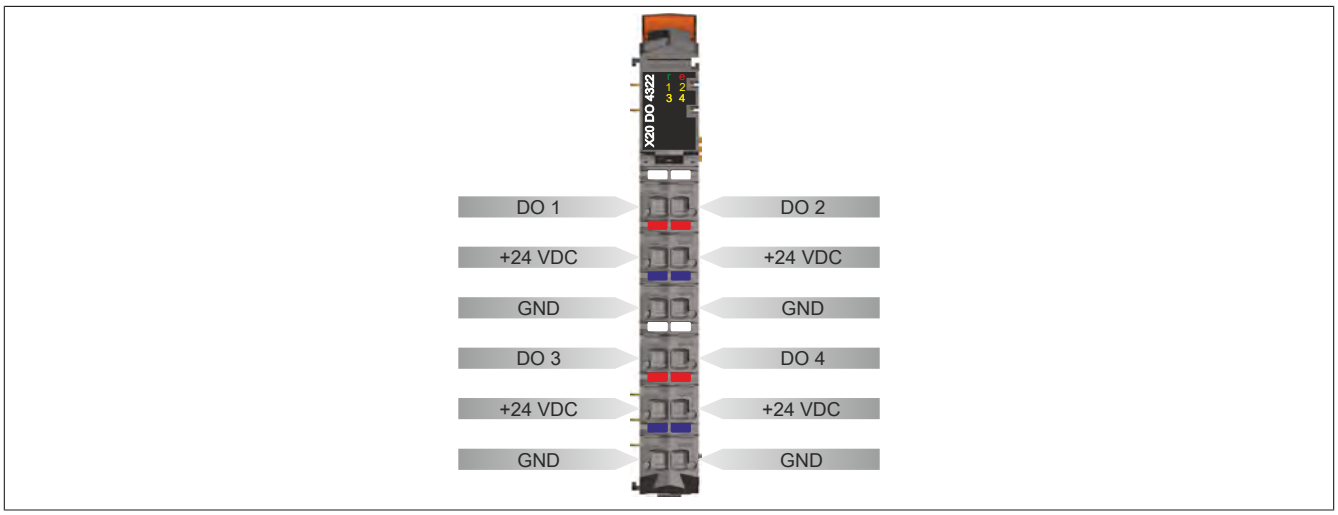
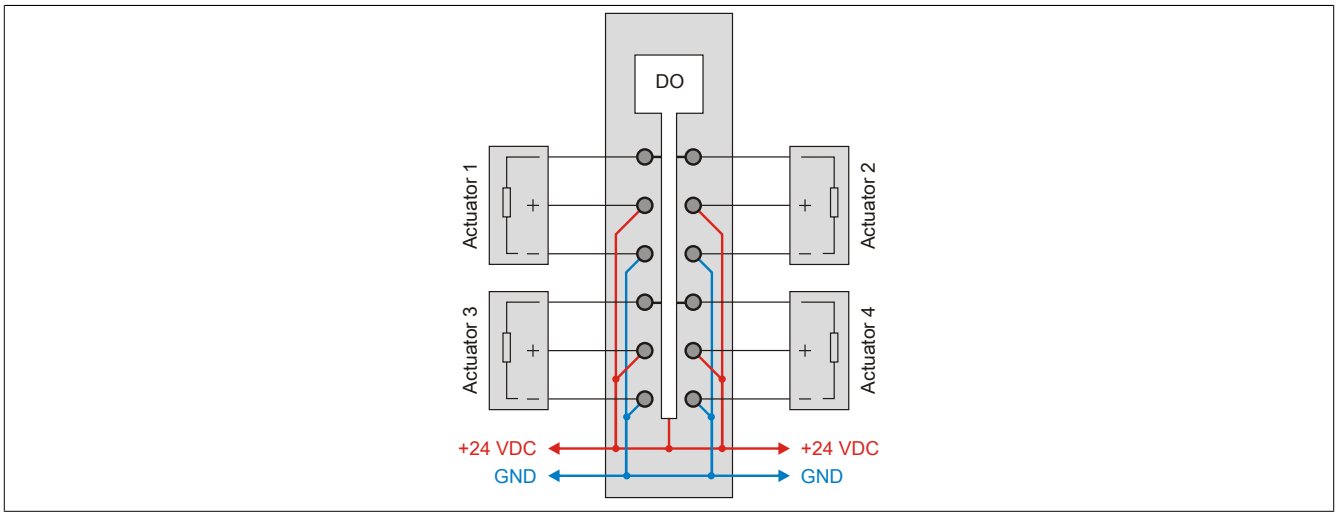
	1 - 4	Orange		Output status of the corresponding digital output

4.15.9.6 Pinout



4.15.9.7 Connection example



Caution!

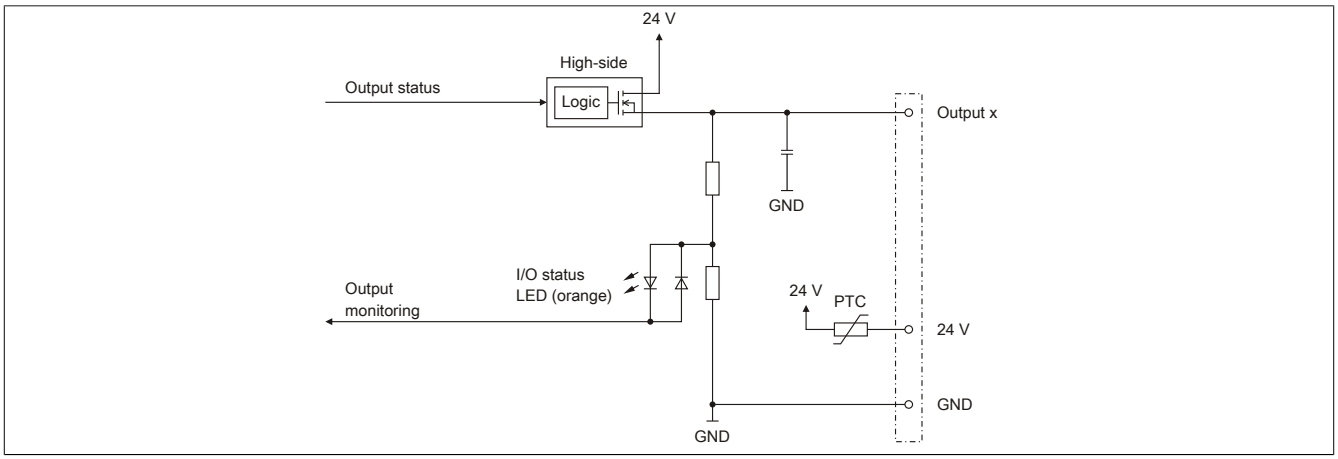
If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.9.8 OSP hardware requirements

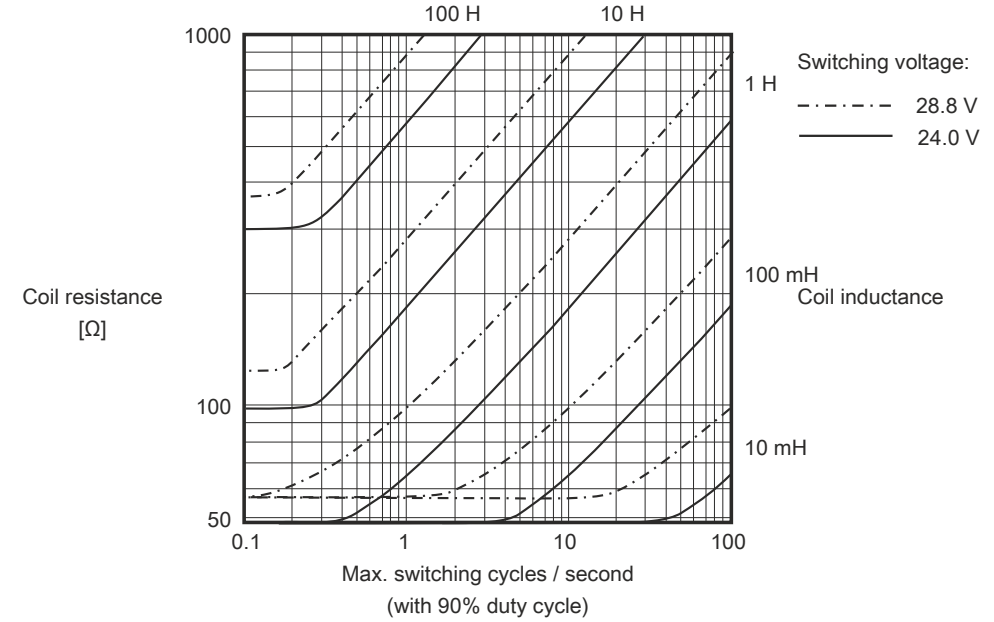
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.9.9 Output circuit diagram



4.15.9.10 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.9.11 Register description

4.15.9.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.9.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.9.11.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	Status of digital outputs 1 to 4	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.9.11.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	-	Status of digital outputs 1 to 4	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.9.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.9.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.9.11.5.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.15.9.11.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.9.11.6.1 Status of digital outputs 1 to 4

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput04

The status of digital outputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit		Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
3	StatusDigitalOutput04	0	Channel 04: No error
		1	Channel 04: Short circuit or overload

4.15.9.11.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.9.11.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.9.11.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.9.11.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.9.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.9.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.10 X20DO4331

4.15.10.1 General information

The module is equipped with 4 outputs for 3-wire connections. The rated output current is 2 A.

- 4 digital outputs with 2 A
- Sink connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

4.15.10.2 Order data

Model number	Short description	Figure

KC	Yes
GOST-R	Yes
Digital outputs	
Design	FET negative switching
Nominal voltage	24 VDC
Switching voltage	24 VDC -15 % / +20 %
Nominal output current	2 A
Total nominal current	8 A
Connection type	3-wire connections
Output circuit	Sink
Output protection	Thermal cutoff if overcurrent or short circuit occurs (see value "Peak short circuit current") Internal inverse diode for switching inductive loads (see section "Switching inductive loads")

Table 311: X20DO4331 - Technical data

Product ID	X20DO4331
Actuator supply	0.5 A in total for output-independent actuator supply
Diagnostic status	Output monitoring with 10 ms delay
Leakage current when switched off	75 µA
$R_{DS(on)}$	35 mΩ
Peak short circuit current	<24 A
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Switching delay	
0 -> 1	<300 µs
1 -> 0	<500 µs
Switching frequency	
Resistive load	Max. 500 Hz
Inductive load	See section "Switching inductive loads"
Braking voltage when switching off inductive loads	Typ. 50 VDC
Isolation voltage between channel and bus	500 V_{eff}
Additional functions	To increase the output current, outputs can be switched in parallel
Actuator supply	
Voltage	Module supply minus voltage drop for short circuit protection
Voltage drop for short circuit protection at 500 mA	Max. 2 V
Short circuit protection	Yes
Power consumption	
Actuator supply	Max. 12 W 3)
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 311: X20DO4331 - Technical data

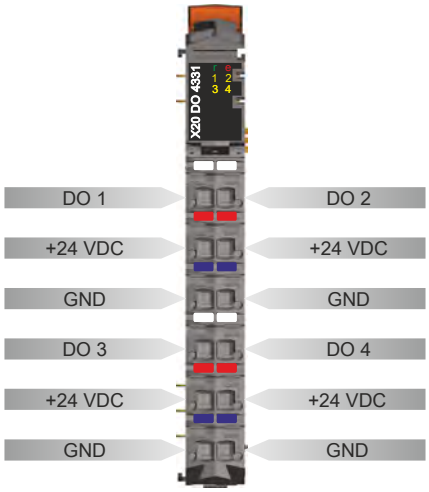
1) Number of outputs x $R_{DS(on)}$ x Nominal output current^2 (A calculation example can be found on the B&R website in the download area for the module.)
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.15.10.4 Status LEDs

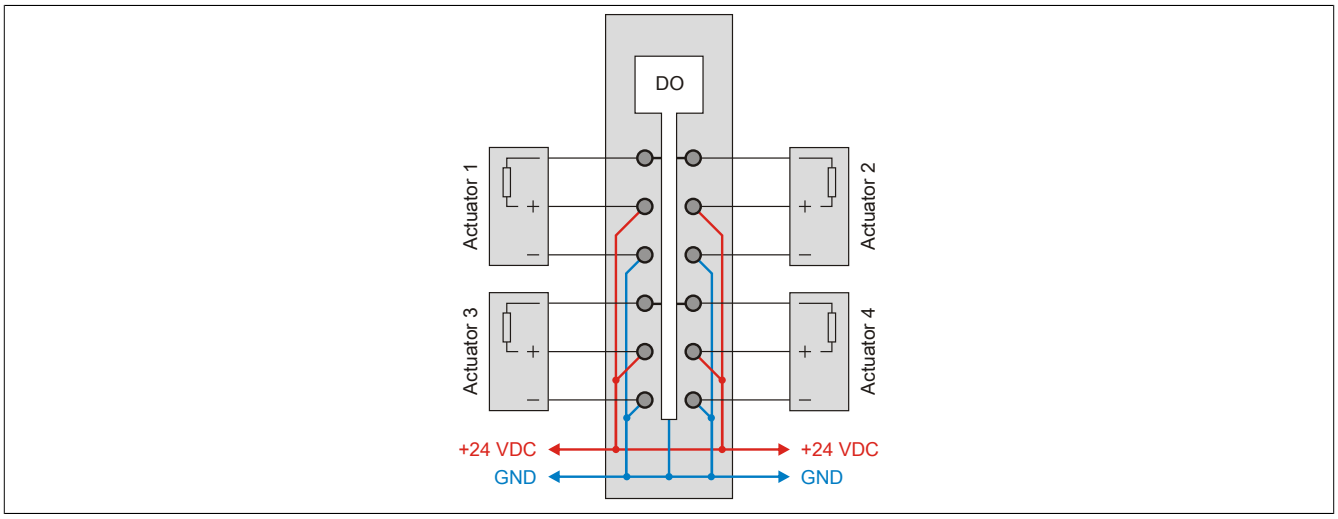
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Output status of the corresponding digital output

4.15.10.5 Pinout



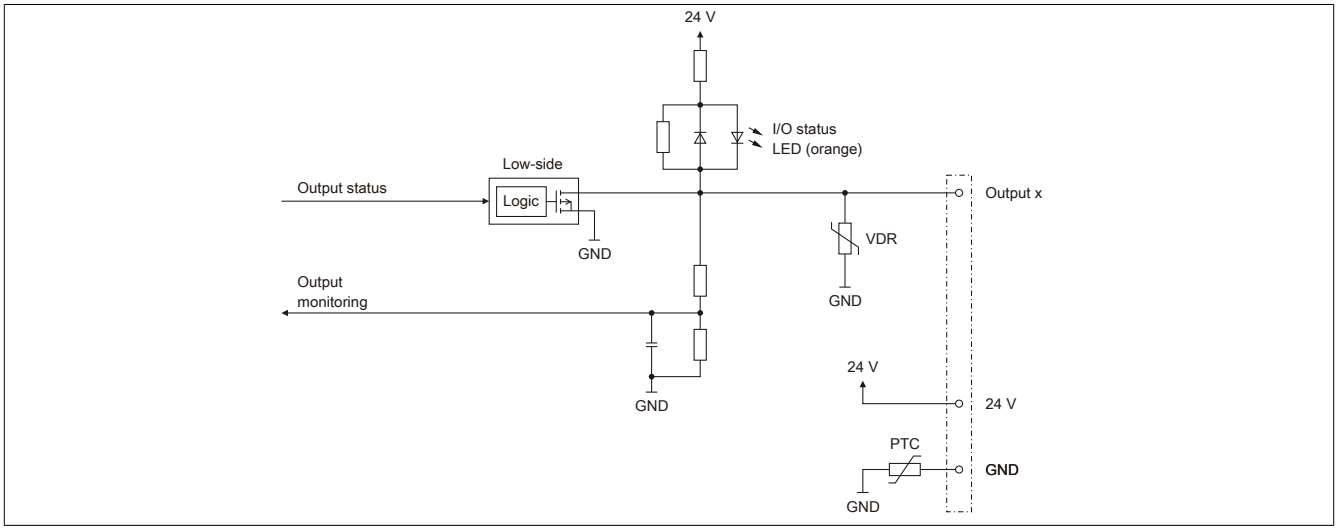
4.15.10.6 Connection example



4.15.10.7 OSP hardware requirements

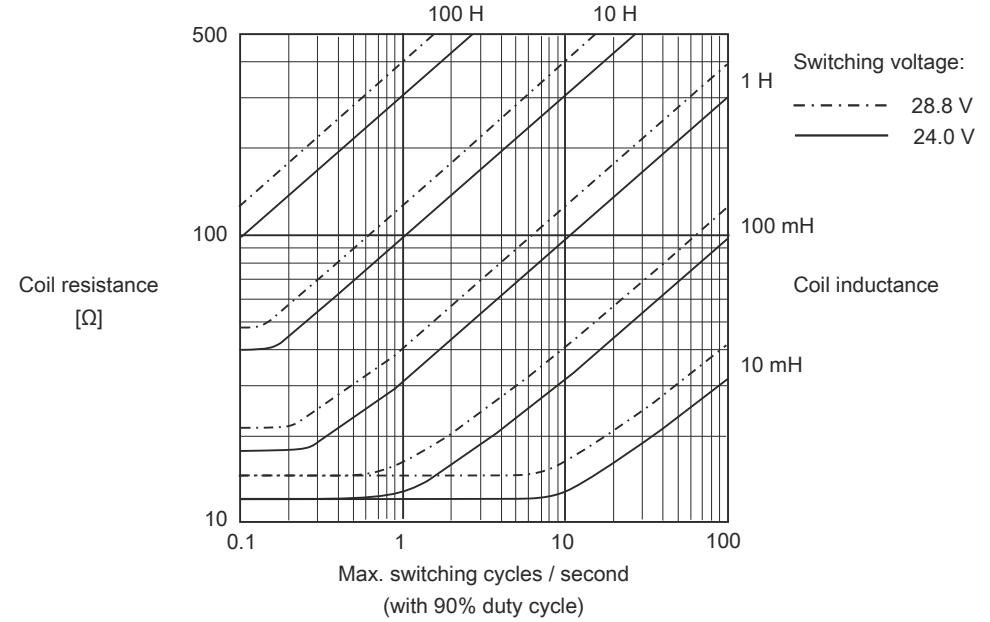
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.10.8 Output circuit diagram

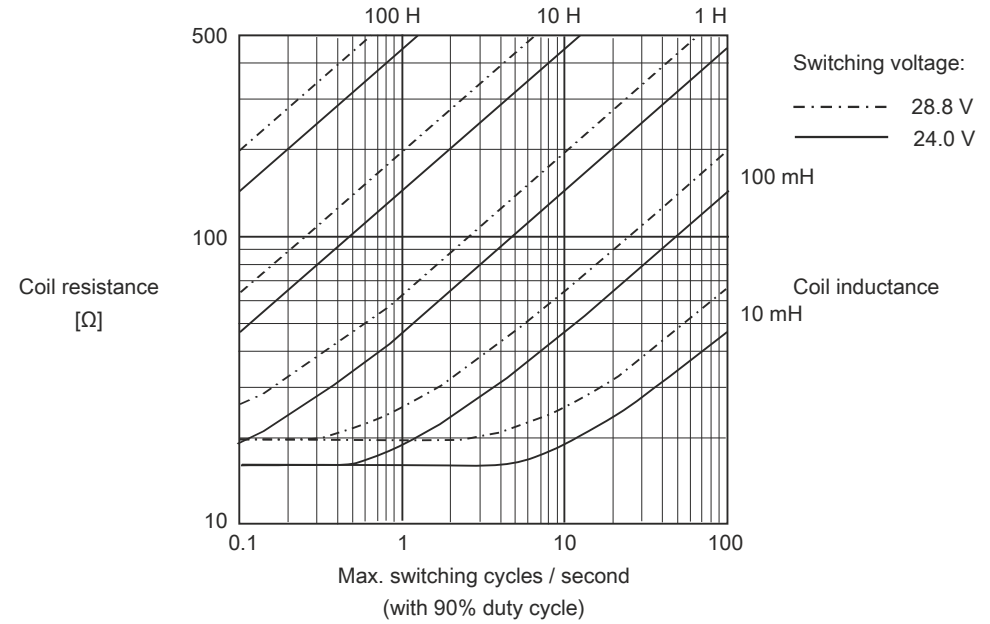


4.15.10.9 Switching inductive loads

Environmental temperature: 40°C, all outputs with the same load.



Environmental temperature: 60°C, all outputs with the same load.



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.10.10 Derating

The outputs of the X20DO4331 can handle up to 2A. To ensure optimal use of the module, it is important to assign the channels properly, and to keep in mind a potential derating.

The following table provides an overview of the number of fully used channels, the resulting best distribution, and a potential derating.

Number of channels using 2A	Division	Derating
1	Any	No
2	Possible divisions: 1, 3 2, 4	No
3	Possible divisions: 1, 2, 4 1, 3, 4	No
4	1 - 4	All channels

Table 312: Operation with 2 A

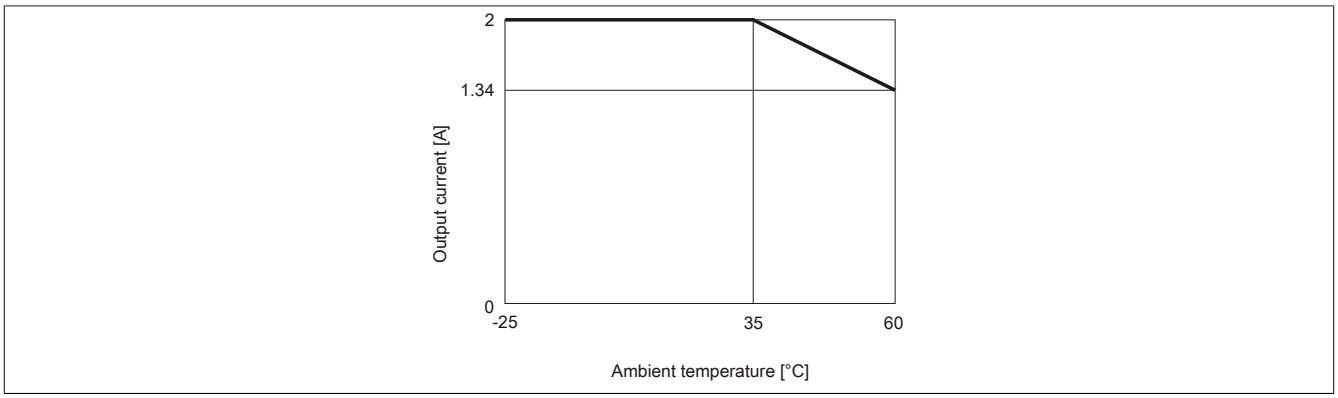


Figure 239: Derating when 4 channels are operated with 2 A

Modules next to the X20DO4331 can have a maximum power consumption of 1.5 W.

4.15.10.11 Register description

4.15.10.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.10.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.10.11.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	Status of digital outputs 1 to 4	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.10.11.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	-	Status of digital outputs 1 to 4	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.10.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.10.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.10.11.5.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.15.10.11.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.10.11.6.1 Status of digital outputs 1 to 4

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput04

The status of digital outputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit		Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
3	StatusDigitalOutput04	0	Channel 04: No error
		1	Channel 04: Short circuit or overload

4.15.10.11.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.10.11.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.10.11.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.10.11.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.10.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.10.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.11 X20(c)DO4332

4.15.11.1 General information

The module is equipped with 4 outputs for 3-wire connections. The rated output current is 2 A.

- 4 digital outputs with 2 A
- Source connection
- 3-wire connections
- 24 VDC and GND for actuator supply
- Integrated output protection
- OSP mode

4.15.11.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Table 314: X20DO4332, X20cDO4332 - Technical data

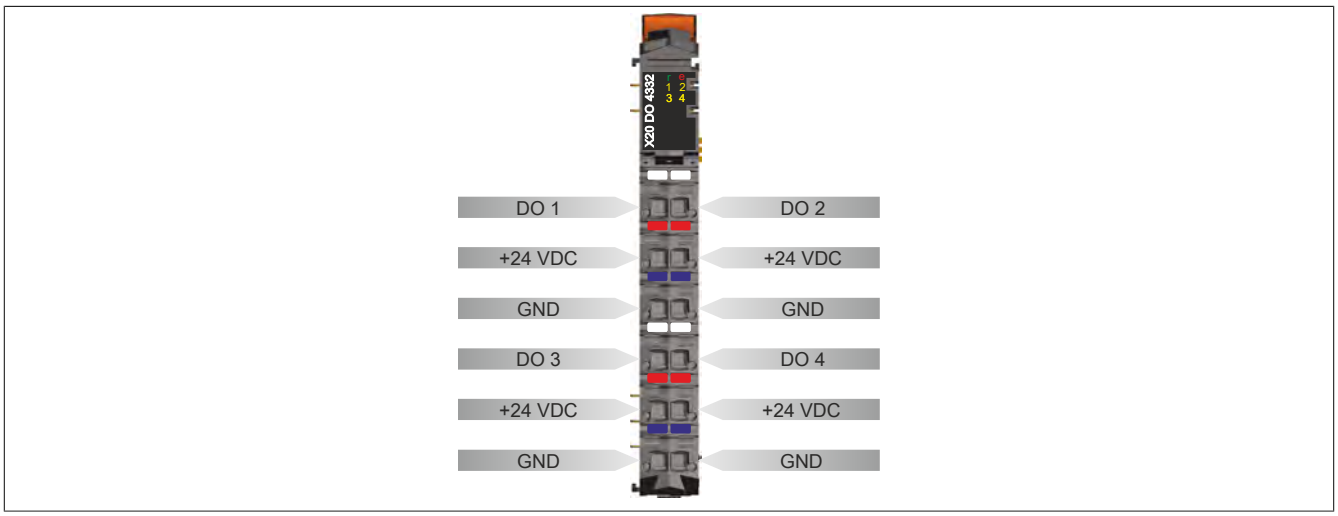
1) Number of outputs x $R_{DS(on)}$ x Nominal output current^2 (A calculation example can be found on the B&R website in the download area for the module.)
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) At loads ≤ 1 kΩ
4) The power consumption of the sensors connected to the module is not permitted to exceed 12 W.

4.15.11.5 Status LEDs

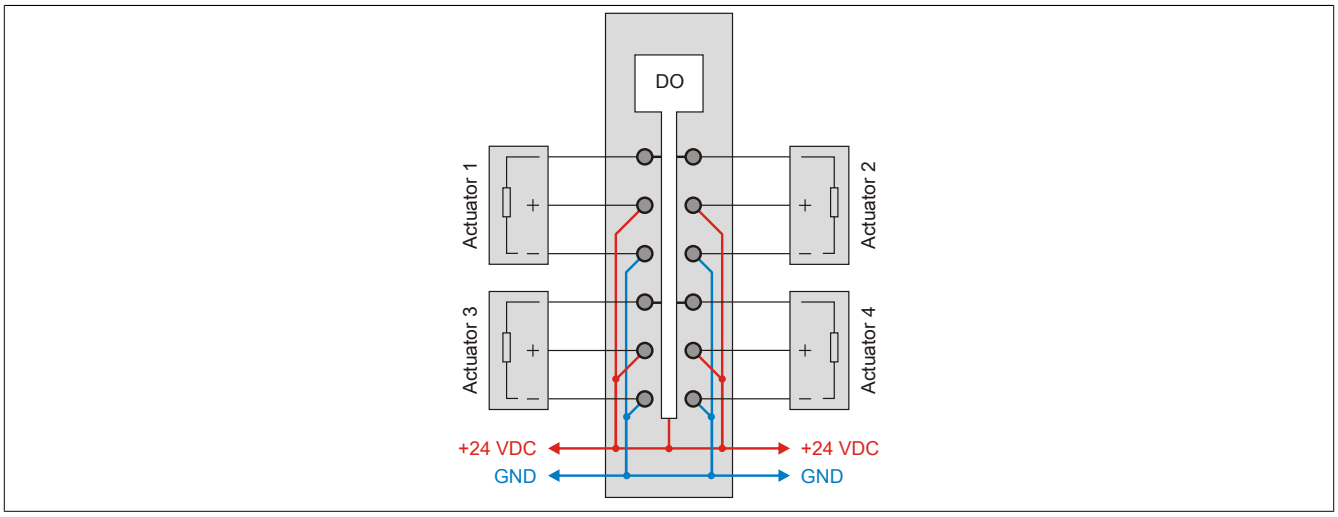
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Output status of the corresponding digital output

4.15.11.6 Pinout



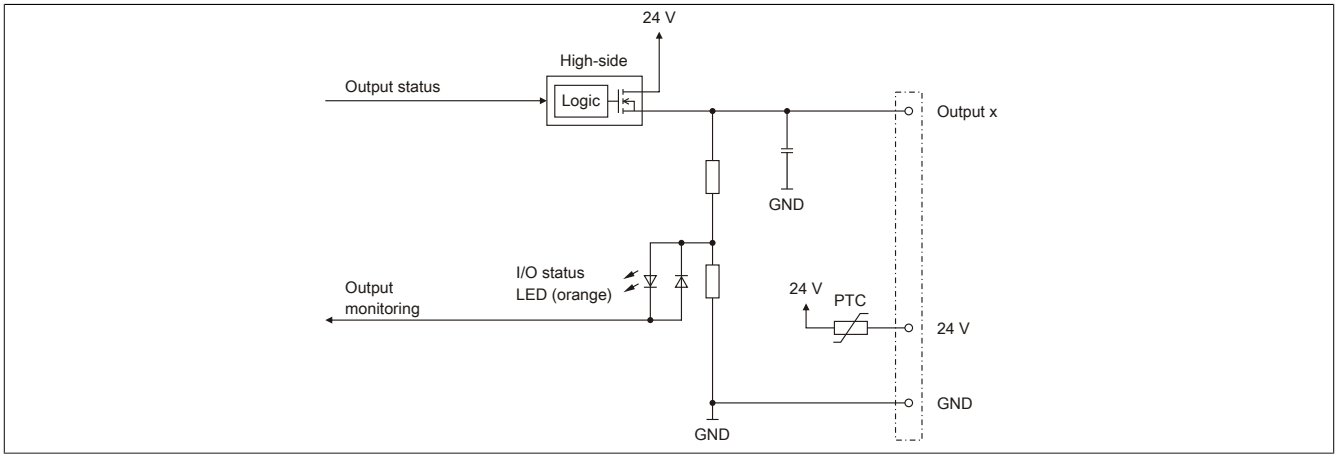
4.15.11.7 Connection example



4.15.11.8 OSP hardware requirements

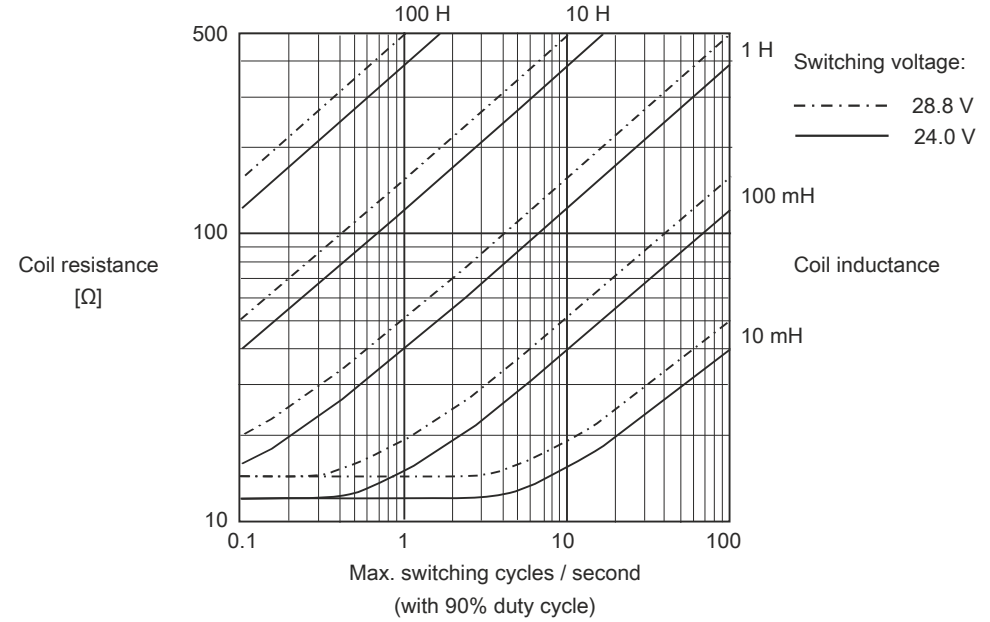
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.11.9 Output circuit diagram

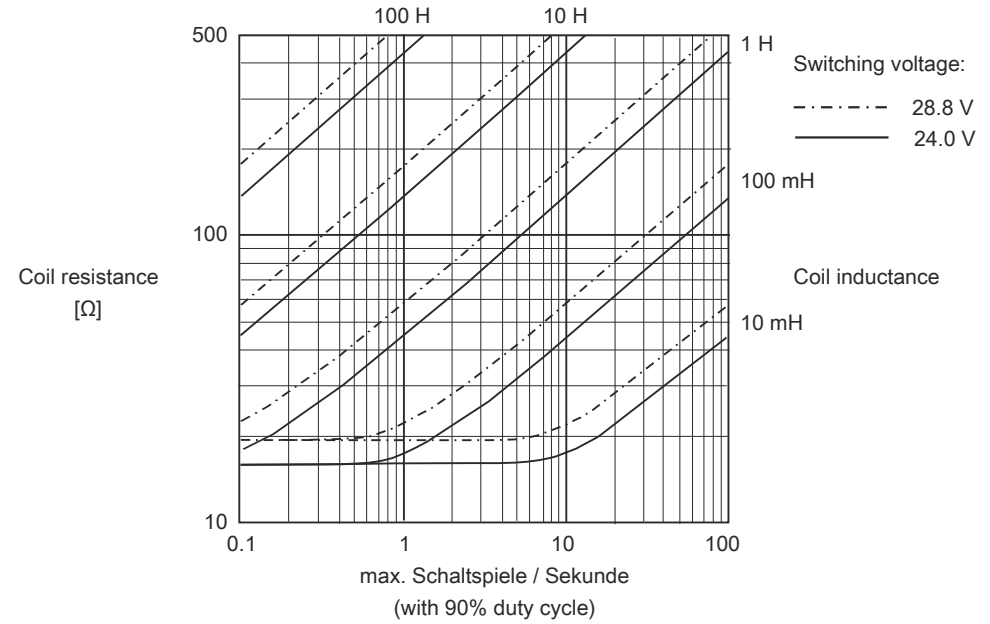


4.15.11.10 Switching inductive loads (Rev. H0 and higher)

Environmental temperature: 50°C, all outputs with the same load.



Environmental temperature: 60°C, all outputs with the same load.



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.11.11 Operation with 2 A

The outputs of the module can handle up to 2 A. With a total current of 4 A, no more than 2 channels are operable at full load. Correct channel assignments are important for achieving optimal use of the module.

The following table provides an overview of the number of fully used channels and the resulting best distribution.

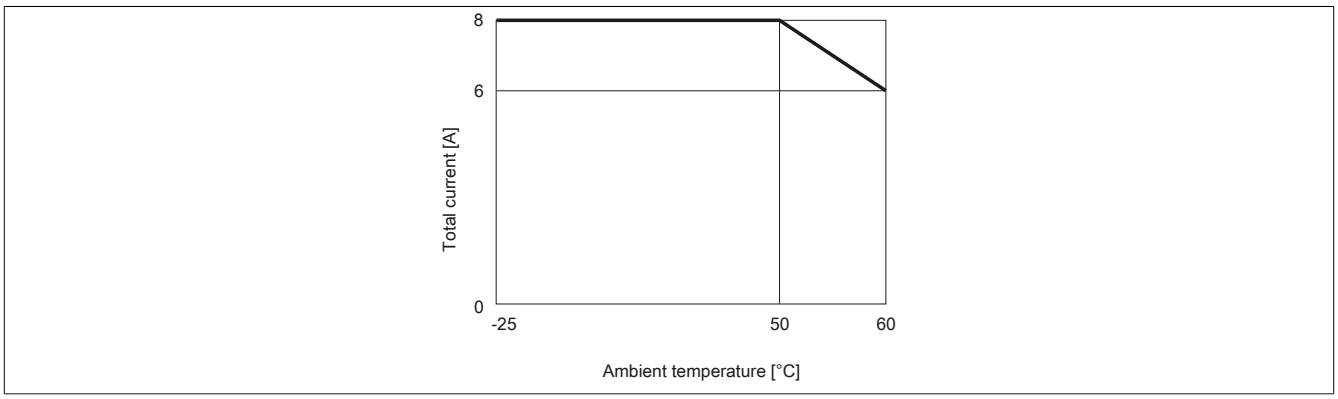
Number of channels using 2A	Division
1	Any
2	The following channel numbers can be assigned: 1, 3 1, 4 2, 4

Information:

This section is only valid up to Rev. H0.

4.15.11.12 Derating

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W.



Information:

This section is only valid for Rev. H0 and higher.

4.15.11.13 Register description

4.15.11.13.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.11.13.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.11.13.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	1	Status of digital outputs 1 to 4	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.11.13.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
30	-	Status of digital outputs 1 to 4	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.11.13.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.11.13.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.11.13.5.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.15.11.13.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.11.13.6.1 Status of digital outputs 1 to 4

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput04

The status of digital outputs 1 to 4 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit		Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
3	StatusDigitalOutput04	0	Channel 04: No error
		1	Channel 04: Short circuit or overload

4.15.11.13.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.11.13.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.11.13.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.11.13.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.11.13.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.11.13.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.12 X20DO4529

4.15.12.1 General information

The module is equipped with 4 relay outputs.

- 4 digital outputs
- Relay module for 115 VAC
- 4 change over contacts
- Single-channel isolated outputs

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

		1	Digital output 04 set

4.15.12.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.12.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.13 X20DO4613

4.15.13.1 General information

The module is a digital output module that is equipped with 4 opto-triac outputs using phase-angle control. L and N are fed to the module for zero-crossing detection.

The 4 outputs are electrically isolated from one another and are used for controlling external power triacs or non-parallel thyristors.

- 4 digital outputs
- Controls external power triacs or non-parallel thyristors
- Outputs with 48 - 240 VAC
- 50 Hz or 60 Hz
- Outputs electrically isolated from one another
- Phase-angle control
- Zero-crossing detection
- Negative half-waves can be switched off
- 2-wire connections
- 240 V coding
- OSP mode
- Frequency mode

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

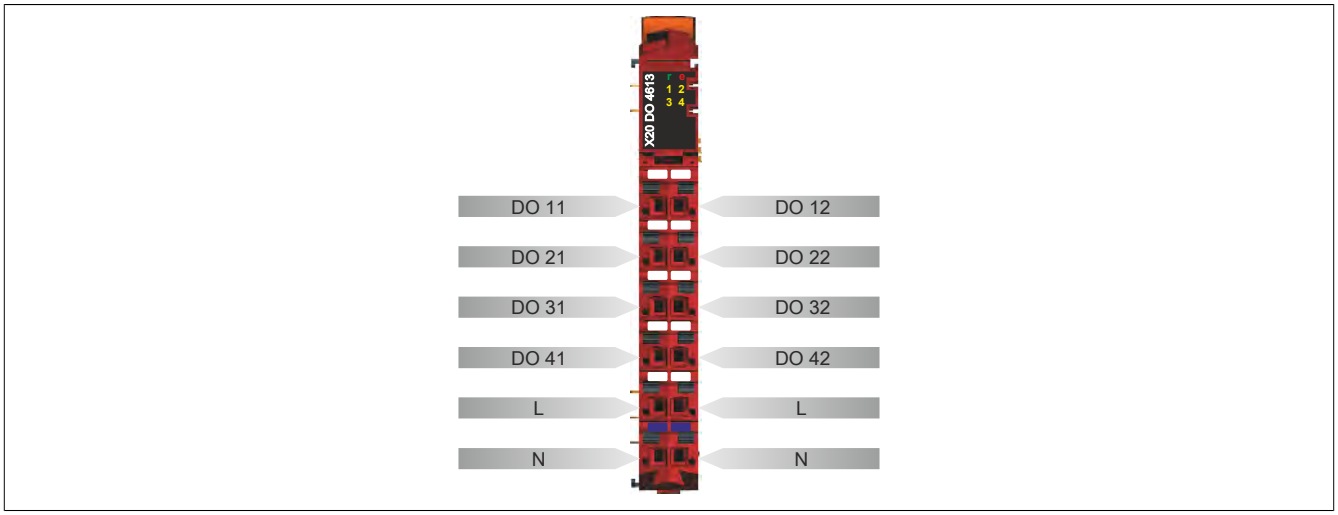
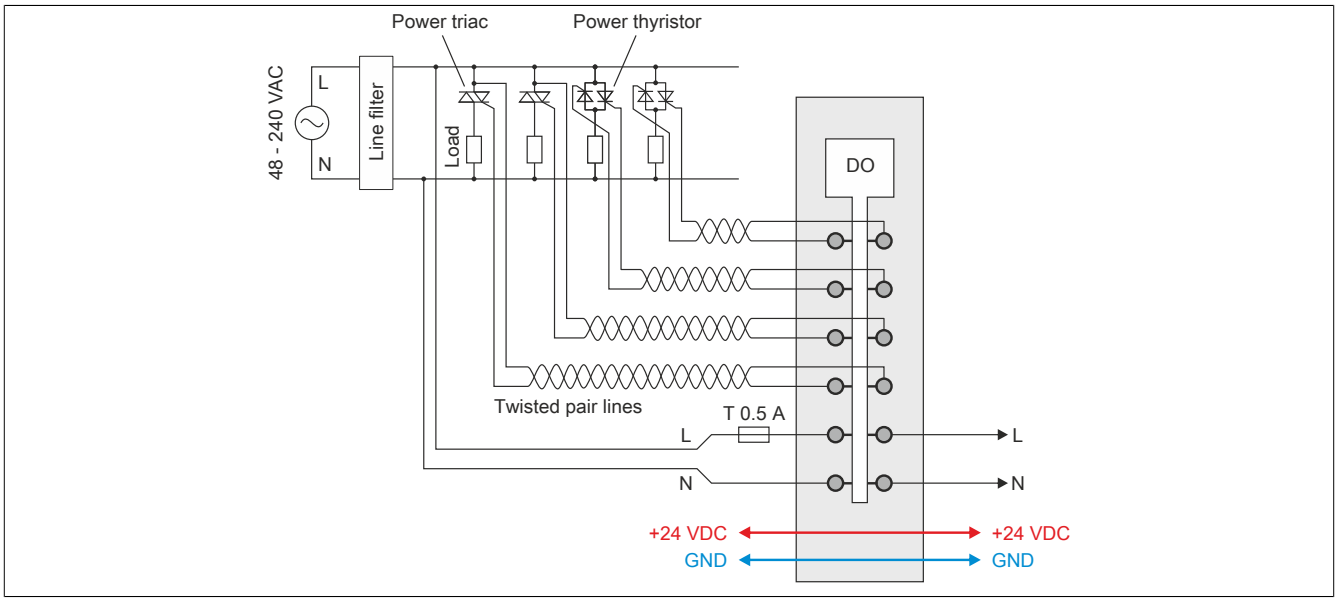
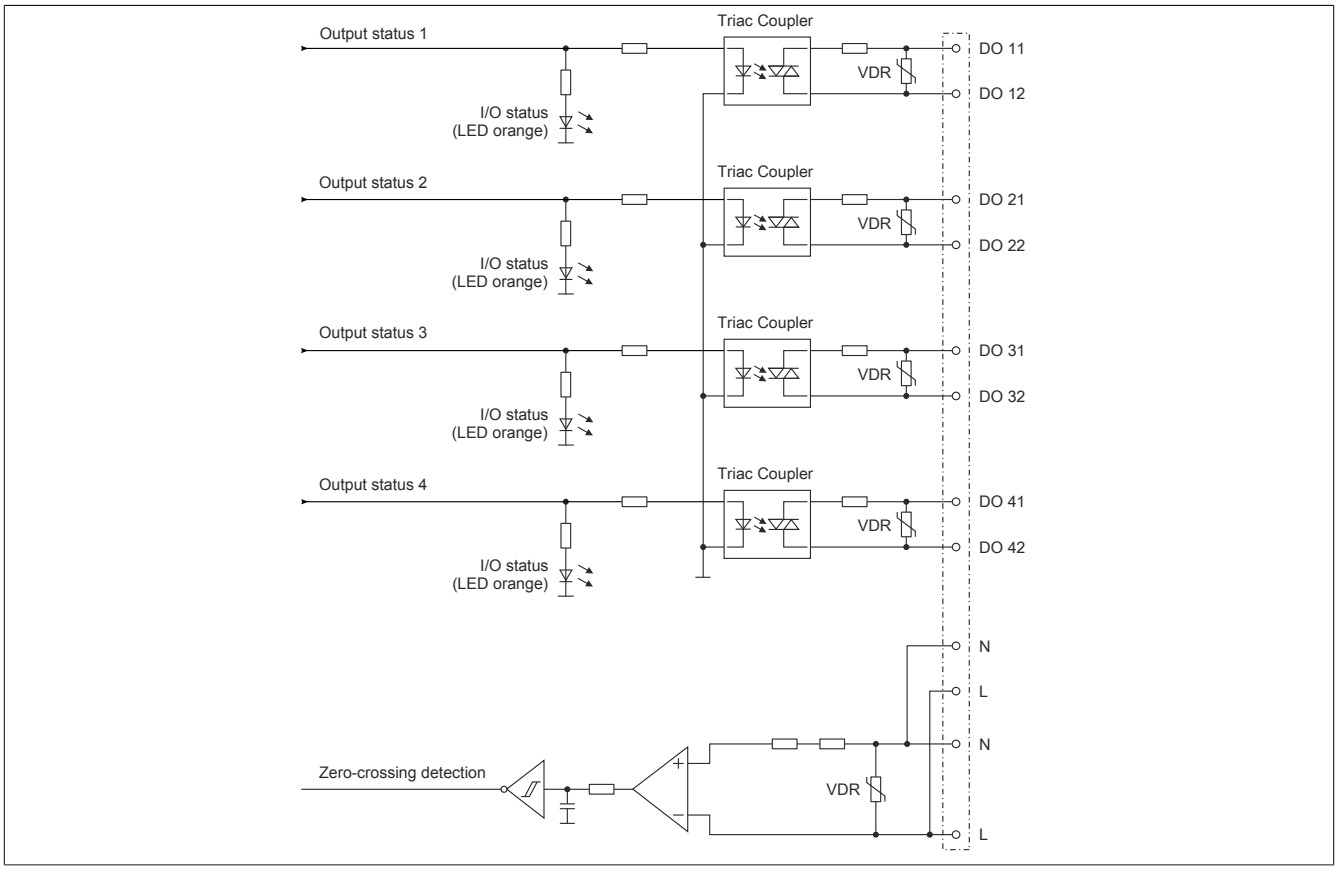
4.15.13.5 Pinout



4.15.13.6 Connection example



4.15.13.7 Output circuit diagram



4.15.13.8 Operating principle

The digital output module DO4613 was designed to control external triacs and thyristors.

The module is equipped with internal zero-crossing detection. Zero-crossing detection is the basis for a software PLL that generates 200 times the zero-crossing frequency. The output signal of the PLL is the base timer for the 4 PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control to the outputs is cut until the PLL is tuned correctly. The tuning procedure can take several seconds. In addition, the "ZeroCrossingStatus" bit is set and the error LED enabled (valid frequency range for the supply is 47 to 63 Hz).

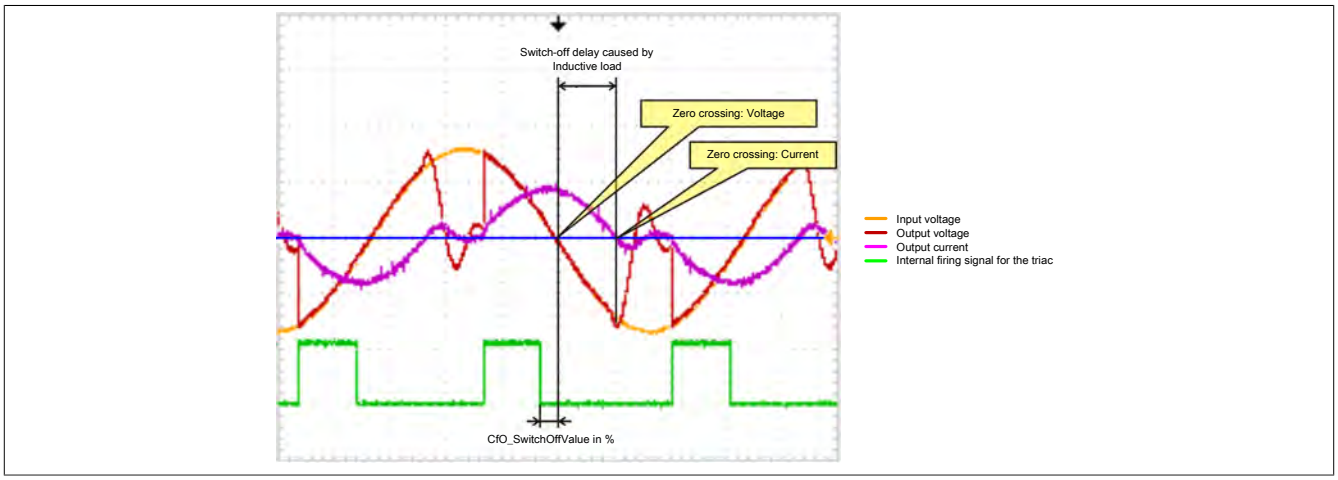
Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.13.9 Operation with inductive loads

As inherent to its functional principal, the triac output is cleared when the current crosses zero. Because zero crossing for current is delayed with inductive loads, it is possible that the triac will be fired again even though it is not completely cleared at higher output values (between 50 and 100% depending on the inductance of the load). In this case, a full-wave is output. This causes the available control range to be reduced (0 to 100%).

For control beyond the point of full-wave control (up to 100%), the value that is physically output no longer changes. However, this does not cause damage to the module.



4.15.13.10 Register description

4.15.13.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.13.10.2 Function model 0 - Standard and Function model 2 - Frequency mode

The only difference between function model 2 and function model 0 is the possibility of generating half-wave patterns in various frequencies. Register 18 "CfO_Frequency" is an additional register for this.

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
2 + N * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18	CfO_Frequency	UINT				•
18 + N * 2	ConfigOutput0N (Index N = 1 to 4)	USINT				•
28	ConfigOutput05	USINT				•
29	CfO_OutputTolerance	USINT				•
Communication						
2	DigitalOutput	USINT			•	
	DigitalOutput01	Bit 0				
	...	...				
	DigitalOutput04	Bit 3				
30	StatusInput01	USINT	•			
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.13.10.3 Function model 1 - OSP

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
2 + N * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18 + N * 2	ConfigOutput0N (Index N = 1 to 4)	USINT				•
28	ConfigOutput05	USINT				•
29	CfO_OutputTolerance	USINT				•
Configuration - OSP						
34	Activating the OSP output in the module	USINT			•	
	OSPValid	Bit 0				
32	CfgOSPMode	USINT				•
36	CfgOSPValue	USINT				•
36 + N * 2	CfgOSPValue0N (Index N = 1 to 4)	USINT				•
Communication						
2	Switching state of digital outputs 1 to 4	USINT			•	
	DigitalOutput01	Bit 0				
	...	...				
	DigitalOutput04	Bit 3				
30	Status of the outputs	USINT	•			
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.13.10.4 Function model 254 - Bus controller

Register	Offset	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General							
2 + N * 2	(N-1) * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18 + N * 2	-	ConfigOutput0N (Index N = 1 to 4)	USINT				•
28	-	ConfigOutput05	USINT				•
29	-	CfO_OutputTolerance	USINT				•
Communication							
30	0	Status of the outputs	USINT	•			
		ZeroCrossingInput	Bit 4				
		ZeroCrossingStatus	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.15.13.10.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.15.13.10.5 General information

The digital output module was designed for phase control of resistive and inductive loads.

The module is equipped with internal zero-crossing detection. Zero crossing detection is the basis for a software PLL that generates 200 times the zero crossing frequency. The output signal of the PLL is the base timer for the 2 PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control of the outputs is cut until the PLL is tuned correctly (can take several seconds). In addition, the "ZeroCrossingStatus" bit is set and the Error LED is enabled (valid frequency range for the supply is 45 to 65 Hz).

Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.13.10.6 Digital outputs

The output state of the outputs defined as digital is transferred to the output ports of the control switch in sync with the connected power mains. The switch-on state is applied when the voltage crosses zero on the positive half-wave and the switch-off state at the zero crossing for current in each half wave.

4.15.13.10.6.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

Information:

The states in these registers are only applied when the channels are set to DIGITAL in register 4.15.13.10.8.3 "ConfigOutput05".

When using the setting "packed outputs" ALL channels must be set to DIGITAL. Mixed operation is not possible.

4.15.13.10.7 Analog outputs

The output value of the outputs defined as analog outputs (unit percent) is switched through to the control ports in sync with power mains. The analog value is output to the TRIAC control port in the range between (output value > SwitchOffValue) and (output value <= 95%) with a resolution of 1%.

Changes to the output value are applied at the next positive half-wave.

4.15.13.10.7.1 Commutation angle for analog outputs 1 - 4

Name:
AnalogOutput01 to AnalogOutput04

These registers are used to set the commutation angle for phase angle control.

Values between 0 and 100 correspond to the output value for the respective channel in percent. Values above 100 correspond to 100%.

Data type	Value
USINT	0 to 100

Information:

The commutation angle for phase angle control set in these registers are only applied when the channels are set to ANALOG in register 4.15.13.10.8.3 "ConfigOutput05".

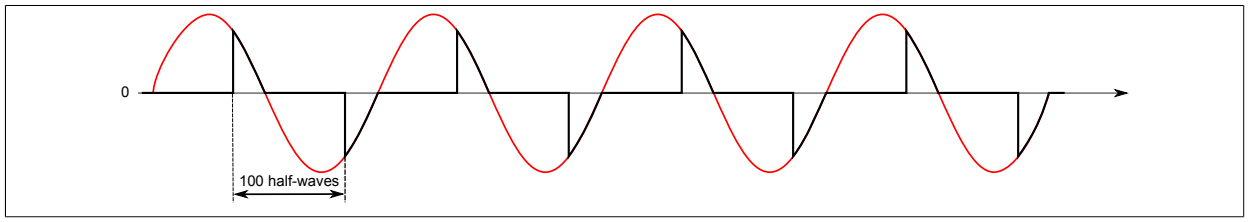
4.15.13.10.8 Output configuration

4.15.13.10.8.1 Configuring the half-wave pattern

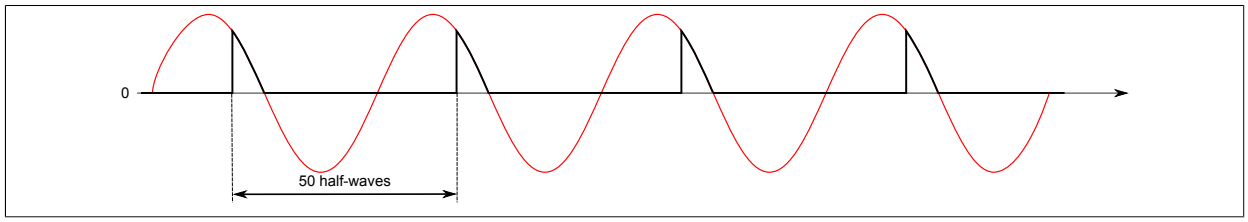
Name:
CfO_Frequency

This register can only be used in function model 2 - Frequency mode and makes it possible to configure the output of half-wave patterns in various frequencies. The commutation angle of the outputs is not affected by this. The following frequency patterns can be configured:

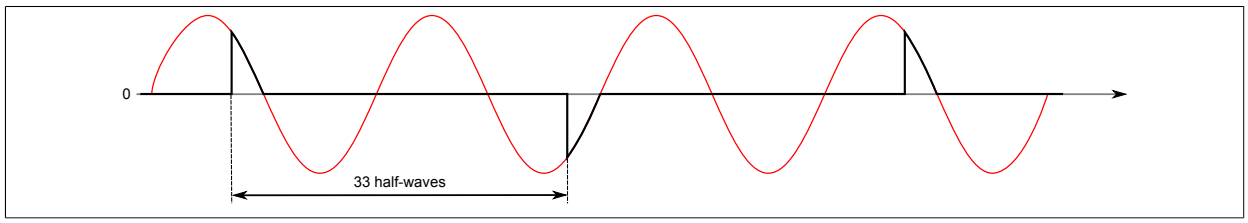
- 100 half-waves



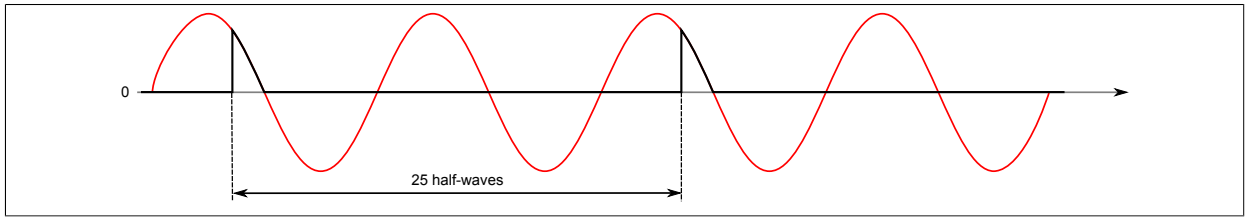
- 50 half-waves



- 33 half-waves



- 25 half-waves



With multichannel operation, the different channels should be operated with delayed half-waves in order to ensure that the load is placed evenly on the module.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Channel 1	0000	100 half-waves/second
		0001	50 half-waves/second
		0010	25 half-waves/second
		0011	33 half-waves/second
		0101	50 half-waves/second delayed by 1 half-wave
		0110	25 half-waves/second delayed by 2 half-waves
		0111	33 half-waves/second delayed by 1 half-wave
4 - 7	Channel 2	0000 to 0111	See channel 1
8 - 11	Channel 3	0000 to 0111	See channel 1
12 - 15	Channel 4	0000 to 0111	See channel 1

Information:

This function is available beginning with firmware version 940. This can be included beginning with hardware variant 8.

4.15.13.10.8.2 Setting the switch-off time

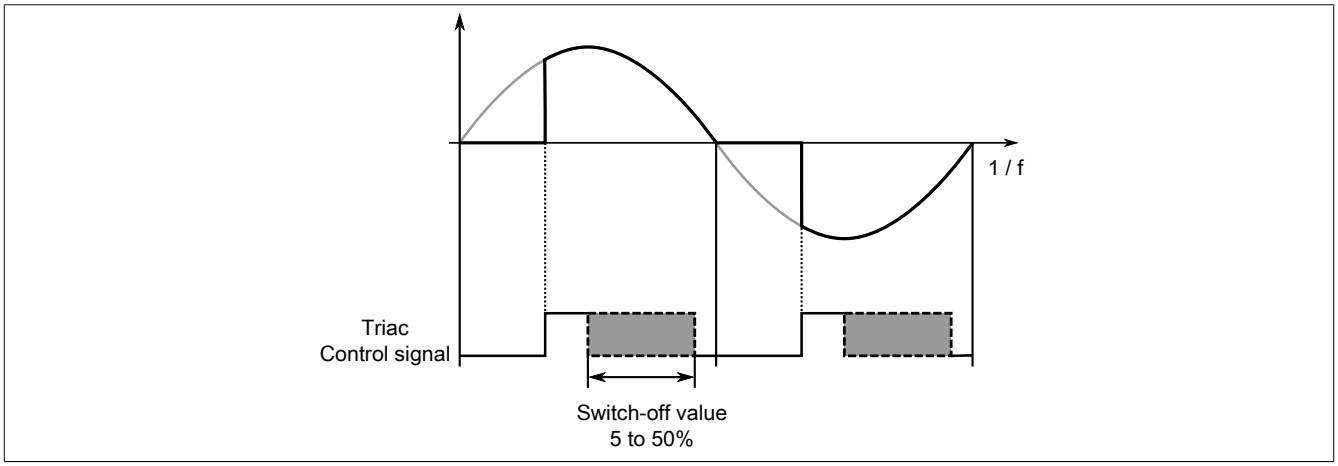
Name:
ConfigOutput01 to ConfigOutput04

This register defines how far in front of the zero cross-over the internal control signal for the TRIAC is switched off. Increasing this value may be necessary in order to prevent unwanted firing of the TRIAC in the event of a slight disturbance in the mains frequency.

With smaller loads, it is important to ensure that this switch off value is not set to large (too early) to prevent switching off prematurely.

The triac can of course only be fired before the set switch-off time.

"SwitchOffValue" in the AS I/O configuration.



Data type	Value	Description
USINT	5 to 50	Switch-off time in %

4.15.13.10.8.3 Configuration of the output channels

Name:
ConfigOutput05

The configuration of the output channels are stored in this register.

"Output type digital/analog" and "Output type full/half wave" in the AS I/O configuration

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1: Digital / Analog output	0	Output channel 1 is defined as a digital output. The output status is defined using bit 0 in the register DigitalOutput 1 - 4
		1	Output channel 1 is defined as an analog output. The output status is defined in the register AnalogOutput01
...		...	
3	Channel 4: Digital / Analog output	0	Output channel 4 is defined as a digital output. The output status is defined using bit 1 in the register DigitalOutput 1 - 4
		1	Output channel 2 is defined as an analog output. The output status is defined in the register AnalogOutput04
4	Channel 1: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 1
		1	Negative half-wave on output channel 1 is suppressed.
...		...	
7	Channel 4: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 4
		1	Negative half-wave on output channel 4 is suppressed.

1) Not available in function model 2 - Frequency mode.

4.15.13.10.8.4 Switching behavior for zero-crossing errors

Name:
CfO_OutputTolerance

This register can be used to set the switching behavior of the trigger. After the number of zero-crossing errors configured in Bit 0 to 4, the output is switched off for at least 3 periods. This is followed by synchronization with the zero signal according to Bit 7.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Trigger for Resync	0 to 30	Number of zero-crossover errors
5 - 6	Reserved	-	
7	Fast settling	0	Fast synchronization
		1	PLL synchronization

Fast synchronization

With this option, the trigger point is closed-loop controlled after each individual zero-crossover and input jitter.

- **Advantage:** Increased tolerance and faster response to deviations in mains frequency
- **Disadvantage:** Increased switch-on jitter for firing signal by zero cross signal ±100 µSec

PLL synchronization

With this option the intervals between zero cross-overs are measured and the PLL frequency is updated accordingly.

- **Advantage:** Jitter-free firing signal
- **Disadvantage:** When the output is switched off, additional measurement phases are required before it can be switched back on.

Information:

This function is available starting with Firmware version 928. This can be installed with hardware version 7 and hardware revision B4 or higher.

4.15.13.10.9 Status of the outputs

Name:
ZeroCrossingInput
ZeroCrossingStatus
StatusInput01

The operating status of the outputs is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("ZeroCrossingInput" through "ZeroCrossingStatus") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0 - 3	Reserved	-	
4	ZeroCrossingInput	0	Zero cross signal during the negative half-wave
		1	Zero cross signal during the positive half-wave
5 - 6	Reserved	-	
7	ZeroCrossingStatus	0	Zero cross signal OK
		1	Zero cross signal has dropped out

4.15.13.10.10 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.13.10.10.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.13.10.10.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.13.10.10.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.13.10.10.4 Define the OSP analog output value

Name:
CfgOSPValue01 to CfgOSPValue04

This register contains the analog output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	0 to 100

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.13.10.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
All channels	250 µs

4.15.13.10.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
All channels	150 µs

4.15.14 X20DO4623

4.15.14.1 General information

The module is a digital output module that is equipped with 4 SSR outputs with zero cross-over switches and uses 2-line connections. The module is also equipped with integrated full-wave control. The supply (L and N) is fed directly to the module.

- 4 digital outputs
- Outputs with integrated snubber circuit
- Outputs with 100 to 240 VAC
- L switching
- 50 Hz or 60 Hz
- 2-wire connections
- Integrated full-wave control
- 240 V coding

> **Danger!**
>
> **Risk of electric shock!**
>
> **The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.**

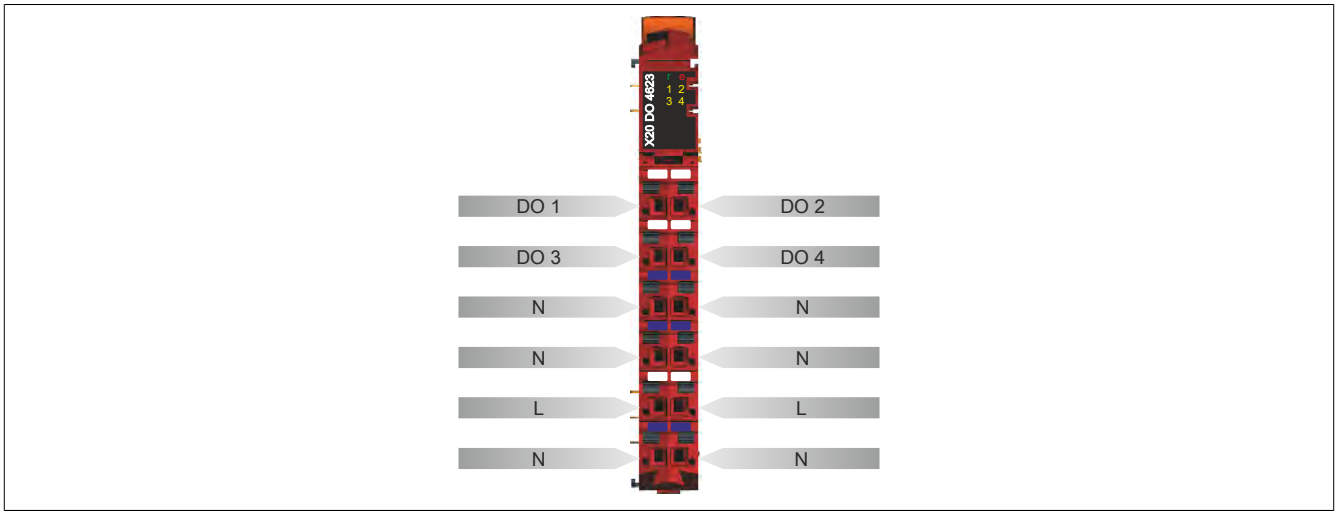
Ta max.: See environmental conditions

4.15.14.4 Status LEDs

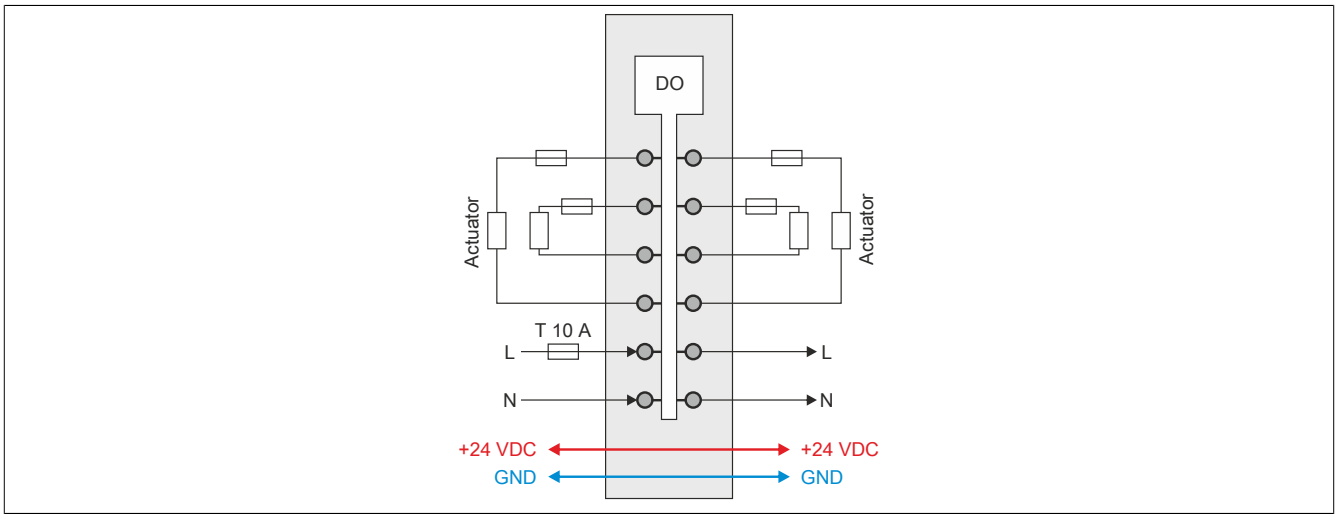
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Zero cross-over signal has dropped out
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Control status of the corresponding digital output

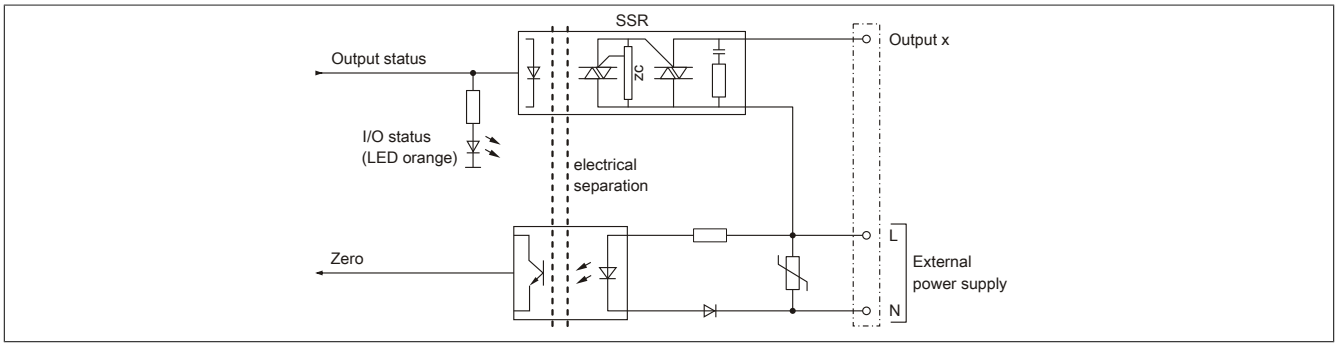
4.15.14.5 Pinout



4.15.14.6 Connection example



4.15.14.7 Output circuit diagram



4.15.14.8 Integrated full-wave control

Full-wave control is used to control power for electrical power consumers that are operated with AC voltage. Temperature control is a typical application

Unlike phase-angle control, the sine wave oscillation form of the mains voltage is not changed during full-wave control. This significantly reduces system perturbation.

The output voltage (channel) is switched on and off at a certain ratio. This switches the multi-cycle packets. A multi-cycle packet consists of a number of complete sine waves throughout a cycle. The relationship between the power-on duration and the cycle duration results in the desired effect of reduced power consumption by the connected power consumer.

With the full-wave control that is integrated in the module, a maximum of 24 full waves can be provided on the outputs per cycle. Control takes place in 4% steps.

Settings		Full waves

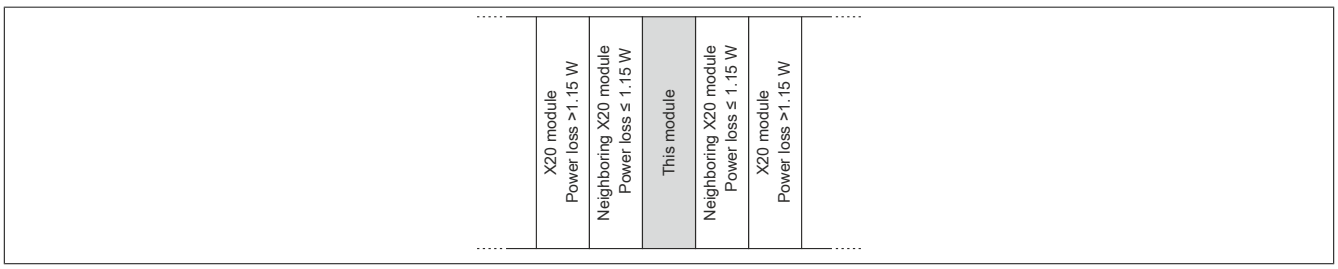
4.15.14.9 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.15.14.10 Register description

4.15.14.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.14.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				
4	1	AnalogOutput01	USINT			•	
6	2	AnalogOutput02	USINT			•	
8	3	AnalogOutput03	USINT			•	
10	4	AnalogOutput04	USINT			•	
28	-	Output configuration 1 - 4 ConfigOutput01	USINT				•
30	1	StatusInput01	USINT	•			
		ZeroCrossingInput	Bit 0				
		ZeroCrossingStatus	Bit 4				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.14.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
4	0	AnalogOutput01	USINT			•	
6	2	AnalogOutput02	USINT			•	
8	4	AnalogOutput03	USINT			•	
10	6	AnalogOutput04	USINT			•	
28	-	Output configuration 1 - 4 ConfigOutput01	USINT				•
30	0	Zero crossing status	USINT	•			
		ZeroCrossingInput	Bit 0				
		ZeroCrossingStatus	Bit 4				

1) The offset specifies where the register is within the CAN object.

4.15.14.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.14.10.4 Digital outputs

The output status is transferred to the control switch asynchronously to the connected network. The outputs switch on when the voltage crosses zero and switch off when the current crosses zero.

4.15.14.10.4.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

Information:

The states are only applied when the channels are set to DIGITAL in Setting the output configuration.

When using the setting "packed outputs" ALL channels must be set to DIGITAL. Mixed operation is not possible.

4.15.14.10.5 Analog outputs

The output value is transferred to the control circuit in sync with the connected power mains according to the firing pattern table (see "Integrated full-wave control"). The analog value is output with a resolution of ~4% over a duration of 24 complete waves. Values > 96% result in full control. Changes to the output value within an interval are applied after the next zero crossover.

4.15.14.10.5.1 Setting the output value from the firing pattern table

Name:
AnalogOutput01 to AnalogOutput04

These registers are used to set the output value from the firing pattern table.

Values between 0 and 100 correspond to the output value for the respective channel in percent. Values above 100 correspond to 100%.

Data type	Value
USINT	0 to 100

Information:

The states in these registers are only applied when the channels are set to ANALOG in Setting the output configuration.

4.15.14.10.5.2 Setting the output configuration

Name:
Output configuration 1 - 4
ConfigOutput01

Each channel can be configured for either "digital" or "analog" operation in this register. Depending on the setting, the corresponding DigitalOutput or AnalogOutput registers must be written.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Description
0	Channel 1	0	Digital register is used
1		1	Analog register is used
...		...	
3	Channel 4	0	Digital register is used
		1	Analog register is used
4 - 7	Reserved	0	

4.15.14.10.6 Zero crossing status

Name:
ZeroCrossingInput
ZeroCrossingStatus
StatusInput01

Zero crossing detection uses a fixed filter time of 1 ms and a scanning frequency of 10 kHz. When a missing or too short period is detected, control is switched off until at least 2 periods are detected correctly, and the status flag is set accordingly. Control is offset by 2 ms from the negative half-wave until the next zero crossover is detected correctly or another error occurs. This is normally at least one complete wave.

Monitoring is activated at the first zero crossover after being switched on.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("ZeroCrossingInput" through "ZeroCrossingStatus") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 17	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	ZeroCrossingInput[1)]	0	Signal during the negative half-wave
		1	Signal during the positive half-wave
1 - 3	Reserved	0	
4	ZeroCrossingStatus	0	No error
		1	Zero crossover failed
5 - 7	Reserved	0	

1) Value is valid if no error has occurred (ZeroCrossingStatus= 0)

4.15.14.10.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard function model	100 µs
Bus controller function model	150 µs

4.15.14.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Function model 0	Equal to the minimum cycle time
Function model 1	Equal to the minimum cycle time

4.15.15 X20(c)DO4633

4.15.15.1 General information

The module is a digital output module with phase-angle control that is equipped with 4 Triac outputs using 2-line connections. The supply (L and N) is fed directly to the module.

- 4 digital outputs
- Outputs with integrated snubber circuit
- Outputs with 12 to 240 VAC
- L switching
- Zero-crossing detection
- Phase-angle control
- Open-circuit detection for each channel
- Negative half-waves can be switched off
- 50 Hz or 60 Hz
- 2-wire connections
- 240 V coding
- OSP mode
- Frequency mode

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.15.15.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.15.15.3 Order data

Model number	Short description	Figure

4.15.15.5 Status LEDs

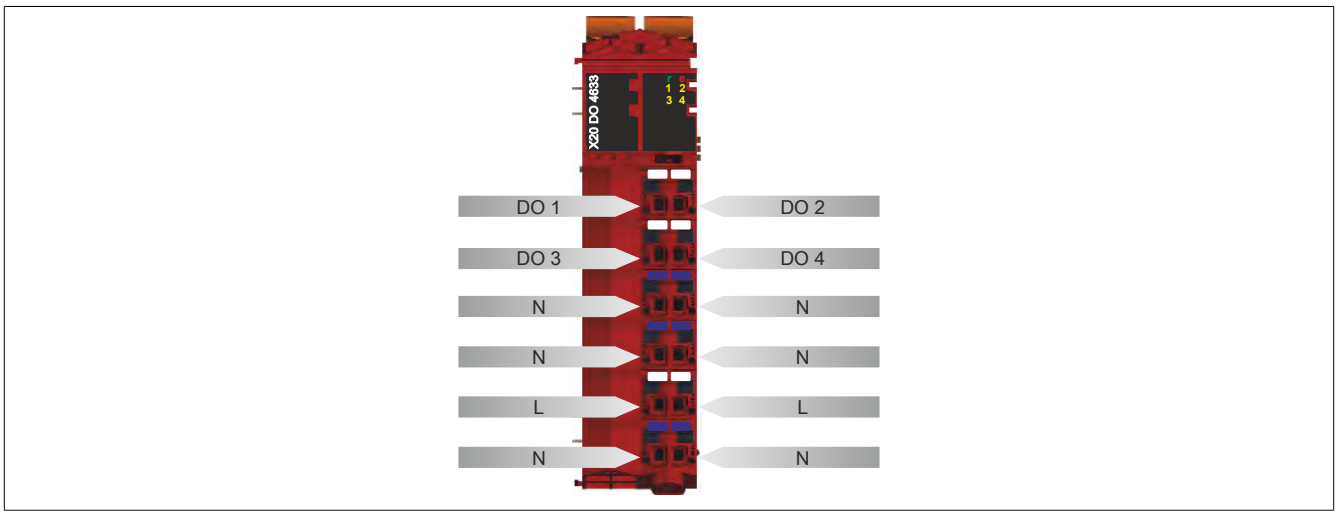
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Loss of zero-crossing signal (I/O supply voltage not applied or too low)
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Control status of the corresponding digital output

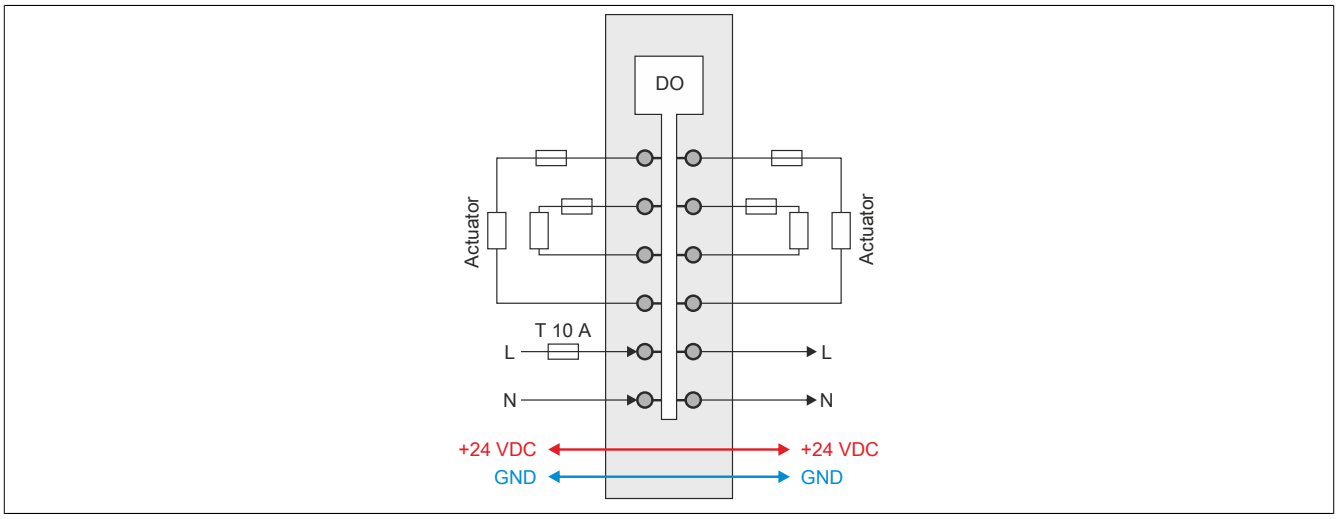
4.15.15.6 Pinout

The following points must be taken into consideration when wiring the module:

- For thermal reasons, wires with a cross-section ≥1.5 mm² must be used to wire the module.
- The neutral return lines for the outputs must be wired to the terminal block separately for each channel and must not be bypassed in the field.
- A line filter must be used for the 240 V supply that provides ≥40 dB attenuation at 150 kHz and works up to 5 MHz.



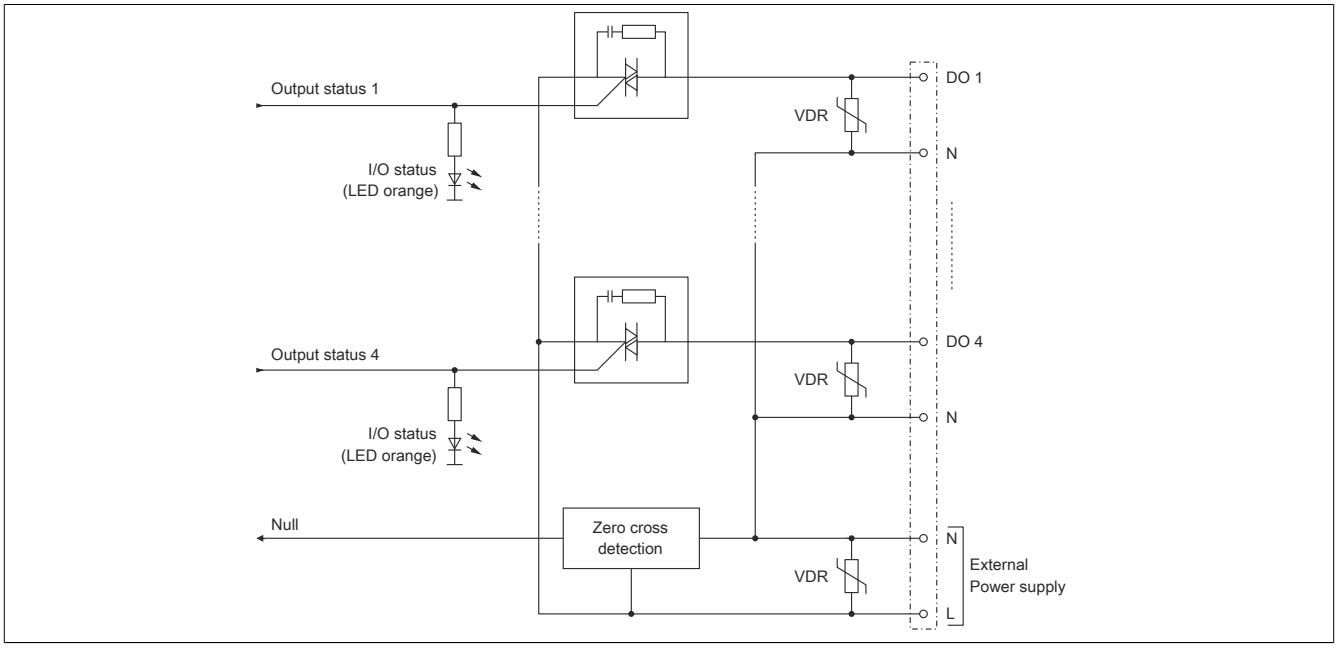
4.15.15.7 Connection example



4.15.15.8 OSP hardware requirements

In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.15.9 Output circuit diagram



4.15.15.10 External fuses

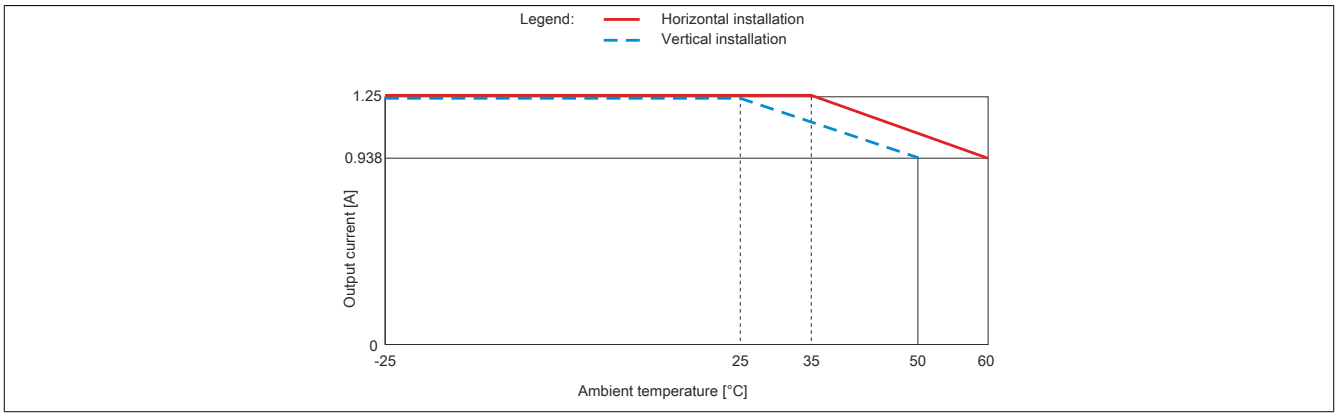
The following protective circuit must be used for safe operation:

	Protective circuit	Value
For the supply lines	Fuse	T 10 A
For the outputs	Fuse	Melting integral $I^2t \leq 36\ A^2s$ when tp = 10 ms
With an inductive load	Varistor[1)]	e.g. varistor with 275 V_{RMS} at 240 VAC
For the supply voltage	Line filter[2)]	Attenuation ≥40 dB at 150 kHz, effective range up to 5 MHz

1) See also section 4.15.6.14 "Operation with inductive loads" on page 1379
2) Meeting the limit values specified in the standards EN 61131, EN 55011 and EN 55022 (each Class A) requires installation of a line filter in the 240 V supply line. Line filters such as the Schaffner FN 2412-8-44 can be used.
If periodic ground transients occur on the supply lines (as can occur with upstream inverters), it is necessary to use an asymmetric filter that keeps these types of changes in potential below a few volts (e.g. "Sinus Plus" from Schaffner) in addition to the symmetric filter.

4.15.15.11 Derating

The derating listed below must be applied for the current:



4.15.15.12 Operating principle

The digital output module was designed for phase control of resistive and and inductive loads. The triac outputs do not have short circuit protection. The integrated open-circuit detection makes it possible to recognize defects on the load or the cabling (see 4.15.6.13 "Open line detection" on page 1378).

The module is equipped with internal zero-crossing detection. Zero-crossing detection is the basis for a software PLL that generates 200 times the zero-crossing frequency. The output signal of the PLL is the base timer for the PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control to the outputs is cut until the PLL is tuned correctly. The tuning procedure can take several seconds. In addition, the "ZeroCrossingStatus" bit is set and the error LED enabled (valid frequency range for the supply is 45 to 65 Hz).

Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.15.13 Open line detection

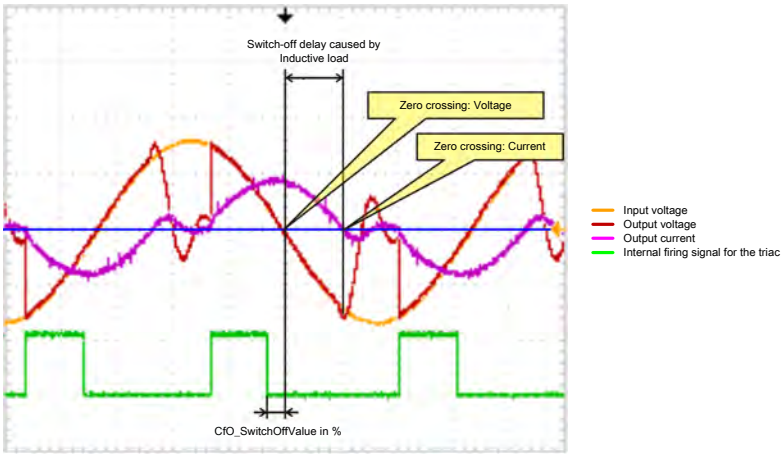
The module is equipped with open-circuit detection. Note that open-circuit detection only works when the output is enabled. An open-circuit will not be detected if the output is turned off.

In addition, open-circuit detection is restricted or doesn't work at all for inductive loads. This depends on the inductance of the load and should be determined beforehand, if necessary.

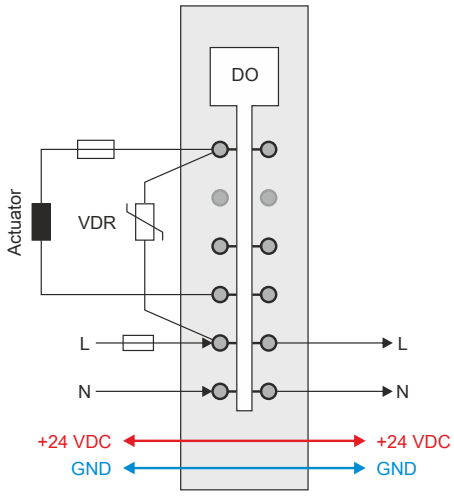
4.15.15.14 Operation with inductive loads

As inherent to its functional principal, the triac output is cleared when the current crosses zero. Because zero crossing for current is delayed with inductive loads, it is possible that the triac will be fired again even though it is not completely cleared at higher output values (between 50 and 100% depending on the inductance of the load). In this case, a full-wave is output. This causes the available control range (0 to 95%) to be changed.

For open line detection (LowCurrentStatus), a pause in control is required where the triac is not permitted to be fired. The full wave that is created with inductive loads causes open line detection to be triggered even though the load on the output is sufficient.
This behavior can be used to detect the full wave and properly adjust the control range (Example: If open line detection is triggered at a control value of 70%, that means that 0 to **70%** corresponds to 0 to **100%** output).



With inductive loads, a suitable varistor must be provided between the output DO x and the phase L (e.g. a varistor with 275 V_{RMS} at 240 VAC).



4.15.15.15 Register description

4.15.15.15.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.15.15.2 Function model 0 - Standard and Function model 2 - Frequency mode

The only difference between function model 2 and function model 0 is the possibility of generating half-wave patterns in various frequencies. Register 18 "CfO_Frequency" is an additional register for this.

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
2 + N * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18	CfO_Frequency	UINT				•
18 + N * 2	CfO_SwitchOffValueN (Index N = 1 to 4)	USINT				•
28	CfO_OutputConfig	USINT				•
29	CfO_OutputTolerance	USINT				•
Communication						
2	DigitalOutput	USINT			•	
	DigitalOutput01	Bit 0				
	...	...				
	DigitalOutput04	Bit 3				
30	StatusInput01	USINT	•			
	LowCurrentStatus1	Bit 0				
	...	...				
	LowCurrentStatus4	Bit 3				
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.15.15.3 Function model 1 - OSP

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General						
2 + N * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18 + N * 2	CfO_SwitchOffValueN (Index N = 1 to 4)	USINT				•
28	CfO_OutputConfig	USINT				•
29	CfO_OutputTolerance	USINT				•
Configuration - OSP						
34	Activating the OSP output in the module	USINT			•	
	OSPValid	Bit 0				
32	Setting the OSP mode	USINT				•
36	CfgOSPValue	USINT				•
36 + N * 2	CfgOSPValue0N (Index N = 1 to 4)	USINT				•
Communication						
2	Switching state of digital outputs 1 to 4	USINT			•	
	DigitalOutput01	Bit 0				
	...	...				
	DigitalOutput04	Bit 3				
30	Status of the outputs	USINT	•			
	LowCurrentStatus1	Bit 0				
	...	...				
	LowCurrentStatus4	Bit 3				
	ZeroCrossingInput	Bit 4				
	ZeroCrossingStatus	Bit 7				

4.15.15.15.4 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration - General							
2 + N * 2	(N-1) * 2	AnalogOutput0N (Index N = 1 to 4)	USINT			•	
18 + N * 2	-	CfO_SwitchOffValueN (Index N = 1 to 4)	USINT				•
28	-	CfO_OutputConfig	USINT				•
29	-	CfO_OutputTolerance	USINT				•
Communication							
30	0	Status of the outputs	USINT	•			
		LowCurrentStatus1	Bit 0				
		...	...				
		LowCurrentStatus4	Bit 3				
		ZeroCrossingInput	Bit 4				
		ZeroCrossingStatus	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.15.15.15.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.15.15.15.5 General information

The digital output module was designed for phase control of resistive and inductive loads. The triac outputs do not have short circuit protection, but have open line detection that can be used to find defects in the consumer or the wiring.

The module is equipped with internal zero-crossing detection. Zero crossing detection is the basis for a software PLL that generates 200 times the zero crossing frequency. The output signal of the PLL is the base timer for the 2 PWM outputs in both digital and analog mode.

Upon detection of lost periods or periods that are too short, control of the outputs is cut until the PLL is tuned correctly (can take several seconds). In addition, the "ZeroCrossingStatus" bit is set and the Error LED is enabled (valid frequency range for the supply is 45 to 65 Hz).

Information:

The jitter of the output signals generated by the PLL and communication can reach 0.5%.

4.15.15.15.6 Digital outputs

The output state of the outputs defined as digital is transferred to the output ports of the control switch in sync with the connected power mains. The switch-on state is applied when the voltage crosses zero on the positive half-wave and the switch-off state at the zero crossing for current in each half wave.

4.15.15.15.6.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

Information:

The states in these registers are only applied when the channels are set to DIGITAL in register 4.15.15.15.8.3 "CfO_OutputConfig".

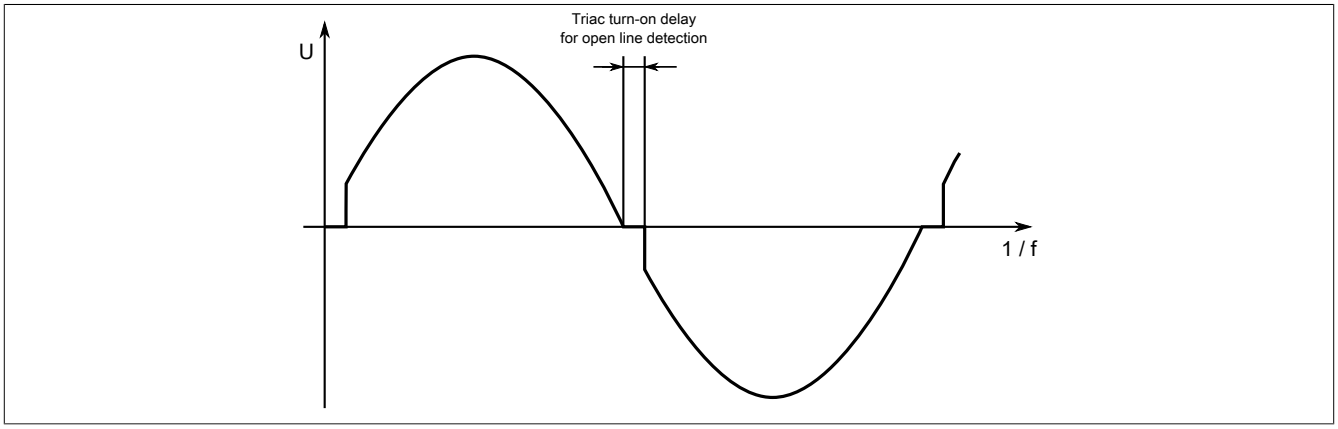
When using the setting "packed outputs" ALL channels must be set to DIGITAL. Mixed operation is not possible.

4.15.15.15.7 Analog outputs

The output value of the outputs defined as analog outputs (unit percent) is switched through to the control ports in sync with power mains. The analog value is output to the TRIAC control port in the range between (output value > SwitchOffValue) and (output value <= 95%) with a resolution of 1%.

A short triac turn-on delay is required for open line detection. Therefore even with output values >= 96%, there is a small pause in control.

Changes to the output value are applied at the next positive half-wave



4.15.15.15.7.1 Commutation angle for analog outputs 1 - 4

Name:
AnalogOutput01 to AnalogOutput04

These registers are used to set the commutation angle for phase angle control.

Values between 0 and 100 correspond to the output value for the respective channel in percent. Values above 100 correspond to 100%.

Data type	Value
USINT	0 to 100

Information:

The commutation angle for phase angle control set in these registers are only applied when the channels are set to ANALOG in register 4.15.15.15.8.3 "CfO_OutputConfig".

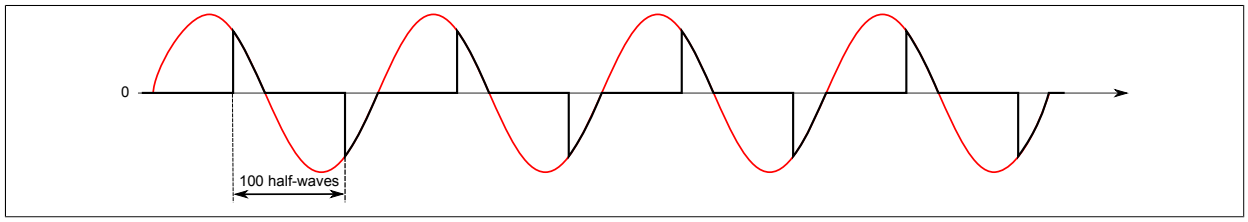
4.15.15.15.8 Output configuration

4.15.15.15.8.1 Configuring the half-wave pattern

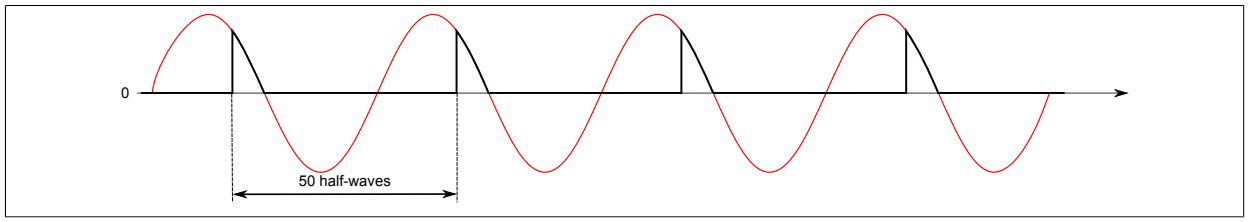
Name:
CfO_Frequency

This register can only be used in function model 2 - Frequency mode and makes it possible to configure the output of half-wave patterns in various frequencies. The commutation angle of the outputs is not affected by this. The following frequency patterns can be configured:

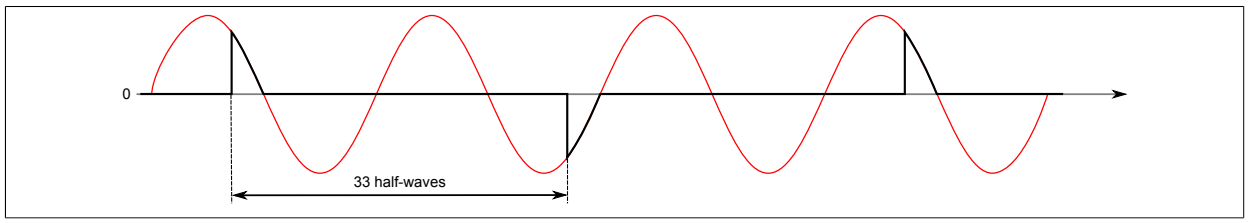
- 100 half-waves



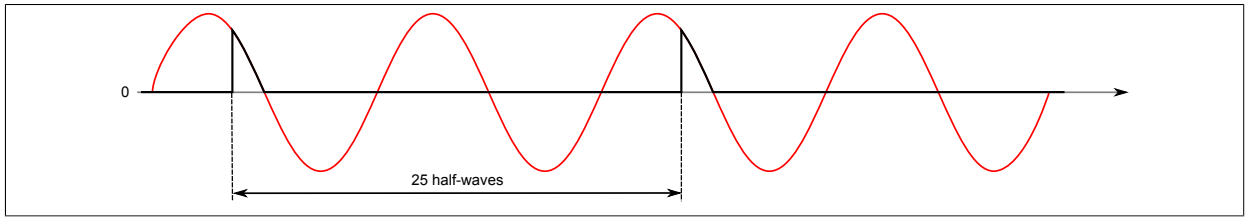
- 50 half-waves



- 33 half-waves



- 25 half-waves



With multichannel operation, the different channels should be operated with delayed half-waves in order to ensure that the load is placed evenly on the module.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Channel 1	0000	100 half-waves/second
		0001	50 half-waves/second
		0010	25 half-waves/second
		0011	33 half-waves/second
		0101	50 half-waves/second delayed by 1 half-wave
		0110	25 half-waves/second delayed by 2 half-waves
		0111	33 half-waves/second delayed by 1 half-wave
4 - 7	Channel 2	0000 to 0111	See channel 1
8 - 11	Channel 3	0000 to 0111	See channel 1
12 - 15	Channel 4	0000 to 0111	See channel 1

Information:

This function is available beginning with firmware version 940. This can be included beginning with hardware variant 8.

4.15.15.15.8.2 Setting the switch-off time

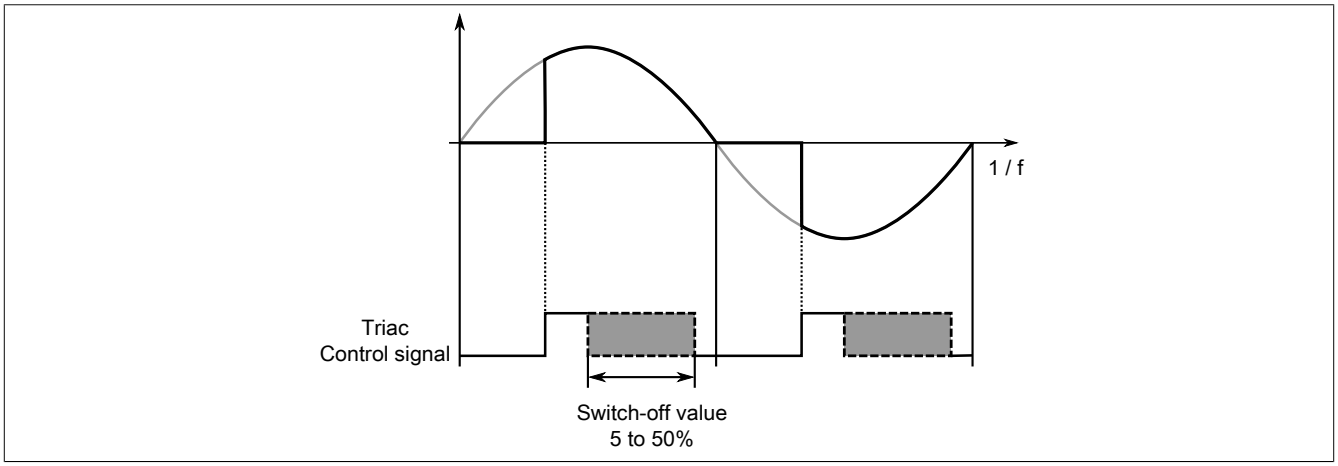
Name:
CfO_SwitchOffValue1 to CfO_SwitchOffValue4

This register defines how far in front of the zero cross-over the internal control signal for the TRIAC is switched off. Increasing this value may be necessary in order to prevent unwanted firing of the TRIAC in the event of a slight disturbance in the mains frequency.

With smaller loads, it is important to ensure that this switch off value is not set to large (too early) to prevent switching off prematurely.

The triac can of course only be fired before the set switch-off time.

"SwitchOffValue" in the AS I/O configuration.



Data type	Value	Description
USINT	5 to 50	Switch-off time in %

4.15.15.15.8.3 Configuration of the output channels

Name:
CfO_OutputConfig

The configuration of the output channels are stored in this register.

"Output type digital/analog" and "Output type full/half wave" in the AS I/O configuration

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1: Digital / Analog output	0	Output channel 1 is defined as a digital output. The output status is defined using bit 0 in the register DigitalOutput 1 - 4
		1	Output channel 1 is defined as an analog output. The output status is defined in the register AnalogOutput01
...		...	
3	Channel 4: Digital / Analog output	0	Output channel 4 is defined as a digital output. The output status is defined using bit 1 in the register DigitalOutput 1 - 4
		1	Output channel 2 is defined as an analog output. The output status is defined in the register AnalogOutput04
4	Channel 1: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 1
		1	Negative half-wave on output channel 1 is suppressed.
...		...	
7	Channel 4: Full-wave / half-wave control[1)]	0	Full-wave control on output channel 4
		1	Negative half-wave on output channel 4 is suppressed.

1) Not available in function model 2 - Frequency mode.

4.15.15.15.8.4 Switching behavior for zero-crossing errors

Name:
CfO_OutputTolerance

This register can be used to set the switching behavior of the trigger. After the number of zero-crossing errors configured in Bit 0 to 4, the output is switched off for at least 3 periods. This is followed by synchronization with the zero signal according to Bit 7.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Trigger for Resync	0 to 30	Number of zero-crossover errors
5 - 6	Reserved	-	
7	Fast settling	0	Fast synchronization
		1	PLL synchronization

Fast synchronization

With this option, the trigger point is closed-loop controlled after each individual zero-crossover and input jitter.

- **Advantage:** Increased tolerance and faster response to deviations in mains frequency
- **Disadvantage:** Increased switch-on jitter for firing signal by zero cross signal ±100 µSec

PLL synchronization

With this option the intervals between zero cross-overs are measured and the PLL frequency is updated accordingly.

- **Advantage:** Jitter-free firing signal
- **Disadvantage:** When the output is switched off, additional measurement phases are required before it can be switched back on.

Information:

This function is available starting with Firmware version 928. This can be installed with hardware version 8 and hardware revision B2 or higher.

4.15.15.15.9 Status of the outputs

Name:
LowCurrentStatus1 through LowCurrentStatus4
ZeroCrossingInput
ZeroCrossingStatus
StatusInput01

The operating status of the outputs is mapped in this register.

In order to do determine the "LowCurrentStatus", the system checks if there is a neutral connection from the output via the consumer shortly before each triac firing.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("LowCurrentStatus1" through "ZeroCrossingStatus") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	LowCurrentStatus1	0	0 = No current flow on activated output 1
		1	No current flow on activated output 1
...		...	
3	LowCurrentStatus4	0	Current flow on activated output 4
		1	No current flow on activated output 4
4	ZeroCrossingInput	0	Zero cross signal during the negative half-wave
		1	Zero cross signal during the positive half-wave
5 - 6	Reserved	-	
7	ZeroCrossingStatus	0	Zero cross signal OK
		1	Zero cross signal has dropped out

4.15.15.15.10 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.15.15.10.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.15.15.10.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.15.15.10.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.15.15.10.4 Define the OSP analog output value

Name:
CfgOSPValue01 to CfgOSPValue04

This register contains the analog output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	0 to 100

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.15.15.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
All channels	250 µs

4.15.15.15.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
All channels	150 µs

4.15.16 X20(c)DO4649

4.15.16.1 General information

The module is equipped with 4 relay outputs.

- 4 digital outputs
- Relay module for 240 VAC / 30 VDC
- 4 normally open contacts
- Single-channel isolated outputs

Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.15.16.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

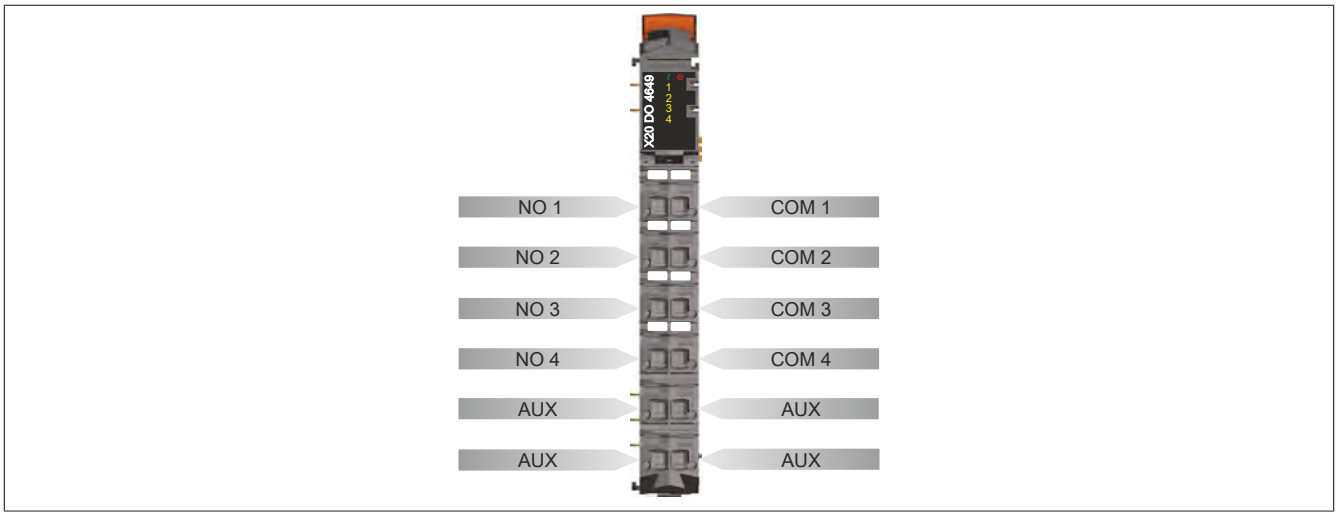
4.15.16.5 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

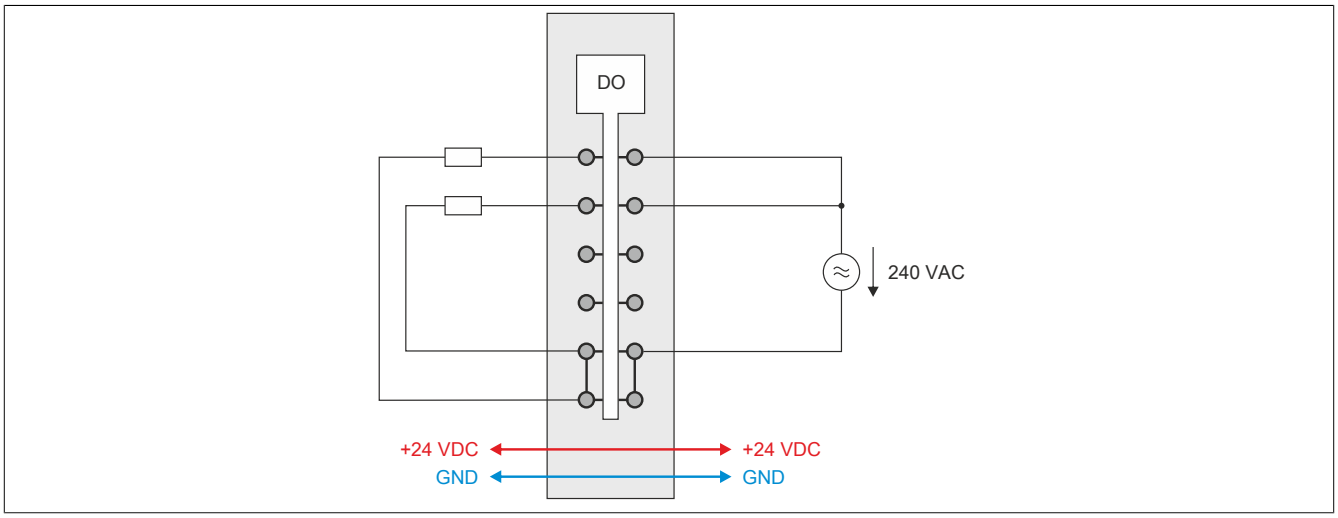
Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange		Output status of the corresponding digital output

4.15.16.6 Pinout

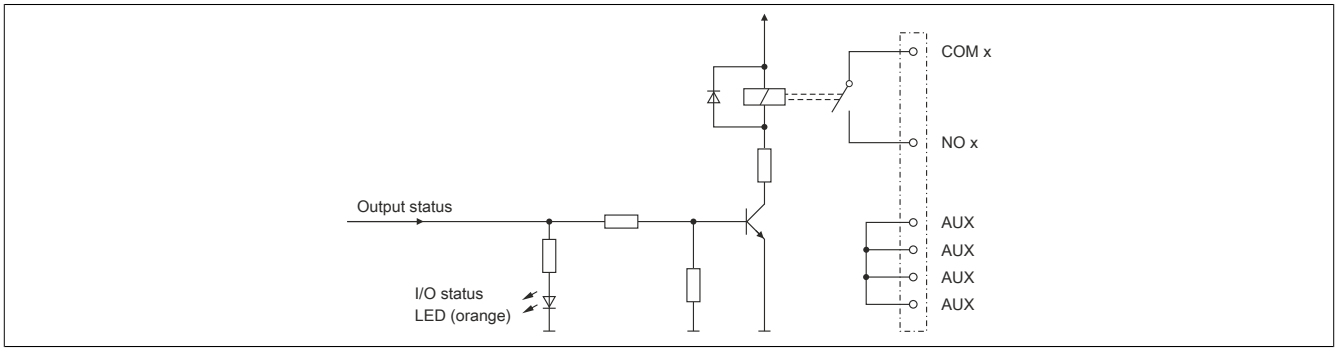
For easy wiring, 4 auxiliary contacts are available on the module starting with revision E0. They are connected together internally and can be loaded with a total of 10 A (see also section "Connection example").



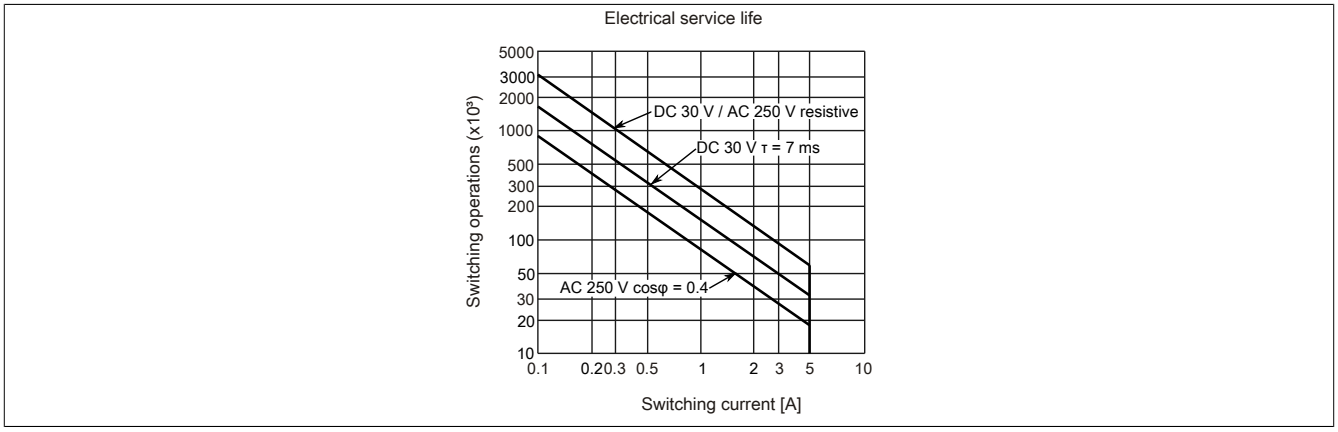
4.15.16.7 Connection example



4.15.16.8 Output circuit diagram



4.15.16.9 Electrical service life



4.15.16.10 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the maximal current per channel is limited to 4 A and maximal total current is limited to 8 A.

4.15.16.11 Register description

4.15.16.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.16.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.16.11.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 4	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput04	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.16.11.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.16.11.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.16.11.4.1 Switching state of digital outputs 1 to 4

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput04

The switching state of digital outputs 1 to 4 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 15	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
3	DigitalOutput04	0	Digital output 04 reset
		1	Digital output 04 set

4.15.16.11.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.16.11.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.17 X20(c)DO6321

4.15.17.1 General information

The module is equipped with 6 outputs for 1 or 2-wire connections. The X20 6-pin terminal block can be used for universal 1-line wiring. 2-line wiring can be implemented using the 12-pin terminal block. The X20DO6321 is designed for sink output wiring.

- 6 digital outputs
- Sink connection
- 2-wire connections
- 24 VDC for signal supply
- Integrated output protection
- 1-wire connection type with 6-pin terminal block

4.15.17.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

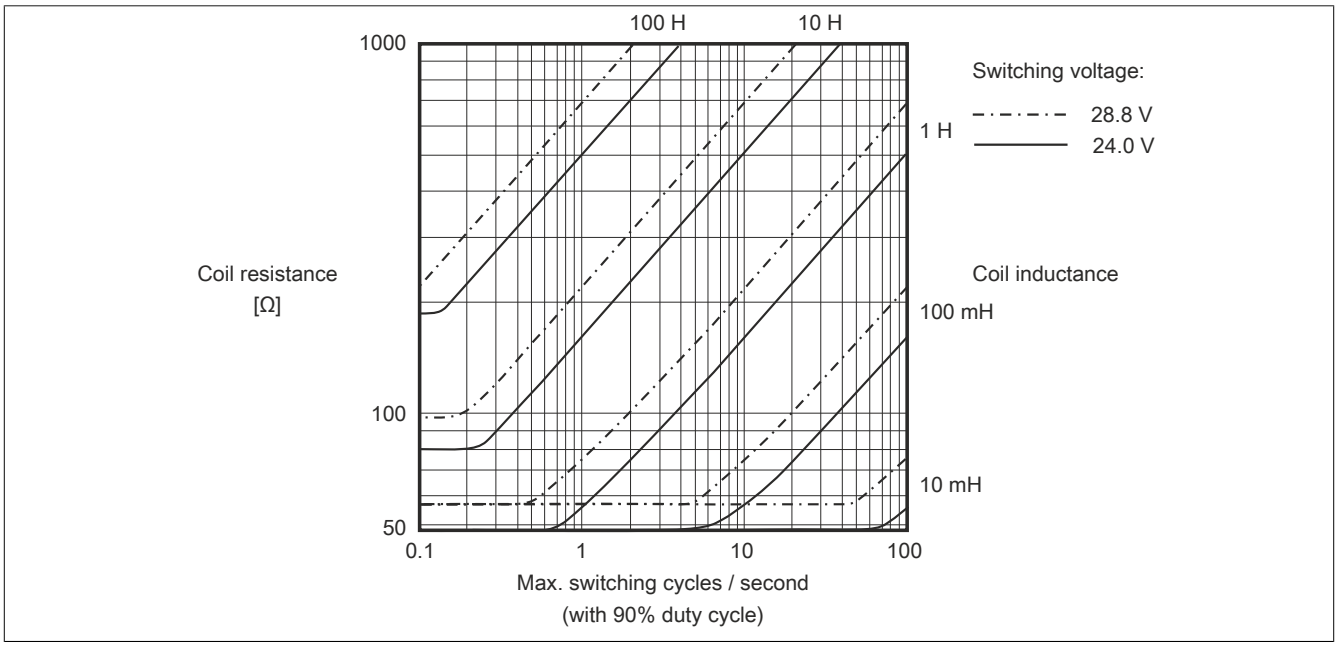
4.15.17.9 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.17.10 Register description

4.15.17.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.17.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput06	Bit 5				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.17.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 6	USINT			•	
		DigitalOutput01	Bit 0				
			...				
		DigitalOutput06	Bit 5				
30	-	Status of digital outputs 1 to 6	USINT		•		
		StatusDigitalOutput01	Bit 0				
			...				
		StatusDigitalOutput06	Bit 5				

1) The offset specifies where the register is within the CAN object.

4.15.17.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.17.10.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.17.10.4.1 Switching state of digital outputs 1 to 6

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput06

The switching state of digital outputs 1 to 6 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
5	DigitalOutput06	0	Digital output 06 reset
		1	Digital output 06 set

4.15.17.10.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.17.10.5.1 Status of digital outputs 1 to 6

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput06

The status of digital outputs 1 to 6 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
5	StatusDigitalOutput06	0	Channel 06: No error
		1	Channel 06: Short circuit or overload

4.15.17.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.17.10.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.18 X20(c)DO6322

4.15.18.1 General information

The module is equipped with 6 outputs for 1 or 2-wire connections. The X20 6-pin terminal block can be used for universal 1-line wiring. 2-line wiring can be implemented using the 12-pin terminal block. The module is designed for source output wiring.

- 6 digital outputs
- Source connection
- 2-wire connections
- GND for signal supply
- Integrated output protection
- 1-wire connection type with 6-pin terminal block
- OSP mode

4.15.18.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

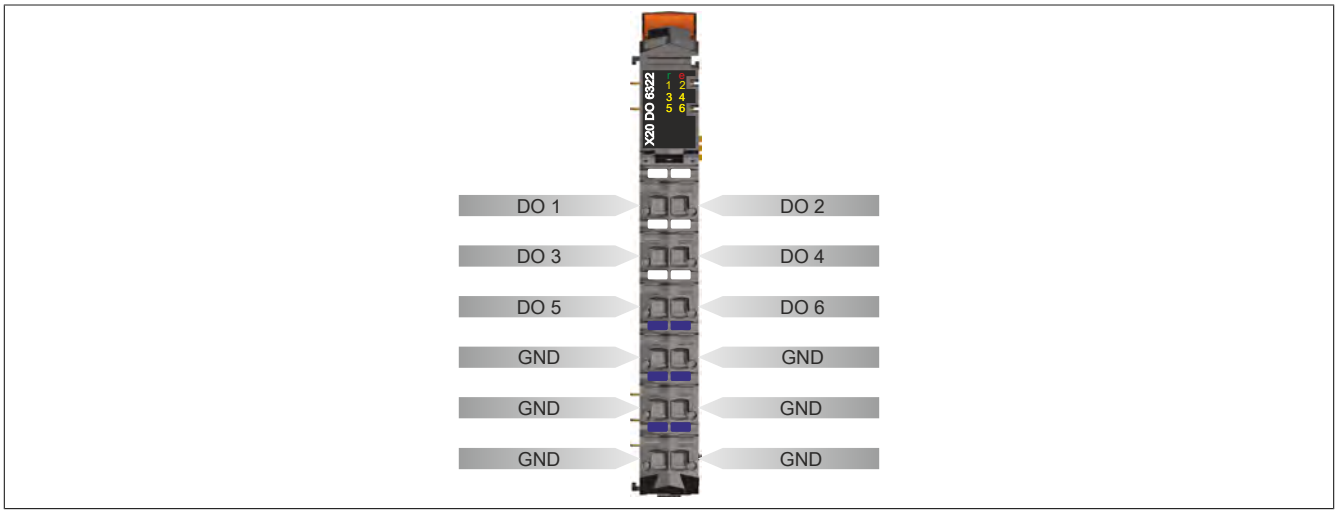
4.15.18.5 Status LEDs

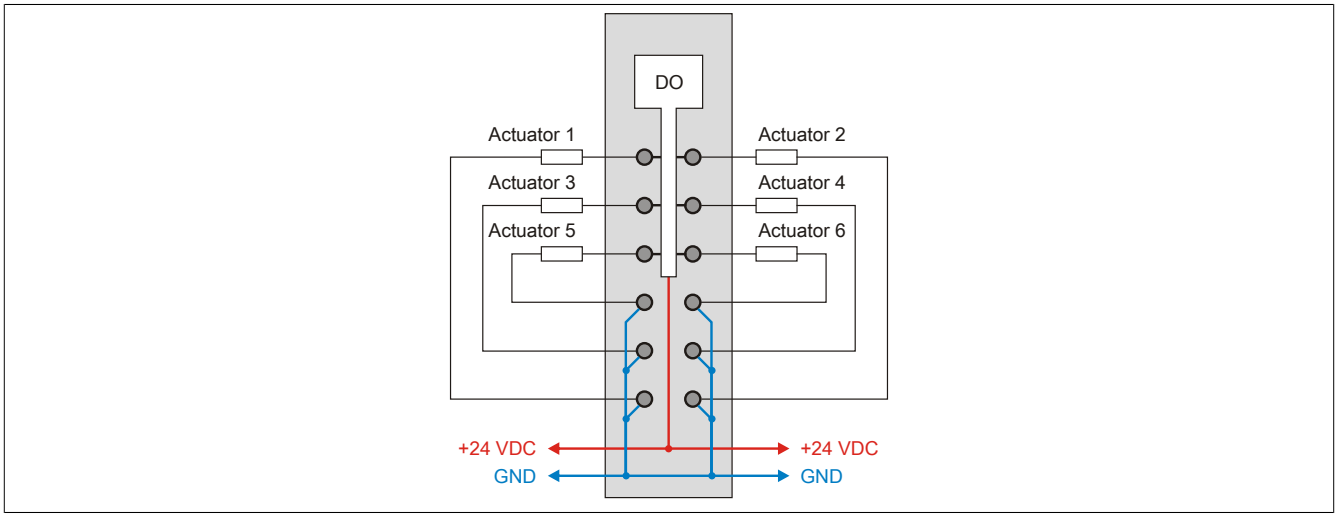
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP state
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Orange		Output status of the corresponding digital output

4.15.18.6 Pinout



4.15.18.7 Connection example



Caution!

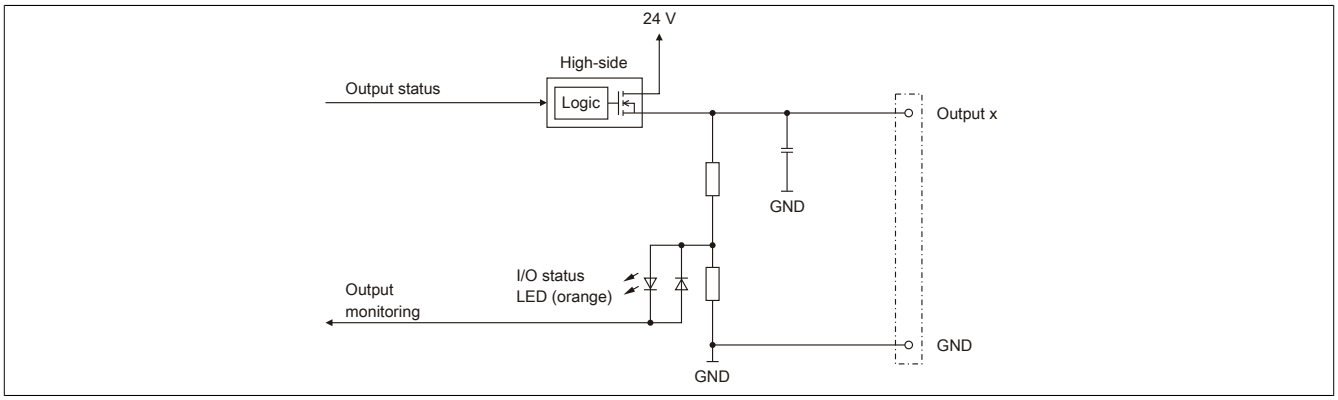
If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.18.8 OSP hardware requirements

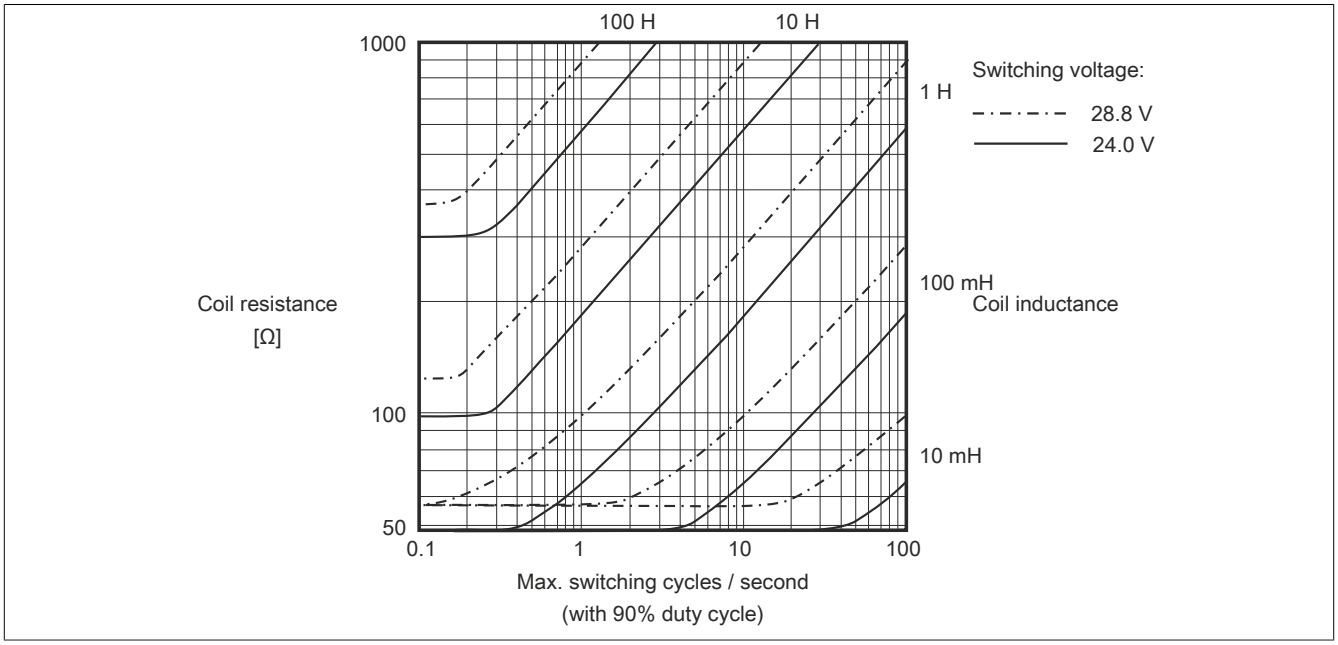
In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.18.9 Output circuit diagram



4.15.18.10 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.18.11 Register description

4.15.18.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.18.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput06	Bit 5				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.18.11.3 Function model 1 - OSP

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 6	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				
30	1	Status of digital outputs 1 to 6	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput06	Bit 5				
34	1	Activating the OSP output in the module	USINT			•	
		OSPValid	Bit 0				
32	-	CfgOSPMode	USINT				•
36	-	CfgOSPValue	USINT				•

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.18.11.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 6	USINT			•	
		DigitalOutput01	Bit 0				
			...				
		DigitalOutput06	Bit 5				
30	-	Status of digital outputs 1 to 6	USINT		•		
		StatusDigitalOutput01	Bit 0				
			...				
		StatusDigitalOutput06	Bit 5				

1) The offset specifies where the register is within the CAN object.

4.15.18.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.18.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.18.11.5.1 Switching state of digital outputs 1 to 6

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput06

The switching state of digital outputs 1 to 6 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
5	DigitalOutput06	0	Digital output 06 reset
		1	Digital output 06 set

4.15.18.11.6 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.18.11.6.1 Status of digital outputs 1 to 6

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput06

The status of digital outputs 1 to 6 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
5	StatusDigitalOutput06	0	Channel 06: No error
		1	Channel 06: Short circuit or overload

4.15.18.11.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.18.11.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.18.11.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.18.11.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.18.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.18.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.19 X20DO6325

4.15.19.1 General information

The module is equipped with six outputs for 1 or 2-wire connections with diagnostic functions. The X20 6-pin terminal block can be used for universal 1-line wiring. Two-line wiring can be implemented using the 12-pin terminal block. The outputs on the module are designed for source connections.

- 6 digital outputs
- Source connection
- 2-wire connections
- GND for signal supply
- Integrated output protection
- 1-wire connection type with 6-pin terminal block
- Diagnostic functions (open line, short circuit and overload/overtemperature)
- OSP mode

4.15.19.2 Order data

Model number	Short description	Figure

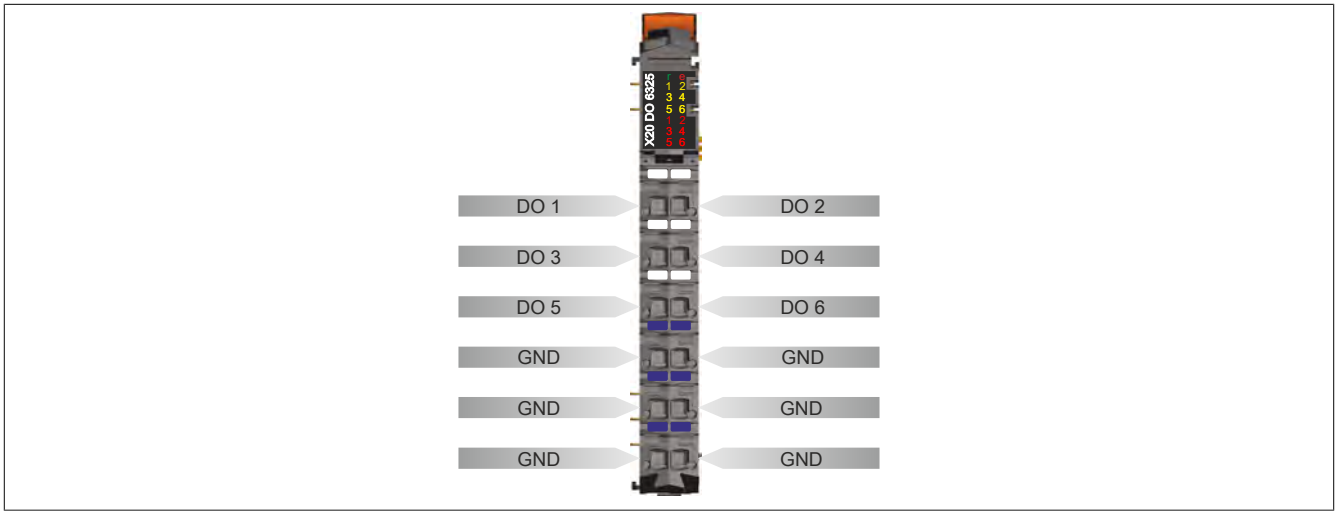
4.15.19.4 LED status indicators

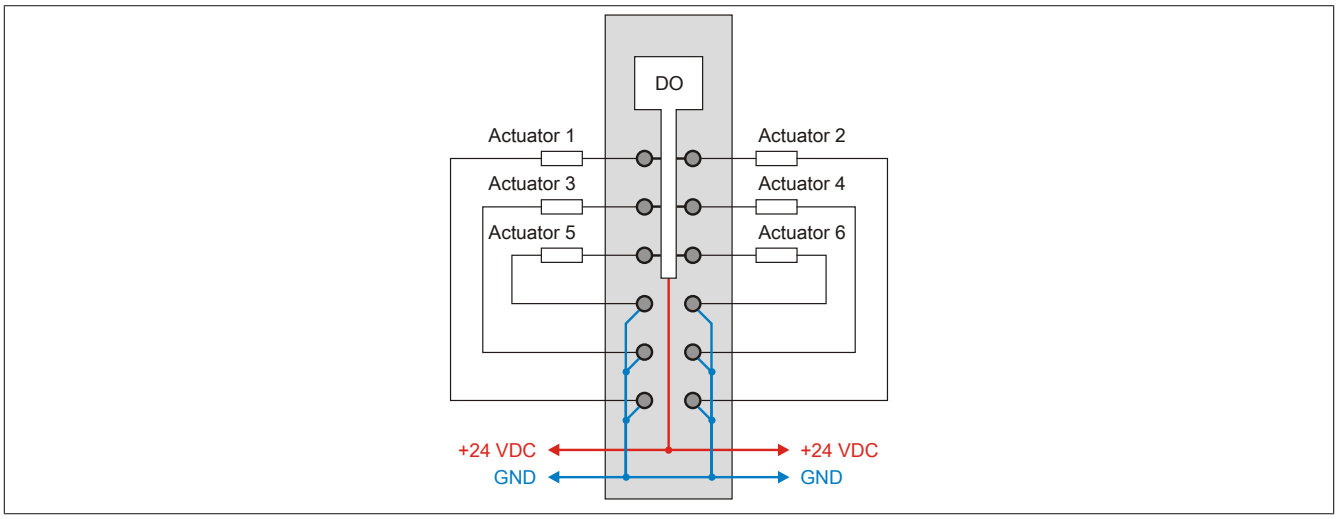
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP mode
	e	Red	Off	No power to module or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
			Double flash	I/O supply is outside valid range.
	e + r	Red on / Green single flash		Invalid firmware
	Channel 1 - 6	Orange		Output status of the corresponding digital output
	Diagnostics 1 - 6	Red		Monitoring of the corresponding digital output was tripped (short circuit, open line or overload)

4.15.19.5 Pinout



4.15.19.6 Connection example



Caution!

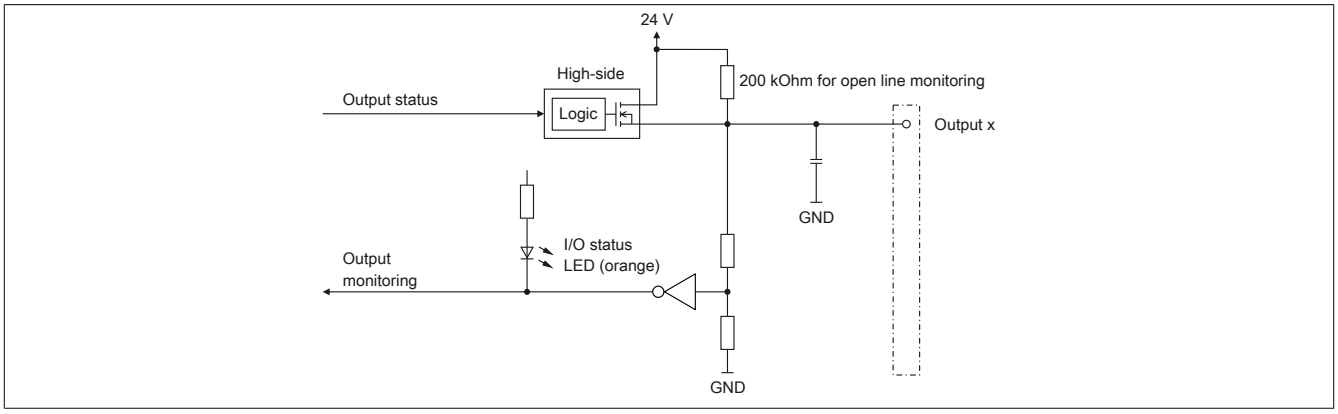
If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.19.7 OSP hardware requirements

In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.15.19.8 Output circuit diagram



4.15.19.9 Open line detection

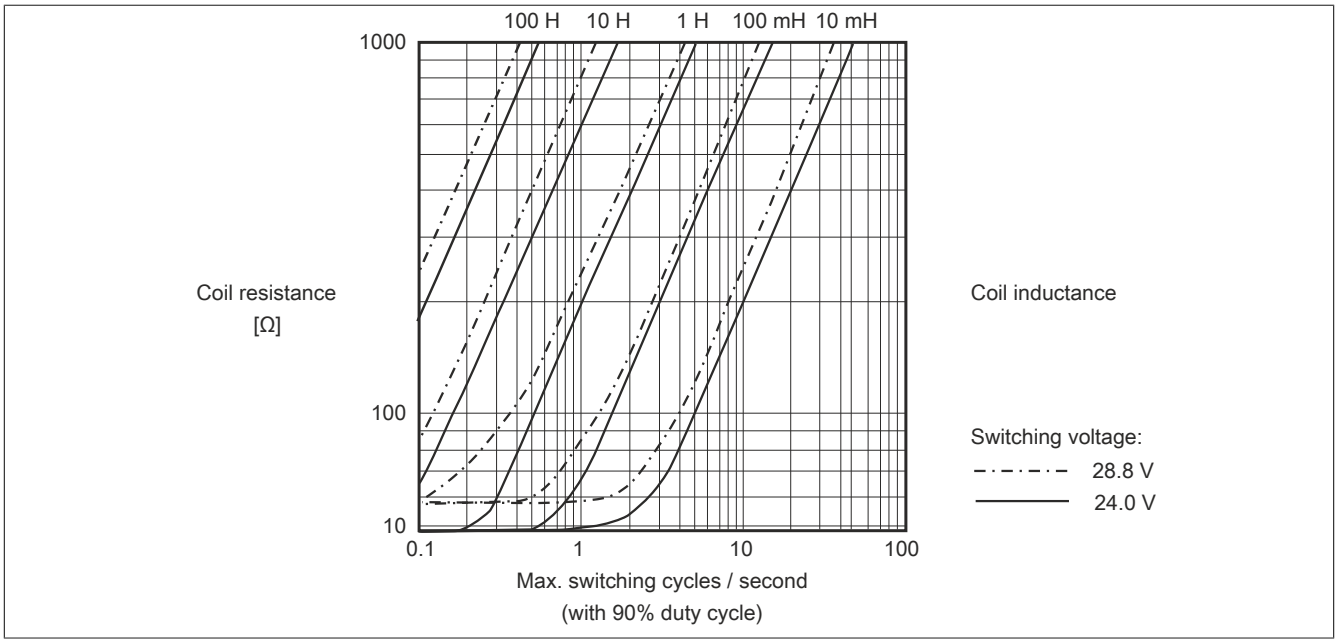
Each output is equipped with an internal 200 kOhm resistor to 24 V for open line detection.

If the charging resistance at the terminal is greater than 25 to 100 kOhm (tolerance range) an open line is therefore detected at 24 V. When switched on, this corresponds to a current of 0.2 to 1 mA with all tolerances taken into consideration.

Supply voltage	Min. load	Max. load	Corresponds to load current when ON
24 V	100 kOhm	25 kOhm	0.2 to 1 mA

4.15.19.10 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.19.11 Register description

4.15.19.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.19.11.2 Function model 0 - Standard

		PowerSupply01	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.15.19.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.19.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.19.11.5.1 Switching state of digital outputs 1 to 6

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput06

The switching state of digital outputs 1 to 6 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
5	DigitalOutput06	0	Digital output 06 reset
		1	Digital output 06 set

4.15.19.11.6 Digital output status

The status of the outputs is checked every 4 ms. To suppress disturbances on the feedback inputs, two readings are compared.

The hardware diagnostics recognize the following states:

- Short circuit to ground GND (when output is ON)
- Short circuit to 24 VDC (when output is OFF)
- Open line (when output is OFF)
- Overtemperature / overload

The error is logged in the corresponding status registers and in the cumulative status register.

An open line error is also indicated by the corresponding LED. The LED indicator can be disabled so that an open (unused) channel does not constantly indicate an error.

4.15.19.11.6.1 Enabling the status LED

Name:
CfgBwStatus

For each output there is a corresponding enable bit. In this register, the bit can be set to define whether or not the status LED should be used to indicate an open line error. This allows the LED to be disabled for unused channels. In the bus controller function model the default value is 0xBF.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 01	0	Open line indicator 01 disabled
		1	Open line indicator 01 enabled
...		...	
5	Channel 06	0	Open line indicator 06 disabled
		1	Open line indicator 06 enabled
6	Reserved	0	
7	PowerSupply01	0	No error status indicators
		1	Monitor supply voltage

4.15.19.11.6.2 Short circuit to GND and overtemperature

Name:
StatusInput01
DigitalStatusGnd01 to DigitalStatusGnd06

In this register, a short circuit or overtemperature error can be indicated by setting the corresponding channel bit. It is not possible to differentiate between short circuit to GND and overload/overtemperature.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalStatusGnd01" through "DigitalStatusGnd06") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalStatusGnd01	0	No error
		1	Channel 1: Short circuit or overload
...		...	
5	DigitalStatusGnd06	0	No error
		1	Channel 6: Short circuit or overload
6 - 7	Reserved	0	

4.15.19.11.6.3 Short circuit to voltage

Name:
StatusInput02
DigitalStatusVcc01 to DigitalStatusVcc06

In this register, a short circuit can be indicated by setting the corresponding channel bit.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalStatusVcc01" through "DigitalStatusVcc06") or whether this register should be displayed as an individual USINT data point ("StatusInput02").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalStatusVcc01	0	No error
		1	Channel 1: Short circuit to voltage
...		...	
5	DigitalStatusVcc06	0	No error
		1	Channel 6: Short circuit to voltage
6 - 7	Reserved	0	

4.15.19.11.6.4 Open line

Name:
StatusInput03
DigitalStatusBw01 to DigitalStatusBw06

In this register, an open line can be indicated by setting the corresponding channel bit.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalStatusBw01" through "DigitalStatusBw06") or whether this register should be displayed as an individual USINT data point ("StatusInput03").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalStatusBw01	0	No error
		1	Channel 1: Open line
...		...	
5	DigitalStatusBw06	0	No error
		1	Channel 6: Open line
6 - 7	Reserved	0	

4.15.19.11.6.5 Cumulative status

Name:
StatusInput04
DigitalStatusSum01 to DigitalStatusSum06
PowerSupply01

Every error found in the other status registers is also shown in this register. This provides an easy way to check whether any errors have occurred.
If the I/O supply fails, Bit 7 is set and all status bits in the other status registers are reset to 0.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points ("DigitalStatusSum01 through DigitalStatusSum06","PowerSupply01") in the AS I/O mapping or whether this register should be displayed as an individual USINT data point ("StatusInput04").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalStatusSum01	0	No error
		1	Channel 1: Error occurred
...		...	
5	DigitalStatusSum06	0	No error
		1	Channel 6: Error occurred
6	Reserved	0	
7	PowerSupply01	0	No error
		1	Pending supply voltage error

4.15.19.11.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.15.19.11.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the responsible task in the master CPU. However, output still occurs according to the configuration of the OSP replacement value.

4.15.19.11.7.2 Setting the OSP mode

Name:
CfgOSPMode

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.15.19.11.7.3 Define the OSP digital output value

Name:
CfgOSPValue

This register contains the digital output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0		0 or 1	OSP output value for channel DigitalOutput00
...		...	
x		0 or 1	OSP output value for channel DigitalOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.15.19.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.15.19.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.20 X20DO6529

4.15.20.1 General information

The module is equipped with 6 relay outputs.

- 6 digital outputs
- Relay module for 115 VAC
- 6 normally open contacts
- Single-channel isolated outputs

> **Danger!**
>
> **Risk of electric shock!**
>
> **The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.**

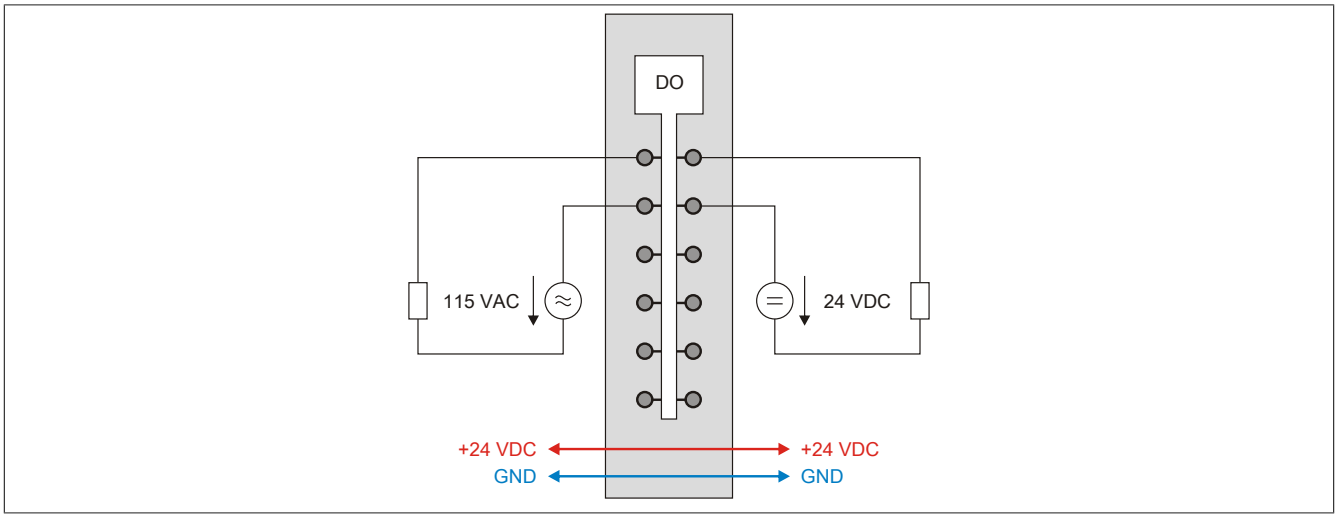
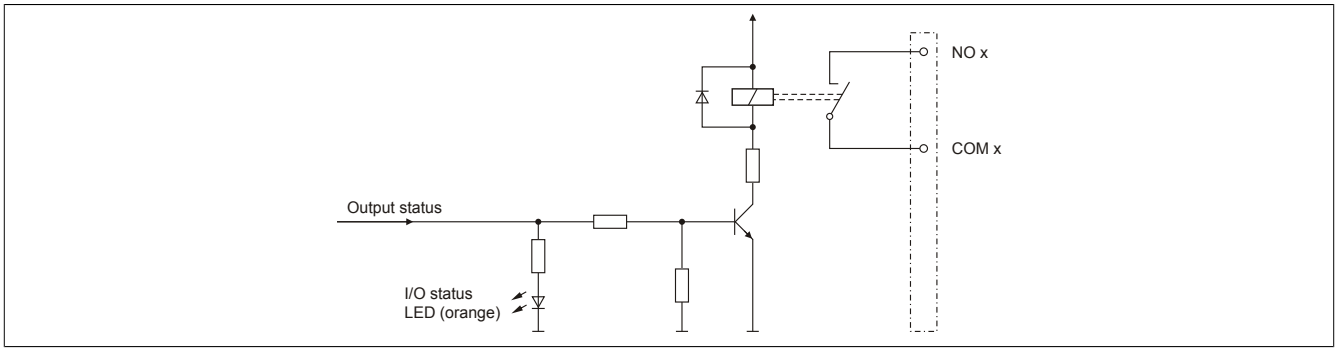
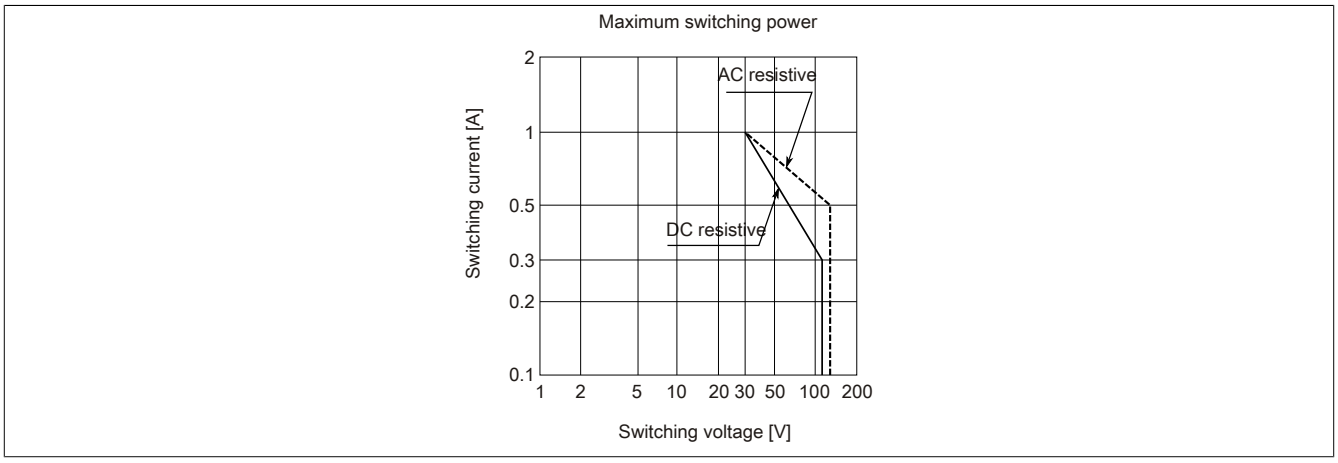
4.15.20.6 Connection example



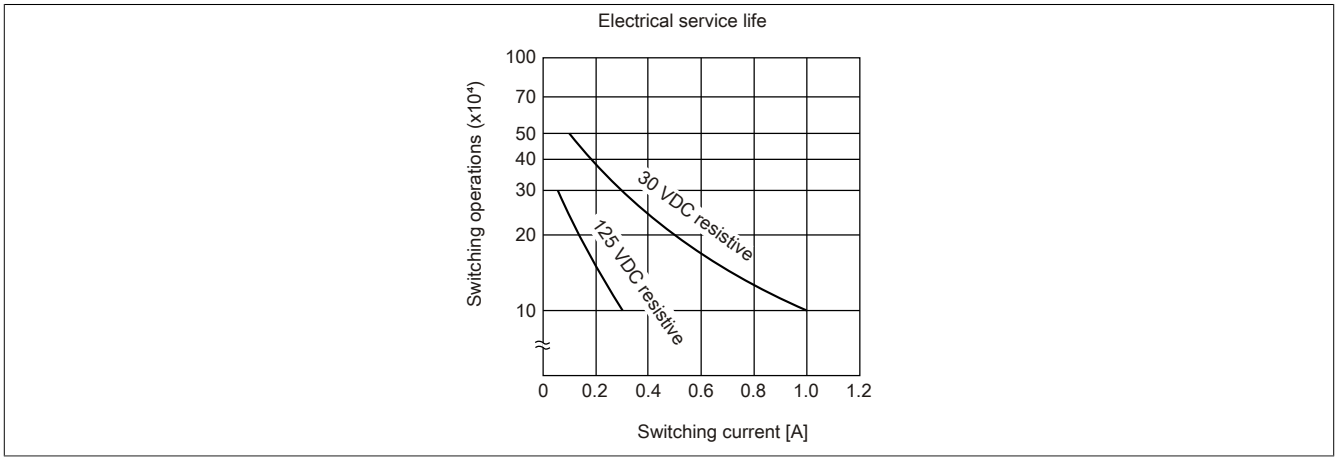
4.15.20.7 Output circuit diagram



4.15.20.8 Maximum switching power



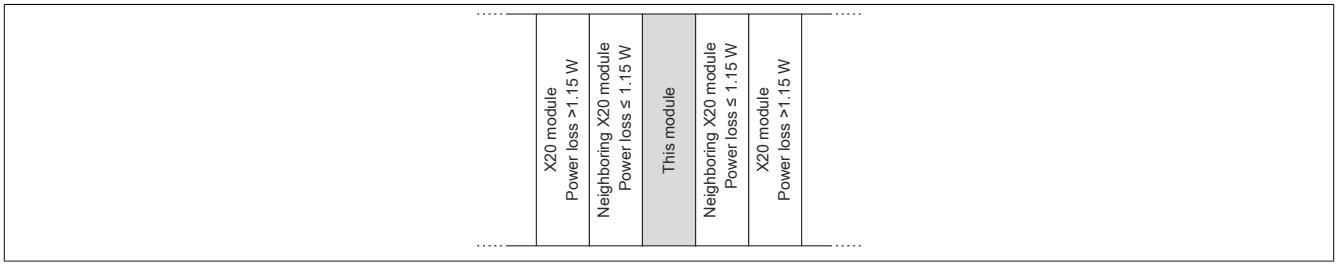
4.15.20.9 Electrical service life



4.15.20.10 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.15.20.11 Register description

4.15.20.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.20.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.20.11.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 6	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				

1) The offset specifies where the register is within the CAN object.

4.15.20.11.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.20.11.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.20.11.4.1 Switching state of digital outputs 1 to 6

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput06

The switching state of digital outputs 1 to 6 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
5	DigitalOutput06	0	Digital output 06 reset
		1	Digital output 06 set

4.15.20.11.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.20.11.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.21 X20(c)DO6639

4.15.21.1 General information

The module is equipped with 6 relay outputs.

- 6 digital outputs
- Relay module for 240 VAC / 30 VDC
- Switching current 2 A
- 6 normally open contacts
- Single-channel isolated outputs

> **Danger!**
>
> **Risk of electric shock!**
>
> **The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.**

4.15.21.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

> **For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.**

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.15.21.3 Order data

4.15.21.10 Register description

4.15.21.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.21.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.21.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 6	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput06	Bit 5				

1) The offset specifies where the register is within the CAN object.

4.15.21.10.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.21.10.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.21.10.4.1 Switching state of digital outputs 1 to 6

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput06

The switching state of digital outputs 1 to 6 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 63	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
5	DigitalOutput06	0	Digital output 06 reset
		1	Digital output 06 set

4.15.21.10.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.21.10.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.22 X20DO8232

4.15.22.1 General information

The module is equipped with 8 outputs for 1-wire connections. The nominal output current is 2 A and the nominal voltage is 12 VDC.

The output supply is fed directly to the module. An additional supply module is not needed. There is no connection between the module and the I/O supply potential on the bus module.

- 8 digital outputs with 2 A
- Rated voltage 12 VDC
- Source connection
- 1-wire connection
- Power feed integrated in the module
- Integrated output protection

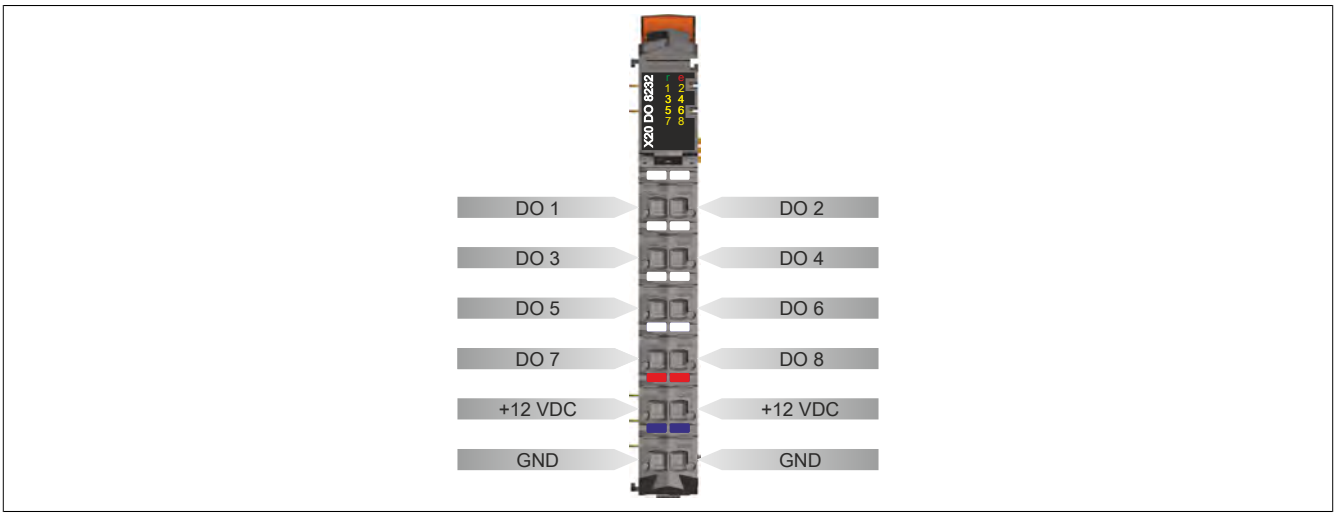
4.15.22.4 Status LEDs

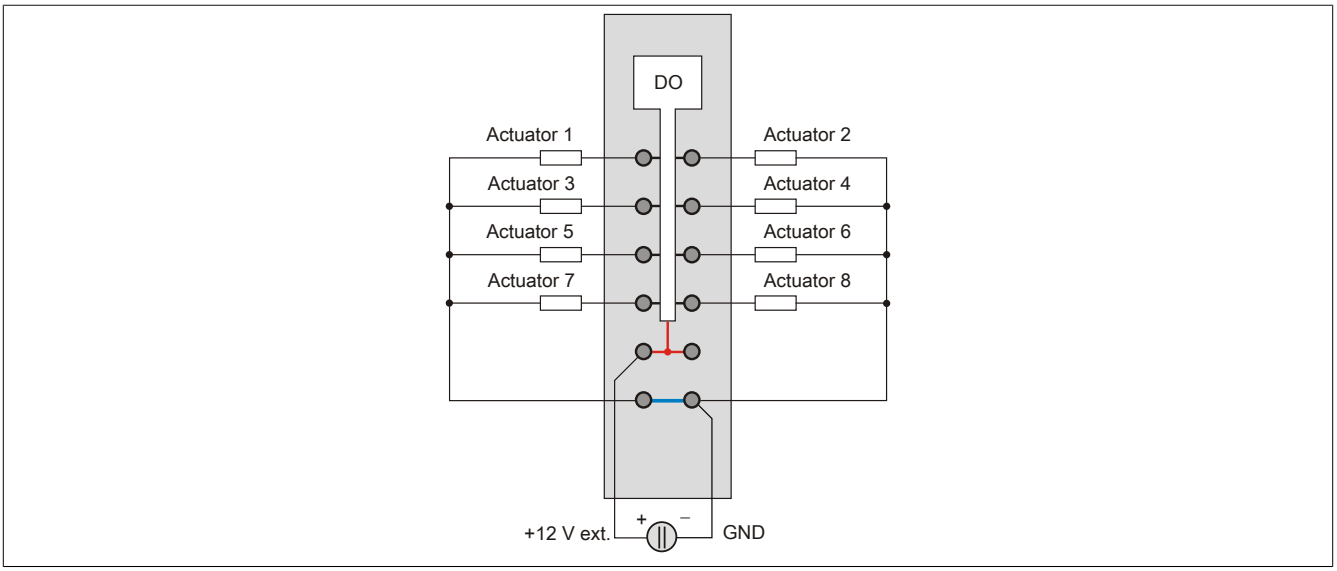
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
			Double flash	External I/O supply is outside the valid range: 12 VDC (-15% / +20%)
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Orange		Output status of the corresponding digital output

4.15.22.5 Pinout



4.15.22.6 Connection example

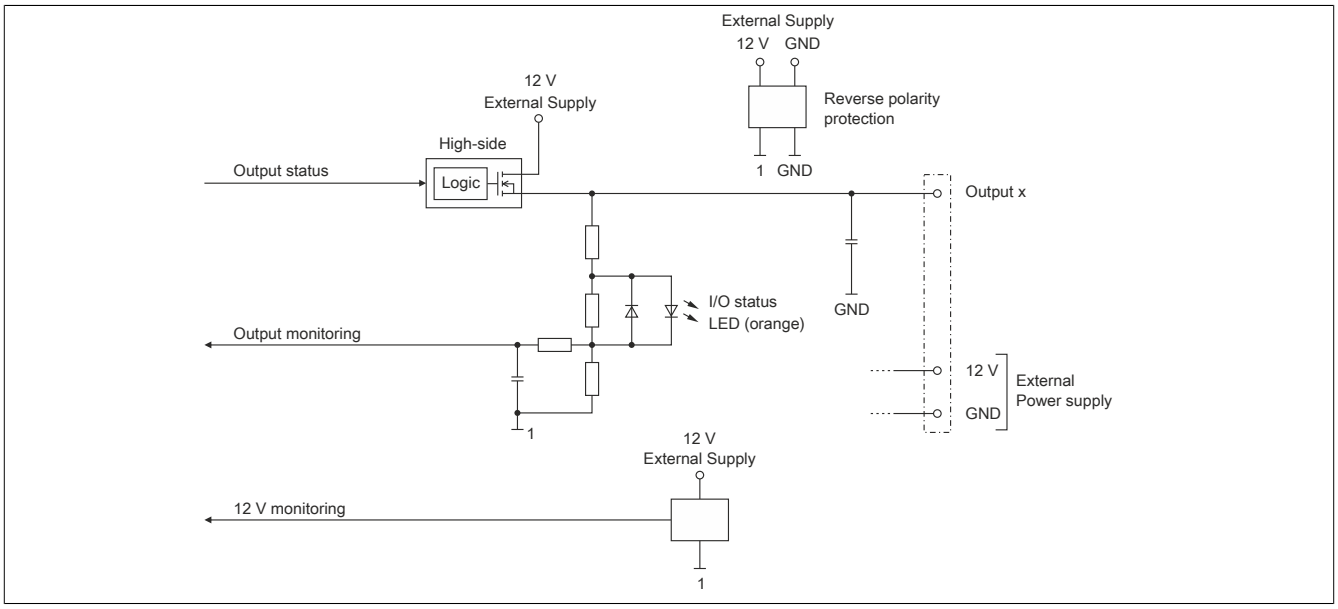


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

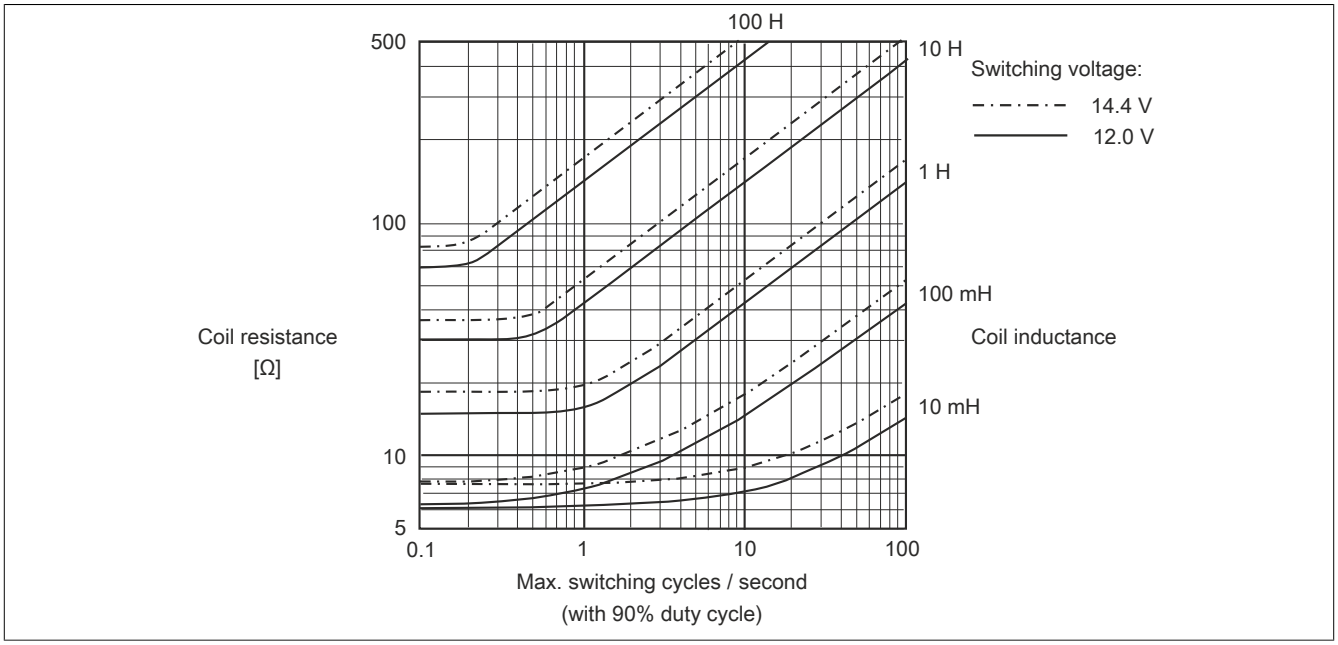
Therefore sufficient cable cross sections or external safety measures must be used.

4.15.22.7 Output circuit diagram

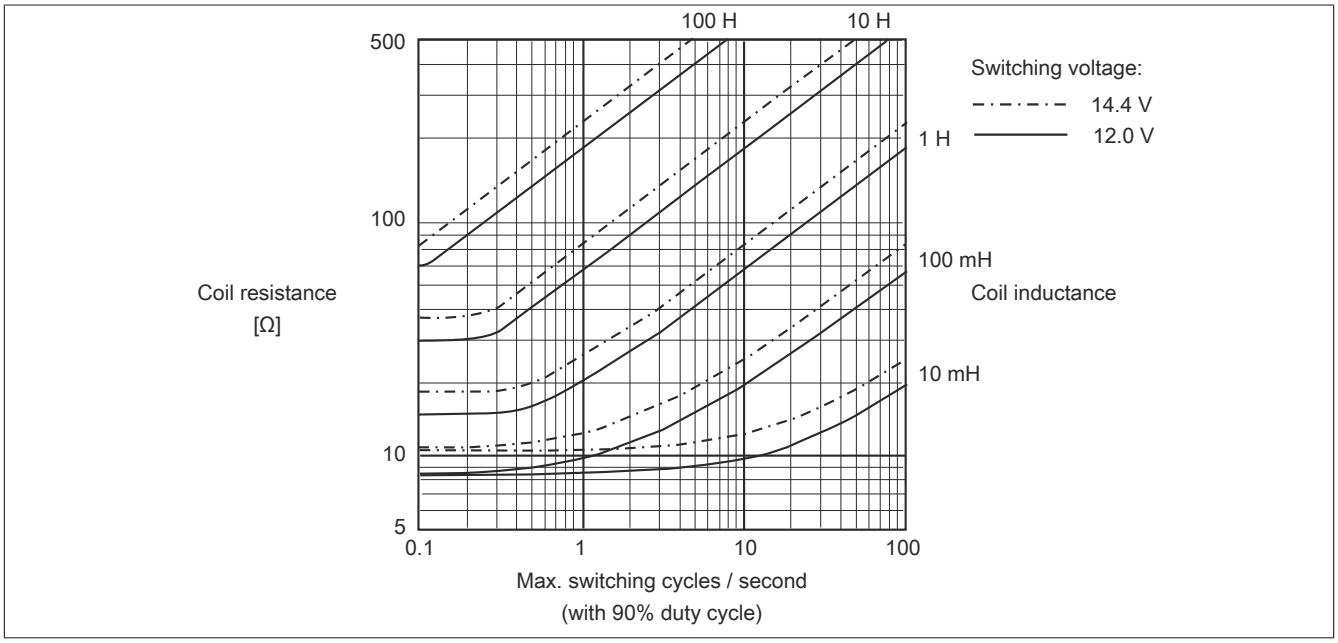


4.15.22.8 Switching inductive loads

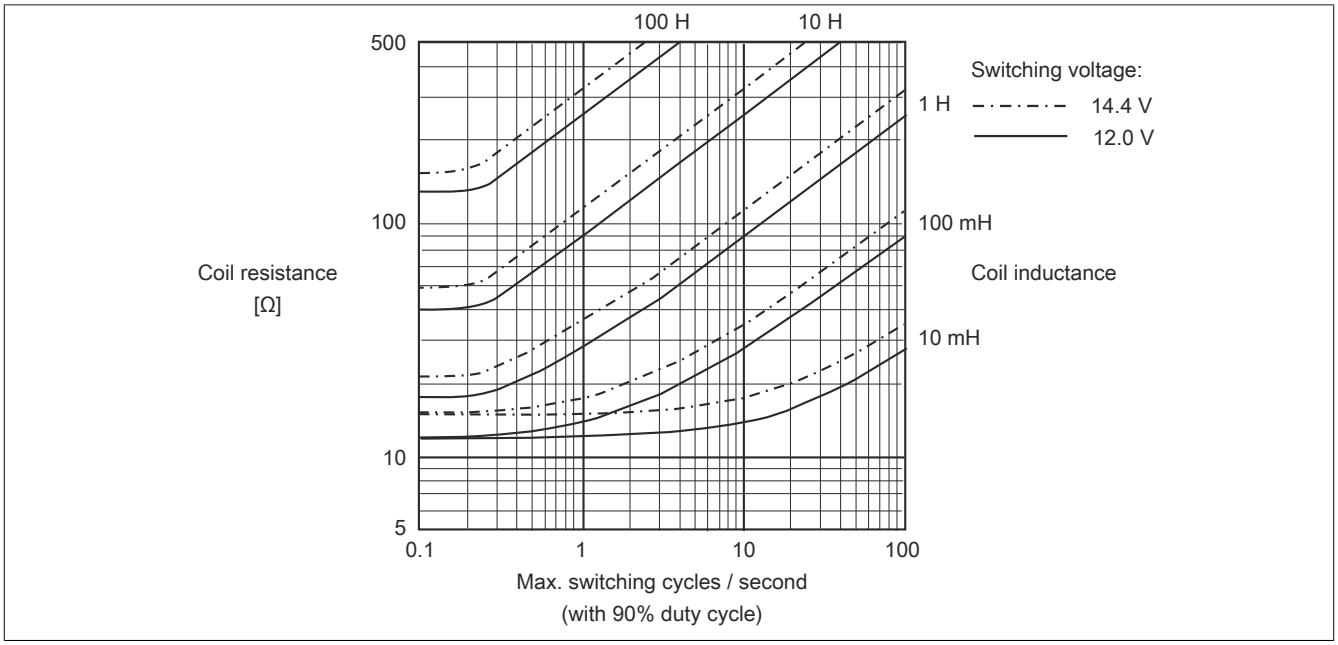
Environmental temperature: 35°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, all outputs with the same load.



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.22.9 Derating

The outputs of the module can handle up to 2 A. With a total current of 8 A, no more than 4 channels are operable at full load. To ensure optimal use of the module, it is important to assign the channels properly, and to keep in mind a potential derating.

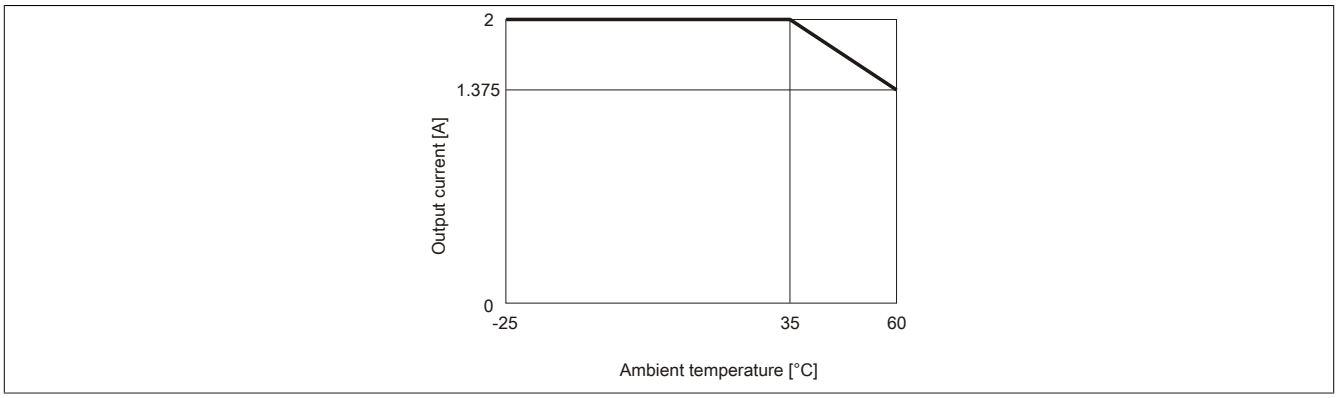
Correct channel assignment is important, since the eight outputs are divided between two output drivers. The channels operated with 2A must therefore be evenly divided between both output drivers.

Output driver 1: Channels 1 - 4
Output driver 2: Channels 5 - 8

The following table provides an overview of the number of fully used channels, the resulting best distribution, and a potential derating.

Number of channels using 2A	Division	Derating
1	Any	No
2	1st channel with 2 A ... channel no. 1 - 4 2nd channel with 2 A ... channel no. 5 - 8	No
3	Assign all even or all odd channel numbers. Examples: 1, 3, 5 2, 4, 6 3, 5, 7 4, 6, 8	 Channels 1 and 3 Channels 2 and 4 Channels 5 and 7 Channels 6 and 8
4	Assign all even or all odd channel numbers. Possible distributions: 1, 3, 5, 7 2, 4, 6, 8	 All channels All channels

Derating when 3 or 4 channels are operated with 2 A:



Information:

Modules next to this module can have a maximum power consumption of 1.0 W.

4.15.22.10 Register description

4.15.22.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.22.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.22.10.3 Function model 1 - Output switching

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
4	1	Switching state of delayed digital outputs 1 to 8	USINT			•	
		DigitalOutput01Delayed	Bit 0				
		...	...				
		DigitalOutput08Delayed	Bit 7				
6	2	Switching mask after the delay time has expired	USINT			•	
		DigitalOutput01DelayEnable	Bit 0				
		...	...				
		DigitalOutput08DelayEnable	Bit 7				
8	3	Setting the delay (OutputDelayTime)	USINT			•	
30	1	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.22.10.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	-	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2		•		

1) The offset specifies where the register is within the CAN object.

4.15.22.10.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.22.10.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.22.10.5.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

4.15.22.10.6 Reading the module ID

Name:
asy_ModulID

This register offers another possibility for reading the module ID.

Data type	Value
UINT	Module ID

4.15.22.10.7 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.22.10.7.1 Status of digital outputs 1 to 8

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput08

This register is used to indicate the status of digital outputs 1 to 8.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

4.15.22.10.8 Operating limit monitoring

The module's output supply is monitored. An I/O supply voltage of <10.2 V is displayed as a warning.

4.15.22.10.8.1 Status of the supply voltage

Name:
asy_SupplyStatus

The status of the I/O supply voltage is mapped in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	0
2	PowerSupply01	0	I/O supply above the warning level of 10.2 V
		1	I/O supply below the warning level of 10.2 V
3 - 7	Reserved	0	0

4.15.22.10.9 Additional function - switch digital outputs w/ delay using switching mask

In function model 1 - Output switching, it is possible to control the digital outputs with a delay.

The OutputDelay mask can be used to activate the delay for each channel individually. The module is controlled here using a 100 µs-based timer and the Output or OutputDelayed register.

Behavior of function model 1 - Output switching

With a timer delay of 0:

Output: DigitalOutput0x bits

When the delay is changed:

The bit string for DigitalOutput0x bits is output. The timer restarts.

Output: DigitalOutput0x bits

After delay time has expired:

The channels with bits set in the OutputDelay mask are adapted to the respective OutputDelayed bits.

Output: DigitalOutput0x bits (if Enable bit = FALSE)
OutputDelayed bits (if Enable bit = TRUE)

Information:

Adjusting the output and restarting the timer take place immediately after transferring the new delay, even if the previous time has not yet passed.

4.15.22.10.9.1 Switching state of delayed digital outputs 1 to 8

Name:
DigitalOutput01Delayed to Digital08Delayed

According to the corresponding bit in the OutputDelay mask, the switching state of all digital outputs 1 to 8 are stored in the OutputDelayed bits after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01Delayed	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08Delayed	0	Digital output 08 reset
		1	Digital output 08 set

Information:

After the delay time has expired, only the channels with a bit set in the OutputDelay mask are adjusted to the OutputDelayed bits.

4.15.22.10.9.2 Switching mask after the delay time has expired

Name:
DigitalOutput01DelayEnable to DigitalOutput08DelayEnable

These registers create the mask for OutputDelay. They define which outputs are switched to the bit string for the OutputDelayed register after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01DelayEnable	0	Digital output 01 remains unchanged
		1	Digital output 01 is toggled
...		...	
7	DigitalOutput08DelayEnable	0	Digital output 08 remains unchanged
		1	Digital output 08 is toggled

4.15.22.10.9.3 Setting the delay

Name:
OutputDelayTime

This register can be used to set the delay in 100 µs steps.

After the delay time has expired, the digital outputs are adjusted according to the switching mask (register 6) and the delayed output pattern (register 4).

Data type	Value
USINT	0 to 255 (in 100 µs steps)[1)]

1) The value 0 disables processing

4.15.22.10.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard function model	100 µs
Bus controller function model	150 µs

4.15.22.10.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Function model 0	Equal to the minimum cycle time
Function model 1	Equal to the minimum cycle time

4.15.23 X20DO8322

4.15.23.1 General information

The module is equipped with 8 outputs for 1-wire connections and designed for source output wiring.

- 8 digital outputs
- Source connection
- 1-wire connections
- Integrated output protection

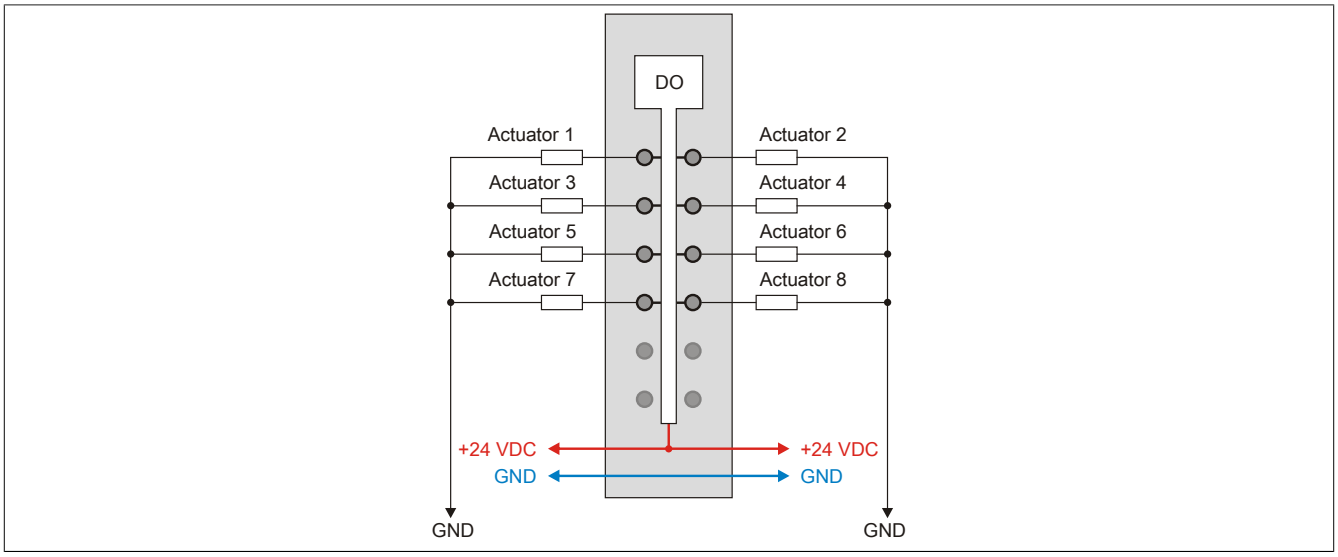
4.15.23.6 Connection example

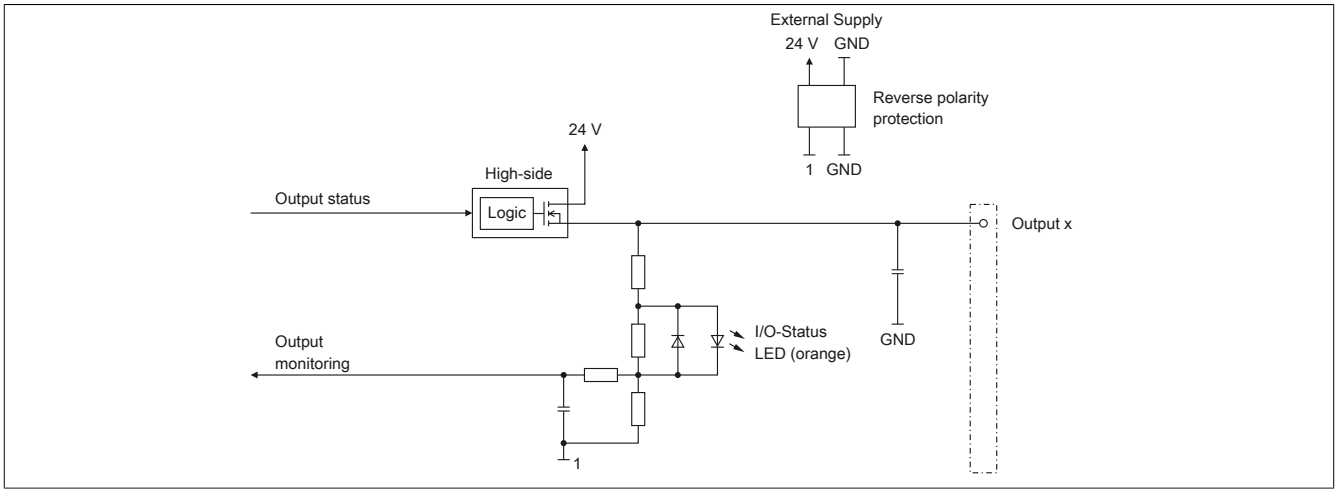


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

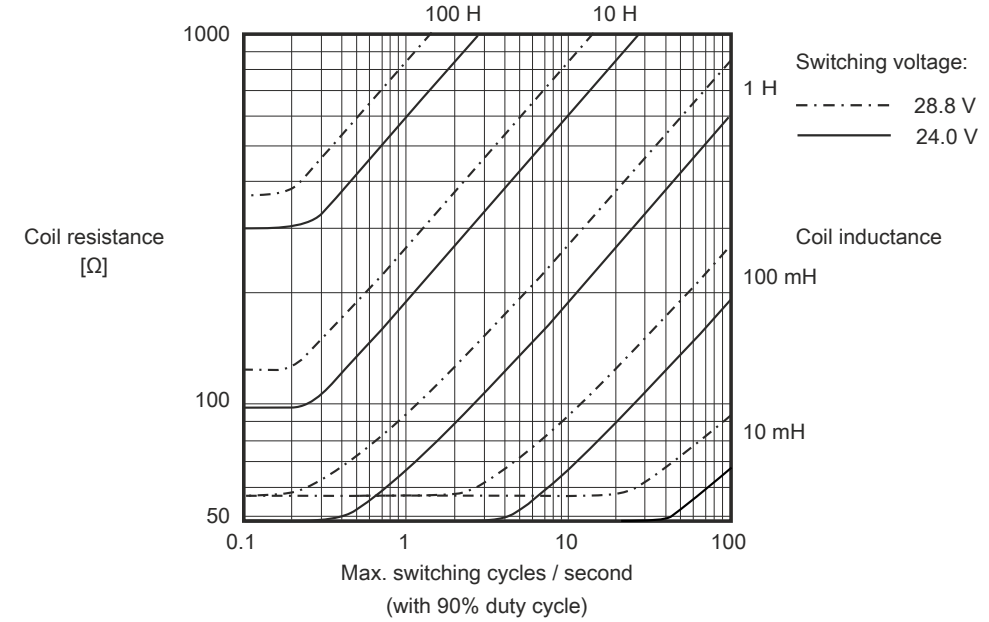
Therefore sufficient cable cross sections or external safety measures must be used.

4.15.23.7 Output circuit diagram

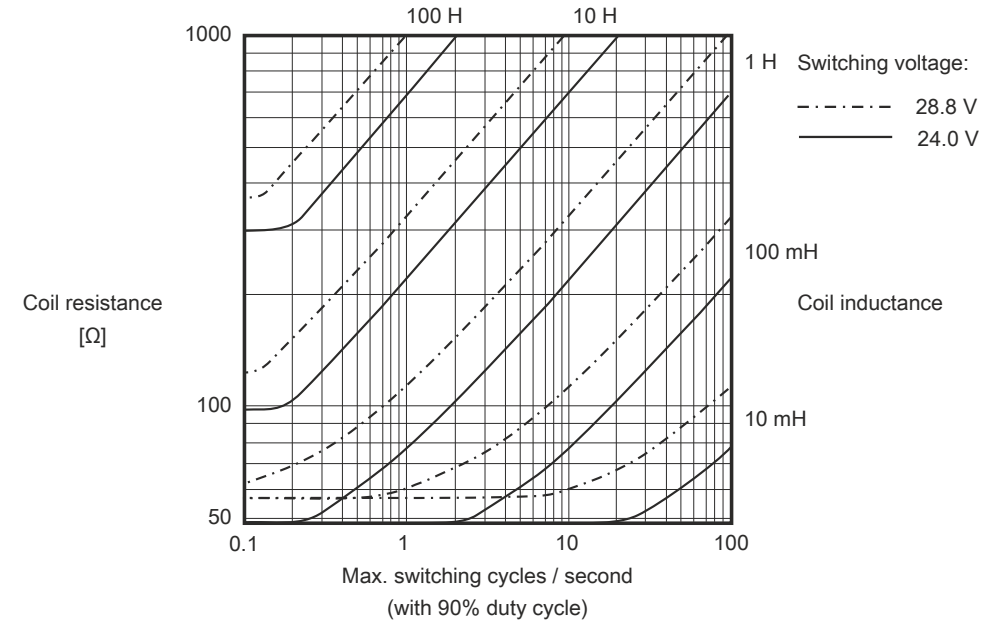


4.15.23.8 Switching inductive loads

Environmental temperature: 55°C, all outputs with the same load



Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.23.9 Register description

4.15.23.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.23.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	1	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.23.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				

1) The offset specifies where the register is within the CAN object.

4.15.23.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.23.9.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.23.9.4.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

4.15.23.9.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.23.9.5.1 Status of digital outputs 1 to 8

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput08

This register is used to indicate the status of digital outputs 1 to 8.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

4.15.23.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.23.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.24 X20DO8323

4.15.24.1 General Information

The module is an electrically isolated 8-channel digital output module. It can be configured as high-side or low-side or as a push/pull output for controlling 12 to 24 VDC DC motors.

- 8 digital outputs
- High-side or low-side connection
- Push/pull outputs
- 1-wire connections
- Integrated output protection

		DigitalOutput08	Bit 7				
4	1	EnableDigitalOutput	USINT			•	
		EnabDigitalOutput01	Bit 0				
		...	...				
		EnabDigitalOutput08	Bit 7				
30	2	StatusInput01	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	3	Cumulative status	USINT	•			
		StatusDigitalOutputs	Bit 0				
		StatusSupplyLO	Bit 4				
		StatusSupplyHI	Bit 5				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.24.8.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
0	0	Digital inputs	USINT	•			
		DigitalInput01	Bit 0				
		...	...				
		DigitalInput08	Bit 7				
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
4	-	Switching between inputs and outputs	USINT				•
		EnabDigitalOutput01	Bit 0				
		...	...				
		EnabDigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	-	Cumulative status	USINT		•		
		StatusDigitalOutputs	Bit 0				
		StatusSupplyLO	Bit 4				
		StatusSupplyHI	Bit 5				

1) The offset specifies where the register is within the CAN object.

4.15.24.8.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.24.8.4 Digital outputs

The output state is sent to the output ports acyclically to the network in the system timer (100 µsec). (max. switch off jitter: 50 µsec, max. switch on jitter: 150 µsec)

The output state must be switched with at least a 300 µsec delay in order to prevent the high-side and low-side drivers from switching together.

4.15.24.8.4.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

4.15.24.8.4.2 Status of digital outputs 1 to 8

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput08

This register is used to indicate the status of digital outputs 1 to 8.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

4.15.24.8.4.3 Switching between inputs and outputs

Name:
EnableDigitalOutput
EnabDigitalOutput01 through EnabDigitalOutput08

In this register, all channels can be connected as inputs or outputs. For each output there is a corresponding switching bit. Clearing this bit switches to tristate mode.

In function model 254 the initial value is 255.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("EnabDigitalOutput01" through "EnabDigitalOutput08") or whether this register should be displayed as an individual USINT data point ("EnableDigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	EnabDigitalOutput01	0	Channel 1 used as input
		1	Channel 1 used as output
...		...	
7	EnabDigitalOutput08	0	Channel 8 used as input
		1	Channel 8 used as output

4.15.24.8.5 Digital inputs

Name:
DigitalInput
DigitalInput01 through DigitalInput08

The status of digital inputs 1 to 8 is mapped in this register.

The status of the digital inputs is read with a minimum update rate of 5 to 8 msec. according to the digital output status sample rate.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalInput01" through "DigitalInput0x") or whether this register should be displayed as an individual USINT data point ("DigitalInput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status - Digital input 1
...		...	
7	DigitalInput08	0 or 1	Input status - Digital input 8

4.15.24.8.6 Cumulative status

Name:
StatusDigitalOutputs
StatusSupplyLO
StatusSupplyHI

The state of output monitoring and the supply voltage for all outputs are collected and mapped to this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutputs	0	No output monitoring
		1	Output monitoring active for at least one channel
1 - 3	Reserved	0	
4	StatusSupplyLO	0	No error
		1	Supply voltage too low (<= 11.5 VDC)
5	StatusSupplyHI	0	No error
		1	Supply voltage too high (> 30 VDC)
6 - 7	Reserved	0	

4.15.24.8.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.24.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
All channels	400 µs

4.15.25 X20(c)DO8331

4.15.25.1 General information

The module is equipped with 8 outputs for 1-wire connections. The rated output current is 2 A.

The output supply is fed directly to the module. An additional supply module is not needed. There is no connection between the module and the I/O supply potential on the bus module.

- 8 digital outputs with 2 A
- Sink connection
- 1-wire connections
- Power feed integrated in the module
- Integrated output protection

4.15.25.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

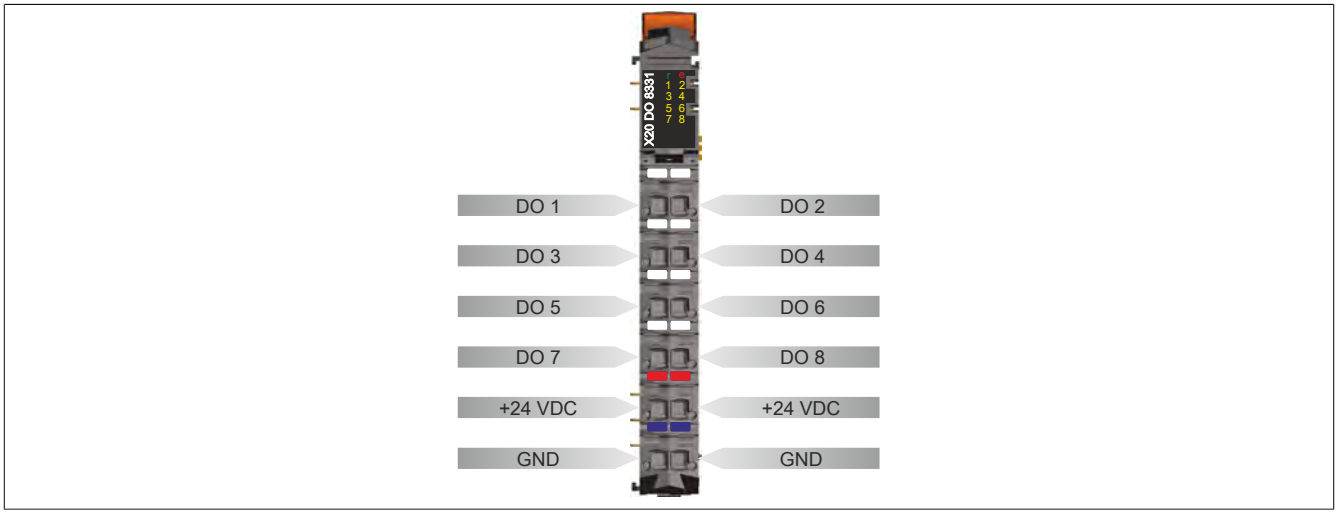
4.15.25.5 Status LEDs

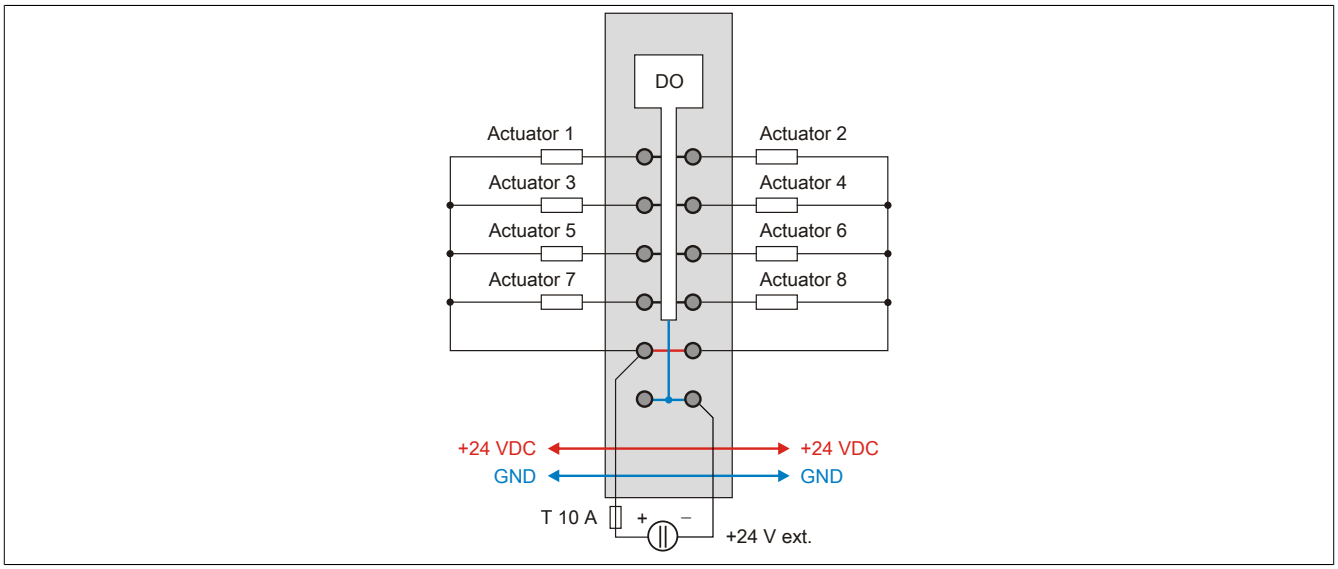
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
			Double flash	I/O supply too low
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Orange		Output status of the corresponding digital output

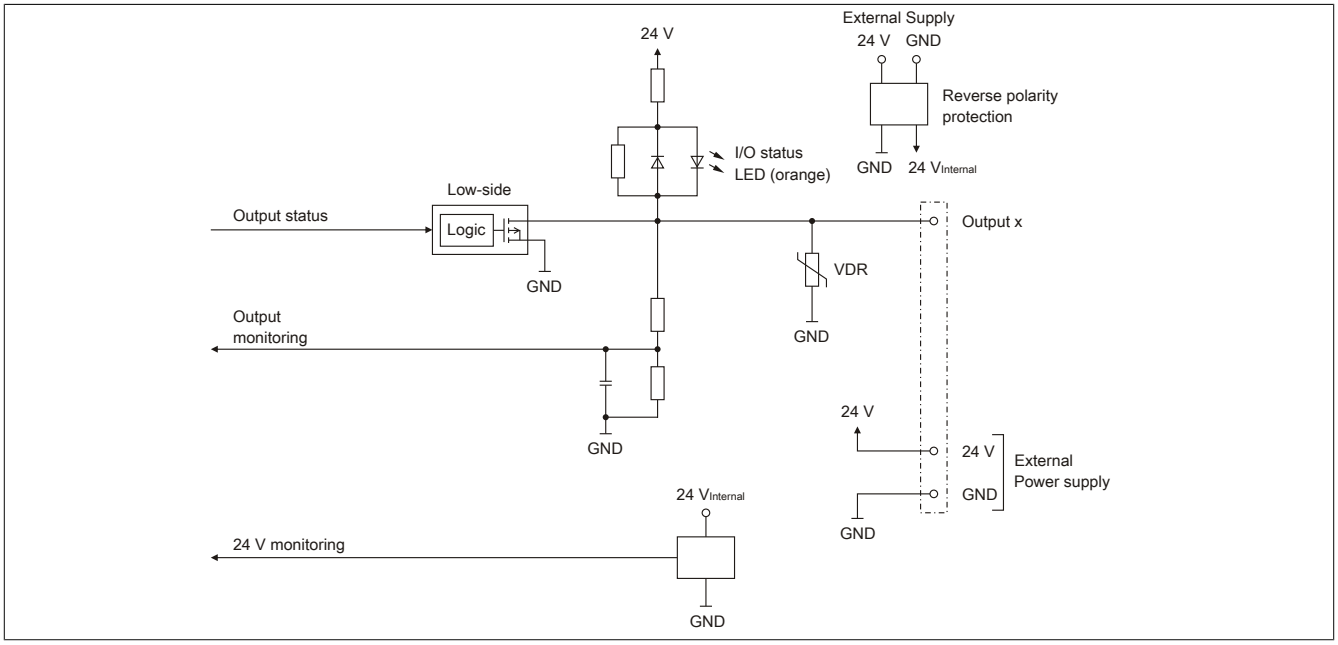
4.15.25.6 Pinout



4.15.25.7 Connection example

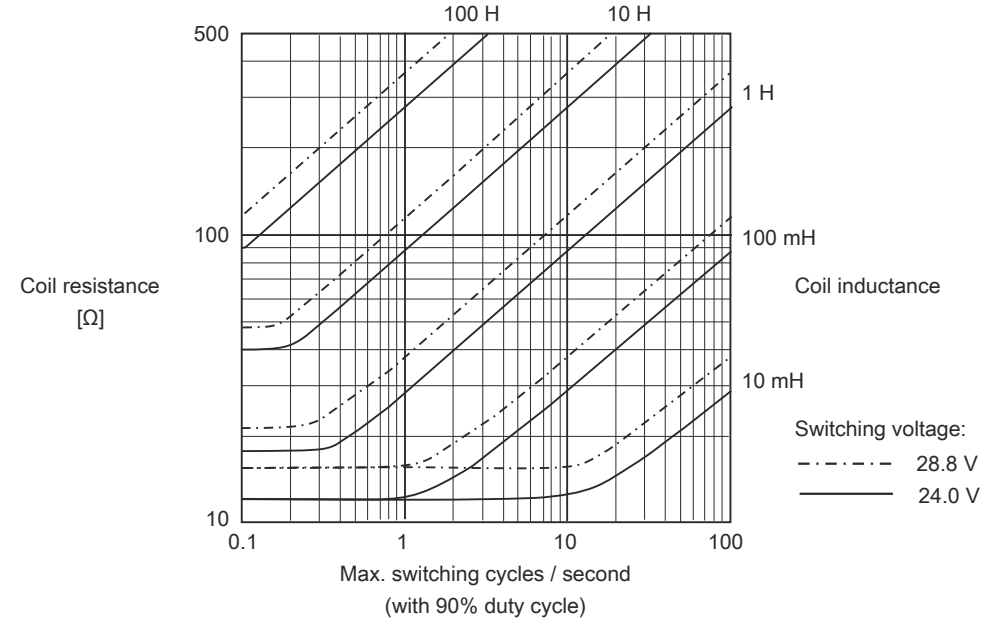


4.15.25.8 Output circuit diagram

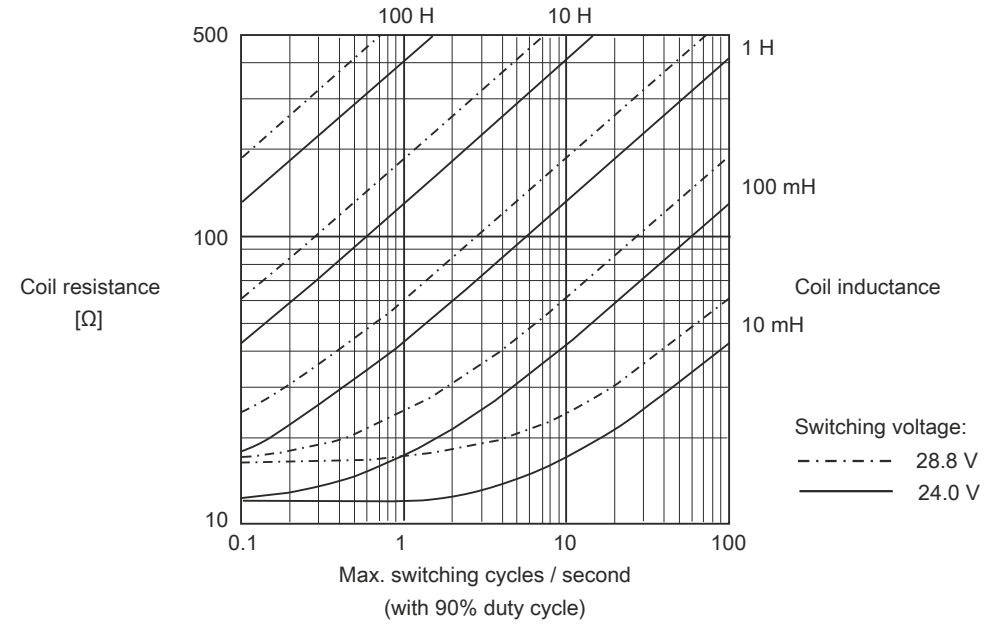


4.15.25.9 Switching inductive loads

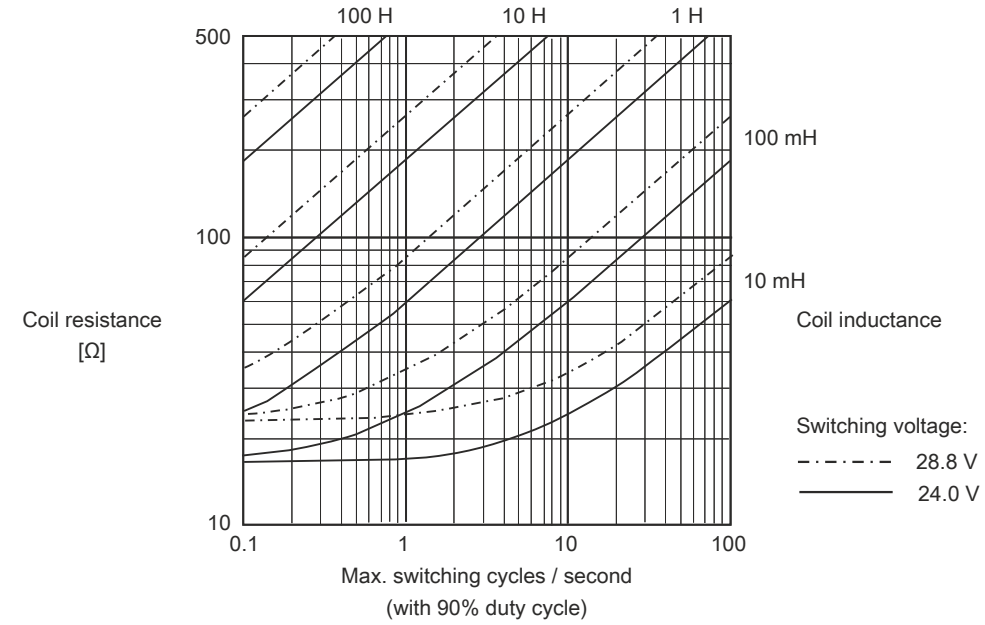
Environmental temperature: 35°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, all outputs with the same load.



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.25.10 Derating

The outputs of the module can handle up to 2 A. With a total current of 8 A, no more than 4 channels are operable at full load. To ensure optimal use of the module, it is important to assign the channels properly, and to keep in mind a potential derating.

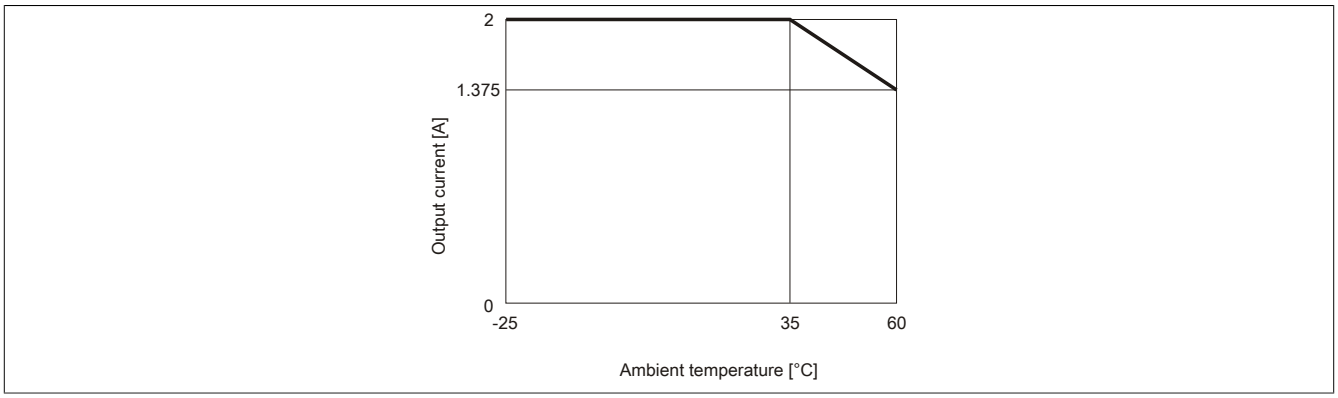
Correct channel assignment is important, since the eight outputs are divided between two output drivers. The channels operated with 2A must therefore be evenly divided between both output drivers.

Output driver 1: Channels 1 - 4
Output driver 2: Channels 5 - 8

The following table provides an overview of the number of fully used channels, the resulting best distribution, and a potential derating.

Number of channels using 2A	Division	Derating
1	Any	No
2	1st channel with 2 A ... channel no. 1 - 4 2nd channel with 2 A ... channel no. 5 - 8	No
3	Assign all even or all odd channel numbers. Examples: 1, 3, 5 2, 4, 6 3, 5, 7 4, 6, 8	 Channels 1 and 3 Channels 2 and 4 Channels 5 and 7 Channels 6 and 8
4	Assign all even or all odd channel numbers. Possible distributions: 1, 3, 5, 7 2, 4, 6, 8	 All channels All channels

Derating when 3 or 4 channels are operated with 2 A:



Information:

Modules next to this module can have a maximum power consumption of 1.5 W.

4.15.25.11 Register description

4.15.25.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.25.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	1	StatusInput01	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.25.11.3 Function model 1 - Output switching

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
4	1	Switching state of delayed digital outputs 1 to 8	USINT			•	
		DigitalOutput01Delayed	Bit 0				
		...	...				
		DigitalOutput08Delayed	Bit 7				
6	2	Switching mask after the delay time has expired	USINT			•	
		DigitalOutput01DelayEnable	Bit 0				
		...	...				
		DigitalOutput08DelayEnable	Bit 7				
8	3	Setting the delay (OutputDelayTime)	USINT			•	
30	1	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.25.11.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		Power Supply01	Bit 2		•		

1) The offset specifies where the register is within the CAN object.

4.15.25.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.25.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.25.11.5.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

4.15.25.11.6 Reading the module ID

Name:
asy_ModulID

This register offers another possibility for reading the module ID.

Data type	Value
UINT	Module ID

4.15.25.11.7 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.25.11.7.1 Status of digital outputs 1 to 8

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput08

This register is used to indicate the status of digital outputs 1 to 8.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

4.15.25.11.8 Operating limit monitoring

The module's output supply is monitored. An I/O supply voltage of <20.4 V is displayed as a warning.

4.15.25.11.8.1 Status of the supply voltage

Name:
asy_SupplyStatus

The status of the I/O supply voltage is mapped in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	
2	PowerSupply01	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - 7	Reserved	0	

4.15.25.11.9 Additional function - switch digital outputs w/ delay using switching mask

In function model 1 - Output switching, it is possible to control the digital outputs with a delay.

The OutputDelay mask can be used to activate the delay for each channel individually. The module is controlled here using a 100 µs-based timer and the Output or OutputDelayed register.

Behavior of function model 1 - Output switching

With a timer delay of 0:

Output: DigitalOutput0x bits

When the delay is changed:

The bit string for DigitalOutput0x bits is output. The timer restarts.

Output: DigitalOutput0x bits

After delay time has expired:

The channels with bits set in the OutputDelay mask are adapted to the respective OutputDelayed bits.

Output: DigitalOutput0x bits (if Enable bit = FALSE)
OutputDelayed bits (if Enable bit = TRUE)

Information:

Adjusting the output and restarting the timer take place immediately after transferring the new delay, even if the previous time has not yet passed.

4.15.25.11.9.1 Switching state of delayed digital outputs 1 to 8

Name:
DigitalOutput01Delayed to Digital08Delayed

According to the corresponding bit in the OutputDelay mask, the switching state of all digital outputs 1 to 8 are stored in the OutputDelayed bits after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01Delayed	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08Delayed	0	Digital output 08 reset
		1	Digital output 08 set

Information:

After the delay time has expired, only the channels with a bit set in the OutputDelay mask are adjusted to the OutputDelayed bits.

4.15.25.11.9.2 Switching mask after the delay time has expired

Name:
DigitalOutput01DelayEnable to DigitalOutput08DelayEnable

These registers create the mask for OutputDelay. They define which outputs are switched to the bit string for the OutputDelayed register after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01DelayEnable	0	Digital output 01 remains unchanged
		1	Digital output 01 is toggled
...		...	
7	DigitalOutput08DelayEnable	0	Digital output 08 remains unchanged
		1	Digital output 08 is toggled

4.15.25.11.9.3 Setting the delay

Name:
OutputDelayTime

This register can be used to set the delay in 100 µs steps.

After the delay time has expired, the digital outputs are adjusted according to the switching mask (register 6) and the delayed output pattern (register 4).

Data type	Value
USINT	0 to 255 (in 100 µs steps)[1)]

1) The value 0 disables processing

4.15.25.11.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard function model	100 µs
Bus controller function model	150 µs

4.15.25.11.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Function model 0	Equal to the minimum cycle time
Function model 1	Equal to the minimum cycle time

4.15.26 X20(c)DO8332

4.15.26.1 General information

The module is equipped with 8 outputs for 1-wire connections. The rated output current is 2 A.

The output supply is fed directly to the module. An additional supply module is not needed. There is no connection between the module and the I/O supply potential on the bus module.

- 8 digital outputs with 2 A
- Source connection
- 1-wire connections
- Power feed integrated in the module
- Integrated output protection

4.15.26.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

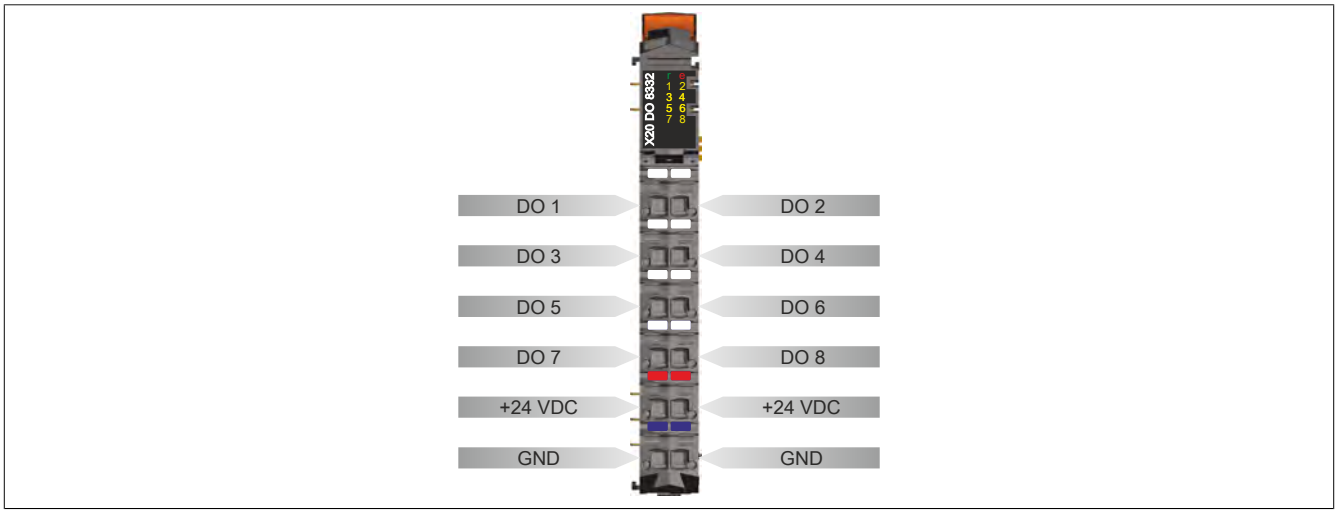
4.15.26.5 Status LEDs

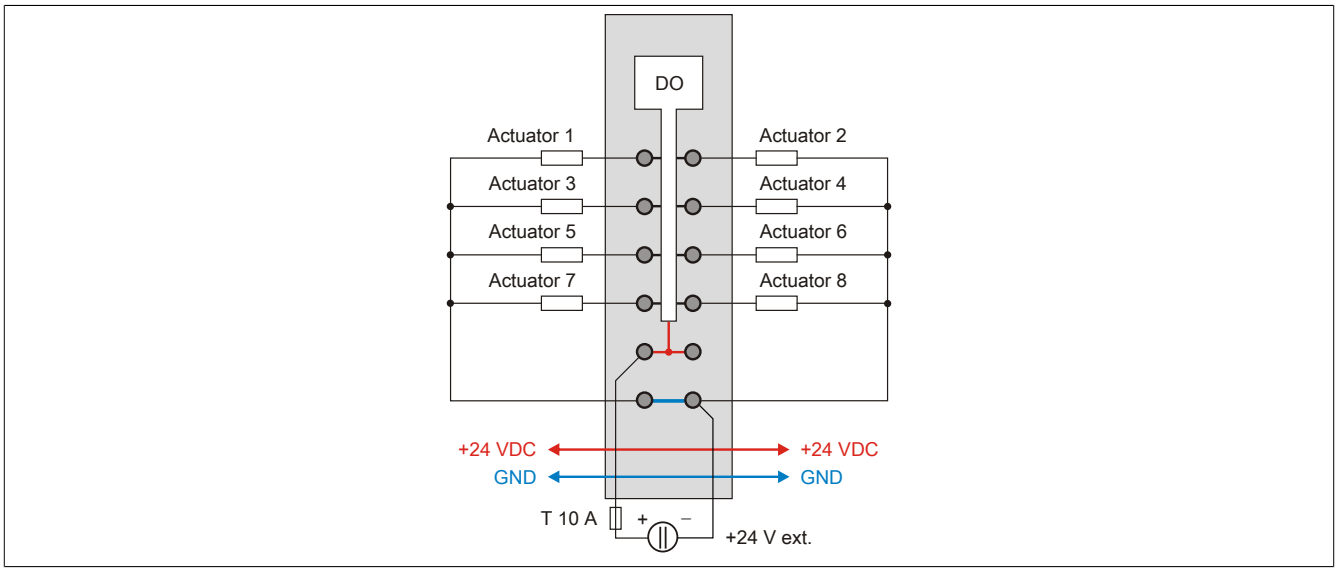
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
			Double flash	I/O supply too low
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Orange		Output status of the corresponding digital output

4.15.26.6 Pinout



4.15.26.7 Connection example

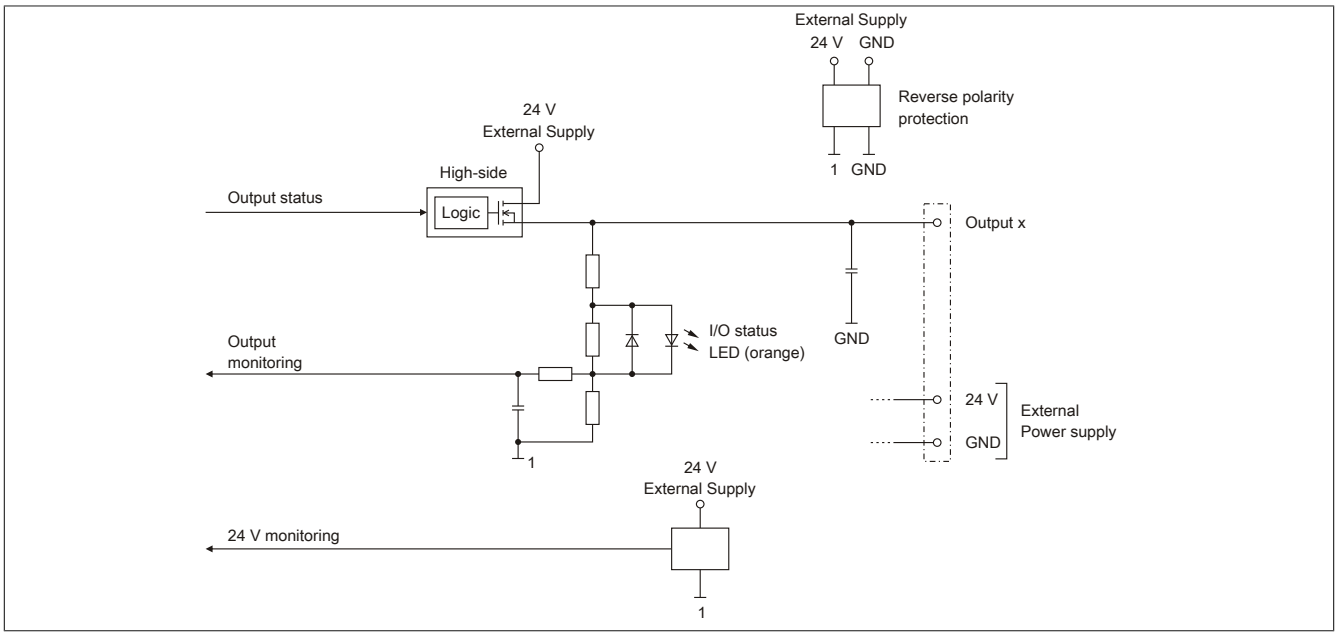


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

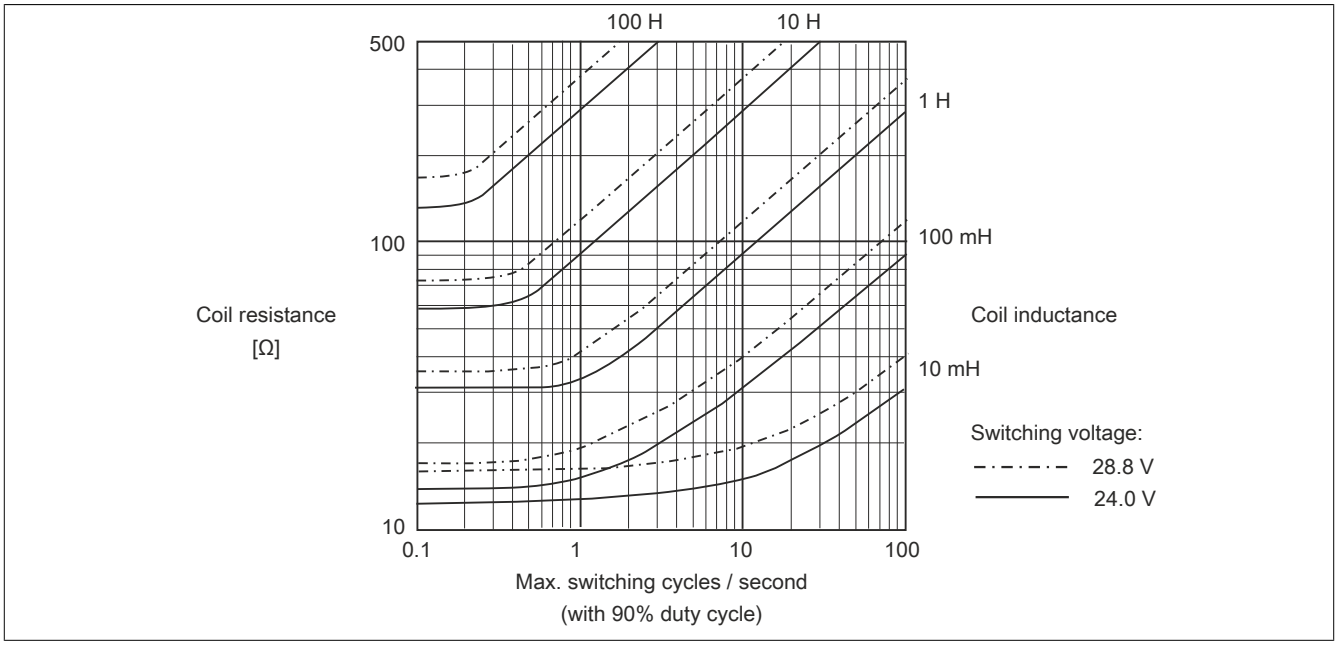
Therefore sufficient cable cross sections or external safety measures must be used.

4.15.26.8 Output circuit diagram

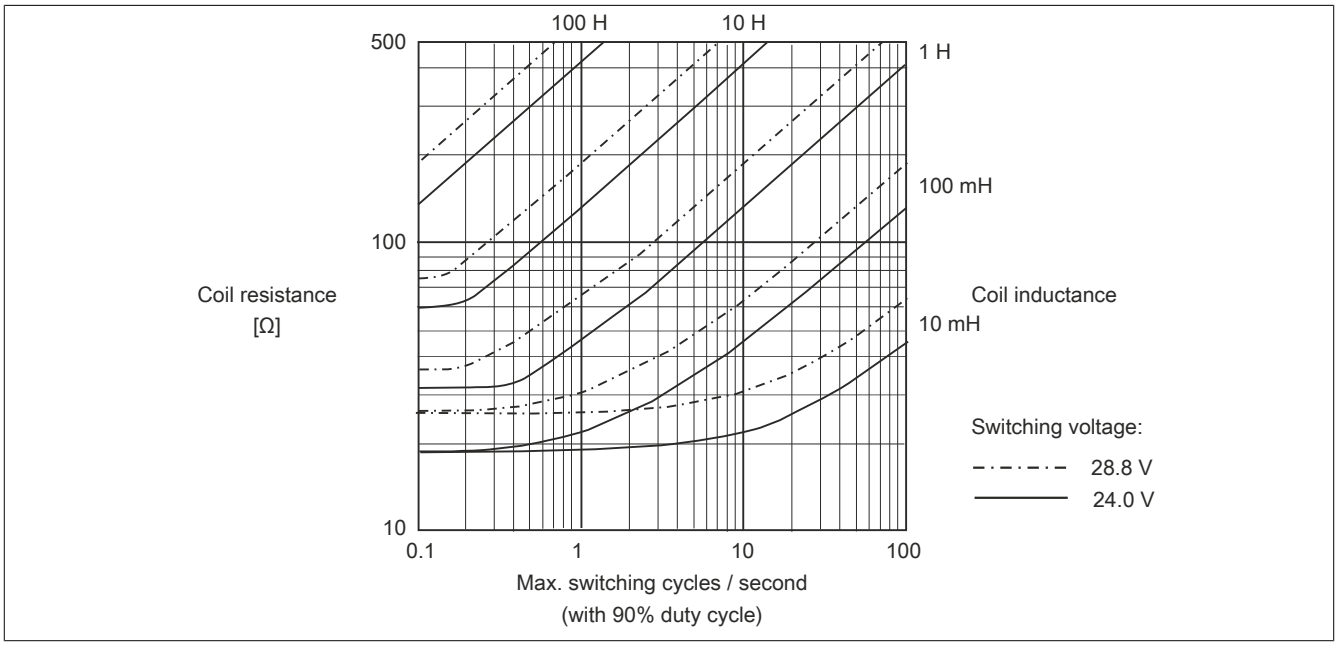


4.15.26.9 Switching inductive loads

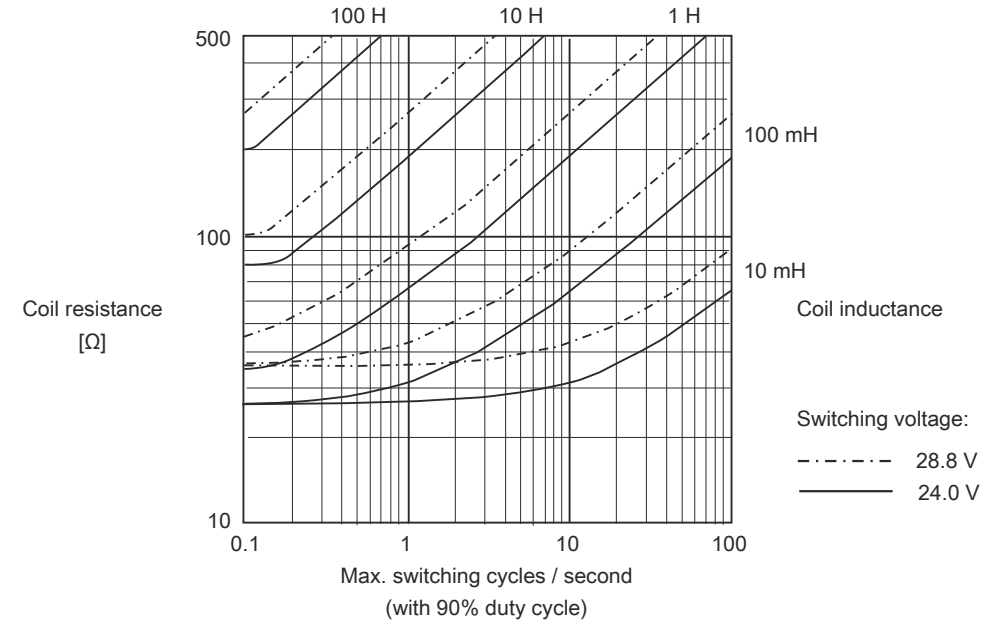
Environmental temperature: 35°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, 4 outputs (1,3,5,7 or 2,4,6,8) with the same load.



Environmental temperature: 60°C, all outputs with the same load.



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.26.10 Derating

The outputs of the module can handle up to 2 A. With a total current of 8 A, no more than 4 channels are operable at full load. To ensure optimal use of the module, it is important to assign the channels properly, and to keep in mind a potential derating.

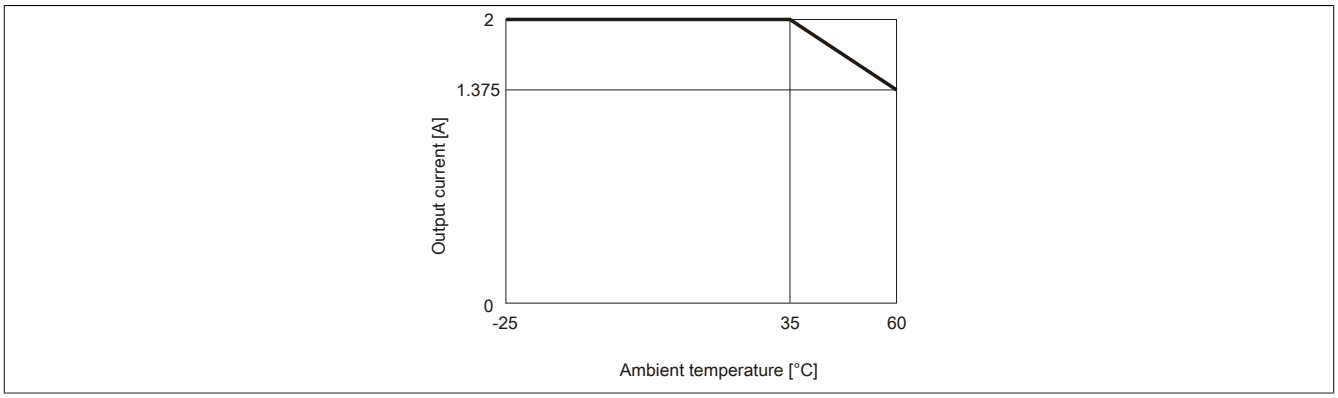
Correct channel assignment is important, since the eight outputs are divided between two output drivers. The channels operated with 2A must therefore be evenly divided between both output drivers.

Output driver 1: Channels 1 - 4
Output driver 2: Channels 5 - 8

The following table provides an overview of the number of fully used channels, the resulting best distribution, and a potential derating.

Number of channels using 2A	Division	Derating
1	Any	No
2	1st channel with 2 A ... channel no. 1 - 4 2nd channel with 2 A ... channel no. 5 - 8	No
3	Assign all even or all odd channel numbers. Examples: 1, 3, 5 2, 4, 6 3, 5, 7 4, 6, 8	 Channels 1 and 3 Channels 2 and 4 Channels 5 and 7 Channels 6 and 8
4	Assign all even or all odd channel numbers. Possible distributions: 1, 3, 5, 7 2, 4, 6, 8	 All channels All channels

Derating when 3 or 4 channels are operated with 2 A:



Information:

Modules next to this module can have a maximum power consumption of 1.5 W.

4.15.26.11 Register description

4.15.26.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.26.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	1	StatusInput01	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.26.11.3 Function model 1 - Output switching

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
4	1	Switching state of delayed digital outputs 1 to 8	USINT			•	
		DigitalOutput01Delayed	Bit 0				
		...	...				
		DigitalOutput08Delayed	Bit 7				
6	2	Switching mask after the delay time has expired	USINT			•	
		DigitalOutput01DelayEnable	Bit 0				
		...	...				
		DigitalOutput08DelayEnable	Bit 7				
8	3	Setting the delay (OutputDelayTime)	USINT			•	
30	1	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		PowerSupply01	Bit 2	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.26.11.4 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
8192	-	Reading the module ID	UINT		•		
8196	-	Status of the supply voltage	USINT		•		
		Power Supply01	Bit 2		•		

1) The offset specifies where the register is within the CAN object.

4.15.26.11.4.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.26.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.26.11.5.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("DigitalOutput").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

4.15.26.11.6 Reading the module ID

Name:
asy_ModulID

This register offers another possibility for reading the module ID.

Data type	Value
UINT	Module ID

4.15.26.11.7 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.26.11.7.1 Status of digital outputs 1 to 8

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput08

This register is used to indicate the status of digital outputs 1 to 8.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of this registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput0x") or whether this register should be displayed as an individual USINT data point ("StatusInput01").

Data type	Value	Information
USINT	0 to 255	Packed outputs = on
	See bit structure	Packed outputs = off or function model <> 0 - Standard

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

4.15.26.11.8 Operating limit monitoring

The module's output supply is monitored. An I/O supply voltage of <20.4 V is displayed as a warning.

4.15.26.11.8.1 Status of the supply voltage

Name:
asy_SupplyStatus

The status of the I/O supply voltage is mapped in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	
2	PowerSupply01	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - 7	Reserved	0	

4.15.26.11.9 Additional function - switch digital outputs w/ delay using switching mask

In function model 1 - Output switching, it is possible to control the digital outputs with a delay.

The OutputDelay mask can be used to activate the delay for each channel individually. The module is controlled here using a 100 µs-based timer and the Output or OutputDelayed register.

Behavior of function model 1 - Output switching

With a timer delay of 0:

Output: DigitalOutput0x bits

When the delay is changed:

The bit string for DigitalOutput0x bits is output. The timer restarts.

Output: DigitalOutput0x bits

After delay time has expired:

The channels with bits set in the OutputDelay mask are adapted to the respective OutputDelayed bits.

Output: DigitalOutput0x bits (if Enable bit = FALSE)
OutputDelayed bits (if Enable bit = TRUE)

Information:

Adjusting the output and restarting the timer take place immediately after transferring the new delay, even if the previous time has not yet passed.

4.15.26.11.9.1 Switching state of delayed digital outputs 1 to 8

Name:
DigitalOutput01Delayed to Digital08Delayed

According to the corresponding bit in the OutputDelay mask, the switching state of all digital outputs 1 to 8 are stored in the OutputDelayed bits after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01Delayed	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08Delayed	0	Digital output 08 reset
		1	Digital output 08 set

Information:

After the delay time has expired, only the channels with a bit set in the OutputDelay mask are adjusted to the OutputDelayed bits.

4.15.26.11.9.2 Switching mask after the delay time has expired

Name:
DigitalOutput01DelayEnable to DigitalOutput08DelayEnable

These registers create the mask for OutputDelay. They define which outputs are switched to the bit string for the OutputDelayed register after the delay time has expired.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01DelayEnable	0	Digital output 01 remains unchanged
		1	Digital output 01 is toggled
...		...	
7	DigitalOutput08DelayEnable	0	Digital output 08 remains unchanged
		1	Digital output 08 is toggled

4.15.26.11.9.3 Setting the delay

Name:
OutputDelayTime

This register can be used to set the delay in 100 µs steps.

After the delay time has expired, the digital outputs are adjusted according to the switching mask (register 6) and the delayed output pattern (register 4).

Data type	Value
USINT	0 to 255 (in 100 µs steps)[1)]

1) The value 0 disables processing

4.15.26.11.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard function model	100 µs
Bus controller function model	150 µs

4.15.26.11.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Function model 0	Equal to the minimum cycle time
Function model 1	Equal to the minimum cycle time

4.15.27 X20(c)DO9321

4.15.27.1 General information

The module is equipped with 12 outputs for 1-wire connections. The module is designed for sink output wiring.

- 12 digital outputs
- Sink connection
- 1-wire connections
- Integrated output protection

4.15.27.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

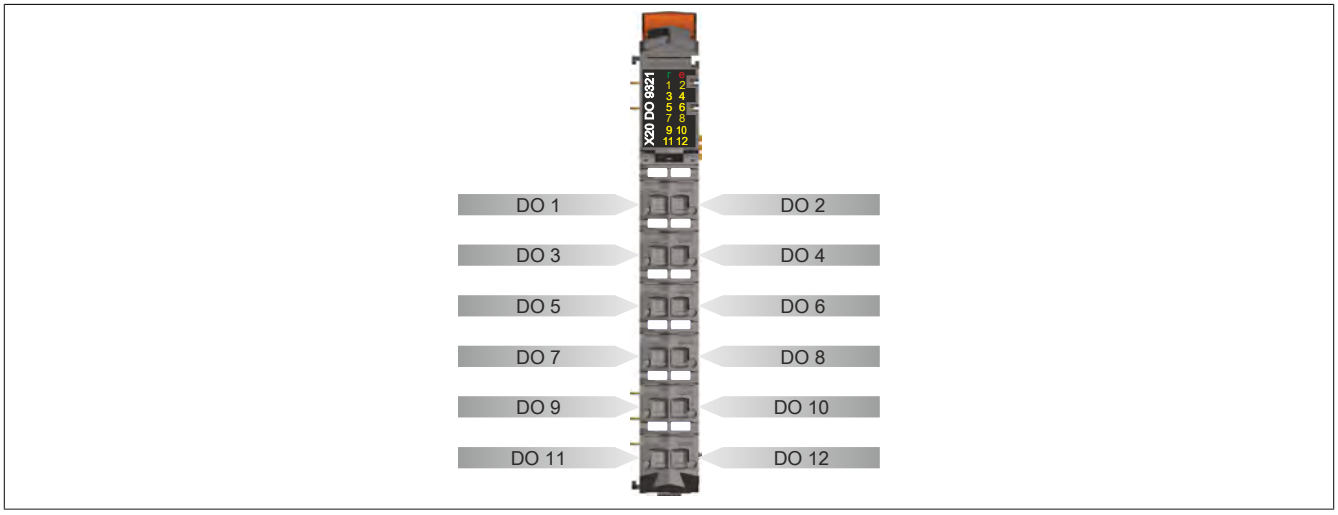
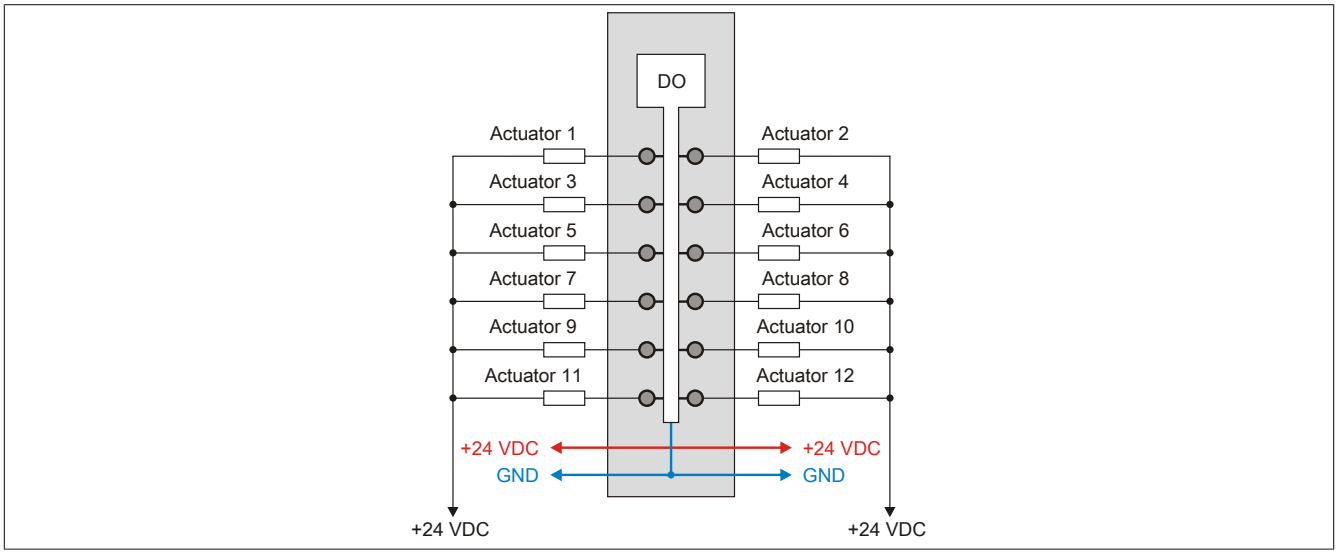
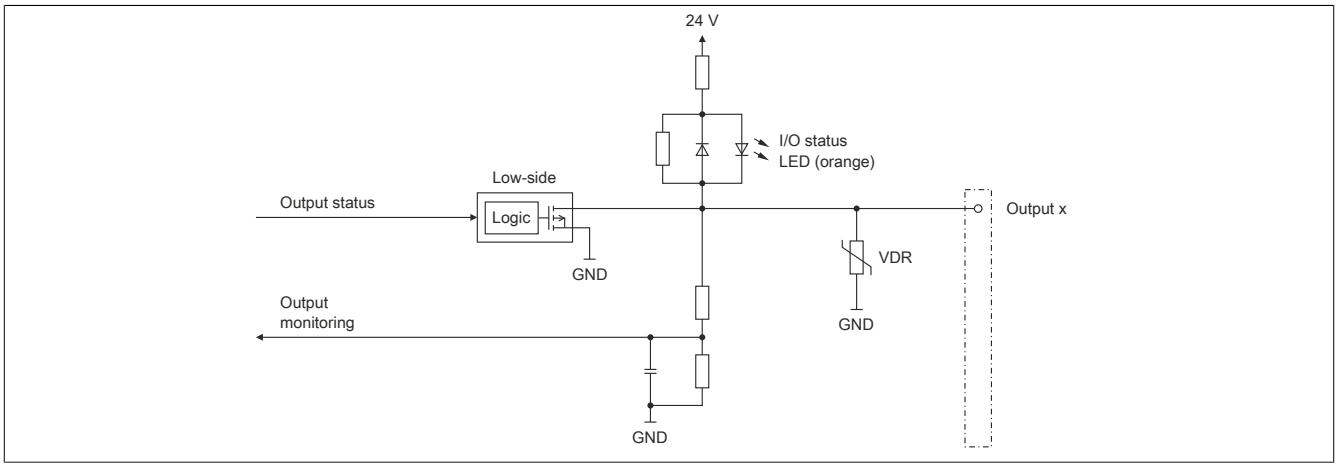
4.15.27.6 Pinout



4.15.27.7 Connection example



4.15.27.8 Output circuit diagram



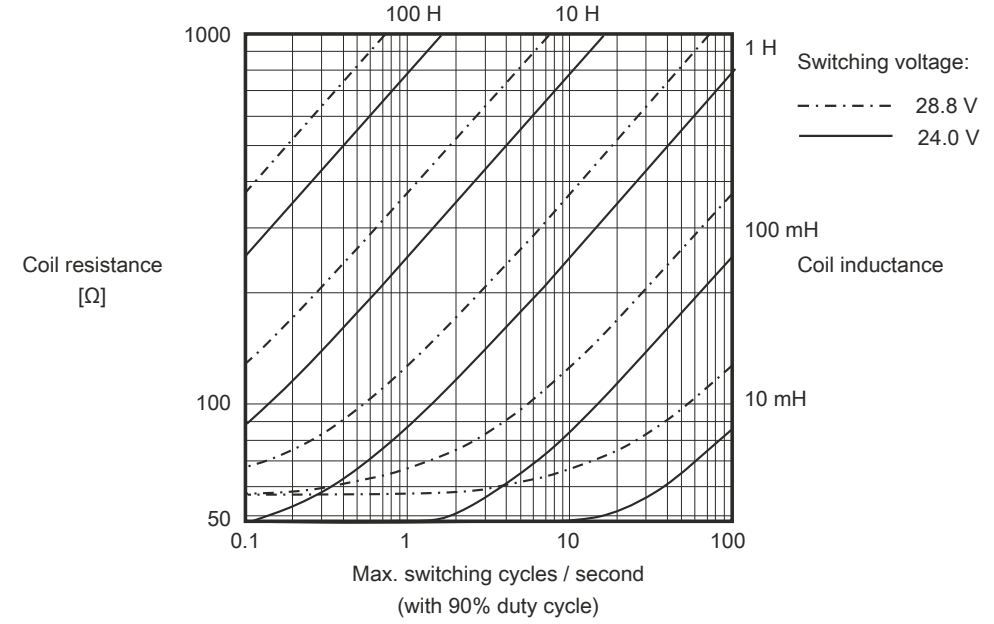
4.15.27.9 Derating

There is no derating when operated below 55°C.

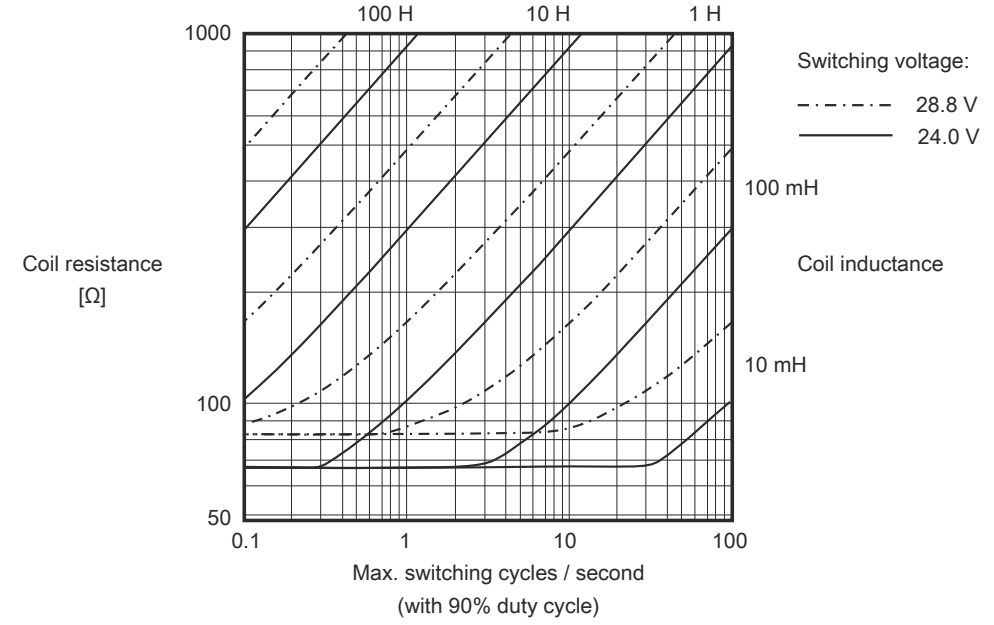
When operated at temperatures above 55°C, the maximal total current per channel is limited to 0,35 A

4.15.27.10 Switching inductive loads

Environmental temperature: 55°C, all outputs with the same load



Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.27.11 Register description

4.15.27.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.27.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
	1	DigitalOutput	UINT			•	
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 12	USINT			•	
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput12	Bit 3				
	1	StatusInput01	UINT	•			
30	1	Status of digital outputs 1 to 8	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	2	Status of digital outputs 9 to 12	USINT	•			
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput12	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.27.11.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 12	USINT			•	
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput12	Bit 3				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	-	Status of digital outputs 9 to 12	USINT		•		
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput12	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.27.11.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.15.27.11.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.27.11.4.1 Switching state of digital outputs 1 to 12

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput12

The switching state of digital outputs 1 to 12 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput12") or whether these registers should be displayed as an individual UINT data point ("DigitalOutput").

Data type	Value
UINT	Packed "DigitalOutput" values
USINT	See bit structure

Bit structure:

Register 2, Offset 0:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

Register 3, Offset 1:

Bit	Name	Value	Information
0	DigitalOutput09	0	Digital output 09 reset
		1	Digital output 09 set
...		...	
3	DigitalOutput12	0	Digital output 12 reset
		1	Digital output 12 set

4.15.27.11.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.27.11.5.1 Status of digital outputs 1 to 12

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput12

The status of digital outputs 1 to 12 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput12") or whether these registers should be displayed as an individual UINT data point ("StatusDigitalOutput").

Data type	Value
UINT	Packed "StatusDigitalOutput" values
USINT	See bit structure

Bit structure:

Register 30, (Offset 1):

Bit	Name	Value	Description
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
7	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

Register 31, (Offset 2):

Bit	Name	Value	Information
0	StatusDigitalOutput09	0	Channel 09: No error
		1	Channel 09: Short circuit or overload
...		...	
3	StatusDigitalOutput12	0	Channel 12: No error
		1	Channel 12: Short circuit or overload

4.15.27.11.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.27.11.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.28 X20(c)DO9322

4.15.28.1 General information

The module is equipped with 12 outputs for 1-wire connections. The module is designed for source output wiring.

- 12 digital outputs
- Source connection
- 1-wire connections
- Integrated output protection

4.15.28.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

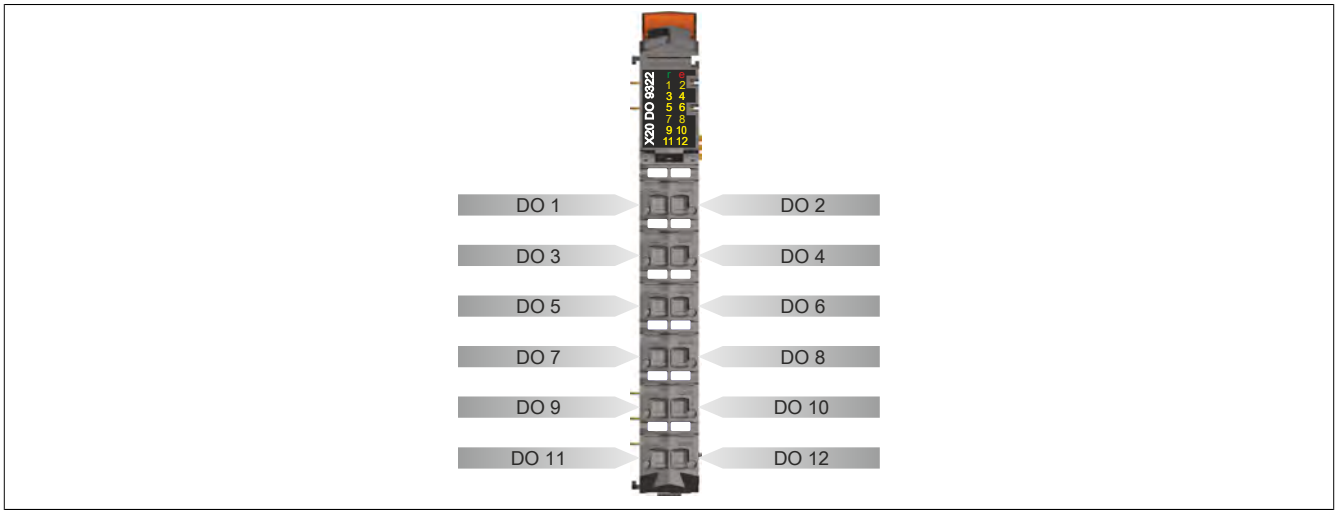
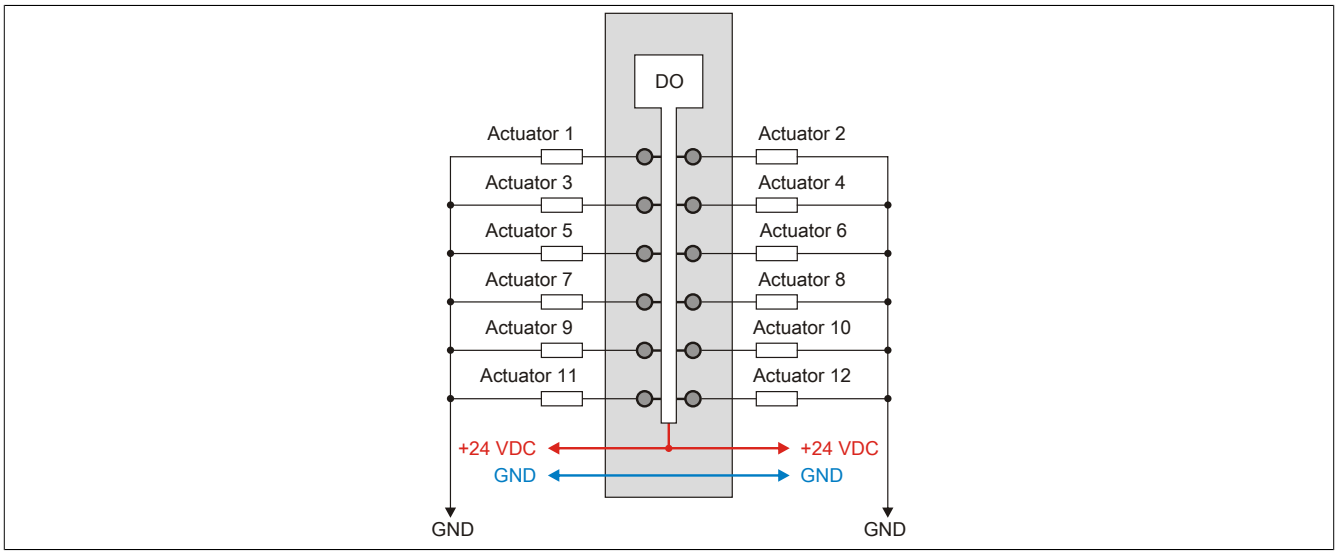
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 12	Orange		Output status of the corresponding digital output

4.15.28.6 Pinout



4.15.28.7 Connection example

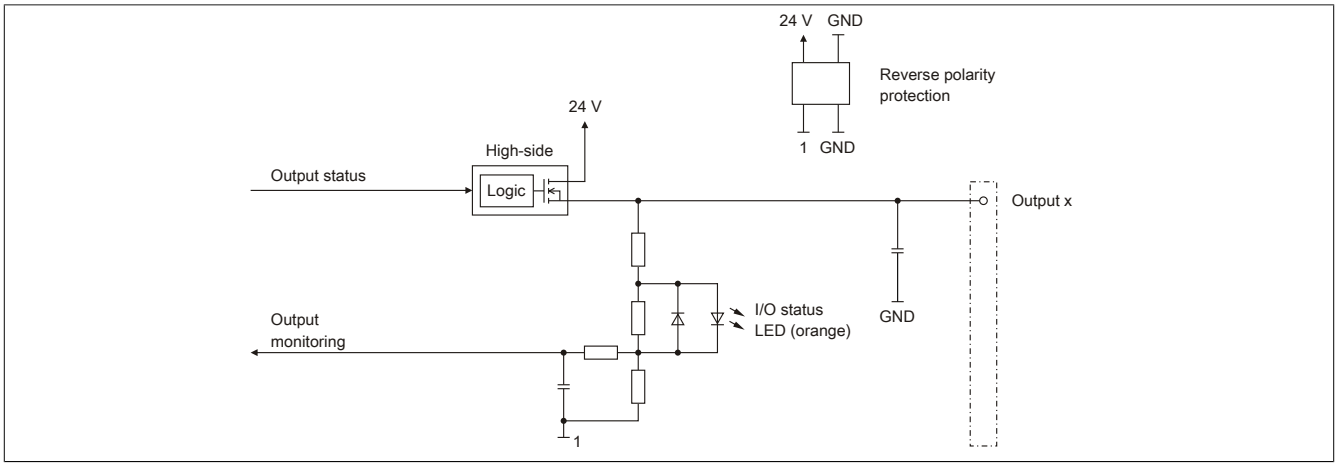


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.28.8 Output circuit diagram



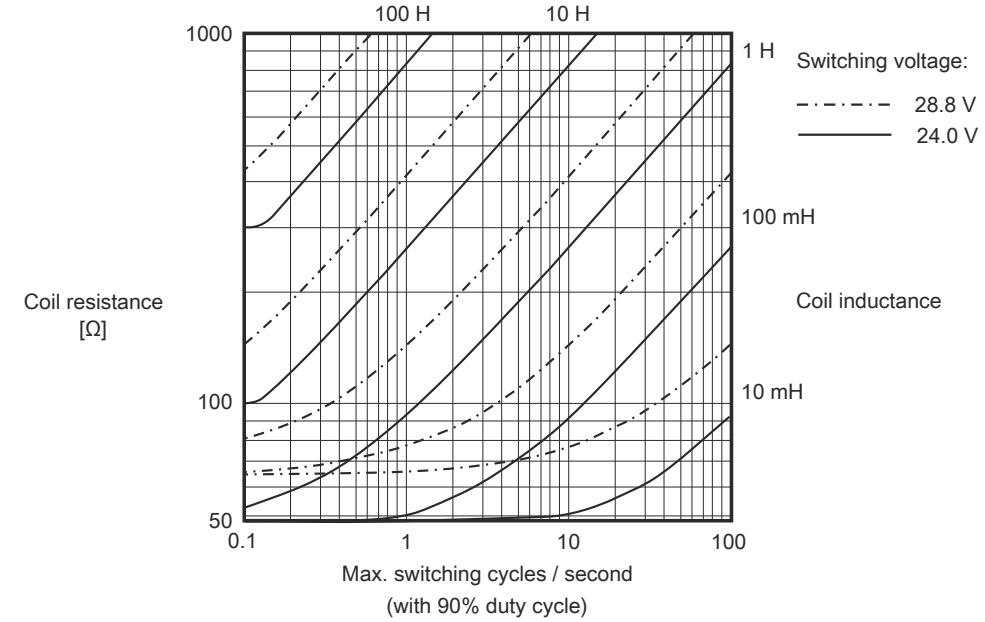
4.15.28.9 Derating

There is no derating when operated below 55°C.

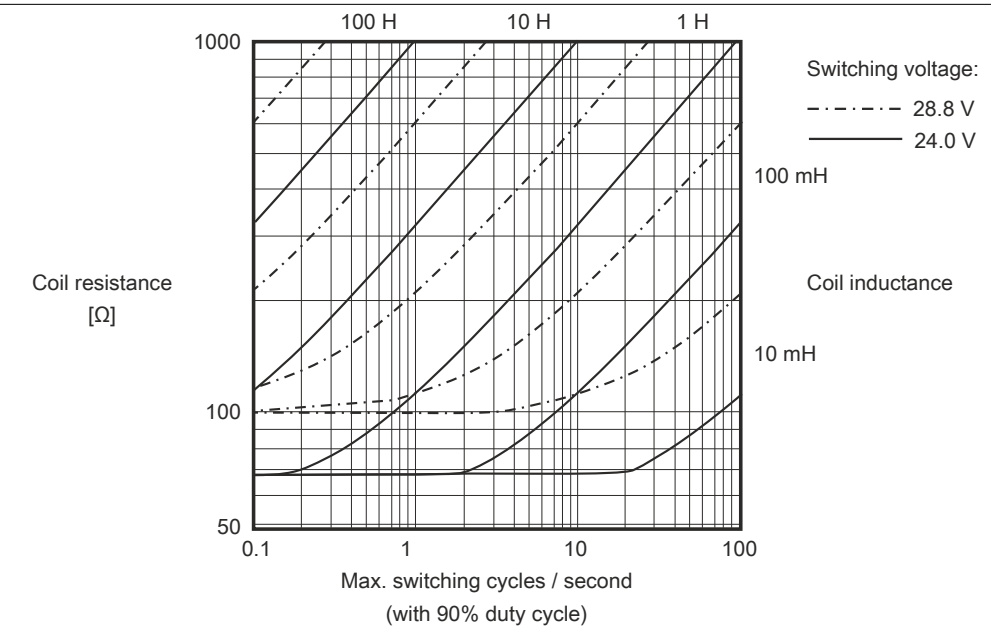
When operated at temperatures above 55°C, the maximal total current per channel is limited to 0,35 A

4.15.28.10 Switching inductive loads

Environmental temperature: 55°C, all outputs with the same load



Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.28.11 Register description

4.15.28.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.28.11.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
	1	DigitalOutput	UINT			•	
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 12	USINT			•	
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput12	Bit 3				
	1	StatusInput01	UINT	•			
30	1	Status of digital outputs 1 to 8	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	2	Status of digital outputs 9 to 12	USINT	•			
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput12	Bit 3				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.28.11.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 12	USINT			•	
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput12	Bit 3				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	-	Status of digital outputs 9 to 12	USINT		•		
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput12	Bit 3				

1) The offset specifies where the register is within the CAN object.

4.15.28.11.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.15.28.11.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.28.11.4.1 Switching state of digital outputs 1 to 12

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput12

The switching state of digital outputs 1 to 12 are stored in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput12") or whether these registers should be displayed as an individual UINT data point ("DigitalOutput").

Data type	Value
UINT	Packed "DigitalOutput" values
USINT	See bit structure

Bit structure:

Register 2, Offset 0:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

Register 3, Offset 1:

Bit	Name	Value	Information
0	DigitalOutput09	0	Digital output 09 reset
		1	Digital output 09 set
...		...	
3	DigitalOutput12	0	Digital output 12 reset
		1	Digital output 12 set

4.15.28.11.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.28.11.5.1 Status of digital outputs 1 to 12

Name:
StatusInput01
StatusDigitalOutput01 to StatusDigitalOutput12

The status of digital outputs 1 to 12 is mapped in this register.

Function model 0 - Standard only:

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput12") or whether these registers should be displayed as an individual UINT data point ("StatusDigitalOutput").

Data type	Value
UINT	Packed "StatusDigitalOutput" values
USINT	See bit structure

Bit structure:

Register 30, (Offset 1):

Bit	Name	Value	Description
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
7	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

Register 31, (Offset 2):

Bit	Name	Value	Information
0	StatusDigitalOutput09	0	Channel 09: No error
		1	Channel 09: Short circuit or overload
...		...	
3	StatusDigitalOutput12	0	Channel 12: No error
		1	Channel 12: Short circuit or overload

4.15.28.11.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.28.11.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.29 X20DOD322

4.15.29.1 General information

The X20DOD322 module is equipped with eight outputs for 1-wire or 2-wire connections. The X20DOD322 is designed for source output wiring.

- 8 digital outputs
- Source connection
- 2-wire connections
- GND for signal supply
- Integrated output protection

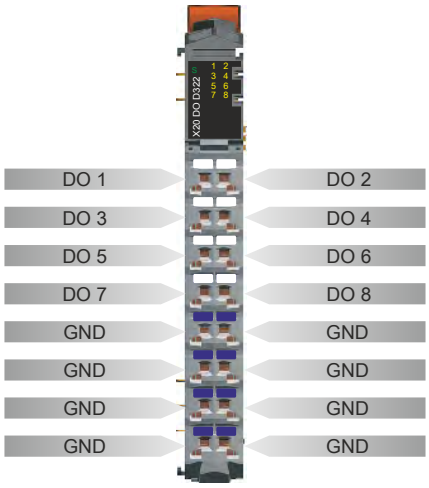
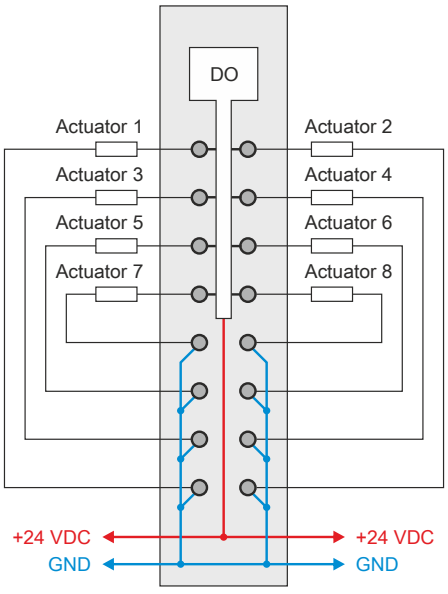
		Red on / Green single flash		Invalid firmware
	1 - 8	Orange		Output status of the corresponding digital output

4.15.29.5 Pinout



4.15.29.6 Connection example

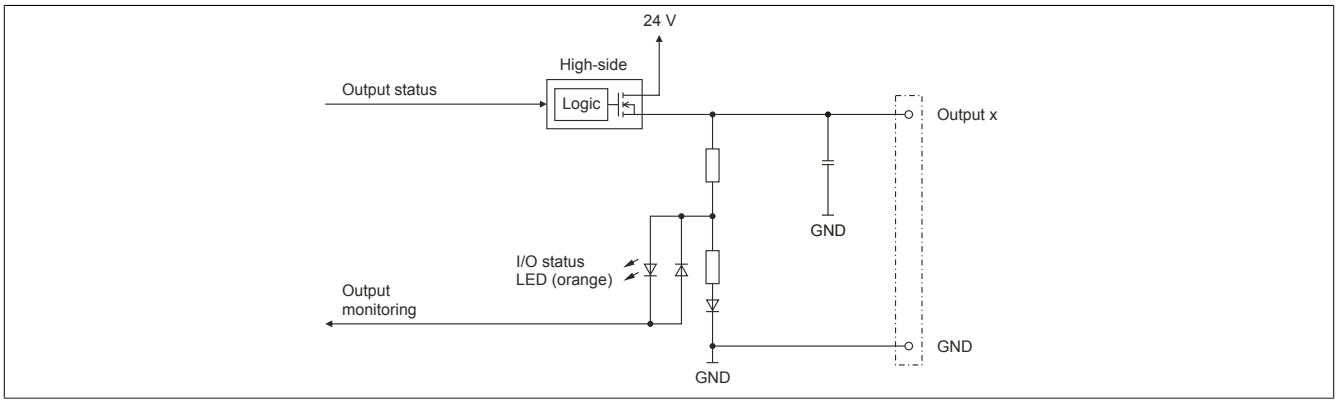


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

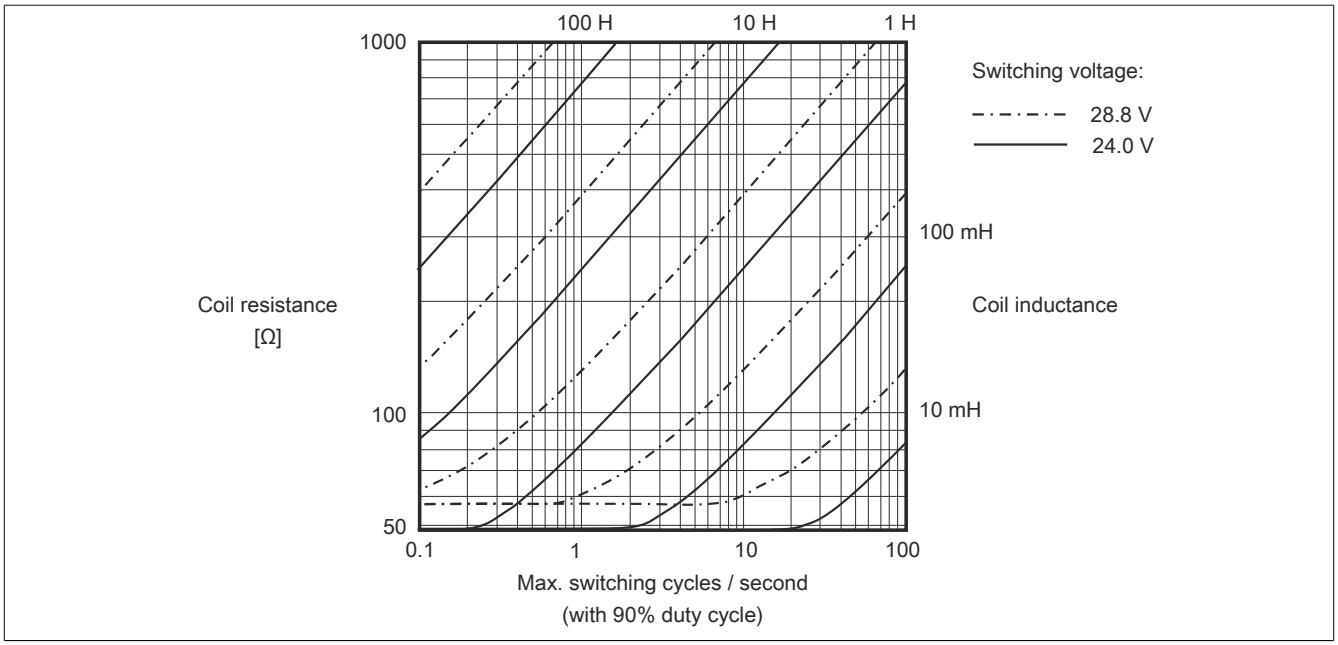
Therefore sufficient cable cross sections or external safety measures must be used.

4.15.29.7 Output circuit diagram



4.15.29.8 Switching inductive loads

Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.29.9 Register description

4.15.29.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.29.9.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	DigitalOutput	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	1	StatusDigitalOutput	USINT	•			
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.29.9.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				

1) The offset specifies where the register is within the CAN object.

4.15.29.9.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.15.29.9.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.29.9.4.1 Switching state of digital outputs 1 to 8

Name:
DigitalOutput or
DigitalOutput01 to DigitalOutput08

The switching state of digital outputs 1 to 8 are stored in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput16") or whether these registers should be displayed as an individual UINT data point ("DigitalOutput").

4.15.29.9.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.29.9.5.1 Status of digital outputs 1 to 8

Name:
StatusDigitalOutput or
StatusDigitalOutput01 to StatusDigitalOutput08

The status of digital outputs 1 to 8 is mapped in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
8	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput16") or whether these registers should be displayed as an individual UINT data point ("StatusDigitalOutput").

4.15.29.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.29.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.15.30 X20DOF322

4.15.30.1 General information

The X20DOF322 module is equipped with 16 outputs for 1-wire connections. The X20DOF322 is designed for source output wiring.

- 16 digital outputs
- Source connection
- 1-wire connections
- Integrated output protection

4.15.30.2 Order data

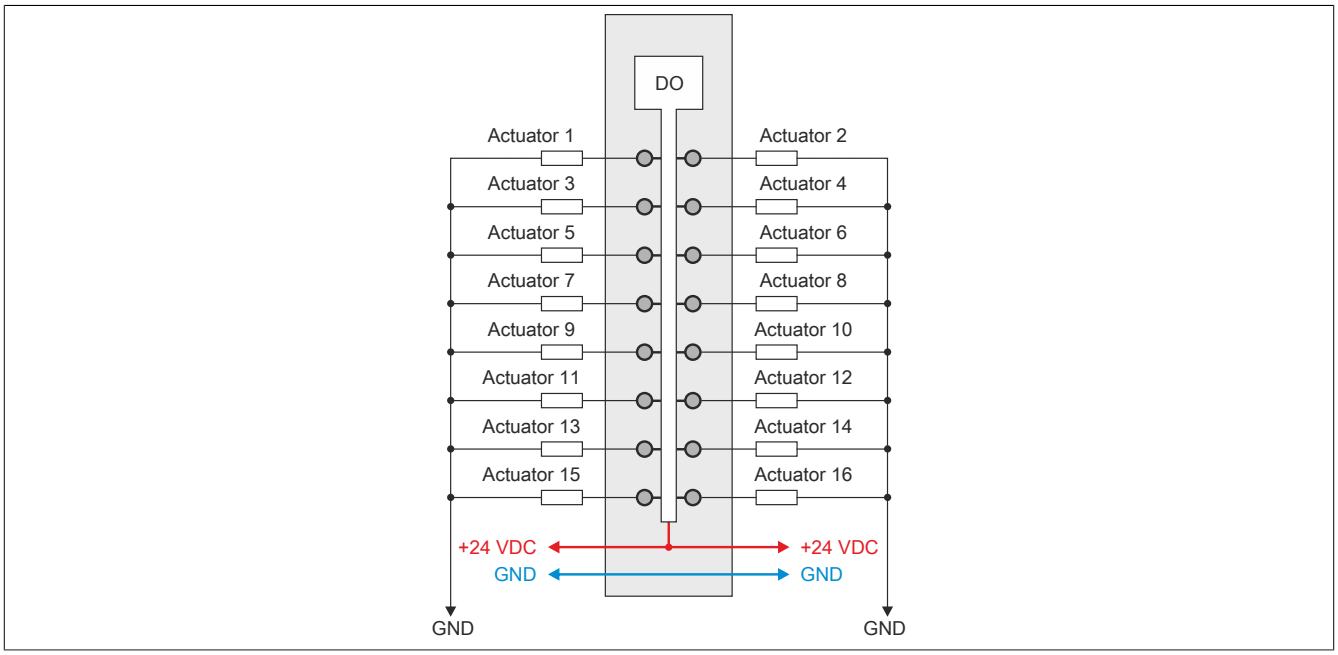
4.15.30.6 Connection example

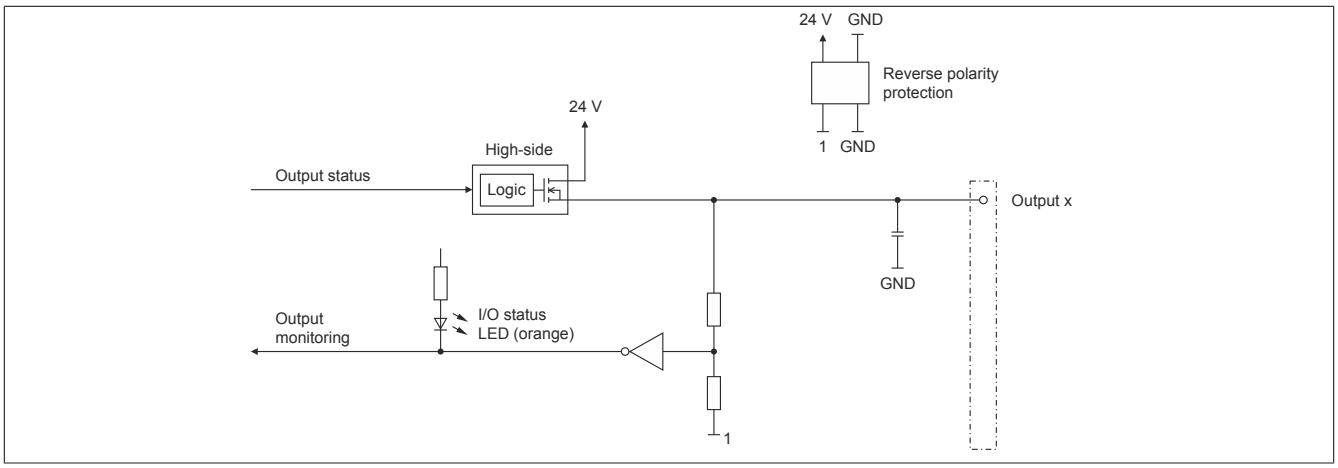


Caution!

If the module is operated outside of specifications, the output current can increase above the maximum permissible nominal current. This applies to individual channels and also to the summation current for the module.

Therefore sufficient cable cross sections or external safety measures must be used.

4.15.30.7 Output circuit diagram



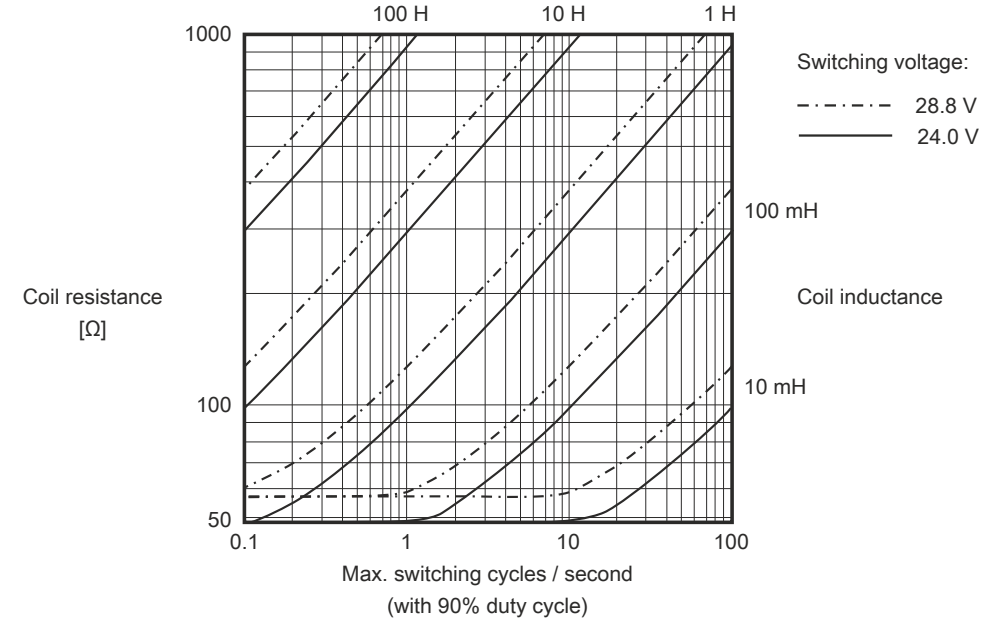
4.15.30.8 Derating

There is no derating when operated below 55°C.

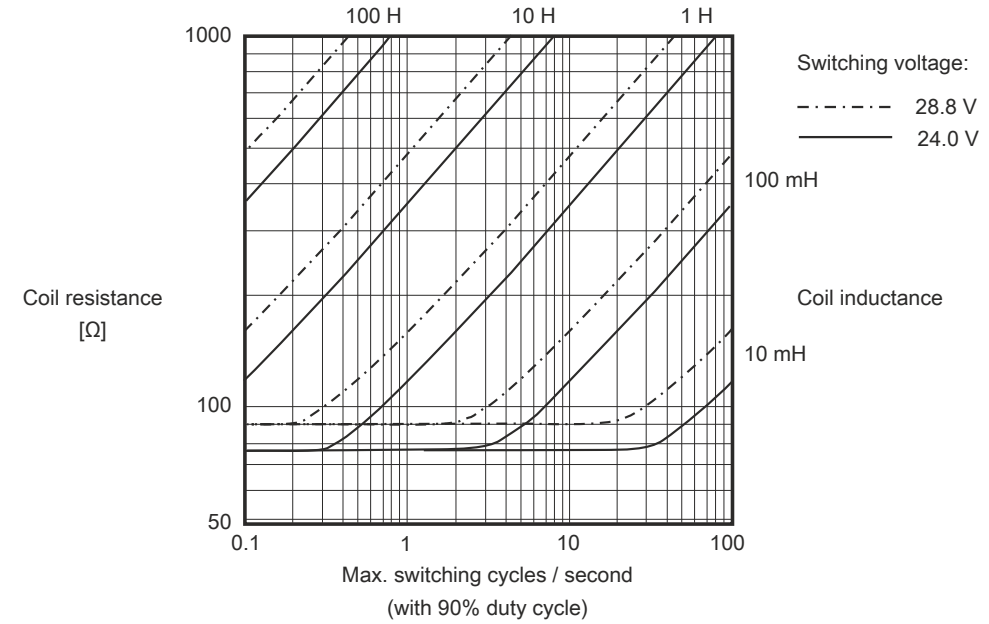
When operated at temperatures above 55°C, the maximal total current per channel is limited to 0,35 A

4.15.30.9 Switching inductive loads

Environmental temperature: 55°C, all outputs with the same load



Environmental temperature: 60°C, all outputs with the same load



Information:

If the maximum number of operating cycles per second is exceeded, an external inverse diode must be used.

Operating conditions outside of the area in the diagram are not permitted!

4.15.30.10 Register description

4.15.30.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.15.30.10.2 Function model 0 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
	0	DigitalOutput	UINT			•	
2	0	Switching state of digital outputs 1 to 8	USINT				
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 16	USINT				
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput16	Bit 7				
	2	StatusDigitalOutput	UINT		•		
30	2	Status of digital outputs 1 to 8	USINT				
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	3	Status of digital outputs 9 to 16	USINT				
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput16	Bit 7				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Acyclic access continues to be based on the register numbers.

4.15.30.10.3 Function model 254 - Bus Controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
2	0	Switching state of digital outputs 1 to 8	USINT			•	
		DigitalOutput01	Bit 0				
		...	...				
		DigitalOutput08	Bit 7				
3	1	Switching state of digital outputs 9 to 16	USINT				
		DigitalOutput09	Bit 0				
		...	...				
		DigitalOutput16	Bit 7				
30	-	Status of digital outputs 1 to 8	USINT		•		
		StatusDigitalOutput01	Bit 0				
		...	...				
		StatusDigitalOutput08	Bit 7				
31	-	Status of digital outputs 9 to 16	USINT				
		StatusDigitalOutput09	Bit 0				
		...	...				
		StatusDigitalOutput16	Bit 7				

1) The offset specifies where the register is within the CAN object.

4.15.30.10.3.1 CAN I/O bus controller

The module occupies 2 digital logical slots on CAN-I/O.

4.15.30.10.4 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.15.30.10.4.1 Switching state of digital outputs 1 to 16

Name:
DigitalOutput or
DigitalOutput01 to DigitalOutput16

The switching state of digital outputs 1 to 16 are stored in this register.

Data type	Value
UINT	Packed "DigitalOutput" values
USINT	See bit structure

Bit structure:

Register 2, Offset 0:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
...		...	
7	DigitalOutput08	0	Digital output 08 reset
		1	Digital output 08 set

Register 3, Offset 1:

Bit	Name	Value	Information
0	DigitalOutput09	0	Digital output 09 reset
		1	Digital output 09 set
...		...	
7	DigitalOutput16	0	Digital output 16 reset
		1	Digital output 16 set

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("DigitalOutput01" through "DigitalOutput16") or whether these registers should be displayed as an individual UINT data point ("DigitalOutput").

4.15.30.10.5 Monitoring status of the digital outputs

On the module, the output states of the outputs are compared to the setpoint states. The control of the output driver is used for the setpoint states.

A change in the output state resets monitoring for that output. The status of each individual channel can be read. A change in the monitoring status generates an error message.

4.15.30.10.5.1 Status of digital outputs 1 to 16

Name:
StatusDigitalOutput or
StatusDigitalOutput01 to StatusDigitalOutput16

The status of digital outputs 1 to 16 is mapped in this register.

Data type	Value
UINT	Packed "StatusDigitalOutput" values
USINT	See bit structure

Bit structure:

Register 30, Offset 1:

Bit	Name	Value	Description
0	StatusDigitalOutput01	0	Channel 01: No error
		1	Channel 01: Short circuit or overload
...		...	
7	StatusDigitalOutput08	0	Channel 08: No error
		1	Channel 08: Short circuit or overload

Register 31, Offset 2:

Bit	Name	Value	Information
0	StatusDigitalOutput09	0	Channel 09: No error
		1	Channel 09: Short circuit or overload
...		...	
7	StatusDigitalOutput16	0	Channel 16: No error
		1	Channel 16: Short circuit or overload

The "packed outputs" setting in the AS I/O configuration is used to determine whether all of these registers' bits should be set up individually as data points in the AS I/O mapping ("StatusDigitalOutput01" through "StatusDigitalOutput16") or whether these registers should be displayed as an individual UINT data point ("StatusDigitalOutput").

4.15.30.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.15.30.10.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
Equal to the minimum cycle time

4.16 Digital signal processing modules

The highly flexible digital signal processor modules can be implemented for a wide range of tasks involving the creation or processing of digital signals.

4.16.1 Brief information

Product ID	Short description	on page
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic	1603
X20DC1073	X20 digital counter module, 1x SinCos, 1 Vss, 400 kHz input frequency, encoder monitoring, NetTime module	1623
X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module	1637
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module	1678
X20DS1828	X20 digital signal module, 1 HIPERFACE interface, NetTime module	1720
X20DS1928	X20 digital signal module, 1 EnDat 2.1/2.2 interface, NetTime module	1780
X20DS4389	X20 digital signal module, 4 digital inputs, 24 VDC, 4 digital outputs, 24 VDC, 0.1 A, oversampling I/O functions, time-triggered I/O functions, NetTime module	1833
X20cDS1119	X20 multifunctional digital signal processor, coated, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module	1637

4.16.2 X20CM1201

4.16.2.1 General information

The module can be used to configure and carry out simple movements. For this purpose, the module has one AB encoder input and a total of 8 digital channels. Four of them are inputs, and the other 4 can be set as either an input or an output. Various output bit patterns are stored directly in the module.

The module is perfectly suited for easy to create drive control tasks for program and event controlled motor movements. Feed movements using drives with 2 speeds and forward/reverse movement are created easily and efficiently.

- Command-dependent digital pattern output
- Counter-dependent output circuit
- Event-controlled abort criteria
- 4 digital inputs
- 4 digital channels, configurable as inputs or outputs

4.16.2.2 Order data

Model number	Short description	Figure
	Digital signal processing and preparation

	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 353: X20CM1201 - Order data

4.16.2.3 Technical data

Product ID	X20CM1201
Short description	
I/O module	1 AB incremental encoder, 24 V, 4 digital inputs, 4 channels configurable as inputs or outputs
General information	
Input voltage	24 VDC -15 % / +20 %
B&R ID code	0x21EF
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Outputs	Yes, using the status LED and software (output error status)
Power consumption	
Bus	0.01 W
Internal I/O	1.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines.
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Digital inputs	
Quantity	4 + 4 additional channels, configurable as inputs or outputs
Nominal voltage	24 VDC
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Approx. 1.3 mA
Input filter	
Hardware	≤2 µs
Software	-
Connection type	1-wire connections
Input circuit	Sink
Input resistance	18.4 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
AB incremental encoder	
Quantity	1
Encoder inputs	24 V, asymmetrical
Counter size	32-bit
Input frequency	Max. 100 kHz
Evaluation	4x
Encoder supply	Module-internal, max. 600 mA
Overload behavior of the encoder supply	Short circuit protection, overload protection
Digital outputs	
Design	Push / Pull / Push-Pull
Quantity	Up to 4, configurable as inputs or outputs using software
Nominal voltage	24 VDC
Switching voltage	24 VDC -15 % / +20 %
Nominal output current	0.1 A
Total nominal current	0.4 A
Connection type	1-wire connections
Output circuit	Sink or source
Output protection	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
Actuator supply	Module-internal, max. 600 mA
Diagnostic status	Output monitoring
Leakage current when switched off	Max. 25 µA
Residual voltage	<0.9 V at 0.1 A rated current
Peak short circuit current	<10 A
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Switching delay	
0 -> 1	<2 µs
1 -> 0	<2 µs
Switching frequency	
Resistive load	Max. 24 kHz
Inductive load	See section "Switching inductive loads" (at 90% duty cycle).
Braking voltage when switching off inductive loads	Switching voltage + 0.6 VDC

Table 354: X20CM1201 - Technical data

Product ID	X20CM1201
Isolation voltage between channel and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5$^{+0.2}$ mm

Ta max.: See environmental conditions

4.16.2.4 LED status indicators

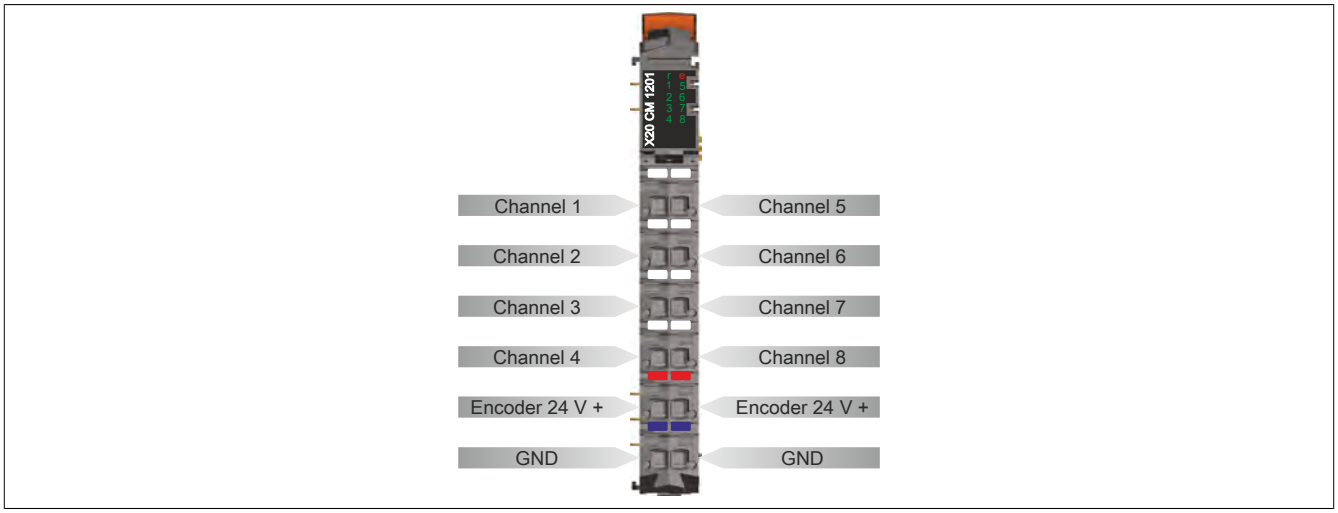
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	1 - 8	Green		Status of the corresponding digital signal

1) Depending on the configuration, a firmware update can take up to several minutes.

4.16.2.5 Pinout

Shielded cables must be used for all signal lines.



4.16.2.6 Connection example

		PowerSupply01	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.16.2.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.16.2.10.4 General

This is a low-end positioning module that supports 2 speed movements in positive and negative directions. No active position check is performed. The movements are started using a command interface and stopped by the position comparator (target position) or user-defined trigger conditions (input edge/ comparison). Every movement step is time-monitored. Up to 8 movement steps can be linked to form one continuous movement.

Position, input states and timeout periods are checked during each system cycle.

4.16.2.10.4.1 Types of movement

The module supports the following types of movement:

- Negative direction - fast
- Negative direction - slow
- Stop
- Positive direction - slow
- Positive direction - fast

The initial state of each type of movement is defined by the user. In order to avoid false input levels on the motor (caused by signal runtimes), and ensure timing (e.g. during direction change), there are additional command parameters to describe a operating mode change:

- 0x93 Negative directional setup state
- 0x88 Negative directional setup time
- 0x8A Negative directional stop time
- 0x95 Positive direction setup state
- 0x89 Positive direction setup time
- 0x8B Positive direction stop time
- 0x94 Stop state

Information:

No directional stop state is defined. To allow error handling, the directional stop state must be the same as STOP. Speed changes in the same direction of movement are not evaluated as changes in the operating mode of the movement.

4.16.2.10.4.2 Movement blocks

The module supports 4 movement blocks: Each movement block contains up to 8 movement steps. Each step is comprised of the following parameters:

- Target position - relative or absolute
- Timeout or delay
- Trigger condition - edge or comparator value (signal level)

A block's movement steps can be executed as one continuous movement. The following parameters must be configured before the movement start command is issued:

- Step activation
- Step target position interpolation - relative or absolute
- Step speed - slow or fast
- Trigger mode - off or "Comparator value = true" or "Comparator value = false"

4.16.2.10.4.3 Movement generator

When a movement start command is issued, the mode of the active movement step is calculated based on the preceding target position. Step parameters may also be changed after the start as long as the step direction is not changed. Otherwise a movement error occurs. To ensure correct directional interpretation, the movement step position/range is limited to ±1073741824.

The target position of a step configured with a trigger is evaluated as the end position (error position). This means the position at the time of the trigger condition becomes the effective target position. Because this position is unknown when the calculation is made by the movement generator, the set end position is used for calculating the next absolute movement step. As a result, it is recommended to proceed with a relative movement step following a triggered step. A successive absolute movement step must be outside the positioning range of the triggered step.

If a movement step is configured as a standstill, i.e. relative position = 0, or the new absolute position = previous target position, a delay has occurred. If no trigger is configured, the parameter step timeout is evaluated as a simple delay time and not as an error state.

4.16.2.10.4.4 Tolerance monitoring

The module constantly monitors the position tolerance, even when no movements are active. Jitter and overshoot tolerances must be configured for both directions. Depending on the previous movement direction, a tolerance window is calculated based on the current target position. Because the movement generator uses the last target position, movements within the tolerance window must be avoided to prevent errors from occurring.

4.16.2.10.4.5 Homing

Homing is not implemented in this module as a movement function. The target position of a completed movement can be applied as the home position via command.

4.16.2.10.4.6 Safety monitoring

A safe input status (masks and comparator values) for positive and negative movements must be configured. Software end positions – minimum and maximum positions – can also be configured for both directions.

The module monitors these two positions from the time the parameter 0x93 or 0x95 "Positive directional setup state" is set. Monitoring is ended when the parameter 0x94 "Stop state" is set.

Because a trigger condition aborts the movement step before a safety check, a hardware limit switch can also be used as a trigger condition without generating an error.

4.16.2.10.5 Command description

4.16.2.10.5.1 No action

This command can be used as a placeholder during development or to separate 2 identical commands.

Code	0x00
Parameter	0
Data 0 to 3	0

4.16.2.10.5.2 Configure display mode

This command can be used to configure how the values in the 4.16.2.10.6.6 "Read parameter number" and 4.16.2.10.6.7 "Read parameter data" registers are displayed. Up to 4 display values can be displayed simultaneously. Possible selections include the command parameters 0xC0 = current position, to 0xC3 = I/O states.

Code	0x01
Parameter	Display control: 0 Scheduler off; Data 0 used for display 1 Scheduler cycle = X2X cycle; The next display cycle starts with each X2X cycle 2 Scheduler cycle = Command cycle; The next display cycle starts with each completed command
Data 0	Parameter number of display cycle 1 (Default: 0xC0 = current position)
...	...
Data 3	Parameter number of display cycle 4 (Default: 0xC0 = current position)

4.16.2.10.5.3 Enables the interface

This command activates the movement interface. The status of the interface is displayed in the 4.16.2.10.6.5 "Read status" register (bit 5). The interface is disabled following a reset. This is necessary to ensure a consistent parameter field.

Code	0x02
Parameter	0
Data 0 to 3	0

4.16.2.10.5.4 Configure parameters

Code	0x03
Parameter	See parameter list

Parameter formats used

DINT value

The possible values depend on the respective command.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Time format

Time in microseconds. System resolution is a result of the system cycle time (default: 50 µs).

Trigger condition

Depending on bits 2 and 3 in the data structure of each movement block, either the "edge" or "comparator value" structure is selected as the trigger condition.

Edge

Bit	Description	Value	Information
0	Falling edge - channel 01	0	Disabled
		1	Enabled
...		...	
7	Falling edge - channel 08	0	Disabled
		1	Enabled

Safe input states

Bit	Description	Value	Information
0	Activation mask - channel 01	0	Disabled
		1	Enabled
...		...	
7	Activation mask - channel 08	0	Disabled
		1	Enabled
8 - 15	Reserved	0	
15	Comparative state - channel 01	0 or 1	
...			
23	Comparative state - channel 08	0 or 1	
24 - 31	Reserved	0	

Error information

This table shows the read display value. The parameter for the display command is 0.

Bit	Description	Value	Information
0	Tolerance error - negative	0	No error
		1	Error occurred
1	Tolerance error - positive	0	No error
		1	Error occurred
2	Timeout	0	No timeout
		1	Timeout
3 - 7	Reserved	0	
8	Safety monitoring error Inputs (hardwire limit switch)	0	No error
		1	Error occurred
9	Safety monitoring error Position (software end position)	0	No error
		1	Error occurred
10 - 15	Reserved	0	
16 - 18	Error status information	000	Reserved
		001	Negative directional stop state
		010	Negative movement
		011	Negative directional setup state
		100	Stop state
		101	Positive directional setup state
		110	Positive movement
		111	Positive directional stop state
19	Reserved	0	
20 - 24	Invalid step number	000 to 111	Number of the step that does not contain any movement information.
		1000	Inactive movement step (tolerance check)
25 - 31	Reserved	0	

I/O states

This table shows the read display value. The parameter for the display command is 0.

Bit	Description	Value	Information
0	Input state - channel 01	0 or 1	
...		...	
7	Input state - channel 08	0 or 1	
8 - 16	Reserved	0	
17	Output state - channel 02	0 or 1	
18	Reserved	0	
19	Output state - channel 04	0 or 1	
20	Reserved	0	
21	Output state - channel 06	0 or 1	
22	Reserved	0	
23	Output state - channel 08	0 or 1	
24 - 31	Reserved	0	

4.16.2.10.5.5 Configure counters

This command can be used to assign the hardware channels to the AB counter. With an ABR counter, the R input can be connected to any hardware channel as the trigger signal.

Code	0x04
Parameter	See parameter structure
Data 0	See data structure
Data 1 to 3	0

Parameter structure:

Bit	Description	Value	Information
0 - 1	Counter connection pair	00	Pair 1 (A: channel 01, B: channel 02)
		01	Pair 2 (A: channel 03, B: channel 04)
		10	Pair 3 (A: channel 05, B: channel 06)
		11	Pair 4 (A: channel 07, B: channel 08)
2 - 7	Reserved	0	

Data structure:

Bit	Description	Value	Information
0 - 1	Counter mode	00	AB encoder
		01	Up/down counter (A: timing, B: up/down signal)
		10	Edge counter - channel A
		11	Edge counter - channel B
2	Counting direction	0	Positive
		1	Negative
3 - 7	Reserved	0	

4.16.2.10.5.6 Homing

Assumes the target position of the last successful movement step as a reference position.

Code	0x05
Parameter	0
Data 0 to 3	Home position

4.16.2.10.5.7 Stops the movement.

The movement step in progress is stopped. This command always results in a movement error.

Code	0x06
Parameter	0
Data 0 to 3	0

4.16.2.10.5.8 Acknowledge movement error

The movement error is is cleared. If this command is executed when the error is still present, the current position is assumed as the target position. The basis of the relative position becomes unclear.

Code	0x07
Parameter	0
Data 0 to 3	0

4.16.2.10.5.9 Start a movement block

This command starts a movement block consisting of up to 8 steps.

Code	0x08 (Block 1) 0x09 (Block 2) 0x0A (Block 3) 0x0B (Block 4)
Parameter	See parameter structure
Data 0 to 3	See data structure

Parameter structure:

Bit	Description	Value	Information
0	Step 1	0	No movement.
		1	Perform movement step.
...		...	
7	Step 8	0	No movement.
		1	Perform movement step.

Data structure:

Bit	Description	Value	Information
0	Step 1 position setting:	0	Relative
		1	Absolute
1	Step 1 speed:	0	Slow
		1	Fast
2 - 3	Step 1 trigger mode:	00	No trigger
		01	Edge trigger
		10	Comparator value "true"
		11	Comparator value "false"
4 - 7	Step 2	x	Like step 1 / Bits 0 to 2
...			
28 - 31	Step 8	x	Like step 1 / Bits 0 to 2

4.16.2.10.5.10 Selecting the debug information

At the end of each movement step, the command parameter "Addr + 3" (see 4.16.2.10.5.4 "Movement blocks - Calculating the address" can be used to read the debug information selected in this register. This debug information is shown in the 4.16.2.10.6.6 "Read parameter number" and 4.16.2.10.6.7 "Read parameter data" registers.

Code	0x00
Parameter	0 Error information (default) 1 Timestamp 2 Current position 3 Target position
Data 0 to 3	0

4.16.2.10.6 Command interface

A command interface is available to the user. A command consists of:

- 4.16.2.10.6.2 "Command" (in the command description: code)
- 4.16.2.10.6.3 "Command parameter" (in the command description: parameters)
- 4.16.2.10.6.4 "Command data" (in the command description: Data 0 to 3)

The following commands can be executed:

- 4.16.2.10.5.1 "No action"
- 4.16.2.10.5.2 "Configure display mode"
- 4.16.2.10.5.3 "Enable the interface"
- 4.16.2.10.5.4 "Configure parameters"
- 4.16.2.10.5.5 "Configure counters"
- 4.16.2.10.5.6 "Perform homing"
- 4.16.2.10.5.7 "Stop the movement"
- 4.16.2.10.5.8 "Acknowledge movement error"
- 4.16.2.10.5.9 "Start a movement block"
- 4.16.2.10.5.10 "Select debug information"

The module returns:

- 4.16.2.10.6.5 "System status"
- 4.16.2.10.6.6 "Displays parameter number"
- 4.16.2.10.6.7 "Displays data content"

The module detects a new command through a change in the command register. The toggle bit must be changed in order to detect when the command issued in the 4.16.2.10.6.5 "System status" register is applied. Identical commands can be executed immediately following one another simply by changing the toggle bit.

4.16.2.10.6.1 Execution of a command

Commands must be sent by the application using the command interface. Due to the simple structure of the command interface, it is also possible to send them via CAN.

All commands are executed as follows:

1 Write command parameters and command data to the respective register.
2 Write command with changed toggle bit.
When bit 7 in the command register is toggled, the module executes the comand with the command parameters and command data.
3 Wait until bit 7 in the response register (System Status) matches bit 7 in the command register.
4 Read additional status information from the response register if necessary.
5 If additional commands should be sent, proceed with step 1.

4.16.2.10.6.2 Send command

Name:
SendCommand

The commands described under 4.16.2.10.5 "Command description" can be sent from this register. Bit 7 must be toggled to apply the commands.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 6	Command code	x	
7	Toggle bit for applying a new command	x	

4.16.2.10.6.3 Send command parameters

Name:
SendCommandParam

Specific parameters for the command to be sent must be entered in this register. The required parameters are listed under 4.16.2.10.5 "Command description" for the respective commands.

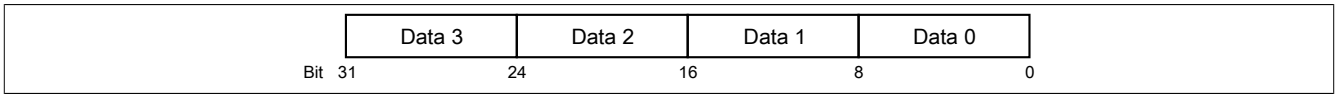
Data type	Value	Information
USINT	x	Command parameter

4.16.2.10.6.4 Send command data

Name:
SendData

Specific parameters for the command to be sent must be entered in this register. The required data is listed under 4.16.2.10.5 "Command description" for the respective commands.

Data 0 to 3 are sent as a single DINT value. The following structure is used:



Data type	Value	Information
DINT	x	Command data 0 to 3

4.16.2.10.6.5 Read status

Name:
ReadStatus

The commands and the current status can be checked in this register. Bit 7 can be used to check whether an issued command has been applied.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	0	
2	Position	0	Not yet reached
		1	Reached
3	Motion	0	In motion
		1	completed
4	Numerator	0	Not yet configured
		1	Configured
5	Interface	0	Not enabled
		1	Enabled
6	Command	0	No error
		1	Error occurred
7	Command toggle bit	x	Value that was read

4.16.2.10.6.6 Read parameter number

Name:
ReadIndex

The parameter number returned for a display command is shown in this register. See 4.16.2.10.5.2 "Configure display mode" and 4.16.2.10.5.10 "Selecting the debug information"

Data type	Value	Information
USINT	x	Parameter numbers

4.16.2.10.6.7 Read parameter data

Name:
ReadData

The parameter data returned for a display command is shown in this register. See 4.16.2.10.5.2 "Configure display mode" and 4.16.2.10.5.10 "Selecting the debug information"

Data type	Value	Information
DINT	x	Parameter data

4.16.2.10.6.8 Special display parameters

The following 4 registers correspond to display parameters 0xC0 to 0xC3 in the command description 4.16.2.10.5.4 "Configure parameters". This frees up the 4.16.2.10.6.7 "ReadData" register for other data.

Indicates the current position.

Name:
ABRPosition

This register shows the current position in the current step. It corresponds with the parameter 0xC0 in section 4.16.2.10.5.4 "Configure parameters".

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Indicates the current target position

Name:
TargetABRposition

This register shows the target position of the current step. It corresponds with the parameter 0xC1 in section 4.16.2.10.5.4 "Configure parameters".

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Displays the error information

Name:
ErrorInfo

The error information is shown in this register. It corresponds with the parameter 0xC2 in section 4.16.2.10.5.4 "Configure parameters".

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Tolerance error - negative	0	No error
		1	Error occurred
1	Tolerance error - positive	0	No error
		1	Error occurred
2	Timeout	0	No timeout
		1	Timeout
3 - 7	Reserved	0	
8	Safety monitoring error Inputs (hardwire limit switch)	0	No error
		1	Error occurred
9	Safety monitoring error Position (software end position)	0	No error
		1	Error occurred
10 - 15	Reserved	0	
16 - 18	Error status information	000	Reserved
		001	Negative directional stop state
		010	Negative movement
		011	Negative directional setup state
		100	Stop state
		101	Positive directional setup state
		110	Positive movement
		111	Positive directional stop state
19	Reserved	0	
20 - 24	Invalid step number	000 to 111	Number of the step that does not contain any movement information.
		1000	Inactive movement step (tolerance check)
25 - 31	Reserved	0	

Status of the digital inputs

Name:
DigitalInput01 to DigitalInput08

The status of the digital inputs or read outputs are shown in this register. It corresponds with the parameter 0xC3 in section 4.16.2.10.5.4 "Configure parameters".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalInput01	0 or 1	Input status - channel 1
...		...	
7	DigitalInput08	0 or 1	Input status - channel 8

4.16.2.10.7 Sample configurations

4.16.2.10.7.1 Movement example

The channels have been set as follows for this example:

Hardware channel	Direction	Function assignment
1	Input	ABR encoder - signal A
2	Input	ABR encoder - signal B
3	Input	ABR encoder - signal R
4	Output	Fast speed
5	Input	Negative limit switch
6	Output	Negative direction
7	Input	Positive limit switch
8	Output	Positive direction

Enable interface

	Value	Description
Code	0x02	
Parameter	0	
Data 0 to 3	0	

Configure parameters

	Value
Code	0x03
Parameter	Parameter numbers
Data 0 to 3	Parameter data

The following parameters must be configured:

Parameter	Data	Description
0x80	APPL	Negative jitter tolerance [µs] (application-specific)
0x81	APPL	Positive jitter tolerance [µs] (application-specific)
0x82	APPL	Negative overshoot tolerance [µs] (application-specific)
0x83	APPL	Positive overshoot tolerance [µs] (application-specific)
0x88	APPL	Negative setup time [µs] (application-specific)
0x89	APPL	Positive setup time [µs] (application-specific)
0x8A	APPL	Negative stop time [µs] (application-specific)
0x8B	APPL	Positive stop time [µs] (application-specific)
0x90	0x0000CCC0	Output configuration: Channel 04, channel 06, channel 08 as push/pull outputs
0x91	0x00280080	Output states - fast negative movement: Set channels 04 and 06, clear channel 08
0x92	0x00200088	Output states - slow negative movement: Set channel 06, clear channels 04 and 08
0x93	0x000000A8	Output states - negative setup: Clear channels 04, 06 and 08
0x94	0x000000A8	Output states - stop: Clear channels 04, 06 and 08
0x95	0x000000A8	Output states - positive setup: Clear channels 04, 06 and 08
0x96	0x00800028	Output states - slow positive movement: Set channel 08, clear channels 04 and 06
0x97	0x00880020	Output states - fast positive movement: Set channels 04 and 08, clear channel 06
0x98	0x00100010	Safe input state - negative: Channel 05 active, status of channel 05 (level) = 1
0x99	0x00400040	Safe input state - positive: Channel 07 active, status of channel 05 (level) = 1 Code 0x04

Configure counters

	Value	Description
Code	0x04	
Parameter	0x00	Counter pair 1
Data 0	0	AB encoder, positive direction
Data 1 to 3	0	

4.16.2.10.7.2 Homing example

Configure parameters

	Value
Code	0x03
Parameter	Parameter numbers
Data 0 to 3	Parameter data

The following parameters must be configured:

Parameter	Data	Description
0x00	0x3FFFFFFF	Relative positive position maximum
0x02	0x00000040	Trigger on input state of channel 07 = 0
0x04	0xC0000001	Relative negative position maximum
0x06	0x00400040	Trigger on input state of channel 07 == 1
0x08	0xC0000001	Relative negative position maximum
0x0A	0x00000004	Trigger on falling edge of channel 03

Start movement

	Value	Description
Code	0x08	Block 1
Parameter	0x07	Activate steps 1 to 3
Data 0 to 3	0x00000**411**	Step 1: absolute, slow, trigger off Step 2: absolute, slow, trigger off Step 3: relative, slow, trigger on edge

Wait until the movement is complete.

Homing

	Value	Description
Code	0x05	
Parameter	0	
Data 0 to 3	x	Home position

4.16.2.10.7.3 Standard positioning example

Configure parameters

	Value
Code	0x03
Parameter	Parameter numbers
Data 0 to 3	Parameter data

The following parameters must be configured:

Parameter	Data	Description
0x00	X1	Pre-stop position
0x04	X2	Stop position

Start movement

	Value	Description
Code	0x08	Block 1
Parameter	0x03	Activate steps 1 and 2
Data 0 to 3	0x0000000**11**	Step 1: absolute, slow, trigger off Step 2: absolute, slow, trigger off

4.16.2.10.7.4 Standard positioning example with stop

Configure parameters

	Value
Code	0x03
Parameter	Parameter numbers
Data 0 to 3	Parameter data

The following parameters must be configured:

Parameter	Data	Description
0x00	X1	Pre-stop position
0x04	X2	Stop position
0x08	0	Relative movement
0x09	T_STOP	Stop delay [µs]

Start movement

	Value	Description
Code	0x08	Block 1
Parameter	0x07	Activate steps 1 to 3
Data 0 to 3	0x00000**011**	Step 1: absolute, slow, trigger off Step 2: absolute, slow, trigger off Step 3: relative, trigger off

4.16.2.10.8 General module register

4.16.2.10.8.1 Configures the system cycle time

Name:
CycleTimeCff

This register configures the module's system cycle time.

Data type	Value	Information
UINT	25 to 255	System cycle time in µs (default = 50 µs)

4.16.2.10.8.2 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.16.2.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.16.2.10.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.16.3 X20DC1073

4.16.3.1 General information

The module is equipped with a SinCos encoder interface. The input signals are monitored. This makes it possible to detect open or shorted lines as well as encoder supply failures.

- SinCos encoder interface
- Encoder input monitoring
- 5 VDC and GND for encoder supply
- NetTime function: Timestamp for position

SinCos encoders

SinCos encoders with 1 V_{ss} are mostly used in linear drives and systems with high-resolution optical or magnetic position measurement systems. The module can process input signals with a frequency of up to 400 kHz.

NetTime position timestamp

Highly dynamic positioning tasks require not only the position value, but also the exact time at which the position was determined. The module has a NetTime function for this, which adds a timestamp to the recorded position with microsecond accuracy.

The module provides the PLC with the position value and timestamp as absolute time value. The NetTime mechanisms ensure that the PLC NetTime clock and the local NetTime clock on the module have exactly the same absolute time at all times.

4.16.3.2 Order data

Model number	Short description	Figure
	Digital signal processing and preparation	
X20DC1073	X20 digital counter module, 1x SinCos, 1 Vss, 400 kHz input frequency, encoder monitoring, NetTime module

4.16.3.3 Technical data

Product ID	X20DC1073
Short description	
I/O module	1x SinCos input
General information	
B&R ID code	0xAEC6
Status indicators	Counting direction, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Counting direction	Yes, using status LED
Power consumption	
Bus	0.01 W
Internal I/O	1.3 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GOST-R	Yes
Encoder inputs	
Type	SinCos
Angular position resolution	13-bit, with a 1 V_{SS} signal
Encoder monitoring	Yes
Max. encoder cable length	Max. 20 m, see "Calculation of the maximum encoder cable length"
Sine/Cosine inputs	
Signal transmission	Differential signals, symmetrical
Signal frequency	DC up to 400 kHz
Differential voltage	1 V_{SS}
Common-mode voltage	Max. ±10 V
Terminating resistor	120 Ω
Encoder supply	
Output voltage	5 V
Min. output voltage at 300 mA	4.86 V
Load capability	300 mA
Protective measures	
Overload protection	Yes
Short circuit protection	Yes
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.16.3.4 LED status indicators

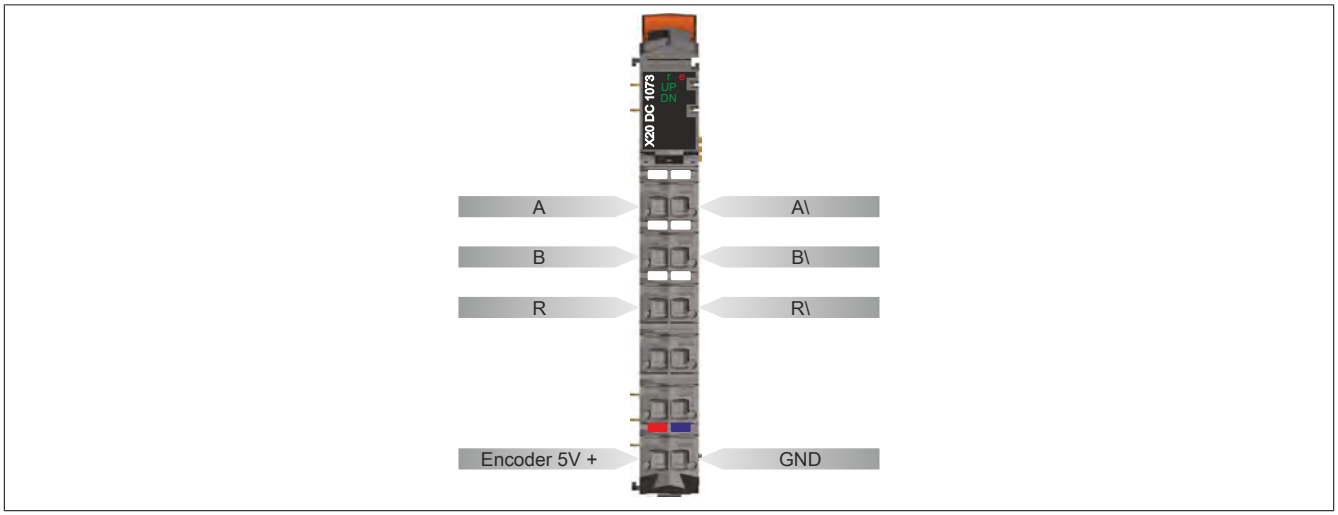
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset state. Possible cause: • Encoder supply error
			Single flash	I/O error. Possible cause: • Sine/Cosine relative position error (open line)
			Single flash, inverted	Error or reset state and I/O error
	UP	Green	On	The "UP/DN" LEDs are lit depending on the rotational direction and the speed of the connected encoder. The "UP" LED indicates when the encoder position changes in the positive direction.
	DN	Green	On	The "DN" LED indicates when the encoder position changes in the negative direction.

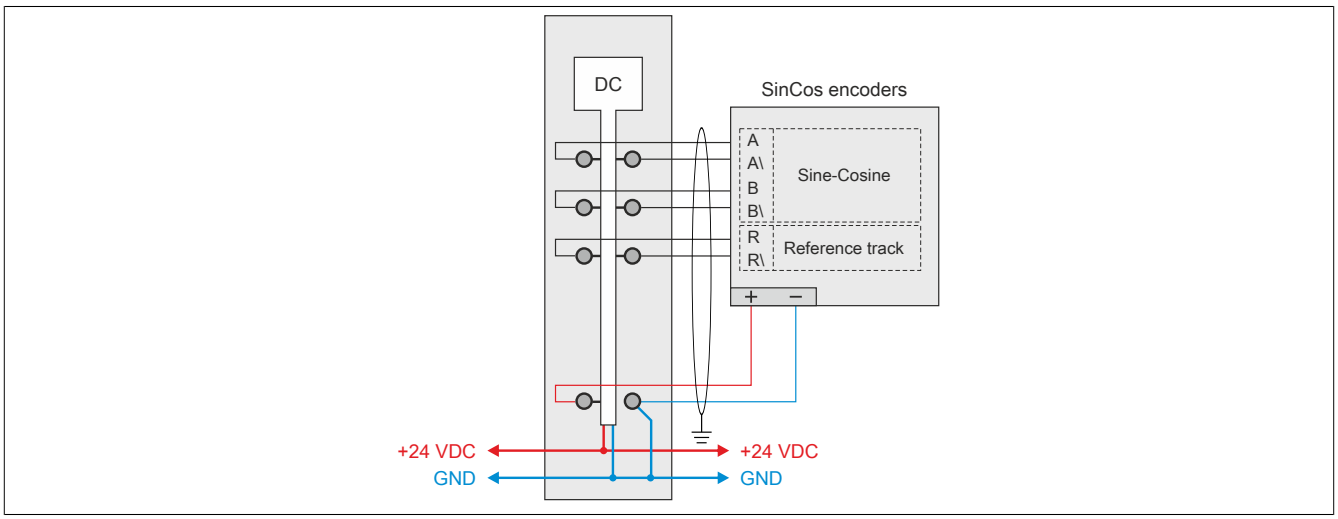
1) Depending on the configuration, a firmware update can take up to several minutes.

4.16.3.5 Pinout

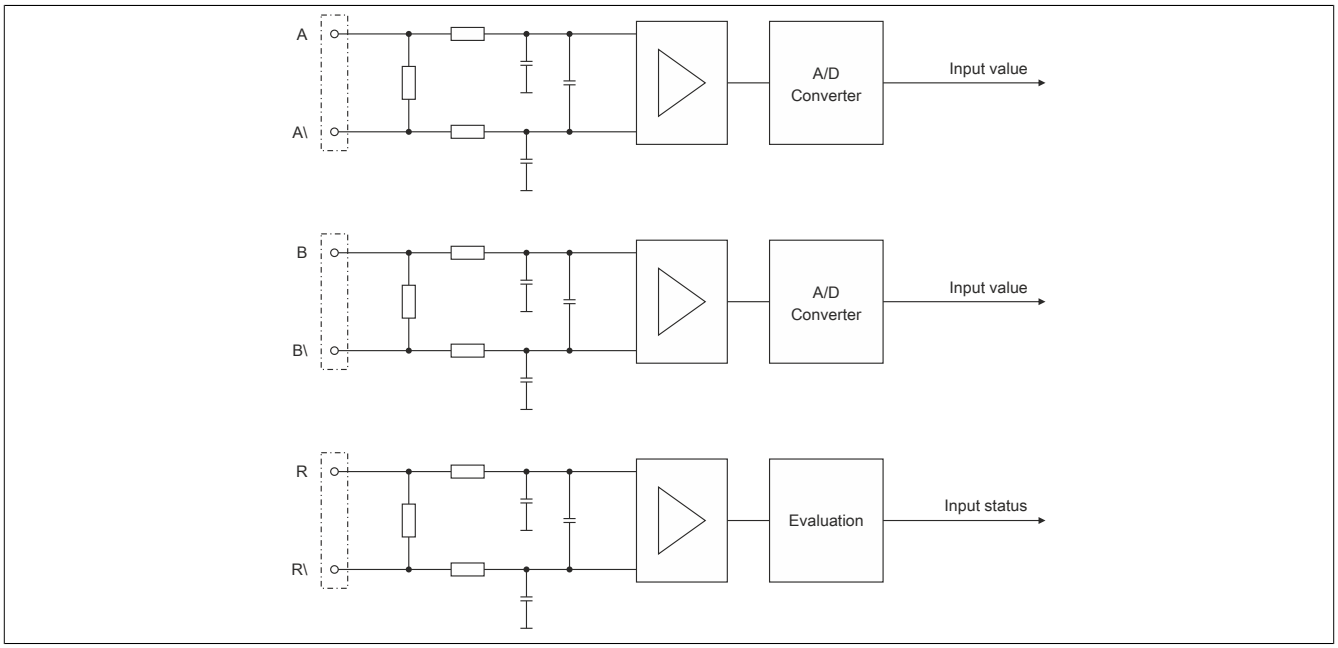
Shielded cables must be used for all signal lines.



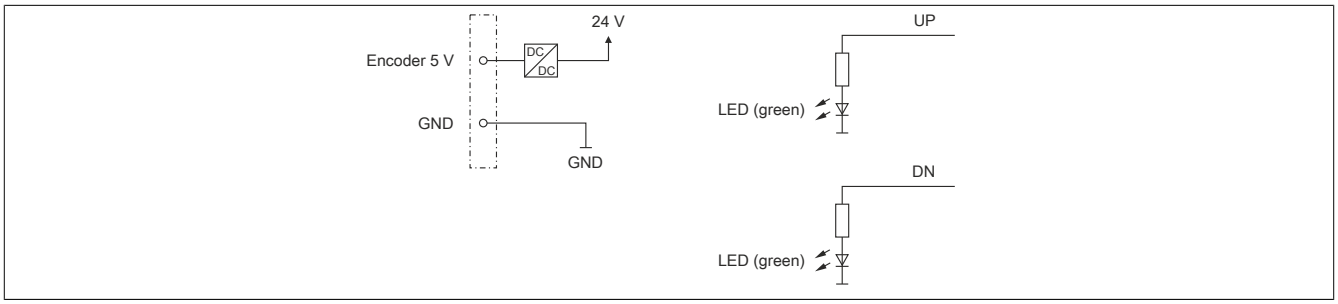
4.16.3.6 Connection example



4.16.3.7 Analog inputs - Input circuit diagram



4.16.3.8 Circuit diagram for the encoder supply and LEDs



4.16.3.9 Calculating the maximum encoder cable length

The following encoder data is assumed for this sample calculation:

Encoder data	
Input voltage	4.75 V – 5.25 V
Max. input current	0.12 A
Module encoder output	
Min. output voltage at 300 mA	4.86 V

Calculation of the maximum voltage drop for the cable

The maximum permitted voltage drop is calculated using the minimum encoder output voltage for the module ($U_{ModuleMin}$) and the minimum encoder input voltage ($U_{EncoderMin}$) of the encoder being used.

$$U_{CableMax} = (U_{ModuleMin} - U_{EncoderMin}) / 2$$

Example: $U_{CableMax} = (4.86\ V - 4.75\ V) / 2 = 0.055\ V$

Calculation of the maximum cable length

$$\text{Cable length}_{Max} = U_{CableMax} * \text{Wire cross section } (mm^2) / (0.01786 * I_{Encoder})$$

This means:

$I_{Encoder}$ Current consumption of encoder in amps

$U_{CableMax}$ Maximum permitted voltage drop in volts

Example with resolver cable "8BCR0xxxx.1111A-0"

Encoder with 120 mA max. current consumption

Resolver cable cross section = 0.25 mm^2

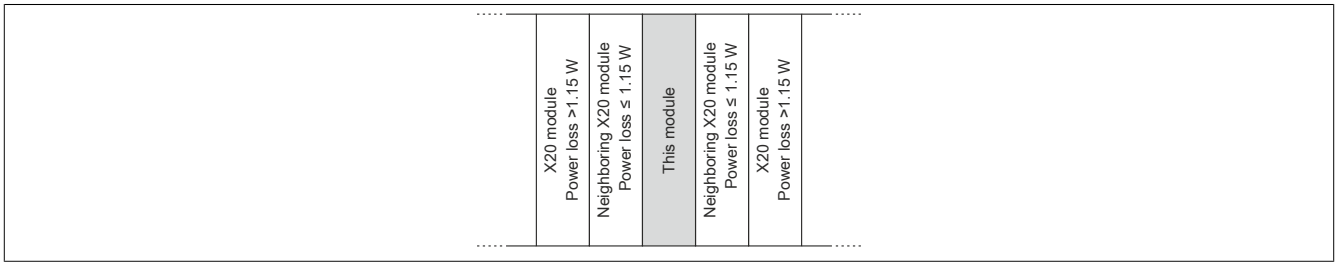
Results in a total cable length of:

$$\text{Cable length}_{Max} = 0.055\ V * 0.25\ mm^2 / 0.01786 * 0.12\ A) = 6.41\ m$$

4.16.3.10 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.16.3.11 Register description

4.16.3.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.16.3.11.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Module configuration

1) The offset specifies the position of the register within the CAN object.

4.16.3.11.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.16.3.11.4 Module configuration

The following configuration register can be used to configure different module settings. They can be used, for example, to modify the module's behavior on an X2X Link network. One configuration register is available for the user.

4.16.3.11.4.1 Data query

Name:
CfO_SIframeGenID

This register can be used to define when the synchronous/cyclic input data is generated. "X2X cycle optimized" should be set for jitter-free data acquisition. "Fast reaction" can be set for the best performance.

Data type	Value	Information
USINT	9	Fast reaction
	14	X2X cycle optimized (bus controller default setting)

4.16.3.11.5 Basic functions

This module can import the position of a motor shaft when used together with a sin/cos encoder. The received position data is prepared in 2 different formats and given a time stamp. 5 registers are available for further processing. This allows the user to select the format that best fits the application at hand.

4.16.3.11.5.1 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.3.11.5.2 Absolute position values

Name:
PositionHW
PositionLW

The absolute position of the encoder is defined using 64-bit resolution. The position value is stored in the PositionHW and PositionLW registers. The upper 32 bits are stored the PositionHW register, while the lower 32 bits are stored in the PositionLW register.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
2x UDINT	0 to 4,294,967,295

4.16.3.11.5.3 SDC position value

Name:
Position

The SDC library requires a signed 32-bit position value. The position's low word can be accessed separately for this. The value can also be used as default position value, however.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.16.3.11.5.4 NetTime of the position values

Name:
PosTime

This register is used to assign each recorded position of the current NetTime value. The NetTime is recorded with µs accuracy.
The SDC library requires a 16 bit value. The NetTime value is therefore also generated in this format.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	NetTime in µs
INT	-32,768 to 32,767	

4.16.3.11.5.5 Counter for position values

Name:
PosCycle

PosCycle is an integer counter that is incremented as soon as the module has saved a new valid position value.

Data type	Value
SINT	-128 to 127

4.16.3.11.6 Error management

Module-based diagnostics

This module can detect errors on its own and differentiates between 2 different types of error.

- **Encoder supply:**
  The encoder voltage supply is below the permitted limit.
- **V_{ss} Sin/Cos:**
  The voltage value for the Sin/Cos track violates the configured limit values.
  → See register 4.16.3.11.7.4 "SinCosVssMin" or 4.16.3.11.7.5 "SinCosVssMax"

4.16.3.11.6.1 Enabling/disabling error messages

Name:
ErrorEnableID_1710
The individual diagnostics can be separately enabled or disabled in this register.

Data type	Value
USINT	See bit structure.

Bit structure

Bit	Name	Value	Information
0	Error detection - Encoder supply	0	Disabled
		1	Enabled (bus controller default setting)
1	Reserved	-	
2	Error detection - V_{ss} Sin/Cos	0	Disabled
		1	Enabled (bus controller default setting)
3 - 7	Reserved	-	

4.16.3.11.6.2 Show error messages

Name:
ErrorStateID_1710

EncoderSupplyError
VssCheckError

This register indicates which error or warning is currently active. For the meaning of individual error messages, see 4.16.3.11.6 "Error management".

Data type	Value
USINT	See bit structure.

Bit structure

Bit	Name	Value	Information
0	EncoderSupplyError	0	No error
		1	Encoder supply error
1	Reserved	-	
2	VssCheckError	0	No error
		1	V_{ss} error on the Sin/Cos track
3 - 7	Reserved	-	

4.16.3.11.6.3 Acknowledge error messages

Name:
ErrorQuitID_1710

AckEncoderSupplyError
AckVssCheckError

This register is used to acknowledge an error message that occurred in the 4.16.3.11.6.2 "Show error messages" register. For the meaning of individual error messages, see 4.16.3.11.6 "Error management".

Data type	Value
USINT	See bit structure.

Bit structure

Bit	Name	Value	Information
0	AckEncoderSupplyError	0	No error acknowledgment
		1	Error acknowledgment
1	Reserved	-	
2	AckVssCheckError	0	No error acknowledgment
		1	Error acknowledgment
3 - 7	Reserved	-	

4.16.3.11.7 Sin/Cos - Analog interface configuration

The module is equipped with an analog interface for detecting a differential sine-, cosine- and reference signal.

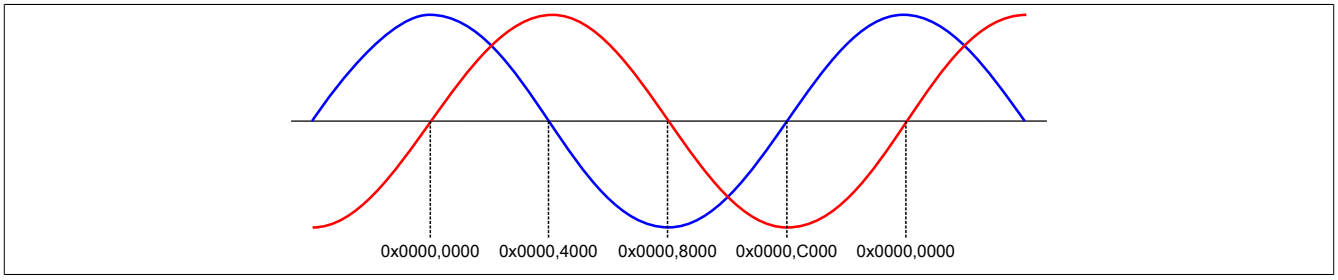
4.16.3.11.7.1 Format of the SinCos signal

The SinCos signal is represented as a position value in the 4.16.3.11.5.2 "Absolute position values" and 4.16.3.11.5.3 "SDC position value" registers. The following relationships apply:

- PositionLW and Position are identical in the function.
- PositionHW extends the integer range of PositionLW by adding multi-turn functionality.

<table>
<tr><td>64-bit register</td><td>PositionHW
(unsigned)</td><td colspan="2">PositionLW
(unsigned)</td></tr>
<tr><td>32-bit register</td><td>-</td><td colspan="2">Position (signed)</td></tr>
<tr><td>Format</td><td>Integer extension
(to 48-bit)</td><td>Integer
(16-bit)</td><td>Decimal places:
(with 13-bit resolution)</td></tr>
<tr><td>Information</td><td></td><td>A full sine wave corresponds to an increment of the integer.</td><td>
<table>
<tr><th>15</th><th>14</th><th>13</th><th>12</th><th>11</th><th>10</th><th>9</th><th>8</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>x</td><td>0</td><td>0</td><td>0</td></tr>
</table>
Important: The lower 3 bits always contain the value 0.
</td></tr>
<tr><td>Word/DWord</td><td>DWord</td><td>Word 1</td><td>Word 0</td></tr>
</table>

Relationship between sine curve (red) and decimal places:



4.16.3.11.7.2 Enabling SinCos

Name:
SinCosEnable

This register must always have the value 1 for configuration reasons.

Data type	Value	Information
USINT	1	Bus controller default: 1

4.16.3.11.7.3 Enabling SinCos reference source

Name:
SinCosRefSource

This register must always have the value 0 for configuration reasons.

Data type	Value	Information
USINT	0	Bus controller default: 0

4.16.3.11.7.4 Configuring the lower Vss value

Name:
SinCosVssMin

This register specifies the lower limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value falls below this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 800

4.16.3.11.7.5 Configuring the upper Vss value

Name:
SinCosVssMax

This register specifies the upper limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value exceeds this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 1200

4.16.3.11.7.6 Configuring the delay time after errors

Name:
SinCosQuitTime

If an error is detected on the analog interface, the last correctly read values remain valid. An interval can be defined in this register at which the module begins receiving correct values again after the error state without processing them further internally. Only then will newly sampled correct analog values be recognized as valid.

Data type	Value	Information
UDINT	0 to 20000000	Values in µs, bus controller default setting: 100000

4.16.3.11.8 Additional encoder position

In addition to the basic function, importing position values, the module can also copy an imported position to the reference register. The copy procedure is triggered by a configurable event.

4.16.3.11.8.1 Configuration

The position of the axis being measured is determined by 3 signals. The Z-signal is triggered exactly once during a single full rotation of the axis, which defines the reference point. The sine and cosine values are offset by 90° and undergo twofold evaluation by the module hardware. During "rough interpolation" the analog sine and cosine values are handled like digital signals. This works in the same way as a conventional ABR module. Fine interpolation takes place simultaneously in another part of the module. This is done using module-specific algorithms.

4.16.3.11.8.2 Configuring the copy procedure

Name:
SinCosCompMode

This register is used to determine when the current position should be copied to the reference register. The register is divided into 2 halves. The upper 4 bits determine which of the signal tracks are relevant for the trigger. The lower 4 bits determine which roughly interpolated states the individual signal tracks must demonstrate in order for the copying procedure to take place.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Latch - Sine track	0	Copy when sine is negative
		1	Copy when sine is positive (bus controller default setting)
1	Latch - Cosine track	0	Copy when cosine is negative
		1	Copy when cosine is positive (bus controller default setting)
2	Latch - Reference track (Z-track)	0	Copy when reference is negative
		1	Copy when reference is positive (bus controller default setting)
3	Reserved	-	
4	Sine track	0	Irrelevant for latch
		1	Relevant for latch (bus controller default setting)
5	Cosine track	0	Irrelevant for latch
		1	Relevant for latch (bus controller default setting)
6	Reference track (Z-track)	0	Irrelevant for latch
		1	Relevant for latch (bus controller default setting)
7	Reserved	-	

Call

The reference registers can be called the same way as the registers for the current position.

4.16.3.11.8.3 Reference position (to 64-bit)

Name:
ReferenceHW
ReferenceLW

This register prepares the value of the encoder position at the time a specific event occurred.

The 64-bit position value is placed in the registers ReferenceHW and ReferenceLW. The upper 32 bits are in the ReferenceHW register and the lower 32 bits in the ReferenceLW register.

Data type	Value
UDINT	0 to 4,294,967,295

4.16.3.11.8.4 Reference position (to 32-bit)

Name:
Reference
Reference

Just like the position registers, the lower 32 bits of the reference position can also be addressed separately. The result if interpreted as a signed value.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.16.3.11.8.5 Counter for reference values

Name:
RefCycle

This register acts as an integer counter that is incremented as soon as the module has determined a new valid reference value.

Data type	Value
SINT	-128 to 127

4.16.3.11.9 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.16.3.11.10 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.16.4 X20(c)DS1119

4.16.4.1 General information

The module being used is a multifunctional digital signal processor module. It's flexibility allows it to be implemented for a wide range of tasks involving the creation or processing of digital signals. For example, two main uses include encoder emulation and controlling stepper output stages with pulse and direction signals. When used for encoder emulation, frequency inverters or servo axes with the speed follow function can follow a real or virtual master axis.

A further important feature is the timestamp function, which is integrated in the module. It can be used, for example, to create ramp curves for the counter in the encoder emulation virtually independent of bus cycle times. It's only necessary to enter the target counter value and the time at which it should be reached. The module generates the appropriate counter values, precisely in microsecond resolution and independently of the bus clock.

- 3 digital 5 V channels, configurable as inputs or outputs
- 2 digital 24 V input channels
- 1 universal counter pair (2 event counters, AB counter or up/down counter)
- Linear movement generator (A/B; direction/frequency) with one reference pulse
- SSI absolute encoder

4.16.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.16.4.3 Order data

4.16.4.11.3 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.16.4.11.4 General

4.16.4.11.4.1 Use with Automation Studio

The module is supported via X2X Link and POWERLINK.

X2X Link supports a up to 28 bytes of synchronous data per module. To optimize use and to prevent needless data transfer, the data points can be adjusted as needed in Automation Studio. Data points that are not needed can be disabled, and the bit width of the data points can be defined.

4.16.4.11.4.2 Timestamp function

The timestamp function is based on synchronized timers. When a timestamp event occurs, the module immediately saves the current net time. After the respective data is transmitted to the CPU, including this precise time, the CPU can then evaluate the data using its own net time (or system time).

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise time defined by the CPU.

The resolution of the timestamp is up to 1/8 µs in both directions.

4.16.4.11.4.3 Synchronization jitter

Because the CPU – which determines the X2X net time – and the module have different clocks, the module's internal X2X net time must be synchronized with the CPU's net time. Due to this synchronization, the module's internal X2X net time is corrected by a maximum of 1/8 µs per system cycle if necessary. This synchronization jitter becomes noticeable when using the net time with 1/8 µs resolution (max. ±1/8 µs).

If a 100% exact 1/8 µs resolution without jitter is required, then the "localtime 1/8 µs" must be used (see the 4.16.4.11.11.3 "CfO_EdgeDetectUnitMode" register).

4.16.4.11.5 General registers

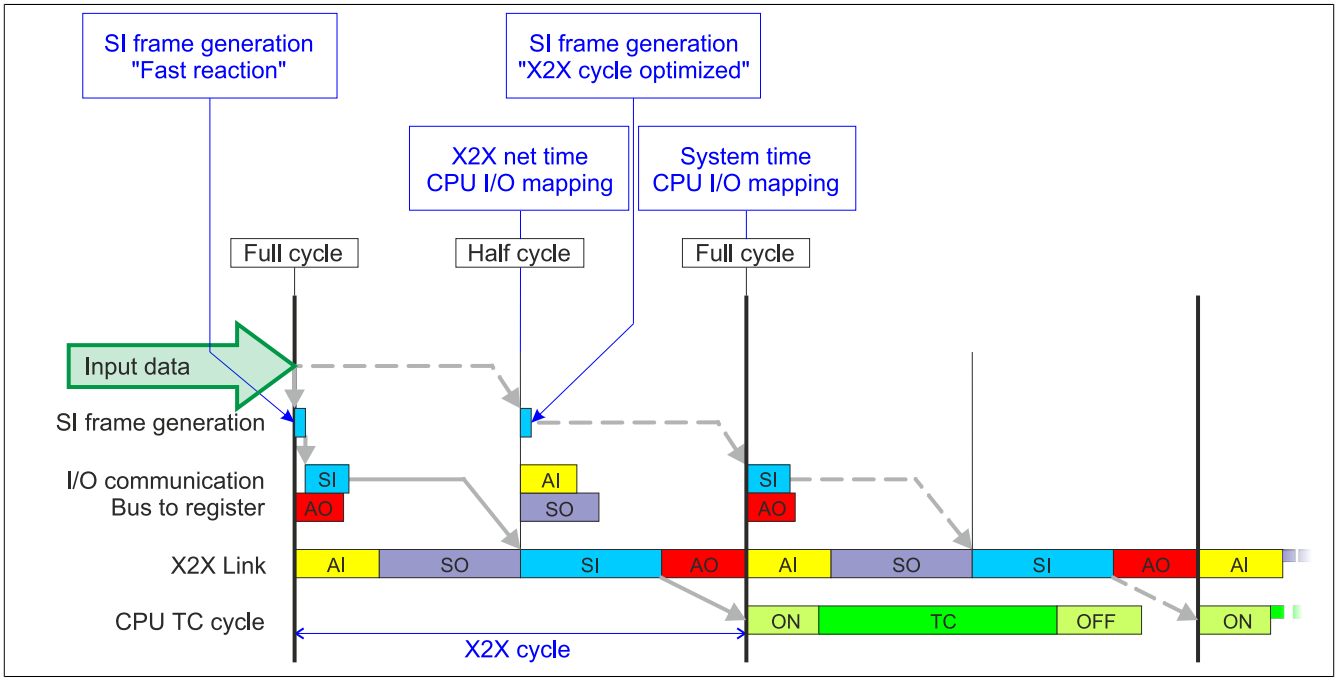
4.16.4.11.5.1 "CfO_SIframeGenID" register

Name:
CfO_SIframeGenID
"SI-frame generation" in the AS I/O configuration.

This register determines when the synchronous input data is generated for transfer. This has a decisive effect on the timing of the input data.

The setting "Fast reaction" causes the input data to be available one X2X cycle sooner in the CPU. However, this setting also has a negative effect on the minimum X2X cycle time.

Data type	Value	Information
USINT	9	X2X cycle optimized
	14	Fast reaction



4.16.4.11.5.2 "ProtocolError" register

Name:
ProtocolError

This register contains an error counter that specifies the number of X2X protocol errors. In the I/O configuration, the "Network information" parameter can be used to help configure a data point for this register with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.4.11.5.3 "ProtocolSequenceViolation" register

Name:
ProtocolSequenceViolation

This register contains an error counter that specifies the number of X2X sequence violations. In the I/O configuration, the "Network information" parameter can be used to help configure a data point with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.4.11.5.4 "SDCLifeCount" register

Name:
SDCLifeCount

Counter that is incremented with each system timer cycle. The "SDC information" setting in the AS I/O configuration can be used to activate this register in the I/O mapping as the data point, "SDCLifeCount".

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.4.11.6 Error handling

If one of the functions detects an error, then an error bit is set in one of the error state registers. The application is now able to react accordingly and acknowledge the errors by setting a respective bit in the "Acknowledge error message" registers. This causes the bit to be reset in the error state register. If the source of the error persists, then the error bit is set again as soon as the error is detected again (i.e. cannot be reset).

Acknowledging the error does not affect the module's functionality. If possible, the module automatically resumes processing as soon as the source of the error has been corrected.

If an error occurs (not a warning), this is indicated by the red "e" LED on the module (double flash). This signal is automatically acknowledged as soon as the source of the error has been corrected.

4.16.4.11.6.1 Error state register - Output data and edge detection

Name:
OutputControlError
OutputCopyError
EdgeDetectError

Errors in the output data and cycle time settings are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	OutputControlError	0	No error
		1	The module did not receive new data in time while in the mode "Output control mode = single", meaning that a bit that has already been output would have been output again by the output control buffer.
5	OutputCopyError	0	No error
		1	Oversampling output data could not be copied to the output control buffer. (e.g. an attempt was made to write oversampling output data to an address outside of the OversampleOutputWindow).
6	EdgeDetectError	0	No error
		1	Cycle time violation edge detection: The "EdgeDetectPollCycle" must be smaller than or equal to 255 µs. This error is caused if the cycle defined in the 4.16.4.11.11.1 "CfO_EdgeDetectPollCycleID" register is > 255 µs.
7	Reserved	-	

4.16.4.11.6.2 Error state register - SSI

Name:
SSICycleTimeViolation
SSIParityError

SSI interface errors are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	SSICycleTimeViolation	0	No error
		1	Error occurred, possible causes: • SSI transfer takes longer than the defined "Update cycle". • Monoflop check is enabled and the SSI data line does not assume the defined level after the transfer is complete.
1	SSIParityError	0	No error
		1	SSI parity error
2 - 7	Reserved	-	

4.16.4.11.6.3 Error state register - Movement functions

Name:
MovFifoEmpty
MovFifoFull
MovTargetTimeViolation
MovMaxFrequencyViolation

Movement function errors are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovFifoEmpty	0	No error
		1	The position/timestamp FIFO is empty.
1	MovFifoFull	0	No error
		1	The position/timestamp FIFO has exceeded the size defined in the 4.16.4.11.12.3 "FifoSize" register.
2	MovTargetTimeViolation	0	No error
		1	This only occurs when the 4.16.4.11.12.18 "MovTargetTime" is in the past.
3	MovMaxFrequencyViolation	0	No error
		1	The maximum output frequency setpoint has exceeded the maximum frequency configured in the 4.16.4.11.12.4 "CfO_SpeedLimit" register.
4 - 7	Reserved	-	

4.16.4.11.6.4 Acknowledge error message register - Output data and edge detection

Name:
QuitOutputControlError
QuitOutputCopyError
QuitEdgeDetectError

Error messages from the 4.16.4.11.6.1 "Error state - Output data and edge detection" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	QuitOutputControlError	0	No change
		1	Acknowledge error
5	QuitOutputCopyError	0	No change
		1	Acknowledge error
6	QuitEdgeDetectError	0	No change
		1	Acknowledge error
7	Reserved	-	

4.16.4.11.6.5 Acknowledge error message register - SSI

Name:
SSIQuitCycleTimeViolation
SSIQuitParityError

Error messages from the 4.16.4.11.6.2 "Error state - SSI" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	SSIQuitCycleTimeViolation	0	No change
		1	Acknowledge error
1	SSIQuitParityError	0	No change
		1	Acknowledge error
2 - 7	Reserved	-	

4.16.4.11.6.6 Acknowledge error message register - Movement functions

Name:
MovQuitFifoEmpty
MovQuitFifoFull
MovQuitTargetTimeViolation
MovQuitMaxFrequencyViolation

Error messages from the 4.16.4.11.6.3 "Error state - Movement functions" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovQuitFifoEmpty	0	No change
		1	Acknowledge error
1	MovQuitFifoFull	0	No change
		1	Acknowledge error
2	MovQuitTargetTimeViolation	0	No change
		1	Acknowledge error
3	MovQuitMaxFrequencyViolation	0	No change
		1	Acknowledge error
4 - 7	Reserved	-	

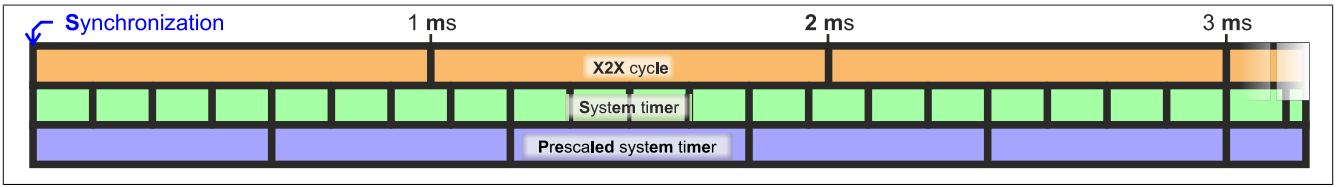
4.16.4.11.7 System timer

The module's individual functions all depend on a system timer. This internal "system cycle time" can be defined from 25 to 255 µs. The functions can also be run with the help of a configurable "prescaled system timer" to minimize the load on the module, thereby making it possible to use the shortest possible X2X cycle time.

The cycle of the "prescaled system timer" (and system timer) is referenced with the X2X Link as soon as the module has been started up and the X2X Link has been initialized. Since the system timer and the module's internal X2X net time use the same clock, the two run synchronously from that point on. An X2X cycle time that is not a multiple of the system cycle time results in an offset, which can be calculated.

The following values apply to the following example:

X2X cycle	1 ms
System timer	150 µs
Prescaled system timer	4



4.16.4.11.7.1 "CfO_SystemCycleTime" register

Name:
CfO_SystemCycleTime
"Cycle time" in the AS I/O configuration.

The cycle time of the system timer can be set in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Information:

A setting < 50 µs has a negative effect on the minimum X2X cycle time!

Data type	Value	Information
UINT	200 to 2047	System timer cycle time in steps of 1/8 µs (25 to 255,875 µs)

4.16.4.11.7.2 "CfO_SystemCycleOffset" register

Name:
CfO_SystemCycleOffset
"Cycle offset" in the AS I/O configuration.

The synchronization time for the system cycle can be offset in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Data type	Value	Information
INT	-32,768 to 32,767	Cycle offset in steps of 1/8 µs (-4096 to 4095.875 µs)

4.16.4.11.7.3 "CfO_SystemCyclePrescaler" register

Name:
CfO_SystemCyclePrescaler
"Cycle prescaler" in the AS I/O configuration.

The prescaler for setting the "Prescaled system timer" can be configured in this register. The cycle time of the specified system timer is a product of the system timer multiple set in this register.

The "prescaled system timer" can be used as alternative time source for the individual functions. This is useful if a function requires a very short system cycle. To reduce the load on the module in such a situation, other functions can be processed in a slow cycle.

Data type	Value	Information
UINT	2 to 128	Multiple of the system timer

4.16.4.11.8 Physical I/O configuration

4.16.4.11.8.1 "CfO_PhyIOConfigCh" registers

Name:
CfO_PhyIOConfigCh01 to CfO_PhyIOConfigCh05

The physical I/O channels can each be configured individually in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Push driver[1)]	0	Disabled
		1	Enabled
1	Pull driver[1)]	0	Disabled
		1	Enabled
2	Input inverted	0	Not inverted
		1	Inverse
3	Output inverted[1)]	0	Not inverted
		1	Inverse
4 - 7	Output function[1)]	0 to 15	See: Overview of output channel functions

1) Only available for I/O channels 1 to 3

Overview of output channel functions

Values of bits 4 to 7	Output channel 1	Output channel 2	Output channel 3
0	Direct I/O	Direct I/O	Direct I/O
1		SSI clock output	
2	ABR emulation (A)	ABR emulation (B)	ABR emulation (reference)
3	Up/down emulation (direction)	Up/down emulation (frequency)	Up/down emulation (reference)
4 - 15	Reserved		

4.16.4.11.9 Direct I/O

Direct I/O makes it possible to use the physical I/Os like normal I/Os. Additionally, the application can only set or reset I/Os (e.g. an output channel is set by the edge generator and manually reset by the application).

4.16.4.11.9.1 "CfO_DirectIOClearMask0_7" register

Name:
CfO_DirectIOClearMask0_7
"Direct control of output channel 01" to "Direct control of output channel 03" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is reset as soon as its direct I/O output channel is reset (4.16.4.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Output channel 0	0	No change
		1	Reset channel
1	Output channel 1	0	No change
		1	Reset channel
2	Output channel 2	0	No change
		1	Reset channel
3 - 7	Reserved	-	

4.16.4.11.9.2 "CfO_DirectIOSetMask0_7" register

Name:
CfO_DirectIOSetMask0_7
"Direct control of output channel 01" to "Direct control of output channel 03" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is set as soon as its direct I/O output channel is set (4.16.4.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Output channel 0	0	No change
		1	Set channel
1	Output channel 1	0	No change
		1	Set channel
2	Output channel 2	0	No change
		1	Set channel
3 - 7	Reserved	-	

4.16.4.11.9.3 "DigitalOutput" register

Name:
DigitalOutput01 to DigitalOutput03

The register contains the bits for controlling the direct I/O output channels. Depending on how the 4.16.4.11.9.1 "CfO_DirectIOClearMask0_7" and 4.16.4.11.9.2 "CfO_DirectIOSetMask0_7" registers are configured, the digital outputs are set to the status of the respective bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalOutput01	0 or 1	Output status of the channel
1	DigitalOutput02	0 or 1	Output status of the channel
2	DigitalOutput03	0 or 1	Output status of the channel
3 - 7	Reserved	-	

4.16.4.11.9.4 "DigitalInput" register

Name:
DigitalInput01 to DigitalInput05

This register displays the status of the digital input channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalInput01	0 or 1	Input status of channel 1
1	DigitalInput02	0 or 1	Input status of channel 2
2	DigitalInput03	0 or 1	Input status of channel 3
3	Reserved	-	
4	DigitalInput04	0 or 1	Input status of channel 4
5	DigitalInput05	0 or 1	Input status of channel 5
6 - 7	Reserved	-	

4.16.4.11.10 Oversampled I/O

"Oversampled I/O" is based on input status buffers and output control buffers. Input data acquisition and output control occur in one sample cycle (one sample cycle equals one bit in the buffer). The precise time of an input buffer entry is indicated by its position in the buffer and the net time assigned to the buffer.

In "Output control mode = single" every output buffer entry is marked as invalid once it has been executed. This ensures that the outputs are not supplied with invalid data. In this mode, the application needs to ensure that the module is always supplied with valid data.

When using "Output control mode = continuous" the contents of the buffer are output again if the module is not supplied with new oversample output data.

4.16.4.11.10.1 Addressing the output control buffer

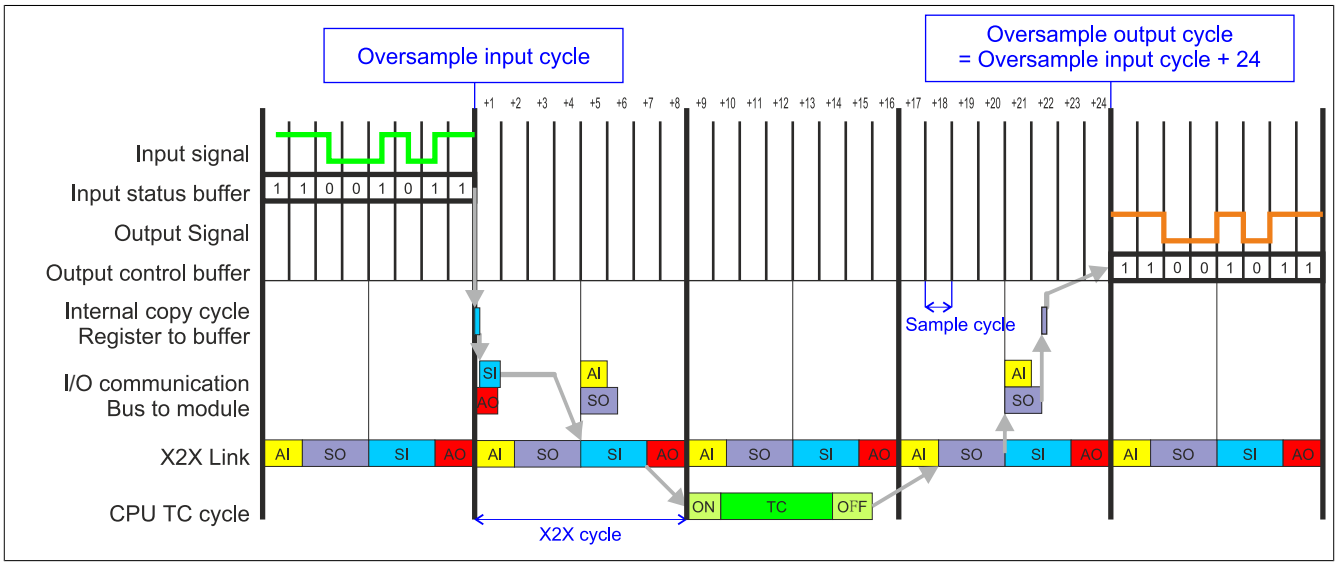
The module has one cyclic 256-bit output control buffer for each oversample channel. One bit is output from these buffers to the configured physical output channels in each "sample cycle". When new data is transferred to one of these buffers, the application must define where in the respective buffer the data should be written to. There are 2 possibilities (absolute or relative "Output mode" in the AS I/O configuration).

Absolute addressing of the output control buffer

With absolute addressing, in each cycle where "OversampleOutputValidate = True", in addition to the oversample output sample data (in the 4.16.4.11.10.15 "OversampleOutput0NSample" registers) an address must also be transferred in the 4.16.4.11.10.13 "OversampleOutputCycle" register. This address determines where in the output control buffer the new data should be copied to. In order to calculate this address, you must account for the contents of the 4.16.4.11.10.17 "OversampleInputCycle" register, which contains the address of the most recently output data, and the transfer time to the module. To help avoid incorrect addressing of the output control buffer, the buffer section that is capable of being written to can be limited using the 4.16.4.11.10.8 "OversampleOutputWindow" register. This window will always be shifted relative to the current sample address. An "OutputCopyError" will be triggered if an attempt is made to write to an address that is outside of this window.

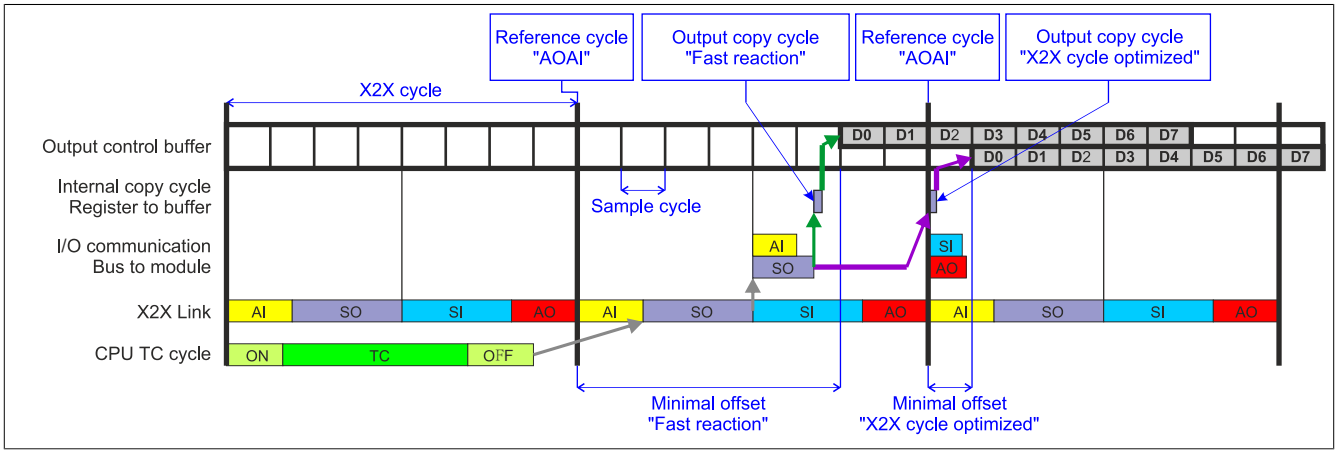
Example

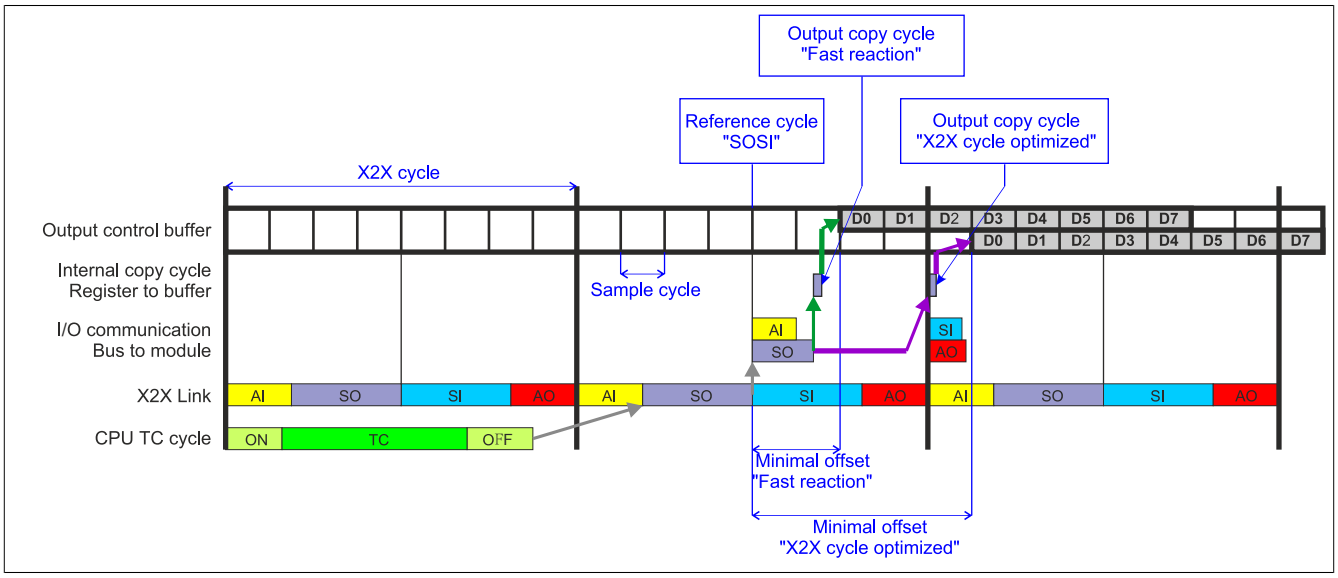
Timing from oversample input cycle to oversample output cycle in absolute output mode ("SI-frame generation = Fast reaction", "Output copy cycle = Fast reaction", 8 samples per X2X cycle):



Relative addressing of the output control buffer

When "OversampleOutputValidate = True", then the oversample output sample data is automatically copied to an address relative to the last referenced address at the defined "output copy cycle" time. The 4.16.4.11.10.14 "OversampleSampleOffset" register serves as the offset. The new data cannot start being output immediately at the "output copy cycle" time because it takes time to copy the data from the registers to the buffer. This means that an offset of 0 is not allowed. The relative output control buffer address + offset must point to an address within the "oversample output window". The "oversample output window" is always offset relative to the current sample address. An "OutputCopyError" is triggered if an attempt is made to write to an address that is outside of this window.





4.16.4.11.10.2 "CfO_OversampleMode" register

Name:
CfO_OversampleMode
"Output mode" in the AS I/O configuration
"Output control mode" in the AS I/O configuration.

The output control buffer can be configured globally for all channels in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Addressing the output control buffer "Output mode" in the AS I/O configuration.	0	Absolute addressing of the output control buffer
		1	Relative addressing of the output control buffer
1	Cyclic output control "Output control mode" in the AS I/O configuration.	0	Single Output control buffer entry is marked invalid after execution.
		1	Continuous Output control buffer entry is not changed.
2 - 7	Reserved	-	

Cyclic output control

If cyclic output control is enabled, then all data in the output control buffer is marked invalid as soon as it is output ("Output control mode = single"). An OutputControlError is generated if the module does not receive data in time, thereby causing a situation in which a bit that has already been output would be output in the buffer again. In such a situation, the output assumes the "Output default state" configured in the 4.16.4.11.10.10 "CfO_OversampleConfigOutput" register.

If cyclic output control is disabled, then the data is output again if the output control buffer overflows ("Output control mode = continuous").

Information:

All 256 bits of the output control buffer are always output.

4.16.4.11.10.3 "CfO_OversampleSampleCycleID" register

Name:
CfO_OversampleSampleCycleID
"Sample cycle" in the AS I/O configuration.

The source of the sample cycle can be configured in this register. During each sample cycle, one bit from the output control buffers of the oversampled I/O channels is output to the configured physical output, and the status of the configured inputs is entered in one bit of the respective input status buffer.

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the sample cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle.

4.16.4.11.10.4 "CfO_OversampleRelativeCycleID" register

Name:
CfO_OversampleRelativeCycleID
"Reference cycle" in the AS I/O configuration.

The source of the user interface reference cycle can be configured in this register.

- The input data is referenced at the time of the "reference cycle". The referenced data is then copied to the "oversample input sample register" at the time of "SI frame generation", while taking the "OversampleInputWindow" into account.
- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle, and with it also the output data production and input data acquisition (e.g. to the X2X cycle).

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the reference cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle.

4.16.4.11.10.5 "CfO_OversampleConsumeCycleID" register

Name:
CfO_OversampleConsumeCycleID
"Output copy cycle" in the AS I/O configuration.

At the time of the output copy cycle, data is copied from the 4.16.4.11.10.15 "OversampleOutput0NSample" registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

Data type	Value	Information
USINT	10	X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle.
	15	Fast reaction The output data is copied to the output control buffer immediately after being received.

4.16.4.11.10.6 "CfO_OversampleOutputBits" register

Name:
CfO_OversampleOutputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the 4.16.4.11.10.15 "OversampleOutputONSample" registers to the output control buffers at the time of the "output copy cycle".

Data type	Value	Information
USINT	1 to 64	Output bits

4.16.4.11.10.7 "CfO_OversampleInputBits" register

Name:
CfO_OversampleInputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register during "SI frame generation".

Data type	Value	Information
USINT	1 to 64	Input bits

4.16.4.11.10.8 "CfO_OversampleOutputWindow" register

Name:
CfO_OversampleOutputWindow
"Output control mode" in the AS I/O configuration.

Determines the area in the output control buffer in which data can be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An "OutputCopyError" is triggered if an attempt is made to write output sample data to a location outside of this window.
In AS, with the setting "Output control mode = Single", this register is set to 128 bits and with the setting "Output control mode = Continuous" it is set to 255 bits.

Data type	Value	Information
USINT	0 to 255	Output window

4.16.4.11.10.9 "CfO_OversampleInputWindow" register

Name:
CfO_OversampleInputWindow
"Input mode" in the AS I/O configuration.

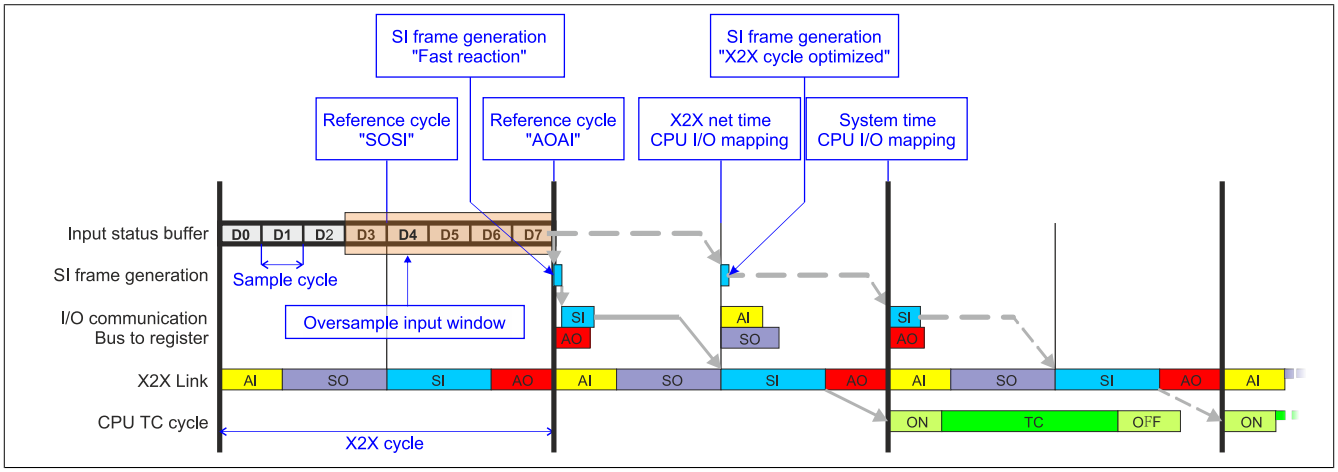
The "OversampleInputWindow" determines when the input data is referenced. It is located chronologically before "SI frame generation". If the reference time ("reference cycle") is within this window, then the referenced data is copied from the input status buffer to the OversampleInput0NSample register. If the time at which the reference occurs is outside the "OversampleInputWindow" then the data that is most recent at the time of "SI frame generation" is copied from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register.
This register is limited internally with to the value set in the 4.16.4.11.10.7 "CfO_OversampleInputBits" register.

Information:

As a result, the "OversampleInputTime" and the "OversampleInputCycle" are set either at the reference time or at the time of "SI frame generation".

In Automation Studio, this register is set to 63 when "Input mode = Referenced values" and to 0 when "Input mode = Most recent values".

Data type	Value	Information
USINT	0 to 63	Input window



4.16.4.11.10.10 "CfO_OversampleConfigOutput" register

Name:
CfO_OversampleConfigOutput
"Oversample I/O 01 →Output" to "Oversample I/O 04 →Output" in the AS I/O configuration
"Oversample I/O 01 →Output control" to "Oversample I/O 04 →Output control" in the AS I/O configuration
"Oversample I/O 01 →Output default state" to "Oversample I/O 04 →Output default state" in the AS I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits determine which level the respective output assumes before oversampling is started. Furthermore, the output is set to the defined "Output default state" in the event of an error.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical output channel "Oversample I/O 0x →Output" in the AS I/O configuration	0	Output channel 1
		1	Output channel 2
		2	Output channel 3
4	Output: Clear "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be reset by the oversample channel.
		1	Output can be reset by the oversample channel.
5	Output: Set "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be set by the oversample channel.
		1	Output can be set by the oversample channel.
6	Output default state: Clear "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not cleared by default
		1	Output cleared by default
7	Output default state: Set "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not set by default
		1	Output set by default

4.16.4.11.10.11 "CfO_OversampleConfigInput" register

Name:
CfO_OversampleConfigInput
"Oversample I/O 01 →input" to "Oversample I/O 04 →input" in the AS I/O configuration

This register determines which physical input channel an oversample I/O input should be linked to.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical input channel	0	Input channel 1
		1	Input channel 2
		2	Input channel 3
		3	Reserved
		4	Input channel 4
		5	Input channel 5
4 - 7	Reserved	-	

4.16.4.11.10.12 Oversample register - Configuration

Name:
OversampleEnable
OversampleOutputValidate

This register can be used to configure oversampling and the copy procedure for the output buffer.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	OversampleEnable	0	Disables oversampling (with the next reference cycle)
		1	Enables oversampling (with the next reference cycle)
1	OversampleOutputValidate	0	Disable the copy procedure to the output control buffer.
		1	Enables the copy procedure to the output control buffer. • Used to synchronize the oversampling procedure at startup. • This makes it possible to prevent new data from being transferred to the 4.16.4.11.10.15 "OversampleOutput0NSample" registers in each X2X cycle.
2 - 7	Reserved	-	

4.16.4.11.10.13 "OversampleOutputCycle" register

Name:
OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

Data type	Value	Information
USINT	0 to 255	Address of the output control buffer

4.16.4.11.10.14 "OversampleSampleOffset" register

Name:
OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. (Sample address at the time of the "reference cycle" + Offset = address to which the new output sample data is copied in the output control buffer).

Data type	Value	Information
USINT	0 to 255	Offset of output sample data

4.16.4.11.10.15 "OversampleOutputSample" register

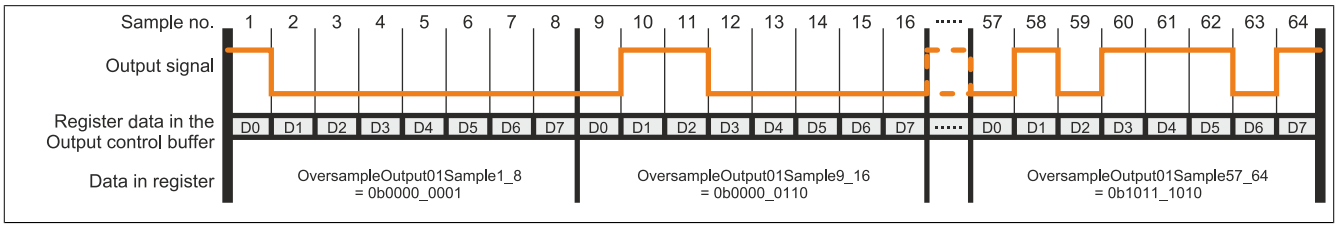
Name:
OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer during the "output copy cycle". 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.
Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

Data type	Value	Information
USINT	0 to 255	Output sample data

Example

Assignment of "OversampleOutputSample" register data to output signal



4.16.4.11.10.16 "OversampleInputTime" register

Name:
OversampleInputTime

This register contains the 2 low-order bytes of the X2X net time from the moment at which the oversample input data was referenced. This provides an easy way to accurately calculate the time of each individual input sample.

Data type	Value	Information
INT	-32,768 to 32,767	X2X net time of the input data

4.16.4.11.10.17 "OversampleInputCycle" register

Name:
OversampleInputCycle

This register provides the width of the input status buffer address for the input sample data.
Furthermore, the value in this register can be used for referencing an absolute addressing of the output control buffer.

Data type	Value	Information
USINT	0 to 255	Input status buffer address

4.16.4.11.10.18 "OversampleInputSample" register

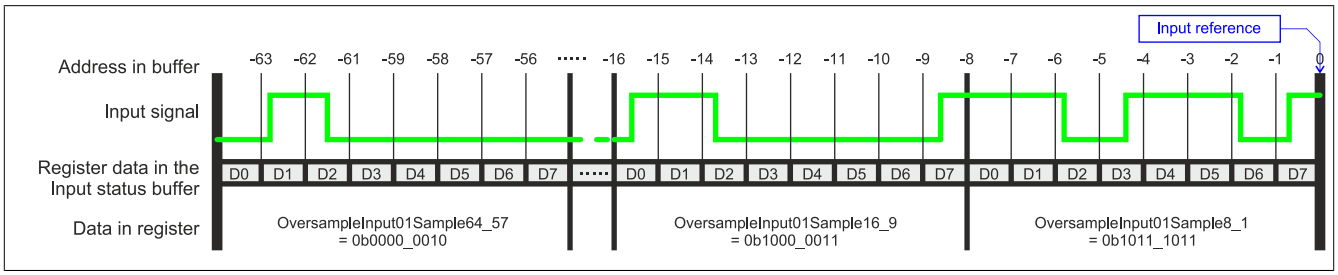
Name:
OversampleInput01Sample8_1 to OversampleInput04Sample8_1
OversampleInput01Sample16_9 to OversampleInput04Sample16_9
OversampleInput01Sample24_17 to OversampleInput04Sample24_17
OversampleInput01Sample32_25 to OversampleInput04Sample32_25
OversampleInput01Sample40_33 to OversampleInput04Sample40_33
OversampleInput01Sample48_41 to OversampleInput04Sample48_41
OversampleInput01Sample56_49 to OversampleInput04Sample56_49
OversampleInput01Sample64_57 to OversampleInput04Sample64_57

The data of the four oversample input status buffers are copied to this register at the time of "SI frame generation". A maximum of 64 samples (8 bytes) per oversample I/O channel can be synchronously retrieved from the oversample input status buffer with each X2X cycle.
The most recent input sample bit is stored in "OversampleInputSample8_1" bit 7. The oldest input sample is stored in "OversampleInputSample64_57" bit 0.

Data type	Value	Information
USINT	0 to 255	Input sample data

Example

Input signal and resulting data in "OversampleInputSample"



4.16.4.11.11 Edge detection

The module's edge detection function identifies edges with µs precision. The concept is based on a maximum of 4 units. A master and a slave edge can be configured for each unit.

At each master edge, the net time of the master edge and the net time of a previous slave edge (if present) are logged. A "master counter" and a "slave counter" can always be used to determine how many edges have been detected since the last X2X cycle.

4.16.4.11.11.1 "CfO_EdgeDetectPollCycleID" register

Name:
CfO_EdgeDetectPollCycleID
"Polling cycle" in the AS I/O configuration.

The source of the polling cycle can be configured in this register.

Information:

The polling cycle must be less than or equal to 255 µs. Setting the cycle > 255 µs causes an EdgeDetectError.

Data type	Value	Information
USINT	2	System timer The time set in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used for the polling cycle.
	3	Prescaled system timer The time set in the 4.16.4.11.7.3 "CfO_SystemCyclePrescaler" register is used for the polling cycle.

4.16.4.11.11.2 "CfO_EdgeDetectEventEnable" register

Name:
CfO_EdgeDetectEventEnable
"Edge detection mode" in the AS I/O configuration.

The bits in this register determine at which edges on the individual input channels an interrupt should be triggered for the edge detection.

In the AS IO configuration, this register is initialized with 0x00000000 when "Edge detection mode = polling" and with 0xFFFFFFFF when "Edge detection mode = event triggered".

In "event triggered" mode, the net time of each edge is recorded immediately at interrupt. However, an extremely large amount of interrupts within a short amount of time can prevent the module from being able to process any other operations in time!

In "polling" mode, only the net time of the first edge that occurs within a polling cycle is recorded. This ensures that the module is not overloaded by too many edges.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Physical input 1	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
1	Physical input 2	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
2	Physical input 3	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
3	Reserved	-	
4	Physical input 4	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
5	Physical input 5	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
6 - 15	Reserved	-	
16	Physical input 1	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
17	Physical input 2	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
18	Physical input 3	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
19	Reserved	-	
20	Physical input 4	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
21	Physical input 5	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
22 - 31	Reserved	-	

4.16.4.11.11.3 "CfO_EdgeDetectUnitMode" register

Name:
CfO_EdgeDetectUnit01Mode to CfO_EdgeDetectUnit04Mode
"Time base" in the AS I/O configuration.
"Slave edge" in the AS I/O configuration.
"Master edge" in the AS I/O configuration.

When using a "time base" with 1/8 µs resolution, keep in mind that the timestamps produced also have a resolution of exactly 1/8 µs. The respective conversions must be made for calculating in combination with the CPU system time or X2X net time.

Furthermore, synchronization jitter also plays a role when using the setting "time base = net time resolution 1/8 µs" (see: 4.16.4.11.4.3 "Synchronization jitter"). This means that exactly identical input edges can cause slight differences in the results. If a 100% exact 1/8 µs resolution is required, then the "local resolution 1/8 µs" must be used.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	"Time base" in the AS I/O configuration.	0	Local time 1/8 µs (AS: Local resolution 1/8 µs)
		1	Local time 1 µs (AS: Local resolution 1 µs)
		2	Net time 1/8 µs (AS: Net time resolution 1/8 µs)
		3	Net time 1 µs (AS: Net time resolution 1 µs)
2 - 5	Reserved	-	
6	"Slave edge" in the AS I/O configuration.	0	Disabled
		1	Enabled
7	"Master edge" in the AS I/O configuration.	0	Disabled
		1	Enabled

4.16.4.11.11.4 "CfO_EdgeDetectUnitLeading" register

Name:
CfO_EdgeDetectUnit01Leading to CfO_EdgeDetectUnit04Leading
"Slave leading" in the AS I/O configuration.

When a slave edge occurs, the current net time is always saved within the module. A FIFO is provided inside the module which always stores the last 256 slave stamps (even when a master edge occurs).

This value determines from which position the slave time should be retrieved from the FIFO when a master edge occurs. This can be used to measure average periodic signals over multiple cycles.

Data type	Value	Information
USINT	0 to 255	Position in the slave edge FIFO

4.16.4.11.11.5 "CfO_EdgeDetectUnitMaster" register

Name:
CfO_EdgeDetectUnit01Master to CfO_EdgeDetectUnit01Master
"Master edge" in the AS I/O configuration.

Determines the source of the master edge for the respective "Edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	1	Rising edge on physical input 2
	2	Rising edge on physical input 3
	4	Rising edge on physical input 4
	5	Rising edge on physical input 5
	16	Falling edge on physical input 1
	17	Falling edge on physical input 2
	18	Falling edge on physical input 3
	20	Falling edge on physical input 4
	21	Falling edge on physical input 5

4.16.4.11.11.6 "CfO_EdgeDetectUnitSlave" register

Name:
CfO_EdgeDetectUnit01Slave to CfO_EdgeDetectUnit04Slave
"Slave edge" in the AS I/O configuration.

Determines the source of the slave edge for the respective "Edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	1	Rising edge on physical input 2
	2	Rising edge on physical input 3
	4	Rising edge on physical input 4
	5	Rising edge on physical input 5
	16	Falling edge on physical input 1
	17	Falling edge on physical input 2
	18	Falling edge on physical input 3
	20	Falling edge on physical input 4
	21	Falling edge on physical input 5

4.16.4.11.11.7 "EdgeDetectMastercount" register

Name:
EdgeDetect01Mastercount to EdgeDetect04Mastercount

The reference pulses of the detected master edges are counted in this register.

Data type	Value	Information
SINT	-128 to 127	Number of detected master edges (8-bit)
INT	-32,768 to 32,767	Number of detected master edges (16-bit)

4.16.4.11.11.8 "EdgeDetectSlavecount" register

Name:
EdgeDetect01Slavecount to EdgeDetect04Slavecount

Counts the number of detected slave edges consecutively. The contents of this register are only updated when a master edge occurs. These counters can detect if multiple slave edges occur before a master edge.

Data type	Value	Information
SINT	-128 to 127	Number of detected slave edges (8-bit)
INT	-32,768 to 32,767	Number of detected slave edges (16-bit)

4.16.4.11.11.9 "EdgeDetectDifference" register

Name:
EdgeDetect01Difference to EdgeDetect04Difference

Contains the time difference between a master edge and the last slave edge addressed via "Slave leading".

Data type	Value	Information
INT	-32,768 to 32,767	Time difference between master/slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Time difference between master/slave edge (32-bit)

4.16.4.11.11.10 "EdgeDetectMastertime" register

Name:
EdgeDetect01Mastertime to EdgeDetect04Mastertime

The exact net time is copied in this register when a master edge occurs.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of master edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of master edge (32-bit)

4.16.4.11.11.11 "EdgeDetectSlavetime" register

Name:
EdgeDetect01Slavetime to EdgeDetect04Slavetime

When a master edge occurs, the exact net time of any slave edge that may have occurred prior to the master edge and addressed by "Slave leading" is copied in this register. If multiple slave edges occur before a master edge, then only the net time of the last edge that was not ignored by "Slave leading" is stored. The 4.16.4.11.11.8 "EdgeDetectSlavecount" register can be used to detect multiple edges.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the slave edge (32-bit)

4.16.4.11.12 Movement functions

Encoder emulation can be used to generate up/down counters (direction/frequency) and ABR encoder signals. The movement function can be operated in 2 different modes:

- Position control mode
- Speed control mode

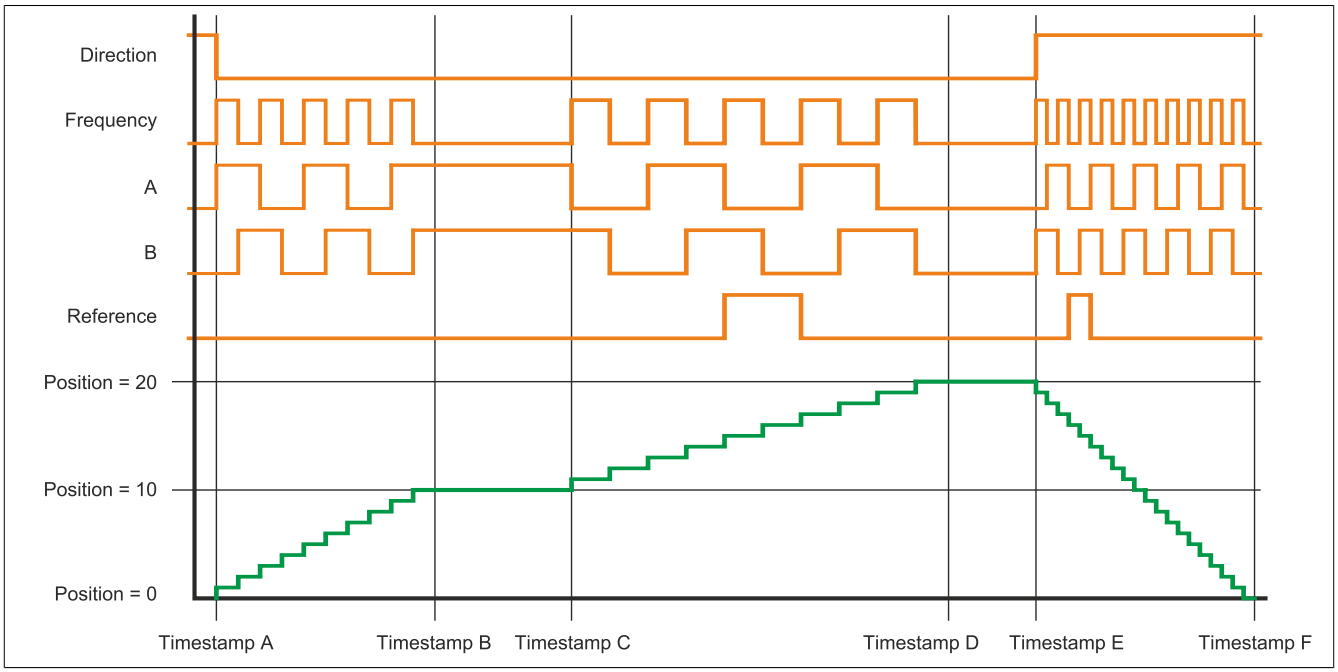
4.16.4.11.12.1 Position control mode

Each time the 4.16.4.11.12.18 "MovTargetTime" register changes, a new position setpoint is transferred from the 4.16.4.11.12.19 "MovPosition" register to the FIFO. The time/position data in the FIFO is then processed in such a manner that the positions are always reached at the time of the respective timestamps. This means that the module internally ensures that the positions are reached by the defined timestamps (number/frequency of the pulses is calculated automatically). The timestamps can be based on the X2X net time, the CPU's system time or the 4.16.4.11.12.21 "MovCurrentTime" register. Timestamps that are set in a manner that does not allow the required position change to be reached before the timestamp (output frequency of the pulse would exceed 4.16.4.11.12.4 "CfO_SpeedLimit") cause a MovMaxFrequencyViolation error.

Selected values for the example "Timing of movement":

Timestamp A = MovTimeValid + 40,000	Position for timestamp A = 0
Timestamp B = Timestamp A + 40.000	Position for timestamp B = 10
Timestamp C = Timestamp B + 25.000	Position for timestamp C = 10
Timestamp D = Timestamp C + 70,000	Position for timestamp D = 20
Timestamp E = Timestamp D + 15,000	Position for timestamp E = 20
Timestamp F = Timestamp E + 40,000	Position for timestamp F = 0

Configuration: Reference pulse = Start and end position, Start position = 15, End position = 17



4.16.4.11.12.2 Speed control mode

In speed control mode, the application only specifies the speed setpoint. The module returns the current position in the 4.16.4.11.12.22 "MovPosition (32-bit)" register.

The internal timing is designed so that the value 16,777,216 (0x01000000) in the 4.16.4.11.12.20 "MovSpeed" register results in exactly one increment per "control period".

This creates the following relationship for 32-bit speed setpoints ("Data format of speed values = 32-bit):

$$MovSpeed = vOut * 2^{resol} * period$$

Unlike other registers, the 2 higher-value bytes of "MovSpeed (32-bit)" are set when the "MovSpeed (32-bit)" register is written. This creates the following relationship for the direct calculation with "MovSpeed (16-bit)"

$$MovSpeed = \frac{vOut * 2^{resol} * period}{2^{16}}$$

Variable	Description	Unit
MovSpeed	Value for "MovSpeed" register (16 or 32-bit)	
vOut	Desired output speed Each edge represents one increment (rising or falling).	Inc/s
resol	Value configured for the 4.16.4.11.12.13 "CfO_ResolSpeed" register	Bits
period	Value configured for the 4.16.4.11.12.11 "CfO_SpeedCycleTime_32Bit" register **Information:** **Must be set in µs in Automation Studio. The calculation is performed in s, however.**	s

4.16.4.11.12.3 "FifoSize" register

Name:
FifoSize
"Number of Fifo entries" in the AS I/O configuration.

Determines the size of the FIFO for MovTargetTime and MovTargetPosition. One timestamp and one position that should be reached by the timestamp can be transferred to the FIFO per X2X cycle.

Data type	Value	Information
USINT	0	FIFO disabled
	3	8 entries (2^3)
	4	16 entries (2^4)
	5	32 entries (2^5)
	6	64 entries (2^6)
	7	128 entries (2^7)
	8	256 entries (2^8)

4.16.4.11.12.4 "CfO_SpeedLimit" register

Name:
CfO_SpeedLimit
"Max. movement frequency" in the AS I/O configuration.

Configures the maximum permitted output frequency and the maximum internal computing frequency. The higher internal computing frequencies of 2, 4, 8, 16, 32 and 64 MHz can only be achieved by configuring n bits as decimal places (see 4.16.4.11.12.12 "CfO_ResolPosition" register).

Data type	Value	Max. increment frequency	Max. frequency for frequency output channel	Max. frequency for A/B output channel
USINT	253	64 MHz	500 kHz	250 kHz
	254	32 MHz		
	255	16 MHz		
	0	8 MHz		
	1	4 MHz		
	2	2 MHz		
	3	1 MHz (default)		
	4	500 kHz	250 kHz	125 kHz
	5	250 kHz (default)	125 kHz	625 kHz
	6	125 kHz	625 kHz	3125 kHz

Information:

In Position control mode, the increment frequencies 16, 32 and 64 MHz are not permitted to be used when a 29-bit timestamp is set (see 4.16.4.11.12.7 "CfO_TimeStampRange" register) due to an internal range violation.

4.16.4.11.12.5 "CfO_Mode" register

Name:
CfO_Mode

This register can be used to configure the mode of the movement functions.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Must be enabled when working without timestamps. Enabled in AS if: • Movement = "speed control" • Movement = "position control and "data format / mode of preset time = local time"	0	Disabled
		1	Enabled
1	If this function is enabled, then a new positioning movement is triggered as soon as the value changes in the 4.16.4.11.12.19 "MovPosition" register. Enabled in AS if: • Movement = "position control and "data format / mode of preset time = local time"	0	No position control (speed control)
		1	Position control enabled (position control)
2	Reference mode "Configuration reference pulse 1" in the AS I/O configuration.	0	Start/end position
		1	Start position and span
3 - 7	Reserved	-	

4.16.4.11.12.6 "CfO_FormatAdjust" register

Name:
CfO_FormatAdjust

This register determines the number of absolute bits that can be output on the signal output (With a direction/frequency signal, the bit with the lowest value can be output directly on the frequency output. With an AB signal, 2 bits are possible.)

Data type	Value	Information
USINT	1 to 2	Number of absolute bits (AS default = 1)

4.16.4.11.12.7 "CfO_TimeStampRange" register

Name:
CfO_TimeStampRange
"Data format/mode of target time" in the AS I/O configuration.

The width of the transferred timestamp data in the module is configured in this register.

Information:

Because the module uses an internal resolution of 1/8 µs, timestamp data is processed internally at a maximum width of 29 bits.

Data type	Value	Information
SINT	16	16-bit timestamp ("16-bit" selected in the AS I/O configuration)
	24	24-bit timestamp ("local time" or "speed control" movement selected in the AS I/O configuration)
	29	29-bit timestamp ("29-bit" selected in the AS I/O configuration)

4.16.4.11.12.8 "CfO_PositionsRange" register

Name:
CfO_PositionsRange
"Target position range" in the AS I/O configuration.

The number of bits for position control are configured in this register. The "PositionRange" must be reduced if, for example, the movement function should follow the absolute value of a 12-bit SSI encoder. In this case, the bit width of the movement position also has to be limited to the number of bits of the encoder, or else the movement position would not also overrun if the encoder were to overrun. In this case, the module would attempt (in the opposite direction) to reach the position of an encoder that had just overrun.

Example

The 12-bit SSI encoder overruns from 2047 to -2048. The module would generate 4096 negative increments if more than 12 bits were defined for "CfO_PositionRange" in order to reach position -2048 from the position 2047.

Information:

If the 16-bit value of the 4.16.4.11.12.22 "MovPosition" register is used, then the bit width of the position must also be limited to ≤16 bits or else this would also result in incorrect overrun behavior.

Data type	Value	Information
SINT	8 to 32	Number of bits for position control

4.16.4.11.12.9 "CfO_TimeStampDelay" register

Name:
CfO_TimeStampDelay

All timestamps are delayed by the value defined in this register.

Data type	Value	Information
DINT	0 to 1000000	Timestamp delay in µs

4.16.4.11.12.10 "CfO_ReferenceRange" register

Name:
CfO_ReferenceRange
"Reference range" in the AS I/O configuration.

This register determines the number of bits that can be used for the reference position comparison. This makes it possible to generate a reference pulse every 2^n increments.

Information:

The number of bits set in this register must not be higher than the number of bits set for MovReferenceStart and MovReferenceStopMargin.

Data type	Value	Information
SINT	4 to 32	Number of bits for position comparison

4.16.4.11.12.11 "CfO_SpeedCycleTime_32Bit" register

Name:
CfO_SpeedCycleTime_32Bit
"Control period" in the AS I/O configuration.

The control period for "speed control" mode can be set in this register in steps of 1/8 µs.

Information:

The value defined in the AS I/O configuration under "Control period" is automatically multiplied by 8 and then used as CfO_SpeedCycleTime_32bit.

Data type	Value	Information
UDINT	400 to 40000	Control period for "speed control" mode

4.16.4.11.12.12 "CfO_ResolPosition" register

Name:
CfO_ResolPosition
"Position resolution" in the AS I/O configuration.

This register contains the number of bits as decimal place for jitter reduction. Internally, the module adds 2^n (n = number of decimal places) to the frequency, which results in edge switching times with a higher resolution. The output switching frequency is not increased from a hardware perspective, but the edge timing is more precise.

Data type	Value	Information
SINT	0	Default, no decimal places
	1 to 14	Selection of bits as decimal places

Information:

Keep in mind that each configured decimal place also limits the maximum number range by that number of bits.

For example: 0 decimal places →maximum position range = 29 bits

3 decimal places →maximum position range = 26 bits

Also keep in mind that the CfO_SpeedLimit parameter must be adjusted for these higher computing frequencies based on the number of configured decimal places.

4.16.4.11.12.13 "CfO_ResolSpeed" register

Name:
CfO_ResolSpeed
"Speed resolution" in the AS I/O configuration.

This register contains the number of bits as decimal place for jitter reduction of the speed value. Internally, the module adds 2^n (n = number of decimal places) to the frequency, which results in edge speed values with a higher resolution.

Due to the bit limitation, a 16 or 32-bit speed value is set in the AS I/O configuration. Since the internal calculation is always based on 32-bit, when configured to 16-bit an offset of 16 must always be added to the desired number of decimal places.

Data type	Value	Information
SINT	0 to 31	Selection of bits as decimal places
	24	Standard

Information:

Keep in mind that each configured decimal place also limits the maximum number range by that number of bits.

4.16.4.11.12.14 "CfO_ReferenceStart / MovReferenceStart" register

Name:
CfO_Reference0Start
MovReferenceStart
"Start position" in the AS I/O configuration.

The start position for the reference pulse is shown in these registers.

In the positive direction, the output (R) is set when the start position is reached. In negative direction, the output is reset as soon as the value falls below the start position value.

Data type	Value	Information
INT	-32,768 to 32,767	Start position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Start position (32-bit)

4.16.4.11.12.15 "CfO_ReferenceStopMargin / MovReferenceStopMargin" register

Name:
CfO_Reference0StopMargin
MovReferenceStopMargin
"End position or margin" in the AS I/O configuration.

The end position or the margin in which the reference pulse is output is configured in these registers.

If "Reference mode = Start/end position" is used in the 4.16.4.11.12.5 "CfO_Mode" register, then the output (R) is reset when the end position is reached in the positive direction. In the negative direction, the output is set as soon as the value falls below the end position value.

When "Reference mode = Start position and span", the content of this register is added to the start position and the resulting sum is used as the end position.

Data type	Value	Information
INT	-32,768 to 32,767	End position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	End position (32-bit)

4.16.4.11.12.16 "CfO_AccelDataInit / MovAcceleration" register

Name:
CfO_AccelDataInit
MovAcceleration
"Acceleration value" in the AS I/O configuration.

This register shows the acceleration value in increments per control period².

- 32-bit: 16777216 (0x01000000) corresponds to 1 increment per control period²
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period²

Data type	Value	Information
UINT	0 to 65,535	Acceleration value (16-bit)
UDINT	0 to 4,294,967,296	Acceleration value (32-bit)

4.16.4.11.12.17 "MovementControl" register

Name:
MovPosEnable
MovSpeedEnable

This register can be used to enable position and speed control.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovPosEnable	0	Position control disabled
		1	Position control enabled
1	MovSpeedEnable	0	Speed control disabled
		1	Speed control enabled
2 - 6	Reserved	-	
7	Movement reset (immediate stop)	0	Passive reset
		1	Active reset

4.16.4.11.12.18 "MovTargetTime" register

Name:
MovTargetTime

Timestamp data is shown in this register.Each time this register changes, the new position data (MovTargetPosition) and timestamp data are transferred to the FIFO. When "MovSpeedEnable = True", the module calculates the output speed (frequency) so that the "MovTargetPosition" is reached at "MovTargetTime".

Data type	Value	Information
INT	-32,768 to 32,767	Timestamp (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Timestamp (32-bit)

Information:

Only 29 bits of this register are processed internally.

4.16.4.11.12.19 "MovTargetPosition" register

Name:
MovTargetPosition

Position data is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Position (32-bit)

4.16.4.11.12.20 "MovSpeed" register

Name:
MovSpeed

This register shows the speed setpoint for "speed control" mode in increments per control period.

- 32-bit: 16,777,216 (0x01000000) corresponds to 1 increment per control period
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period

Data type	Value	Information
INT	-32,768 to 32,767	Speed setpoint (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Speed setpoint (32-bit)

4.16.4.11.12.21 "MovTimeValid" register

Name:
MovTimeValid

This register displays the net time of the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current position (16-bit).
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current position (32-bit)

4.16.4.11.12.22 "MovPosition" register

Name:
MovPosition

This register shows the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Current position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Current position (32-bit)

4.16.4.11.13 Synchronous serial interface (SSI)

The synchronous serial interface makes it possible to receive data from SSI absolute encoders.

Two lines are needed for data exchange:

SSI clock:	Generated by the module on output 2 (if configured).
SSI data:	A data bit is transferred from the encoder to the module with each clock pulse (input 1 can be used as the SSI input).

4.16.4.11.13.1 SSI transfer process

When the first edge occurs on the SSI clock, a monoflop is triggered in the encoder and the current parallel pending value is latched to the offset register (the low level of the monoflop prevents other values from being added to the offset register during data transfer).

The highest value bit is then transferred to the module when the next edge occurs.

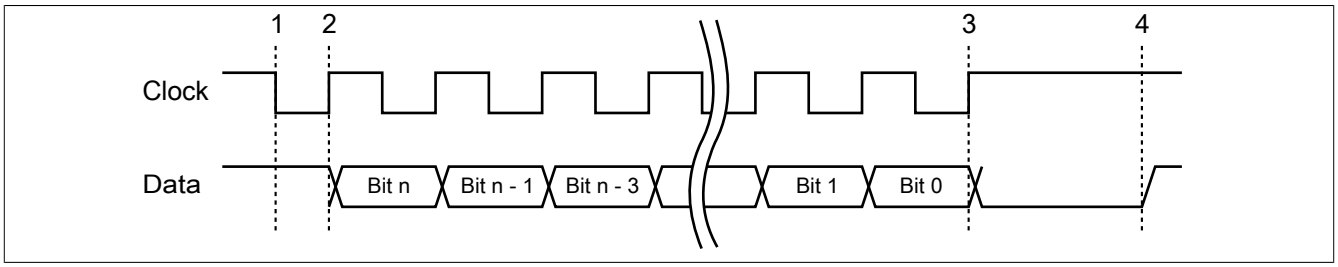
With each subsequent cycle, the next lowest bit is transferred. The cycles re-trigger the monoflop constantly so that its output prevents new data from being accepted.

The sequence of cycles stops once the number of data bits defined in the 4.16.4.11.13.4 "CfO_DataBits" register has been received.

The monoflop is no longer triggered. After a certain amount of time has passed (depending on the encoder), the monoflop's output re-assumes the output level, thereby enabling parallel data to be accepted once again in the encoder's offset register.

When the "Monoflop check" is run, the data line is queried for the configured level before a new transfer is started. This makes it possible to ensure that the monoflop really has reset before a new transfer is started.

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.16.4.11.13.2 "CfO_CycleSelect" register

Name:
CfO_CycleSelect
"Update cycle" in the AS I/O configuration.

SSI transfer is started at the update cycle. The clock sequence is generated on the SSI clock output. The first edge of the clock signal triggers the monoflop in the encoder and latches the current position. At the same time, the current net time is also recorded in the 4.16.4.11.13.6 "SSITimeValid" register. As soon as all bits have been transferred via the SSI, the position is passed on with the next "SIframeGenCycle" via the X2X Link. A SSICycleTimeViolation error is reported if the SSI transfer is not completed within the SSI update cycle (e.g. system timer as update cycle). The SSI transfer is still fully completed and then started again with the next update cycle.

Data type	Value	Information
USINT	2	System timer
	3	Prescaled system timer
	10	AOAI
	14	SOSI

4.16.4.11.13.3 "CfO_PhysicalMode" register

Name:
CfO_PhysicalMode
"Parity bit" in the AS I/O configuration
"Monoflop check" in the AS I/O configuration
"Data format" in the AS I/O configuration
"Clock frequency" in the AS I/O configuration

The SSI interface is configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	"Parity bit" in the AS I/O configuration.[1)]	00	Disabled
		01	Even parity
		10	Uneven parity
		11	Ignored (the parity bit is transferred, but not evaluated).
2 - 3	"Monoflop check" in the AS I/O configuration.[2)]	00	Disabled
		01	Low level (data signal is checked for low level after the monoflop has reset).
		10	High level (data signal is checked for high level after the monoflop has reset).
		11	Ignored (the necessary cycle is triggered, but not evaluated).
4	"Data format" in the AS I/O configuration.	0	Encoder with binary output
		1	Encoder with Gray Code. The module converts the position data into binary format.
5	Reserved	-	
6 - 7	"Clock frequency" in the AS I/O configuration.	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz

1) If the parity bit does not match, then a SSIParityError is generated and the position data is not accepted in the "SSIPosition" register.
2) A new SSI transfer is not started until the data signal has assumed the level defined for the "monoflop check" after the transfer. This then triggers the error SSICycleTimeViolation.

4.16.4.11.13.4 "CfO_DataBits" register

Name:
CfO_DataBits
"Valid SSI bit length" in the AS I/O configuration.

Determines the number of valid data bits to be transferred via the SSI. The valid data bits are used for the SSI-Position.

Data type	Value	Information
USINT	1 to 32	Number of valid data bits

4.16.4.11.13.5 "CfO_NullBits" register

Name:
CfO_NullBits
"Leading zero bits" in the AS I/O configuration.

This register can be used to configure the number of leading zero bits. The leading zero bits can be required before the valid data bits.

Data type	Value	Information
USINT	0 to 31	Number of leading zero bits

4.16.4.11.13.6 "SSITimeValid" register

Name:
SSITimeValid

This register displays the net time of the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current position (16-bit).
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current position (32-bit)

4.16.4.11.13.7 "SSITimeChanged" register

Name:
SSITimeChanged

The net time of the last position change is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the last position change (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the last position change (32-bit)

4.16.4.11.13.8 "SSIPosition" register

Name:
SSIPosition

This register shows the current position sent via the SSI interface.

Data type	Value	Information
INT	-32,768 to 32,767	Current position (16-bit)
UDINT	0 to 4,294,967,295	Current position (32-bit)
DINT	-2,147,483,648 to 2,147,483,647	

4.16.4.11.14 Counter

The universal counter pair can be used in 3 different modes. Signals up to 600 kHz, depending on the system timer, are reliably measured. Up to 4 latch inputs can be configured in all modes. Enabled latch inputs are negated if necessary and connected with a logical AND operation for a latch condition. If the latch condition is met, the current counter value is stored in a separate register.

Inputs

The physical inputs have fixed assignments based on the respective mode.

Mode	Input 1	Input 2	Input 3	Input 4
Edge counters	Counter input for counter 1 Latch input 1	Counter input for counter 2 Latch input 2	- Latch input 3	- Latch input 4
Up/down counter	Counting direction Latch input 1	Counter frequency Latch input 2	- Latch input 3	- Latch input 4
Incremental encoder	A Latch input 1	B Latch input 2	- Latch input 3	- Latch input 4

Latch function

As latch inputs, inputs 1 to 4 can each be polled to determine if they have a high or low level.

In "Latch mode = continuous", the counters are latched once as soon as "LatchEnable = TRUE" and the configured latch condition is met. If the latch condition is met again, then the counter value is also latched again. (i.e. One latch event is triggered with each rising edge on the output of the AND operation of all latch inputs).

In "Latch mode = single", the counters are latched once as soon as "LatchEnable = TRUE" and the configured latch condition is met. If the latch condition is met again, then the counter value is not automatically copied again. Another latch event can only be processed after "LatchEnable = False" and then "LatchEnable = True" again.

4.16.4.11.14.1 "CfO_CounterCycleSelect" register

Name:
CfO_CounterCycleSelect
"Update cycle" in the AS I/O configuration.

The update cycle for the counter values is configured in this register.

Information:

The maximum counting frequency depends on the cycle. The module can process a maximum of 200 increments (edges) within a counter cycle.

Data type	Value	Information
USINT	2	System timer
	3	Prescaled system timer
	10	AOAI time of X2X cycle
	14	SOSI time of X2X cycle

4.16.4.11.14.2 "CfO_CounterMode" register

Name:
CfO_CounterMode
"Counter mode" in the AS I/O configuration.

The counter mode is configured in this register.

Data type	Value	Information
USINT	0	Edge counters In this mode, the two counters are used as edge counters. The counter input of counter 1 is linked permanently to input 1 and the counter input of the second counter is linked permanently to input 2. Both rising as well as falling edges are counted.
	2	Up/down counter The up/down counter works according to the direction/frequency principle. Input 1 determines the counting direction (LOW = positive, HIGH = negative), input 2 serves as the counting frequency input. Both rising as well as falling edges on the counting frequency input are counted.
	3	Incremental encoder (AB counter) When configured as an AB counter, input 1 serves as the A channel and input 2 as the B channel. All edges are evaluated (4x evaluation).

4.16.4.11.14.3 "CfO_LatchMode" register

Name:
CfO_LatchMode
"Latch mode" in the AS I/O configuration.

The latch mode is configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	LatchMode	0	Single shot
		1	Continuous
1 - 7	Reserved	-	

4.16.4.11.14.4 "CfO_LatchComparator" register

Name:
CfO_LatchComparator
"Latch level channel 01" to "Latch level channel 04" in the AS I/O configuration.

The latch comparators for the counter inputs are configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparison level for latch comparator on input 1	0	Low
		1	High
...		...	
3	Comparison level for latch comparator on input 4	0	Low
		1	High
4	Enable latch comparator on input 1	0	Disabled
		1	Enabled
...		...	
7	Enable latch comparator on input 4	0	Disabled
		1	Enabled

4.16.4.11.14.5 "CounterControl" register

Name:
CounterReset
LatchEnable

This register can be used to clear counter values or enable the latch.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CounterReset	0	No action
		1	Delete counter
1	LatchEnable	0	Disabled
		1	Enabled
2 - 7	Reserved	-	

4.16.4.11.14.6 "LatchCount" register

Name:
LatchCount

Latch events are counted in this register. This counter can be used to detect whether a new value has been latched.

Data type	Value	Information
SINT	-128 to 127	Latch counter

4.16.4.11.14.7 "CounterTimeValid" register

Name:
CounterTimeValid

This register displays the X2X net time of the current counter value.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current counter value (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current counter value (32-bit)

4.16.4.11.14.8 "CounterTimeChanged" register

Name:
Counter01TimeChanged to Counter02TimeChanged

The net time of the last change to the respective counter is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the last change to the respective counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the last change to the respective counter (32-bit)

4.16.4.11.14.9 "CounterValue" register

Name:
CounterValue01 to CounterValue02

This register shows the current value of the respective counter.

Data type	Value	Information
INT	-32,768 to 32,767	Value of the respective counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Value of the respective counter (32-bit)

4.16.4.11.14.10 "CounterLatch" register

Name:
CounterLatch01 to CounterLatch02

As soon as the latch conditions defined in the 4.16.4.11.14.4 "CfO_LatchComparator" register have been met, the contents of the respective CounterValue register are copied to this register.

Data type	Value	Information
INT	-32,768 to 32,767	Latch counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Latch counter (32-bit)

4.16.4.11.14.11 "CounterRel" register

Name:
CounterRel01 to CounterRel02

The value of the respective counter, relative to the last latch of the respective counter is calculated in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Counter value relative to the last latch (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Counter value relative to the last latch (32-bit)

4.16.4.11.15 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. In general, a "Fast reaction" setting and a very short system cycle (50 µs) have a negative influence on the minimum X2X cycle time. This can lead to errors when the X2X cycle time is short.

4.16.5 X20DS1319

4.16.5.1 General information

The module being used is a multifunctional digital signal processor module. It's flexibility allows it to be implemented for a wide range of tasks involving the creation or processing of digital signals. For example, two main uses include encoder emulation and controlling stepper output stages with pulse and direction signals. When used for encoder emulation, frequency inverters or servo axes with the speed follow function can follow a real or virtual master axis.

A further important feature is the timestamp function, which is integrated in the module. It can be used, for example, to create ramp curves for the counter in the encoder emulation virtually independent of bus cycle times. It's only necessary to enter the target counter value and the time at which it should be reached. The module generates the appropriate counter values, precisely in microsecond resolution and independently of the bus clock.

- 4 digital input channels
- 4 digital channels, configurable as inputs or outputs
- 1 universal counter pair (2 event counters, AB counter or up/down counter)
- Linear movement generator (A/B; direction/frequency) with up to 2 reference pulses
- SSI absolute encoder

4.16.5.2 Order data

Model number	Short description	Figure
	Digital signal processing and preparation	
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 359: X20DS1319 - Order data

4.16.5.3 Technical data

Product ID	X20DS1319
Short description	
I/O module	4 digital input channels, 4 digital channels configurable as inputs or outputs, 1 universal counter pair (2 event counters, AB counter or up/down counter), linear movement generator (A/B; direction/frequency) with up to two reference pulses, SSI absolute encoder, relative or absolute times of input edges in µs resolution, time-triggered I/O, I/O oversampling
General information	
B&R ID code	0x2547
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Inputs/Outputs	Yes, using status LED
Power consumption	
Bus	0.01 W
Internal I/O	1.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines.
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2	Yes
KC	Yes
GL	Yes
GOST-R	Yes
Linear movement generator	
Quantity	1
Encoder outputs	24 V, asymmetrical (A/B; direction/frequency)
Counter size	16/32-bit
Digital inputs	
Quantity	4 + 4, configurable as inputs or outputs using software
Nominal voltage	24 VDC
Input voltage	24 VDC -15% / +20%
Input current at 24 VDC	Approx. 1.3 mA
Input filter	
Hardware	≤2 µs
Software	-
Input circuit	Sink
Additional functions	SSI absolute encoder, universal counter pair, latch function for universal counter pair
Input resistance	18.4 kΩ
Input frequency	100 kHz
Switching threshold	
Low	<5 VDC
High	>15 VDC
Overload behavior of the encoder supply	Short circuit protection, overload protection
Isolation voltage between channel and bus	500 V_{eff}
SSI absolute encoder	
Quantity	1
Counter size	Encoder-dependent up to 32-bit
Max. transfer rate	125 kbit/s
Encoder supply	Module-internal, max. 600 mA
Nominal voltage	24 V, asymmetrical
Universal counter pair	
Quantity	1
Operating modes	2x event counter, up/down counter, AB counter
Encoder inputs	24 V, asymmetrical
Counter size	16/32-bit
Input frequency	Max. 100 kHz
Evaluation	
AB counter	4x
Event counter	2x
Up/Down counter	2x
Signal form	Square wave pulse
Encoder supply	Module-internal, max. 600 mA
Digital outputs	
Design	Push / Pull / Push-Pull
Quantity	Up to 4, configurable as inputs or outputs using software
Nominal voltage	24 VDC
Switching voltage	24 VDC -15% / +20%

Table 360: X20DS1319 - Technical data

Product ID	X20DS1319
Nominal output current	0.1 A
Total nominal current	0.4 A
Output circuit	Sink and/or source
Output protection	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
Diagnostic status	Output monitoring
Leakage current when switched off	Max. 25 µA
Residual voltage	<0.9 V at 0.1 A rated current
Peak short circuit current	<10 A
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Switching delay	
0 -> 1	<2 µs
1 -> 0	<2 µs
Switching frequency	
Resistive load	Max. 125 kHz
Inductive load	See section "Switching inductive loads"
Braking voltage when switching off inductive loads	Switching voltage + 0.6 VDC
Additional functions	Timing for SSI absolute encoder, linear movement generator
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 360: X20DS1319 - Technical data

4.16.5.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	I/O error. Possible causes: • SSI error[2]
			Double flash	System error. Possible causes: • Motion function error[3] • I/O oversampling error[4] • Edge detection error[4]
			Triple flash	I/O error and system error occur together
			On	Error or reset status
	1 - 8	Green		Status of the corresponding digital signal

1) Depending on the configuration, a firmware update can take up to several minutes.
2) See 4.16.4.11.6.2 "Error state - SSI" register for the exact error description.
3) See 4.16.5.11.6.3 "Error state - Motion functions" register for the exact error description.
4) See 4.16.4.11.6.1 "Error state - Output data and edge detection" register for the exact error description.

4.16.5.5 Pinout

Shielded cables must be used for all signal lines.

4.16.5.11 Register description

4.16.5.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.16.5.11.2 Function model 0 - default

Register	Name	Data type	Read		Write

4.16.5.11.3 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.16.5.11.4 General

4.16.5.11.4.1 Use with Automation Studio

The module is supported via X2X Link and POWERLINK.

X2X Link supports a up to 28 bytes of synchronous data per module. To optimize use and to prevent needless data transfer, the data points can be adjusted as needed in Automation Studio. Data points that are not needed can be disabled, and the bit width of the data points can be defined.

4.16.5.11.4.2 Timestamp function

The timestamp function is based on synchronized timers. When a timestamp event occurs, the module immediately saves the current net time. After the respective data is transmitted to the CPU, including this precise time, the CPU can then evaluate the data using its own net time (or system time).

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise time defined by the CPU.

The resolution of the timestamp is up to 1/8 µs in both directions.

4.16.5.11.4.3 Synchronization jitter

Because the CPU – which determines the X2X net time – and the module have different clocks, the module's internal X2X net time must be synchronized with the CPU's net time. Due to this synchronization, the module's internal X2X net time is corrected by a maximum of 1/8 µs per system cycle if necessary. This synchronization jitter becomes noticeable when using the net time with 1/8 µs resolution (max. ±1/8 µs).

If a 100% exact 1/8 µs resolution without jitter is required, then the "localtime 1/8 µs" must be used (see the 4.16.4.11.11.3 "CfO_EdgeDetectUnitMode" register).

4.16.5.11.5 General registers

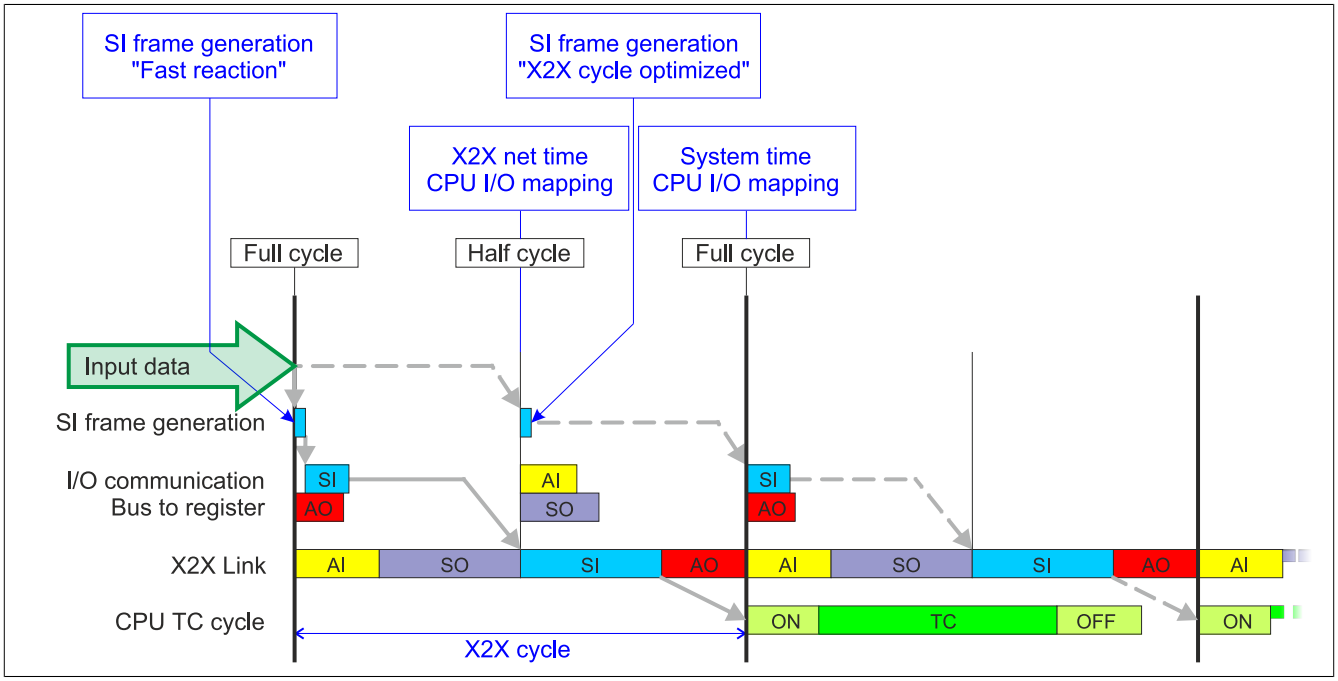
4.16.5.11.5.1 "CfO_SIframeGenID" register

Name:
CfO_SIframeGenID
"SI-frame generation" in the AS I/O configuration.

This register determines when the synchronous input data is generated for transfer. This has a decisive effect on the timing of the input data.

The setting "Fast reaction" causes the input data to be available one X2X cycle sooner in the CPU. However, this setting also has a negative effect on the minimum X2X cycle time.

Data type	Value	Information
USINT	9	X2X cycle optimized
	14	Fast reaction



4.16.5.11.5.2 "ProtocolError" register

Name:
ProtocolError

This register contains an error counter that specifies the number of X2X protocol errors. In the I/O configuration, the "Network information" parameter can be used to help configure a data point for this register with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.5.11.5.3 "ProtocolSequenceViolation" register

Name:
ProtocolSequenceViolation

This register contains an error counter that specifies the number of X2X sequence violations. In the I/O configuration, the "Network information" parameter can be used to help configure a data point with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.5.11.5.4 "SDCLifeCount" register

Name:
SDCLifeCount

Counter that is incremented with each system timer cycle. The "SDC information" setting in the AS I/O configuration can be used to activate this register in the I/O mapping as the data point, "SDCLifeCount".

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.5.11.6 Error handling

If one of the functions detects an error, then an error bit is set in one of the error state registers. The application is now able to react accordingly and acknowledge the errors by setting a respective bit in the "Acknowledge error message" registers. This causes the bit to be reset in the error state register. If the source of the error persists, then the error bit is set again as soon as the error is detected again (i.e. cannot be reset).

Acknowledging the error does not affect the module's functionality. If possible, the module automatically resumes processing as soon as the source of the error has been corrected.

If an error occurs (not a warning), this is indicated by the red "e" LED on the module (double flash). This signal is automatically acknowledged as soon as the source of the error has been corrected.

4.16.5.11.6.1 Error state register - Output data and edge detection

Name:
OutputControlError
OutputCopyError
EdgeDetectError

Errors in the output data and cycle time settings are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	OutputControlError	0	No error
		1	The module did not receive new data in time while in the mode "Output control mode = single", meaning that a bit that has already been output would have been output again by the output control buffer.
5	OutputCopyError	0	No error
		1	Oversampling output data could not be copied to the output control buffer. (e.g. an attempt was made to write oversampling output data to an address outside of the OversampleOutputWindow).
6	EdgeDetectError	0	No error
		1	Cycle time violation edge detection: The "EdgeDetectPollCycle" must be smaller than or equal to 255 µs. This error is caused if the cycle defined in the 4.16.4.11.11.1 "CfO_EdgeDetectPollCycleID" register is > 255 µs.
7	Reserved	-	

4.16.5.11.6.2 Error state register - SSI

Name:
SSICycleTimeViolation
SSIParityError

SSI interface errors are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	SSICycleTimeViolation	0	No error
		1	Error occurred, possible causes: • SSI transfer takes longer than the defined "Update cycle". • Monoflop check is enabled and the SSI data line does not assume the defined level after the transfer is complete.
1	SSIParityError	0	No error
		1	SSI parity error
2 - 7	Reserved	-	

4.16.5.11.6.3 Error state register - Movement functions

Name:
MovFifoEmpty
MovFifoFull
MovTargetTimeViolation
MovMaxFrequencyViolation

Movement function errors are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovFifoEmpty	0	No error
		1	The position/timestamp FIFO is empty.
1	MovFifoFull	0	No error
		1	The position/timestamp FIFO has exceeded the size defined in the 4.16.4.11.12.3 "FifoSize" register.
2	MovTargetTimeViolation	0	No error
		1	This only occurs when the 4.16.4.11.12.18 "MovTargetTime" is in the past.
3	MovMaxFrequencyViolation	0	No error
		1	The maximum output frequency setpoint has exceeded the maximum frequency configured in the 4.16.5.11.12.5 "CfO_SpeedLimit" register.
4 - 7	Reserved	-	

4.16.5.11.6.4 Acknowledge error message register - Output data and edge detection

Name:
QuitOutputControlError
QuitOutputCopyError
QuitEdgeDetectError

Error messages from the 4.16.4.11.6.1 "Error state - Output data and edge detection" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	QuitOutputControlError	0	No change
		1	Acknowledge error
5	QuitOutputCopyError	0	No change
		1	Acknowledge error
6	QuitEdgeDetectError	0	No change
		1	Acknowledge error
7	Reserved	-	

4.16.5.11.6.5 Acknowledge error message register - SSI

Name:
SSIQuitCycleTimeViolation
SSIQuitParityError

Error messages from the 4.16.4.11.6.2 "Error state - SSI" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	SSIQuitCycleTimeViolation	0	No change
		1	Acknowledge error
1	SSIQuitParityError	0	No change
		1	Acknowledge error
2 - 7	Reserved	-	

4.16.5.11.6.6 Acknowledge error message register - Movement functions

Name:
MovQuitFifoEmpty
MovQuitFifoFull
MovQuitTargetTimeViolation
MovQuitMaxFrequencyViolation

Error messages from the 4.16.5.11.6.3 "Error state register - Movement functions"register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovQuitFifoEmpty	0	No change
		1	Acknowledge error
1	MovQuitFifoFull	0	No change
		1	Acknowledge error
2	MovQuitTargetTimeViolation	0	No change
		1	Acknowledge error
3	MovQuitMaxFrequencyViolation	0	No change
		1	Acknowledge error
4 - 7	Reserved	-	

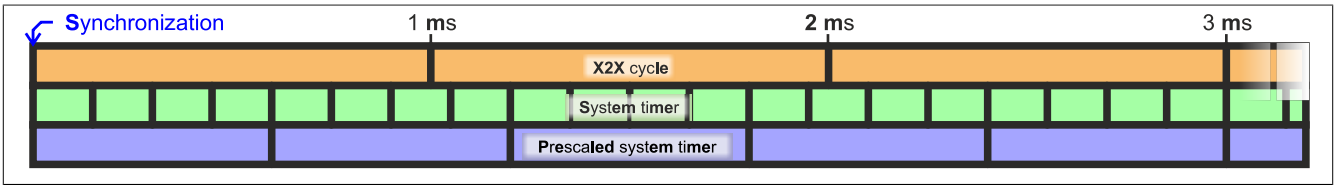
4.16.5.11.7 System timer

The module's individual functions all depend on a system timer. This internal "system cycle time" can be defined from 25 to 255 µs. The functions can also be run with the help of a configurable "prescaled system timer" to minimize the load on the module, thereby making it possible to use the shortest possible X2X cycle time.

The cycle of the "prescaled system timer" (and system timer) is referenced with the X2X Link as soon as the module has been started up and the X2X Link has been initialized. Since the system timer and the module's internal X2X net time use the same clock, the two run synchronously from that point on. An X2X cycle time that is not a multiple of the system cycle time results in an offset, which can be calculated.

The following values apply to the following example:

X2X cycle	1 ms
System timer	150 µs
Prescaled system timer	4



4.16.5.11.7.1 "CfO_SystemCycleTime" register

Name:
CfO_SystemCycleTime
"Cycle time" in the AS I/O configuration.

The cycle time of the system timer can be set in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Information:

A setting < 50 µs has a negative effect on the minimum X2X cycle time!

Data type	Value	Information
UINT	200 to 2047	System timer cycle time in steps of 1/8 µs (25 to 255,875 µs)

4.16.5.11.7.2 "CfO_SystemCycleOffset" register

Name:
CfO_SystemCycleOffset
"Cycle offset" in the AS I/O configuration.

The synchronization time for the system cycle can be offset in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Data type	Value	Information
INT	-32,768 to 32,767	Cycle offset in steps of 1/8 µs (-4096 to 4095.875 µs)

4.16.5.11.7.3 "CfO_SystemCyclePrescaler" register

Name:
CfO_SystemCyclePrescaler
"Cycle prescaler" in the AS I/O configuration.

The prescaler for setting the "Prescaled system timer" can be configured in this register. The cycle time of the specified system timer is a product of the system timer multiple set in this register.

The "prescaled system timer" can be used as alternative time source for the individual functions. This is useful if a function requires a very short system cycle. To reduce the load on the module in such a situation, other functions can be processed in a slow cycle.

Data type	Value	Information
UINT	2 to 128	Multiple of the system timer

4.16.5.11.8 Physical I/O configuration

4.16.5.11.8.1 "CfO_PhyIOConfigCh" registers

Name:
CfO_PhyIOConfigCh01 to CfO_PhyIOConfigCh08

The physical I/O channels can each be configured individually in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Push driver[1)]	0	Disabled
		1	Enabled
1	Pull driver[1)]	0	Disabled
		1	Enabled
2	Input inverted	0	Not inverted
		1	Inverse
3	Output inverted[1)]	0	Not inverted
		1	Inverse
4 - 7	Output function[1)]	0 to 15	See: Overview of output channel functions

1) Only available for the I/O channels 3, 4, 7 and 8.

Overview of output channel functions

Values of bits 4 to 7	Output channel 3	Output channel 4	Output channel 7	Output channel 8
0	Direct I/O			
1				SSI clock output
2	ABR emulation (A)	ABR emulation (B)	ABR emulation (reference 1)	ABR emulation (reference 2)
3	Up/down emulation (direction)	Up/down emulation (frequency)	Up/down emulation (reference 1)	Up/down emulation (reference 2)
4 - 15	Reserved			

4.16.5.11.9 Direct I/O

Direct I/O makes it possible to use the physical I/Os like normal I/Os. Additionally, the application can only set or reset I/Os (e.g. an output channel is set by the edge generator and manually reset by the application).

4.16.5.11.9.1 "EdgeGenTimestamp" register

Name:
CfO_DirectIOClearMask0_7
"Direct control of output channel 03" to "Direct control of output channel 08" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is reset as soon as its direct I/O output channel is reset (4.16.5.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	Output channel 3	0	No change
		1	Reset channel
3	Output channel 4	0	No change
		1	Reset channel
4 - 5	Reserved	-	
6	Output channel 7	0	No change
		1	Reset channel
7	Output channel 8	0	No change
		1	Reset channel

4.16.5.11.9.2 "CfO_DirectIOSetMask0_7" register

Name:
CfO_DirectIOSetMask0_7
"Direct control of output channel 03" to "Direct control of output channel 08" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is set as soon as its direct I/O output channel is set (4.16.5.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	Output channel 3	0	No change
		1	Set channel
3	Output channel 4	0	No change
		1	Set channel
4 - 5	Reserved	-	
6	Output channel 7	0	No change
		1	Set channel
7	Output channel 8	0	No change
		1	Set channel

4.16.5.11.9.3 "DigitalOutput" register

Name:
DigitalOutput03 and DigitalOutput04, DigitalOutput07 and DigitalOutput08

This register contains the bits for controlling the direct I/O output channels. Depending on how the 4.16.5.11.9.1 "CfO_DirectIOClearMask0_7" and 4.16.5.11.9.2 "CfO_DirectIOSetMask0_7" registers are configured, the digital outputs are set to the status of the respective bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	DigitalOutput03	0 or 1	Output status of channel 3
3	DigitalOutput04	0 or 1	Output status of channel 4
4 - 5	Reserved	-	
6	DigitalOutput07	0 or 1	Output status of channel 7
7	DigitalOutput08	0 or 1	Output status of channel 8

4.16.5.11.9.4 "DigitalInput" register

Name:
DigitalInput01 to DigitalInput08

This register displays the status of the digital input channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalInput01	0 or 1	Input status of channel 1
...	...	...	
7	DigitalInput08	0 or 1	Input status of channel 8

4.16.5.11.10 Oversampled I/O

"Oversampled I/O" is based on input status buffers and output control buffers. Input data acquisition and output control occur in one sample cycle (one sample cycle equals one bit in the buffer). The precise time of an input buffer entry is indicated by its position in the buffer and the net time assigned to the buffer.

In "Output control mode = single" every output buffer entry is marked as invalid once it has been executed. This ensures that the outputs are not supplied with invalid data. In this mode, the application needs to ensure that the module is always supplied with valid data.

When using "Output control mode = continuous" the contents of the buffer are output again if the module is not supplied with new oversample output data.

4.16.5.11.10.1 Addressing the output control buffer

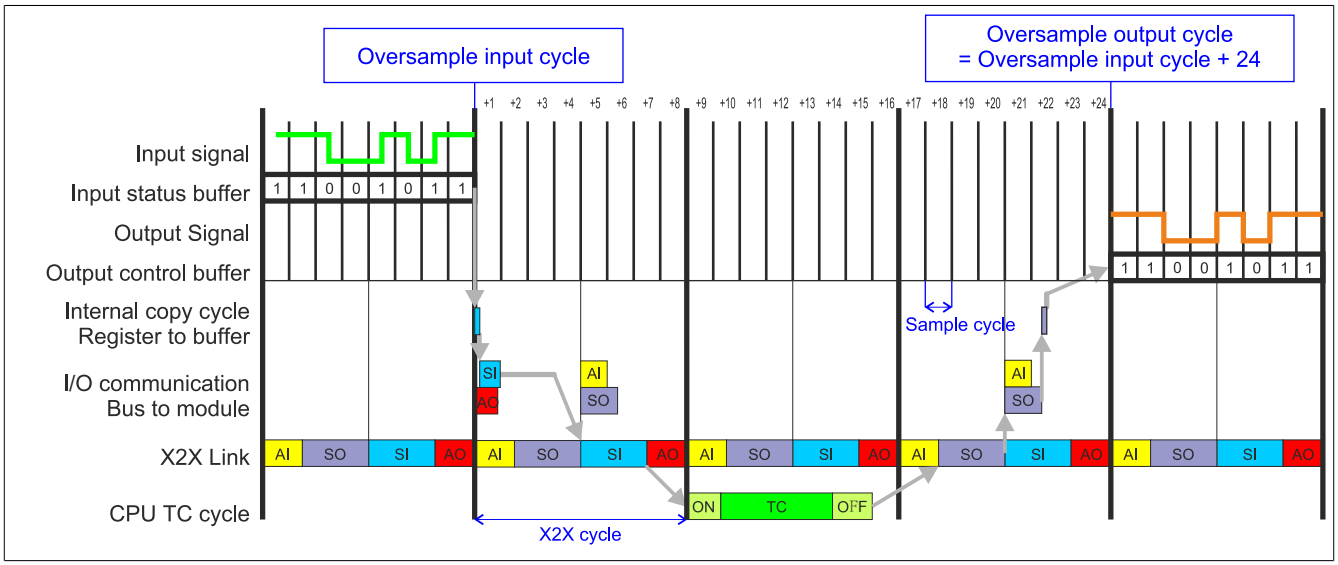
The module has one cyclic 256-bit output control buffer for each oversample channel. One bit is output from these buffers to the configured physical output channels in each "sample cycle". When new data is transferred to one of these buffers, the application must define where in the respective buffer the data should be written to. There are 2 possibilities (absolute or relative "Output mode" in the AS I/O configuration).

Absolute addressing of the output control buffer

With absolute addressing, in each cycle where "OversampleOutputValidate = True", in addition to the oversample output sample data (in the 4.16.4.11.10.15 "OversampleOutput0NSample" registers) an address must also be transferred in the 4.16.4.11.10.13 "OversampleOutputCycle" register. This address determines where in the output control buffer the new data should be copied to. In order to calculate this address, you must account for the contents of the 4.16.4.11.10.17 "OversampleInputCycle" register, which contains the address of the most recently output data, and the transfer time to the module. To help avoid incorrect addressing of the output control buffer, the buffer section that is capable of being written to can be limited using the 4.16.4.11.10.8 "OversampleOutputWindow" register. This window will always be shifted relative to the current sample address. An "OutputCopyError" will be triggered if an attempt is made to write to an address that is outside of this window.

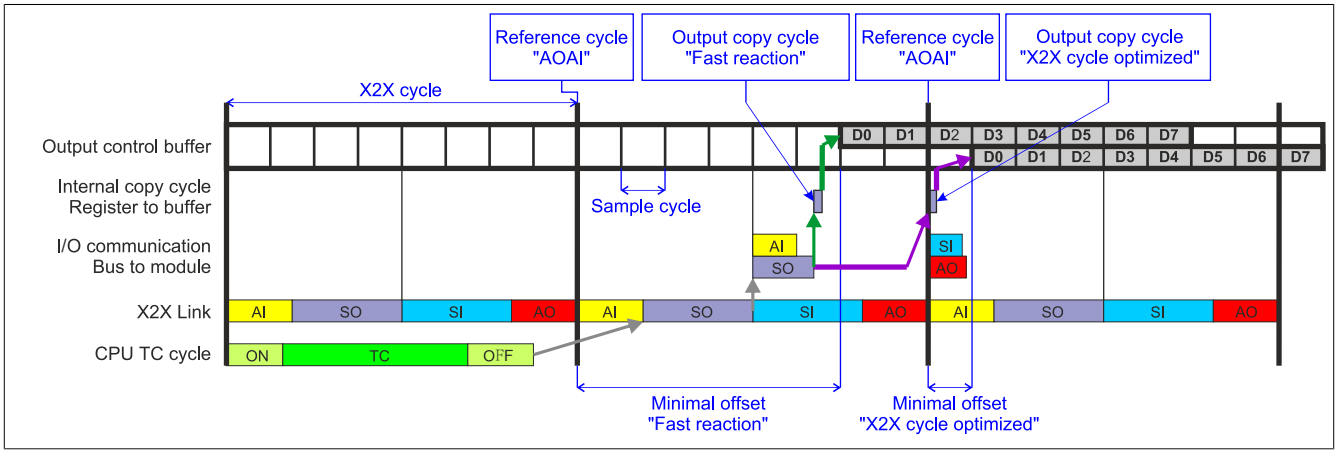
Example

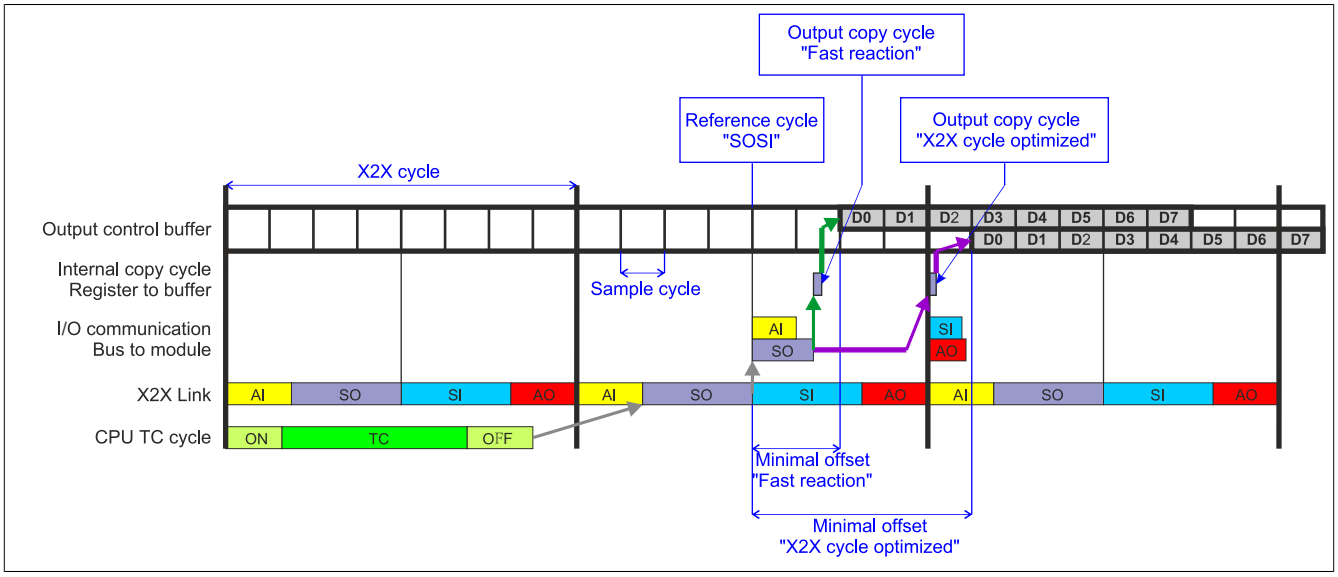
Timing from oversample input cycle to oversample output cycle in absolute output mode ("SI-frame generation = Fast reaction", "Output copy cycle = Fast reaction", 8 samples per X2X cycle):



Relative addressing of the output control buffer

When "OversampleOutputValidate = True", then the oversample output sample data is automatically copied to an address relative to the last referenced address at the defined "output copy cycle" time. The 4.16.4.11.10.14 "OversampleSampleOffset" register serves as the offset. The new data cannot start being output immediately at the "output copy cycle" time because it takes time to copy the data from the registers to the buffer. This means that an offset of 0 is not allowed. The relative output control buffer address + offset must point to an address within the "oversample output window". The "oversample output window" is always offset relative to the current sample address. An "OutputCopyError" is triggered if an attempt is made to write to an address that is outside of this window.





4.16.5.11.10.2 "CfO_OversampleMode" register

Name:
CfO_OversampleMode
"Output mode" in the AS I/O configuration
"Output control mode" in the AS I/O configuration.

The output control buffer can be configured globally for all channels in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Addressing the output control buffer "Output mode" in the AS I/O configuration.	0	Absolute addressing of the output control buffer
		1	Relative addressing of the output control buffer
1	Cyclic output control "Output control mode" in the AS I/O configuration.	0	Single - Output control buffer entry is marked invalid after execution.
		1	Continuous - Output control buffer entry is not changed.
2 - 7	Reserved	-	

Cyclic output control

If cyclic output control is enabled, then all data in the output control buffer is marked invalid as soon as it is output ("Output control mode = single"). An OutputControlError is generated if the module does not receive data in time, thereby causing a situation in which a bit that has already been output would be output in the buffer again. In such a situation, the output assumes the "Output default state" configured in the CfO_OversampleConfigOutput register.

If cyclic output control is disabled, then the data is output again if the output control buffer overflows ("Output control mode = continuous").

Information:

All 256 bits of the output control buffer are always output.

4.16.5.11.10.3 "CfO_OversampleSampleCycleID" register

Name:
CfO_OversampleSampleCycleID
"Sample cycle" in the AS I/O configuration.

The source of the sample cycle can be configured in this register. During each sample cycle, one bit from the output control buffers of the oversampled I/O channels is output to the configured physical output, and the status of the configured inputs is entered in one bit of the respective input status buffer.

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the sample cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle.

4.16.5.11.10.4 "CfO_OversampleRelativeCycleID" register

Name:
CfO_OversampleRelativeCycleID
"Reference cycle" in the AS I/O configuration.

The source of the user interface reference cycle can be configured in this register.

- The input data is referenced at the time of the "reference cycle". The referenced data is then copied to the "oversample input sample register" at the time of "SI frame generation", while taking the "OversampleInputWindow" into account.
- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle, and with it also the output data production and input data acquisition (e.g. to the X2X cycle).

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the reference cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle.

4.16.5.11.10.5 "CfO_OversampleConsumeCycleID" register

Name:
CfO_OversampleConsumeCycleID
"Output copy cycle" in the AS I/O configuration.

At the time of the output copy cycle, data is copied from the 4.16.4.11.10.15 "OversampleOutput0NSample" registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

Data type	Value	Information
USINT	10	X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle.
	15	Fast reaction The output data is copied to the output control buffer immediately after being received.

4.16.5.11.10.6 "CfO_OversampleOutputBits" register

Name:
CfO_OversampleOutputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the 4.16.4.11.10.15 "OversampleOutputONSample" registers to the output control buffers at the time of the "output copy cycle".

Data type	Value	Information
USINT	1 to 64	Output bits

4.16.5.11.10.7 "CfO_OversampleInputBits" register

Name:
CfO_OversampleInputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register during "SI frame generation".

Data type	Value	Information
USINT	1 to 64	Input bits

4.16.5.11.10.8 "CfO_OversampleOutputWindow" register

Name:
CfO_OversampleOutputWindow
"Output control mode" in the AS I/O configuration.

Determines the area in the output control buffer in which data can be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An "OutputCopyError" is triggered if an attempt is made to write output sample data to a location outside of this window.
In AS, with the setting "Output control mode = Single", this register is set to 128 bits and with the setting "Output control mode = Continuous" it is set to 255 bits.

Data type	Value	Information
USINT	0 to 255	Output window

4.16.5.11.10.9 "CfO_OversampleInputWindow" register

Name:
CfO_OversampleInputWindow
"Input mode" in the AS I/O configuration.

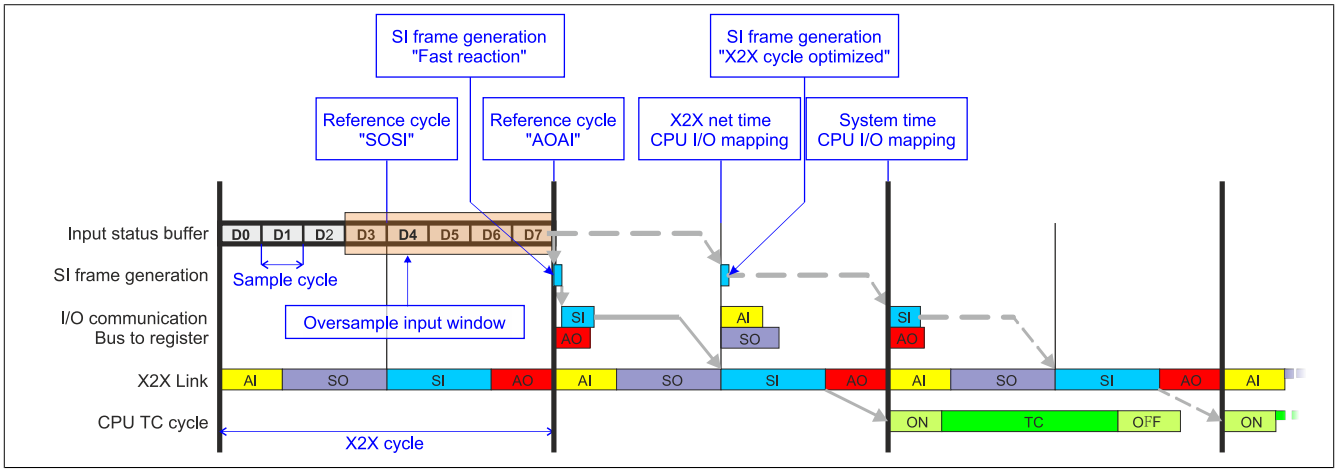
The "OversampleInputWindow" determines when the input data is referenced. It is located chronologically before "SI frame generation". If the reference time ("reference cycle") is within this window, then the referenced data is copied from the input status buffer to the OversampleInput0NSample register. If the time at which the reference occurs is outside the "OversampleInputWindow" then the data that is most recent at the time of "SI frame generation" is copied from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register.
This register is limited internally with to the value set in the 4.16.4.11.10.7 "CfO_OversampleInputBits" register.

Information:

As a result, the "OversampleInputTime" and the "OversampleInputCycle" are set either at the reference time or at the time of "SI frame generation".

In Automation Studio, this register is set to 63 when "Input mode = Referenced values" and to 0 when "Input mode = Most recent values".

Data type	Value	Information
USINT	0 to 63	Input window



4.16.5.11.10.10 "CfO_OversampleConfigInput" register

Name:
CfO_OversampleConfigInput
"Oversample I/O 01 →Input" to "Oversample I/O 04 → Input" in the AS I/O configuration

This register determines which physical input channel an oversample I/O input should be linked to.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical input channel	0	Input channel 1
		..	
		7	Input channel 8
4 - 7	Reserved	-	

4.16.5.11.10.11 "CfO_OversampleConfigOutput" register

Name:
CfO_OversampleConfigOutput
"Oversample I/O 01 → Output" to "Oversample I/O 04 → Output" in the AS I/O configuration
"Oversample I/O 01 → Output control" to "Oversample I/O 04 → Output control" in the AS I/O configuration
"Oversample I/O 01 → Output default state" to "Oversample I/O 04 → Output default state" in the AS I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits determine which level the respective output assumes before oversampling is started. Furthermore, the output is set to the defined "Output default state" in the event of an error.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical output channel "Oversample I/O 0x →Output" in the AS I/O configuration	2	Output channel 3
		3	Output channel 4
		6	Output channel 7
		7	Output channel 8
4	Output: Clear "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be reset by the oversample channel.
		1	Output can be reset by the oversample channel.
5	Output: Set "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be set by the oversample channel.
		1	Output can be set by the oversample channel.
6	Output default state: Clear "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not cleared by default
		1	Output cleared by default
7	Output default state: Set "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not set by default
		1	Output set by default

4.16.5.11.10.12 Oversample register - Configuration

Name:
OversampleEnable
OversampleOutputValidate

This register can be used to configure oversampling and the copy procedure for the output buffer.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	OversampleEnable	0	Disables oversampling (with the next reference cycle)
		1	Enables oversampling (with the next reference cycle)
1	OversampleOutputValidate	0	Disable the copy procedure to the output control buffer.
		1	Enables the copy procedure to the output control buffer. • Used to synchronize the oversampling procedure at startup. • This makes it possible to prevent new data from being transferred to the 4.16.4.11.10.15 "OversampleOutput0NSample" registers in each X2X cycle.
2 - 7	Reserved	-	

4.16.5.11.10.13 "OversampleOutputCycle" register

Name:
OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

Data type	Value	Information
USINT	0 to 255	Address of the output control buffer

4.16.5.11.10.14 "OversampleSampleOffset" register

Name:
OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. (Sample address at the time of the "reference cycle" + Offset = address to which the new output sample data is copied in the output control buffer).

Data type	Value	Information
USINT	0 to 255	Offset of output sample data

4.16.5.11.10.15 "OversampleOutputSample" register

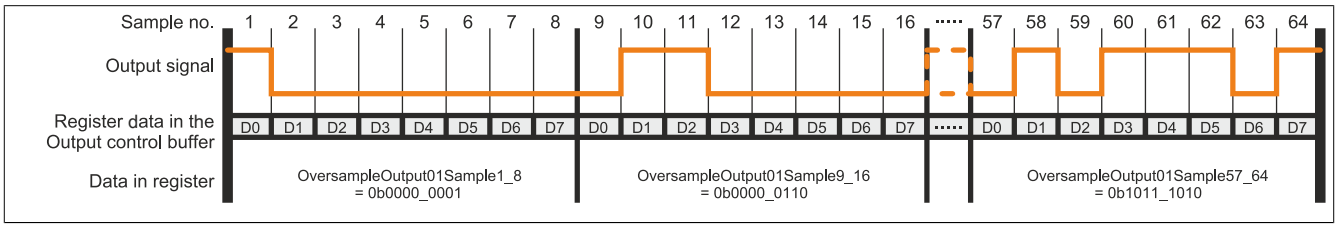
Name:
OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer during the "output copy cycle". 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.
Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

Data type	Value	Information
USINT	0 to 255	Output sample data

Example

Assignment of "OversampleOutputSample" register data to output signal



4.16.5.11.10.16 "OversampleInputTime" register

Name:
OversampleInputTime

This register contains the 2 low-order bytes of the X2X net time from the moment at which the oversample input data was referenced. This provides an easy way to accurately calculate the time of each individual input sample.

Data type	Value	Information
INT	-32,768 to 32,767	X2X net time of the input data

4.16.5.11.10.17 "OversampleInputCycle" register

Name:
OversampleInputCycle

This register provides the width of the input status buffer address for the input sample data.
Furthermore, the value in this register can be used for referencing an absolute addressing of the output control buffer.

Data type	Value	Information
USINT	0 to 255	Input status buffer address

4.16.5.11.10.18 "OversampleInputSample" register

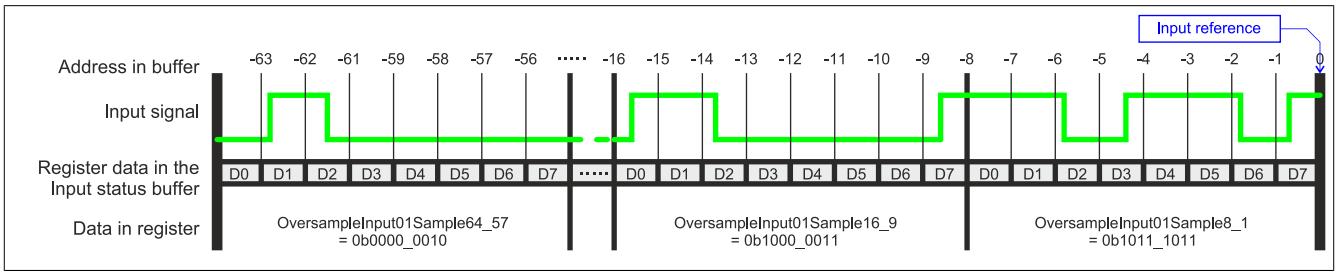
Name:
OversampleInput01Sample8_1 to OversampleInput04Sample8_1
OversampleInput01Sample16_9 to OversampleInput04Sample16_9
OversampleInput01Sample24_17 to OversampleInput04Sample24_17
OversampleInput01Sample32_25 to OversampleInput04Sample32_25
OversampleInput01Sample40_33 to OversampleInput04Sample40_33
OversampleInput01Sample48_41 to OversampleInput04Sample48_41
OversampleInput01Sample56_49 to OversampleInput04Sample56_49
OversampleInput01Sample64_57 to OversampleInput04Sample64_57

The data of the four oversample input status buffers are copied to this register at the time of "SI frame generation". A maximum of 64 samples (8 bytes) per oversample I/O channel can be synchronously retrieved from the oversample input status buffer with each X2X cycle.
The most recent input sample bit is stored in "OversampleInputSample8_1" bit 7. The oldest input sample is stored in "OversampleInputSample64_57" bit 0.

Data type	Value	Information
USINT	0 to 255	Input sample data

Example

Input signal and resulting data in "OversampleInputSample"



4.16.5.11.11 Edge detection

The module's edge detection function identifies edges with µs precision. The concept is based on a maximum of 4 units. A master and a slave edge can be configured for each unit.

At each master edge, the net time of the master edge and the net time of a previous slave edge (if present) are logged. A "master counter" and a "slave counter" can always be used to determine how many edges have been detected since the last X2X cycle.

4.16.5.11.11.1 "CfO_EdgeDetectPollCycleID" register

Name:
CfO_EdgeDetectPollCycleID
"Polling cycle" in the AS I/O configuration.

The source of the polling cycle can be configured in this register.

Information:

The polling cycle must be less than or equal to 255 µs. Setting the cycle > 255 µs causes an EdgeDetectError.

Data type	Value	Information
USINT	2	System timer The time set in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used for the polling cycle.
	3	Prescaled system timer The time set in the 4.16.4.11.7.3 "CfO_SystemCyclePrescaler" register is used for the polling cycle.

4.16.5.11.11.2 "CfO_EdgeDetectEventEnable" register

Name:
CfO_EdgeDetectEventEnable
"Edge detection mode" in the AS I/O configuration.

The bits in this register determine at which edges on the individual input channels an interrupt should be triggered for the edge detection.

In "event triggered" mode, the net time of each edge is recorded immediately an interrupt. However, an extremely large amount of interrupts within a short amount of time can prevent the module from being able to process any other operations in time!

In "polling" mode, only the net time of the first edge that occurs within a polling cycle is recorded. This ensures that the module is not overloaded by too many edges.

In the AS IO configuration, this register is initialized with 0x00000000 when "Edge detection mode = polling" and with 0xFFFFFFFF when "Edge detection mode = event triggered".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Physical input 1	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
...		...	
7	Physical input 8	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
8 - 15	Reserved	-	
16	Physical input 1	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
...		...	
23	Physical input 8	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
24 - 31	Reserved	-	

4.16.5.11.11.3 "CfO_EdgeDetectUnitMode" register

Name:
CfO_EdgeDetectUnit01Mode to CfO_EdgeDetectUnit04Mode
"Time base" in the AS I/O configuration.
"Slave edge" in the AS I/O configuration.
"Master edge" in the AS I/O configuration.

When using a "time base" with 1/8 µs resolution, keep in mind that the timestamps produced also have a resolution of exactly 1/8 µs. The respective conversions must be made for calculating in combination with the CPU system time or X2X net time.

Furthermore, synchronization jitter also plays a role when using the setting "time base = net time resolution 1/8 µs" (see: 4.16.4.11.4.3 "Synchronization jitter"). This means that exactly identical input edges can cause slight differences in the results. If a 100% exact 1/8 µs resolution is required, then the "local resolution 1/8 µs" must be used.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	"Time base" in the AS I/O configuration.	0	Local time 1/8 µs (AS: Local resolution 1/8 µs)
		1	Local time 1 µs (AS: Local resolution 1 µs)
		2	Net time 1/8 µs (AS: Net time resolution 1/8 µs)
		3	Net time 1 µs (AS: Net time resolution 1 µs)
2 - 5	Reserved	-	
6	"Slave edge" in the AS I/O configuration.	0	Disabled
		1	Enabled
7	"Master edge" in the AS I/O configuration.	0	Disabled
		1	Enabled

4.16.5.11.11.4 "CfO_EdgeDetectUnitLeading" register

Name:
CfO_EdgeDetectUnit01Leading to CfO_EdgeDetectUnit04Leading
"Slave leading" in the AS I/O configuration.

When a slave edge occurs, the current net time is always saved within the module. A FIFO is provided inside the module which always stores the last 256 slave stamps (even when a master edge occurs).

This value determines from which position the slave time should be retrieved from the FIFO when a master edge occurs. This can be used to measure average periodic signals over multiple cycles.

Data type	Value	Information
USINT	0 to 255	Position in the slave edge FIFO

4.16.5.11.11.5 "CfO_EdgeDetectUnitMaster" register

Name:
CfO_EdgeDetectUnit01Master to CfO_EdgeDetectUnit01Master
"Master edge" in the AS I/O configuration.

This register is used to select the source of the master edge for the respective "edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	...	...
	7	Rising edge on physical input 8
	16	Falling edge on physical input 1
	...	...
	23	Falling edge on physical input 8

4.16.5.11.11.6 "CfO_EdgeDetectUnitSlave" register

Name:
CfO_EdgeDetectUnit01Slave to CfO_EdgeDetectUnit04Slave
"Slave edge" in the AS I/O configuration.

This register is used to select the source of the slave edge for the respective "edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	...	...
	7	Rising edge on physical input 8
	16	Falling edge on physical input 1
	...	...
	23	Falling edge on physical input 8

4.16.5.11.11.7 "EdgeDetectMastercount" register

Name:
EdgeDetect01Mastercount to EdgeDetect04Mastercount

The reference pulses of the detected master edges are counted in this register.

Data type	Value	Information
SINT	-128 to 127	Number of detected master edges (8-bit)
INT	-32,768 to 32,767	Number of detected master edges (16-bit)

4.16.5.11.11.8 "EdgeDetectSlavecount" register

Name:
EdgeDetect01Slavecount to EdgeDetect04Slavecount

Counts the number of detected slave edges consecutively. The contents of this register are only updated when a master edge occurs. These counters can detect if multiple slave edges occur before a master edge.

Data type	Value	Information
SINT	-128 to 127	Number of detected slave edges (8-bit)
INT	-32,768 to 32,767	Number of detected slave edges (16-bit)

4.16.5.11.11.9 "EdgeDetectDifference" register

Name:
EdgeDetect01Difference to EdgeDetect04Difference

Contains the time difference between a master edge and the last slave edge addressed via "Slave leading".

Data type	Value	Information
INT	-32,768 to 32,767	Time difference between master/slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Time difference between master/slave edge (32-bit)

4.16.5.11.11.10 "EdgeDetectMastertime" register

Name:
EdgeDetect01Mastertime to EdgeDetect04Mastertime

The exact net time is copied in this register when a master edge occurs.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of master edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of master edge (32-bit)

4.16.5.11.11.11 "EdgeDetectSlavetime" register

Name:
EdgeDetect01Slavetime to EdgeDetect04Slavetime

When a master edge occurs, the exact net time of any slave edge that may have occurred prior to the master edge and addressed by "Slave leading" is copied in this register. If multiple slave edges occur before a master edge, then only the net time of the last edge that was not ignored by "Slave leading" is stored. The 4.16.4.11.11.8 "EdgeDetectSlavecount" register can be used to detect multiple edges.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the slave edge (32-bit)

4.16.5.11.12 Movement functions

Encoder emulation can be used to generate up/down counters (direction/frequency) and ABR encoder signals. The movement function can be operated in 2 different modes:

- Position control mode
- Speed control mode

4.16.5.11.12.1 Position control mode

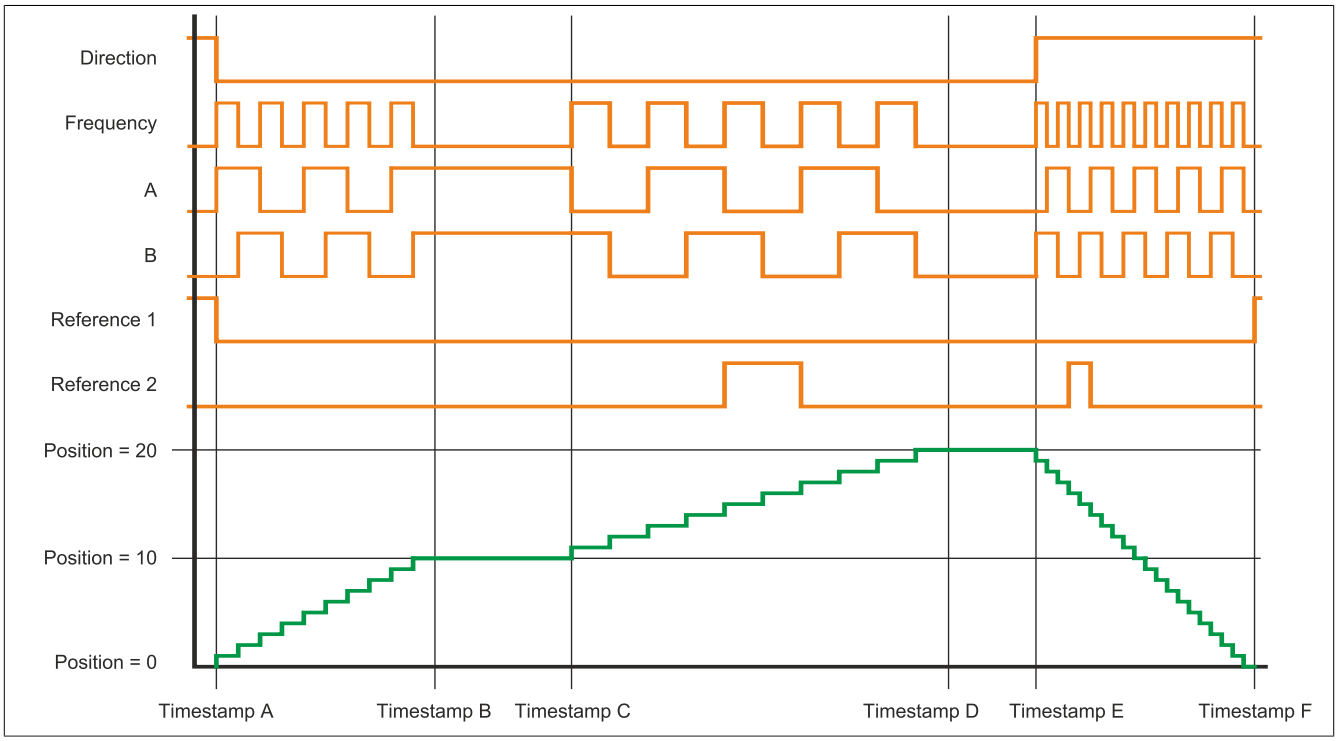
Each time the 4.16.4.11.12.18 "MovTargetTime" register changes, a new position setpoint is transferred from the 4.16.4.11.12.19 "MovPosition" register to the FIFO. The time/position data in the FIFO is then processed in such a manner that the positions are always reached at the time of the respective timestamps. This means that the module internally ensures that the positions are reached by the defined timestamps (number/frequency of the pulses is calculated automatically). The timestamps can be based on the X2X net time, the CPU's system time or the 4.16.4.11.12.21 "MovCurrentTime" register. Timestamps that are set in a manner that does not allow the required position change to be reached before the timestamp (output frequency of the pulse would exceed 4.16.5.11.12.5 "CfO_SpeedLimit") cause a MovMaxFrequencyViolation error.

Selected values for the example "Timing of movement":

Timestamp A = MovTimeValid + 40,000	Position for timestamp A = 0
Timestamp B = Timestamp A + 40.000	Position for timestamp B = 10
Timestamp C = Timestamp B + 25.000	Position for timestamp C = 10
Timestamp D = Timestamp C + 70,000	Position for timestamp D = 20
Timestamp E = Timestamp D + 15,000	Position for timestamp E = 20
Timestamp F = Timestamp E + 40,000	Position for timestamp F = 0

Configuration: Reference pulse 1 = Start position and margin, Start position = 0, Margin = 1

Configuration: Reference pulse 2 = Start and end position, Start position = 15, End position = 17



4.16.5.11.12.2 Speed control mode

In speed control mode, the application only specifies the speed setpoint. The module returns the current position in the 4.16.4.11.12.22 "MovPosition (32-bit)" register.

The internal timing is designed so that the value 16,777,216 (0x01000000) in the 4.16.4.11.12.20 "MovSpeed" register results in exactly one increment per "control period".

This creates the following relationship for 32-bit speed setpoints ("Data format of speed values = 32-bit):

$$MovSpeed = vOut * 2^{resol} * period$$

Unlike other registers, the 2 higher-value bytes of "MovSpeed (32-bit)" are set when the "MovSpeed (32-bit)" register is written. This creates the following relationship for the direct calculation with "MovSpeed (16-bit)"

$$MovSpeed = \frac{vOut * 2^{resol} * period}{2^{16}}$$

Variable	Description	Unit
MovSpeed	Value for "MovSpeed" register (16 or 32-bit)	
vOut	Desired output speed Each edge represents one increment (rising or falling).	Inc/s
resol	Value configured for the 4.16.4.11.12.13 "CfO_ResolSpeed" register	Bits
period	Value configured for the 4.16.4.11.12.11 "CfO_SpeedCycleTime_32Bit" register **Information:** **Must be set in µs in Automation Studio. The calculation is performed in s, however.**	s

4.16.5.11.12.3 "FifoSize" register

Name:
FifoSize
"Number of Fifo entries" in the AS I/O configuration.

Determines the size of the FIFO for MovTargetTime and MovTargetPosition. One timestamp and one position that should be reached by the timestamp can be transferred to the FIFO per X2X cycle.

Data type	Value	Information
USINT	0	FIFO disabled
	3	8 entries (2^3)
	4	16 entries (2^4)
	5	32 entries (2^5)
	6	64 entries (2^6)
	7	128 entries (2^7)
	8	256 entries (2^8)

4.16.5.11.12.4 "CfO_Mode" register

Name:
CfO_Mode

This register can be used to configure the mode of the movement functions.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Must be enabled when working without timestamps. Enabled in AS if: • Movement = "speed control" • Movement = "position control and "data format / mode of preset time = local time"	0	Disabled
		1	Enabled
1	If this function is enabled, then a new positioning movement is triggered as soon as the value changes in the 4.16.4.11.12.19 "MovPosition" register. Enabled in AS if: • Movement = "position control and "data format / mode of preset time = local time"	0	No position control (speed control)
		1	Position control enabled (position control)
2	Reference mode 1 "Configuration reference pulse 1" in the AS I/O configuration.	0	Start/end position
		1	Start position and span
3	Reference mode 2 "Configuration reference pulse 1" in the AS I/O configuration.	0	Start/end position
		1	Start position and span
4 - 7	Reserved	-	

4.16.5.11.12.5 "CfO_SpeedLimit" register

Name:
CfO_SpeedLimit
"Max. movement frequency" in the AS I/O configuration.

Configures the maximum permitted output frequency and the maximum internal computing frequency. The higher internal computing frequencies of 500 kHz and 2, 4, 8, 16, 32 and 64 MHz can only be achieved by configuring n bits as decimal places (see "CfO_ResolPosition" register).

Data type	Value	Max. increment frequency	Max. frequency for frequency output channel	Max. frequency for A/B output channel
USINT	253	64 MHz	125 kHz	625 kHz
	254	32 MHz		
	255	16 MHz		
	0	8 MHz		
	1	4 MHz		
	2	2 MHz		
	3	1 MHz		
	4	500 kHz		
	5	250 kHz (default)		
	6	125 kHz	625 kHz	3125 kHz

Information:

In "position control" mode, the increment frequencies 16, 32 and 64 MHz are not permitted to be used when a 29-bit timestamp is set (see 4.16.4.11.12.7 "CfO_TimeStampRange" register) due to an internal range violation.

4.16.5.11.12.6 "CfO_FormatAdjust" register

Name:
CfO_FormatAdjust

This register determines the number of absolute bits that can be output on the signal output (With a direction/frequency signal, the bit with the lowest value can be output directly on the frequency output. With an AB signal, 2 bits are possible.)

Data type	Value	Information
USINT	1 to 2	Number of absolute bits (AS default = 1)

4.16.5.11.12.7 "CfO_TimeStampRange" register

Name:
CfO_TimeStampRange
"Data format/mode of target time" in the AS I/O configuration.

The width of the transferred timestamp data in the module is configured in this register.

Information:

Because the module uses an internal resolution of 1/8 µs, timestamp data is processed internally at a maximum width of 29 bits.

Data type	Value	Information
SINT	16	16-bit timestamp ("16-bit" selected in the AS I/O configuration)
	24	24-bit timestamp ("local time" or "speed control" movement selected in the AS I/O configuration)
	29	29-bit timestamp ("29-bit" selected in the AS I/O configuration)

4.16.5.11.12.8 "CfO_PositionsRange" register

Name:
CfO_PositionsRange
"Target position range" in the AS I/O configuration.

The number of bits for position control are configured in this register. The "PositionRange" must be reduced if, for example, the movement function should follow the absolute value of a 12-bit SSI encoder. In this case, the bit width of the movement position also has to be limited to the number of bits of the encoder, or else the movement position would not also overrun if the encoder were to overrun. In this case, the module would attempt (in the opposite direction) to reach the position of an encoder that had just overrun.

Example

The 12-bit SSI encoder overruns from 2047 to -2048. The module would generate 4096 negative increments if more than 12 bits were defined for "CfO_PositionRange" in order to reach position -2048 from the position 2047.

Information:

If the 16-bit value of the 4.16.4.11.12.22 "MovPosition" register is used, then the bit width of the position must also be limited to ≤16 bits or else this would also result in incorrect overrun behavior.

Data type	Value	Information
SINT	8 to 32	Number of bits for position control

4.16.5.11.12.9 "CfO_ReferenceRange" register

Name:
CfO_Reference0Range to CfO_Reference1Range
"Reference#1 range" to "Reference#2 range" in the AS I/O configuration.

This register determines the number of bits that can be used for the reference position comparison. This makes it possible to generate a reference pulse every 2^n increments.

Information:

The number of bits set in this register must not be higher than the number of bits set for 4.16.5.11.12.14 "MovReferenceStart" and 4.16.5.11.12.15 "MovReferenceStopMargin".

Data type	Value	Information
SINT	4 to 32	Number of bits for position comparison

4.16.5.11.12.10 "CfO_TimeStampDelay" register

Name:
CfO_TimeStampDelay

All timestamps are delayed by the value defined in this register.

Data type	Value	Information
DINT	0 to 1000000	Timestamp delay in µs

4.16.5.11.12.11 "CfO_SpeedCycleTime_32Bit" register

Name:
CfO_SpeedCycleTime_32Bit
"Control period" in the AS I/O configuration.

The control period for "speed control" mode can be set in this register in steps of 1/8 µs.

Information:

The value defined in the AS I/O configuration under "Control period" is automatically multiplied by 8 and then used as CfO_SpeedCycleTime_32bit.

Data type	Value	Information
UDINT	400 to 40000	Control period for "speed control" mode

4.16.5.11.12.12 "CfO_ResolPosition" register

Name:
CfO_ResolPosition
"Position resolution" in the AS I/O configuration.

This register contains the number of bits as decimal place for jitter reduction. Internally, the module adds 2^n (n = number of decimal places) to the frequency, which results in edge switching times with a higher resolution. The output switching frequency is not increased from a hardware perspective, but the edge timing is more precise.

Data type	Value	Information
SINT	0	Default, no decimal places
	1 to 14	Selection of bits as decimal places

Information:

Keep in mind that each configured decimal place also limits the maximum number range by that number of bits.

For example: 0 decimal places →maximum position range = 29 bits

3 decimal places →maximum position range = 26 bits

Also keep in mind that the 4.16.5.11.12.5 "CfO_SpeedLimit" register must be adjusted for these higher computing frequencies based on the number of configured decimal places.

4.16.5.11.12.13 "CfO_ResolSpeed" register

Name:
CfO_ResolSpeed
"Speed resolution" in the AS I/O configuration.

This register contains the number of bits as decimal place for jitter reduction of the speed value. Internally, the module adds 2^n (n = number of decimal places) to the frequency, which results in edge speed values with a higher resolution.

Due to the bit limitation, a 16 or 32-bit speed value is set in the AS I/O configuration. Since the internal calculation is always based on 32-bit, when configured to 16-bit an offset of 16 must always be added to the desired number of decimal places.

Data type	Value	Information
SINT	0 to 31	Selection of bits as decimal places
	24	Standard

Information:

Keep in mind that each configured decimal place also limits the maximum number range by that number of bits.

4.16.5.11.12.14 "CfO_ReferenceStart / MovReferenceStart" register

Name:
CfO_Reference0Start to CfO_Reference1Start
MovReference1Start to MovReference2Start
"Start position" in the AS I/O configuration

The start position for the reference pulse is shown in these registers.

In the positive direction, the output (R) is set when the start position is reached. In negative direction, the output is reset as soon as the value falls below the start position value.

Data type	Value	Information
INT	-32,768 to 32,767	Start position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Start position (32-bit)

4.16.5.11.12.15 "CfO_ReferenceStopMargin / MovReferenceStopMargin" register

Name:
CfO_Reference0StopMargin to CfO_Reference1StopMargin
MovReference1StopMargin to MovReference2StopMargin
"End position or margin" in the AS I/O configuration

The end position or the margin in which the reference pulse is output is configured in these registers.

If "Reference mode x = Start/end position" is used in the 4.16.5.11.12.4 "CfO_Mode" register, then the output (R) is reset when the end position is reached in the positive direction. In the negative direction, the output is set as soon as the value falls below the end position value.

When "Reference mode x = Start position and span", the content of this register is added to the start position and the resulting sum is used as the end position.

Data type	Value	Information
INT	-32,768 to 32,767	End position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	End position (32-bit)

4.16.5.11.12.16 "CfO_AccelDataInit / MovAcceleration" register

Name:
CfO_AccelDataInit
MovAcceleration
"Acceleration value" in the AS I/O configuration.

This register shows the acceleration value in increments per control period².

- 32-bit: 16777216 (0x01000000) corresponds to 1 increment per control period²
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period²

Data type	Value	Information
UINT	0 to 65,535	Acceleration value (16-bit)
UDINT	0 to 4,294,967,296	Acceleration value (32-bit)

4.16.5.11.12.17 "MovementControl" register

Name:
MovPosEnable
MovSpeedEnable

This register can be used to enable position and speed control.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	MovPosEnable	0	Position control disabled
		1	Position control enabled
1	MovSpeedEnable	0	Speed control disabled
		1	Speed control enabled
2 - 6	Reserved	-	
7	Movement reset (immediate stop)	0	Passive reset
		1	Active reset

4.16.5.11.12.18 "MovTargetTime" register

Name:
MovTargetTime

Timestamp data is shown in this register.Each time this register changes, the new position data (MovTargetPosition) and timestamp data are transferred to the FIFO. When "MovSpeedEnable = True", the module calculates the output speed (frequency) so that the "MovTargetPosition" is reached at "MovTargetTime".

Data type	Value	Information
INT	-32,768 to 32,767	Timestamp (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Timestamp (32-bit)

Information:

Only 29 bits of this register are processed internally.

4.16.5.11.12.19 "MovTargetPosition" register

Name:
MovTargetPosition

Position data is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Position (32-bit)

4.16.5.11.12.20 "MovSpeed" register

Name:
MovSpeed

This register shows the speed setpoint for "speed control" mode in increments per control period.

- 32-bit: 16,777,216 (0x01000000) corresponds to 1 increment per control period
- 16-bit: 256 (0x0100) corresponds to 1 increment per control period

Data type	Value	Information
INT	-32,768 to 32,767	Speed setpoint (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Speed setpoint (32-bit)

4.16.5.11.12.21 "MovTimeValid" register

Name:
MovTimeValid

This register displays the net time of the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current position (16-bit).
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current position (32-bit)

4.16.5.11.12.22 "MovPosition" register

Name:
MovPosition

This register shows the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Current position (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Current position (32-bit)

4.16.5.11.13 Synchronous serial interface (SSI)

The synchronous serial interface makes it possible to receive data from SSI absolute encoders.

Two lines are needed for data exchange:

SSI clock:	Generated by the module on output 7 (if configured).
SSI data:	A data bit is transferred from the encoder to the module with each clock pulse (input 5 can be used as the SSI input).

4.16.5.11.13.1 SSI transfer process

When the first edge occurs on the SSI clock, a monoflop is triggered in the encoder and the current parallel pending value is latched to the offset register (the low level of the monoflop prevents other values from being added to the offset register during data transfer).

The highest value bit is then transferred to the module when the next edge occurs.

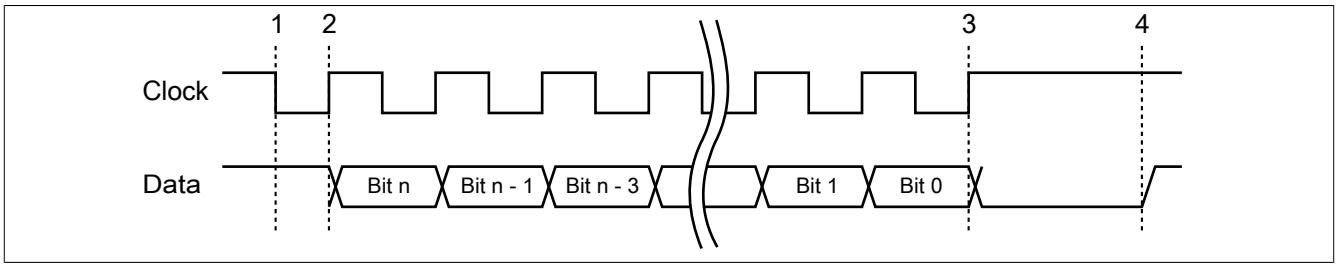
With each subsequent cycle, the next lowest bit is transferred. The cycles re-trigger the monoflop constantly so that its output prevents new data from being accepted.

The sequence of cycles stops once the number of data bits defined in the 4.16.4.11.13.4 "CfO_DataBits" register has been received.

The monoflop is no longer triggered. After a certain amount of time has passed (depending on the encoder), the monoflop's output re-assumes the output level, thereby enabling parallel data to be accepted once again in the encoder's offset register.

When the "Monoflop check" is run, the data line is queried for the configured level before a new transfer is started. This makes it possible to ensure that the monoflop really has reset before a new transfer is started.

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.16.5.11.13.2 "CfO_CycleSelect" register

Name:
CfO_CycleSelect
"Update cycle" in the AS I/O configuration.

SSI transfer is started at the update cycle. The clock sequence is generated on the SSI clock output. The first edge of the clock signal triggers the monoflop in the encoder and latches the current position. At the same time, the current net time is also recorded in the 4.16.4.11.13.6 "SSITimeValid" register. As soon as all bits have been transferred via the SSI, the position is passed on with the next "SIframeGenCycle" via the X2X Link. A SSICycleTimeViolation error is reported if the SSI transfer is not completed within the SSI update cycle (e.g. system timer as update cycle). The SSI transfer is still fully completed and then started again with the next update cycle.

Data type	Value	Information
USINT	2	System timer
	3	Prescaled system timer
	10	AOAI
	14	SOSI

4.16.5.11.13.3 "CfO_PhysicalMode" register

Name:
CfO_PhysicalMode
"Parity bit" in the AS I/O configuration
"Monoflop check" in the AS I/O configuration
"Data format" in the AS I/O configuration
"Clock frequency" in the AS I/O configuration

The SSI interface is configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	"Parity bit" in the AS I/O configuration.[1)]	00	Disabled
		01	Even parity
		10	Uneven parity
		11	Ignored (the parity bit is transferred, but not evaluated).
2 - 3	"Monoflop check" in the AS I/O configuration.[2)]	00	Disabled
		01	Low level (data signal is checked for low level after the monoflop has reset).
		10	High level (data signal is checked for high level after the monoflop has reset).
		11	Ignored (the necessary cycle is triggered, but not evaluated).
4	"Data format" in the AS I/O configuration.	0	Encoder with binary output
		1	Encoder with Gray Code. The module converts the position data into binary format.
5	Reserved	-	
6 - 7	"Clock frequency" in the AS I/O configuration.	00 to 10	Not permitted
		11	125 kHz

1) If the parity bit does not match, then a SSIParityError is generated and the position data is not accepted in the "SSIPosition" register.
2) A new SSI transfer is not started until the data signal has assumed the level defined for the "monoflop check" after the transfer. This then triggers the error SSICycleTimeViolation.

4.16.5.11.13.4 "CfO_DataBits" register

Name:
CfO_DataBits
"Valid SSI bit length" in the AS I/O configuration.

Determines the number of valid data bits to be transferred via the SSI. The valid data bits are used for the SSI-Position.

Data type	Value	Information
USINT	1 to 32	Number of valid data bits

4.16.5.11.13.5 "CfO_NullBits" register

Name:
CfO_NullBits
"Leading zero bits" in the AS I/O configuration.

This register can be used to configure the number of leading zero bits. The leading zero bits can be required before the valid data bits.

Data type	Value	Information
USINT	0 to 31	Number of leading zero bits

4.16.5.11.13.6 "SSITimeValid" register

Name:
SSITimeValid

This register displays the net time of the current position.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current position (16-bit).
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current position (32-bit)

4.16.5.11.13.7 "SSITimeChanged" register

Name:
SSITimeChanged

The net time of the last position change is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the last position change (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the last position change (32-bit)

4.16.5.11.13.8 "SSIPosition" register

Name:
SSIPosition

This register shows the current position sent via the SSI interface.

Data type	Value	Information
INT	-32,768 to 32,767	Current position (16-bit)
UDINT	0 to 4,294,967,295	Current position (32-bit)
DINT	-2,147,483,648 to 2,147,483,647	

4.16.5.11.14 Counter

The universal counter pair can be used in 3 different modes. Here, signals up to 100kHz are reliably measured. Up to 4 latch inputs can be configured in all modes. Enabled latch inputs are negated if necessary and connected with a logical AND operation for a latch condition. If the latch condition is met, the current counter value is stored in a separate register.

Inputs

The physical inputs have fixed assignments based on the respective mode.

Mode	Input 1	Input 2	Input 5	Input 6
Edge counters	Counter input for counter 1 Latch input 1	Counter input for counter 2 Latch input 2	- Latch input 3	- Latch input 4
Up/down counter	Counting direction Latch input 1	Counter frequency Latch input 2	- Latch input 3	- Latch input 4
Incremental encoder	A Latch input 1	B Latch input 2	- Latch input 3	- Latch input 4

Latch function

As latch inputs, inputs 1, 2, 5, and 6 can each be polled to determine if they have a HIGH or LOW level.

In "Latch mode = continuous", the counters are latched once as soon as "LatchEnable = TRUE" and the configured latch condition is met. If the latch condition is met again, then the counter value is also latched again. (i.e. One latch event is triggered with each rising edge on the output of the AND operation of all latch inputs).

In "Latch mode = single", the counters are latched once as soon as "LatchEnable = TRUE" and the configured latch condition is met. If the latch condition is met again, then the counter value is not automatically copied again. Another latch event can only be processed after "LatchEnable = False" and then "LatchEnable = True" again.

4.16.5.11.14.1 "CfO_CounterCycleSelect" register

Name:
CfO_CounterCycleSelect
"Update cycle" in the AS I/O configuration.

The update cycle for the counter values is configured in this register.

Information:

The maximum counting frequency depends on the cycle. The module can process a maximum of 200 increments (edges) within a counter cycle.

Data type	Value	Information
USINT	2	System timer
	3	Prescaled system timer
	10	AOAI time of X2X cycle
	14	SOSI time of X2X cycle

4.16.5.11.14.2 "CfO_CounterMode" register

Name:
CfO_CounterMode
"Counter mode" in the AS I/O configuration.

The counter mode is configured in this register.

Data type	Value	Information
USINT	0	Edge counters In this mode, the two counters are used as edge counters. The counter input of counter 1 is linked permanently to input 1 and the counter input of the second counter is linked permanently to input 2. Both rising as well as falling edges are counted.
	2	Up/down counter The up/down counter works according to the direction/frequency principle. Input 1 determines the counting direction (LOW = positive, HIGH = negative), input 2 serves as the counting frequency input. Both rising as well as falling edges on the counting frequency input are counted.
	3	Incremental encoder (AB counter) When configured as an AB counter, input 1 serves as the A channel and input 2 as the B channel. All edges are evaluated (4x evaluation).

4.16.5.11.14.3 "CfO_LatchMode" register

Name:
CfO_LatchMode
"Latch mode" in the AS I/O configuration.

The latch mode is configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	LatchMode	0	Single shot
		1	Continuous
1 - 7	Reserved	-	

4.16.5.11.14.4 "CfO_LatchComparator" register

Name:
CfO_LatchComparator

"Latch level channel 0x" in the AS I/O configuration.

The latch comparators for the counter inputs are configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparison level for latch comparator on input 1	0	LOW
		1	HIGH
1	Comparison level for latch comparator on input 2	0	LOW
		1	HIGH
2	Comparison level for latch comparator on input 5	0	LOW
		1	HIGH
3	Comparison level for latch comparator on input 6	0	LOW
		1	HIGH
4	Enable latch comparator on input 1	0	Disabled
		1	Enabled
5	Enable latch comparator on input 2	0	Disabled
		1	Enabled
6	Enable latch comparator on input 5	0	Disabled
		1	Enabled
7	Enable latch comparator on input 6	0	Disabled
		1	Enabled

4.16.5.11.14.5 "CounterControl" register

Name:
CounterReset
LatchEnable

This register can be used to clear counter values or enable the latch.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CounterReset	0	No action
		1	Delete counter
1	LatchEnable	0	Disabled
		1	Enabled
2 - 7	Reserved	-	

4.16.5.11.14.6 "LatchCount" register

Name:
LatchCount

Latch events are counted in this register. This counter can be used to detect whether a new value has been latched.

Data type	Value	Information
SINT	-128 to 127	Latch counter

4.16.5.11.14.7 "CounterTimeValid" register

Name:
CounterTimeValid

This register displays the X2X net time of the current counter value.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the current counter value (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the current counter value (32-bit)

4.16.5.11.14.8 "CounterTimeChanged" register

Name:
Counter01TimeChanged to Counter02TimeChanged

The net time of the last change to the respective counter is shown in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the last change to the respective counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the last change to the respective counter (32-bit)

4.16.5.11.14.9 "CounterValue" register

Name:
CounterValue01 to CounterValue02

This register shows the current value of the respective counter.

Data type	Value	Information
INT	-32,768 to 32,767	Value of the respective counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Value of the respective counter (32-bit)

4.16.5.11.14.10 "CounterLatch" register

Name:
CounterLatch01 to CounterLatch02

As soon as the latch conditions defined in the 4.16.5.11.14.4 "CfO_LatchComparator" register have been met, the contents of the respective CounterValue register are copied to this register.

Data type	Value	Information
INT	-32,768 to 32,767	Latch counter (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Latch counter (32-bit)

4.16.5.11.14.11 "CounterRel" register

Name:
CounterRel01 to CounterRel02

The value of the respective counter, relative to the last latch of the respective counter is calculated in this register.

Data type	Value	Information
INT	-32,768 to 32,767	Counter value relative to the last latch (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Counter value relative to the last latch (32-bit)

4.16.5.11.15 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. In general, a "Fast reaction" setting and a very short system cycle (50 µs) have a negative influence on the minimum X2X cycle time. This can lead to errors when the X2X cycle time is short.

4.16.6 X20DS1828

4.16.6.1 General information

The module is equipped with 1 HIPERFACE encoder interface. This module can be used to evaluate encoders installed in motors from other manufacturers as well as encoders for external axes (encoders that sample any machine movement). The input signals are monitored. This makes it possible to detect open or shorted lines as well as encoder supply failures.

- HIPERFACE encoder interface
- Encoder input monitoring
- 11 VDC and GND for encoder supply
- NetTime function: Timestamp for position

HIPERFACE

HIPERFACE is a standard developed by Max Stegmann GmbH (www.stegmann.de), which like EnDat incorporates the advantages of absolute and incremental position measurement while also offering a read/write parameter memory in the encoder. With absolute position measurement (the absolute position is sampled serially), a homing procedure for referencing is usually not required. Where necessary, a multi-turn encoder should be installed. To reduce costs, a single-turn encoder and a reference switch can also be used. In this case, a homing procedure must be carried out.

The incremental process allows the short deceleration periods necessary for position measurement when using drives with highly dynamic characteristics. With the sinusoidal incremental signal and the fine resolution in the HIPERFACE module, a very high positioning resolution is achieved in spite of the moderate signal frequencies used.

NetTime position timestamp

Highly dynamic positioning tasks require not only the position value, but also the exact time at which the position was determined. The module has a NetTime function for this, which adds a timestamp to the recorded position with microsecond accuracy.

The module provides the PLC with the position value and timestamp as absolute time value. The NetTime mechanisms ensure that the PLC NetTime clock and the local NetTime clock on the module have exactly the same absolute time at all times.

4.16.6.2 Order data

Model number	Short description	Figure
	Digital signal processing and preparation	
X20DS1828	X20 digital signal module, 1 HIPERFACE interface, NetTime module	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 361: X20DS1828 - Order data

4.16.6.3 Technical data

Product ID	X20DS1828
Short description	
I/O module	1x HIPERFACE interface
General information	
B&R ID code	0xAEC7
Status indicators	Counting direction, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Counting direction	Yes, using status LED
Power consumption	
Bus	0.01 W
Internal I/O	1.3 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GOST-R	Yes
Encoder inputs	
Angular position resolution	13-bit, with a 1 V_{SS} signal
Encoder monitoring	Yes
Max. encoder cable length	10 m
Sine/Cosine inputs	
Signal transmission	Differential signals, symmetrical
Signal frequency	DC up to 200 kHz
Differential voltage	1 V_{SS}
Common-mode voltage	Max. ±10 V
Terminating resistor	120 Ω
Encoder supply	
Output voltage	11 V
Load capability	150 mA
Protective measures	
Overload protection	Yes
Short circuit protection	Yes
Parameter channel (RS485)	
Signal transmission	5 VDC differential signal, EiA RS-485 standard
Transmission status	See HIPERFACE specification
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5 $^{+0.2}$ mm

Table 362: X20DS1828 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.16.6.4 LED status indicators

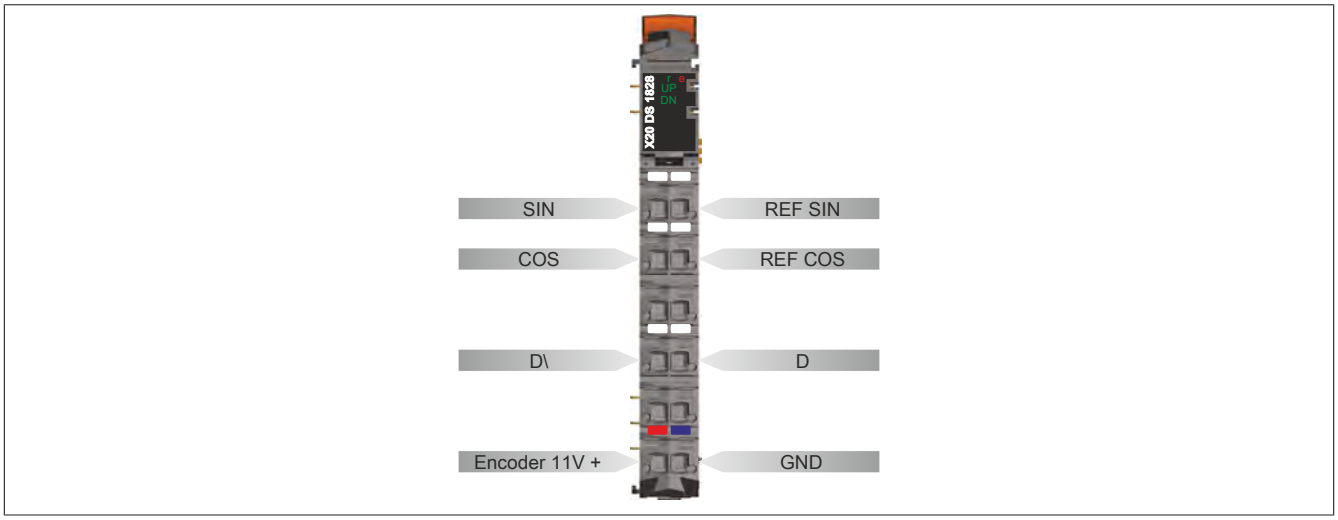
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset state. Possible cause: • Encoder supply error
			Single flash	I/O error - Possible causes: • Sine/Cosine relative position error (open line) • Sine/Cosine absolute position error (reference)
			Double flash	System error. Possible causes: • HIPERFACE communication error
			Triple flash	I/O error and system error
			Single flash, inverted	Error or reset state and I/O error
			Double flash, inverted	Error or reset state and system error
			Triple flash, inverted	Error or reset state, I/O error and system error
	UP	Green	On	The "UP/DN" LEDs are lit depending on the rotational direction and the speed of the connected encoder. The "UP" LED indicates when the encoder position changes in the positive direction.
	DN	Green	On	The "DN" LED indicates when the encoder position changes in the negative direction.

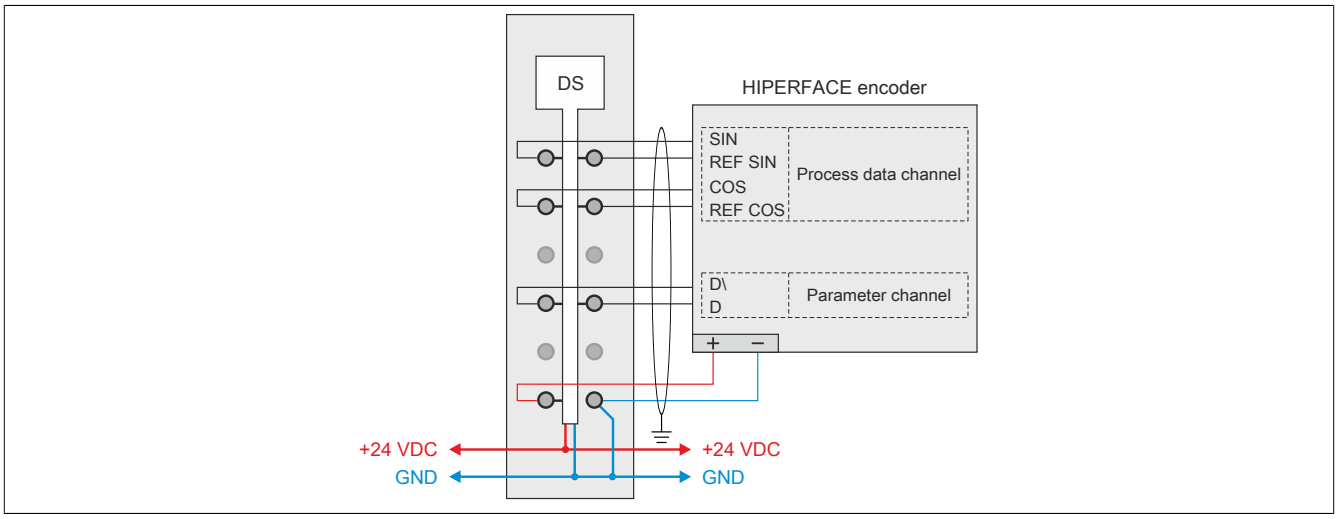
1) Depending on the configuration, a firmware update can take up to several minutes.

4.16.6.5 Pinout

Shielded cables must be used for all signal lines.

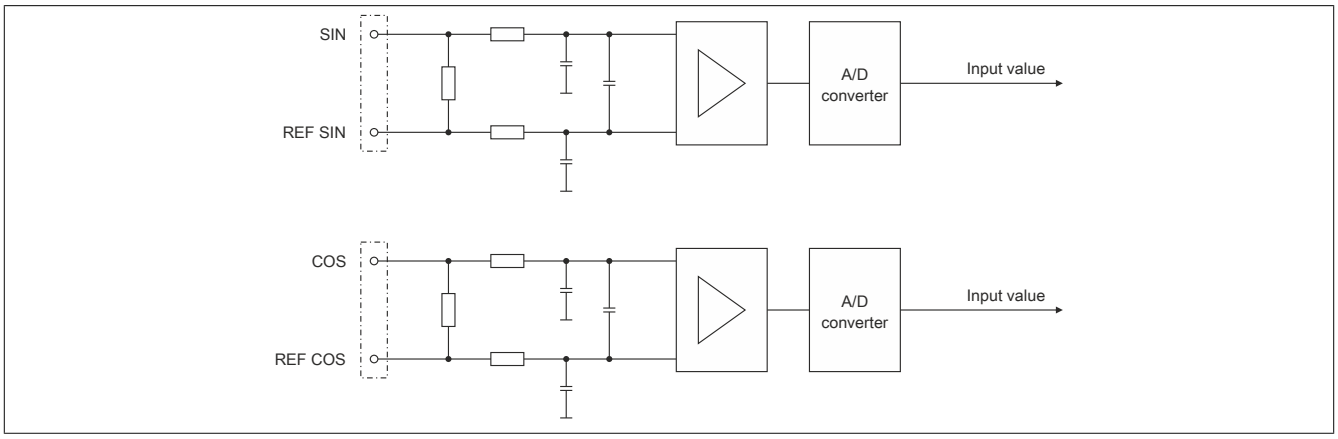


4.16.6.6 Connection example

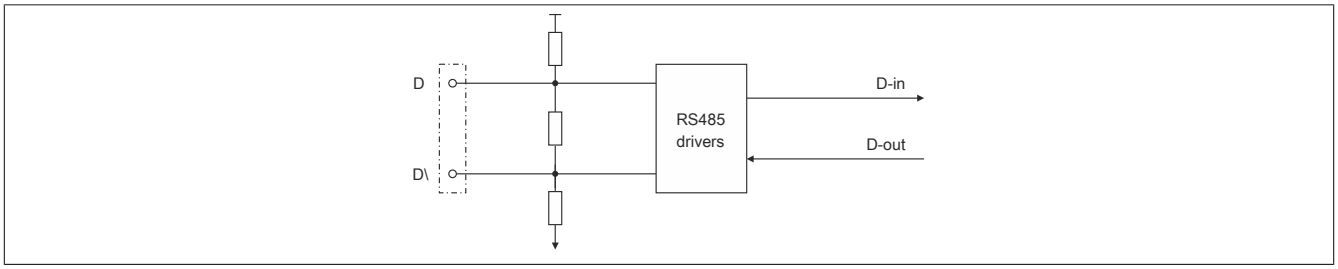


4.16.6.7 Input circuit diagram

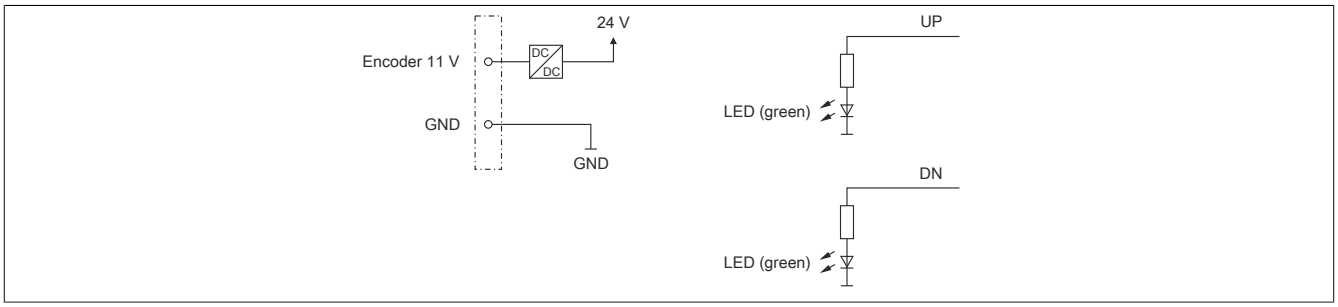
4.16.6.7.1 Diagram for the process data channel (sine-cosine track)



4.16.6.7.2 Circuit diagram for the parameter channel (RS485 interface)



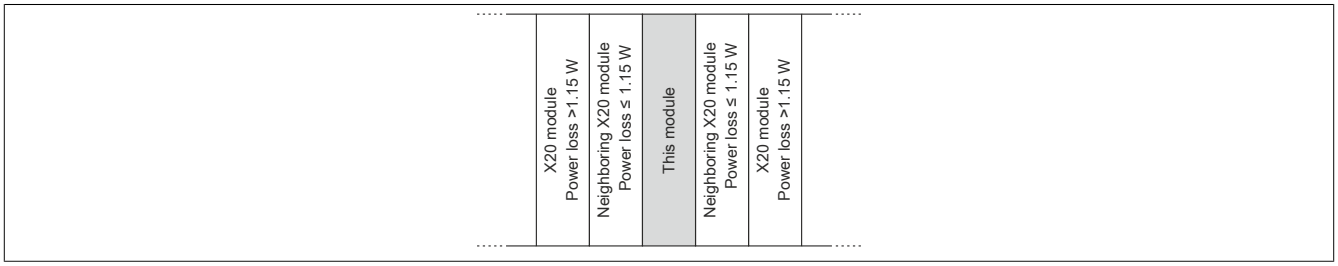
4.16.6.7.3 Circuit diagram for the encoder supply and LEDs



4.16.6.8 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.16.6.9 Register description

4.16.6.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.16.6.9.2 Register overview - Function model 0 (standard)

1) The offset specifies the position of the register within the CAN object.

4.16.6.9.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.16.6.9.4 Module configuration

The following configuration register can be used to configure different module settings. They can be used, for example, to modify the module's behavior on an X2X Link network.

4.16.6.9.4.1 Data query

Name:
CfO_SIframeGenID

This register can be used to define when the synchronous/cyclic input data is generated. "X2X cycle optimized" should be set for jitter-free data acquisition. "Fast reaction" can be set for the best performance.

Data type	Value	Information
USINT	9	Fast reaction
	14	X2X cycle optimized (bus controller default setting)

4.16.6.9.5 Basic functions

This module can read a position when used together with a HIPERFACE encoder. The received position data is prepared in 2 different formats and given a time stamp. 6 registers are available for further processing. This allows the user to select the format that best fits the application at hand.

4.16.6.9.5.1 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.6.9.5.2 Absolute position values

Name:
PositionHW
PositionLW

The absolute position of the encoder is defined using 64-bit resolution. The position value is stored in the PositionHW and PositionLW registers. The upper 32 bits are stored the PositionHW register, while the lower 32 bits are stored in the PositionLW register.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
2x UDINT	0 to 4,294,967,295

4.16.6.9.5.3 SDC position value

Name:
Position

The SDC library requires a signed 32-bit position value. The position's low word can be accessed separately for this. The value can also be used as default position value, however.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.16.6.9.5.4 NetTime of the position values

Name:
PosTime

This register is used to assign each recorded position of the current NetTime value. The NetTime is recorded with µs accuracy.
The SDC library requires a 16 bit value. The NetTime value is therefore also generated in this format.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	NetTime in µs
INT	-32,768 to 32,767	

4.16.6.9.5.5 Counter for position values

Name:
PosCycle

PosCycle is an integer counter that is incremented as soon as the module has saved a new valid position value.

Data type	Value
SINT	-128 to 127

4.16.6.9.6 Error management

This module can be used to diagnose error states. There are 2 ways this module performs error diagnostics:

- Module-based diagnostics
- HIPERFACE-based diagnostics

4.16.6.9.6.1 Module-based diagnostics

Like most B&R modules, this module is also able to detect errors on its own. It diagnoses 5 different errors or warnings. The error bits can be retrieved individually or grouped together.

Enabling/disabling error messages

Name:
ErrorEnableID_0F08

The implemented diagnostic algorithms can be enabled or disabled in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder supply	0	Error detection disabled
		1	Error detection enabled (bus controller default)
1	Reserved	-	
2	Vss Sin/Cos	0	Error detection disabled
		1	Error detection enabled (bus controller default)
3	Position error	0	Error detection disabled
		1	Error detection enabled (bus controller default)
4	HIPERFACE communication	0	Error detection disabled
		1	Error detection enabled (bus controller default)
5	HIPERFACE reference warning	0	Warning disabled
		1	Warning enabled (bus controller default)
6 - 7	Reserved	-	

Encoder supply

The encoder voltage supply is below the permitted limit.

Vss Sin/Cos

The voltage value for the Sin/Cos track violates the configured limit values.
→ See register "SinCosVssMin" or "SinCosVssMax"

Position error

The position value determined violates internal requirements.

HIPERFACE communication

Communication error on the HIPERFACE interface (RS485)
→ See register "HfErrorCode"

HIPERFACE reference warning

The digital interface provides an absolute position value that can be used to accurately describe the axis position. The position value is homed to this absolute value at the beginning of a measurement. The analog interface can be used to incrementally sample changes that occur very rapidly. This enables the module to continue sampling the position value at a high resolution. Both the analog and the digital signal are sampled cyclically. If the value read incrementally deviates from the absolute value during operation, then the warning is generated and the position must be homed again.

Show error messages

Name:
ErrorInfo
EncoderSupplyError
VssCheckError
PositionError
HfComError
HfRefWarning

This register indicates any errors or warnings that have not yet been acknowledged. For the meaning of individual error messages, see register "Enabling/disabling error messages".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EncoderSupplyError	0	No error
		1	Encoder supply error
1	Reserved	-	
2	VssCheckError	0	No error
		1	Vss error on the Sin/Cos track
3	PositionError	0	No error
		1	Position error
4	HfComError	0	No error
		1	HIPERFACE communication error
5	HfRefWarning	0	No warning
		1	HIPERFACE reference warning
6 - 7	Reserved	-	

Acknowledge error messages

Name:
AckErrorInfo
AckEncoderSupplyError
AckVssCheckError
AckPositionError
AckHfComError
AckHfRefWarning

This register is used to acknowledge an error or warning message that occurred in the "Show error messages" register. For the meaning of individual error messages, see register "Enabling/disabling error messages".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	AckEncoderSupplyError	0	No error acknowledgment
		1	Error acknowledgment
1	Reserved	-	
2	AckVssCheckError	0	No error acknowledgment
		1	Error acknowledgment
3	AckPositionError	0	No error acknowledgment
		1	Error acknowledgment
4	AckHfComError	0	No error acknowledgment
		1	Error acknowledgment
5	AckHfRefWarning	0	No acknowledgment
		1	Acknowledgment
6 - 7	Reserved	-	

4.16.6.9.6.2 HIPERFACE-based diagnostics

Memory areas are provided in the HIPERFACE standard for error diagnostics. Error management has been adjusted in order to use error detection in accordance with the HIPERFACE standard. An additional register has been implemented in the module to provide this area in the encoder's memory. This error memory is mirrored in the module's registers and can be interpreted by the user. Detailed information regarding the errors that can be detected in this way can be found in the encoder's manual.

HfErrorCode

Name:
HfErrorCode

This register is used to store the error code that identifies the current problem with the HIPERFACE interface.

Data type	Value
UDINT	See bit structure.

Internally, the register consists of 4 pieces of information.

Bit structure:

Bit	Name	Information
00 - 07	Error ID	See below
08 - 15	Last command	Command that caused the error on the slave
16 - 23	Station address	Address of the faulty HIPERFACE slave
24 - 31	Error counter	Counts the number of errors that have occurred

Bit 00-07 (error ID)
These 8 bits of this register specify the error that has occurred. The error ID is not a standard value, however, and must be looked up in the manual for the HIPERFACE slave. The module also diagnoses a timeout on the HIPERFACE interface. This triggers error ID 255.

4.16.6.9.7 Sin/Cos - Analog interface configuration

In addition to the digital HIPERFACE interface, this module is also equipped with an analog interface for sampling a differential sine-cosine signal. To increase the resolution, the EnDat standard supports cooperation between the analog and digital data. This enables a highly dynamic representation of the position while maintaining high resolution.

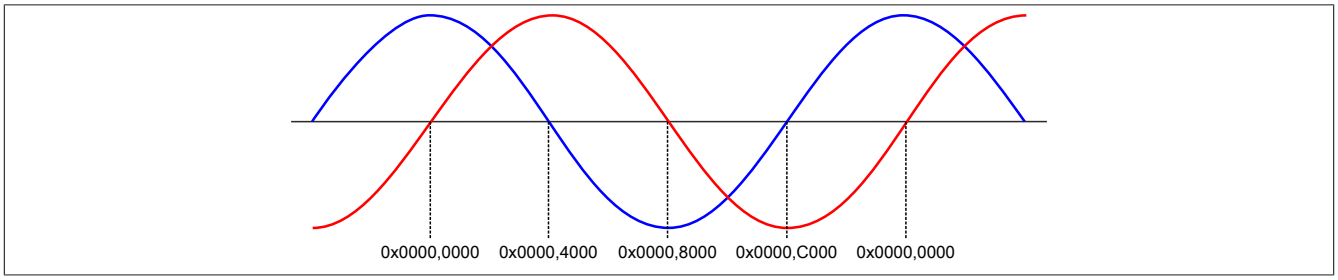
4.16.6.9.7.1 Format of the SinCos signal

The SinCos signal is represented as a position value in the 4.16.3.11.5.2 "Absolute position values" and 4.16.3.11.5.3 "SDC position value" registers. The following relationships apply:

- PositionLW and Position are identical in the function.
- PositionHW extends the integer range of PositionLW by adding multi-turn functionality.

64-bit register	PositionHW (unsigned)	PositionLW (unsigned)	
32-bit register	-	Position (signed)	
Format	Integer extension (to 48-bit)	Integer (16-bit)	Decimal places: (with 13-bit resolution)
Information		A full sine wave corresponds to an increment of the integer.	**15** **14** **13** **12** **11** **10** **9** **8** **7** **6** **5** **4** **3** **2** **1** **0** x x x x x x x x x x x x x 0 0 0 **Important:** The lower 3 bits always contain the value 0.
Word/DWord	DWord	Word 1	Word 0

Relationship between sine curve (red) and decimal places:



4.16.6.9.7.2 Enabling SinCos

Name:
SinCosEnable

This register must always have the value 1 for configuration reasons.

Data type	Value	Information
USINT	1	Bus controller default: 1

4.16.6.9.7.3 SinCosRefSource

Name:
SinCosRefSource

This register must always have the value 3 for configuration reasons.

Data type	Value	Information
USINT	3	Bus controller default: 3

4.16.6.9.7.4 Configuring the lower Vss value

Name:
SinCosVssMin

This register specifies the lower limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value falls below this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 800

4.16.6.9.7.5 Configuring the upper Vss value

Name:
SinCosVssMax

This register specifies the upper limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value exceeds this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 1200

4.16.6.9.7.6 Configuring the delay time after errors

Name:
SinCosQuitTime

If an error is detected on the analog interface, the last correctly read values remain valid. An interval can be defined in this register at which the module begins receiving correct values again after the error state without processing them further internally. Only then will newly sampled correct analog values be recognized as valid.

Data type	Value	Information
UDINT	0 to 20000000	Values in µs, bus controller default setting: 100000

4.16.6.9.8 HIPERFACE

4.16.6.9.8.1 HIPERFACE - Digital interface configuration

HIPERFACE builds upon the RS-485 (EIA-485) specification and permits communication with multiple HIPERFACE slaves.

There are 2 methods available to use the slave data in a PLC program. One is to store the necessary slave values temporarily in the module, where they can then be provided to the CPU. The other is to use the module's FlatStream mode, which supports the full range of commands defined in the HIPERFACE specification.

Additional information regarding the HIPERFACE specification is provided in the "Description of HIPERFACE" document.

HfMode

Name:
HfMode

This register is used to enable the HIPERFACE interface and must always be set to the value 1 for configuration reasons.

Data type	Value	Value
USINT	1	Bus controller default: 1

HfParity

Name:
HfParity

This register configures the parity bit for the interface.

Data type	Value	Information
USINT	69	E → even parity bit; bus controller default
	78	N → no parity bit
	79	O → odd parity bit

HfCharTimeout

Name:
HfCharTimeout

This register configures the time that the module waits after receiving the last data block to add additional data to the current data packet (frame). When this time expires, the data received thus far is saved in a frame. The transfer is complete and the data can be evaluated.

Information:

Time is specified as a char value in order to ensure identical behavior regardless of the baud rate setting.

Data type	Value	Information
USINT	1 to 255	Char; bus controller default: 55

HfBaud

Name:
HfBaud

This register configures the baud rate (transfer rate) of the interface.
The module does not allow a transfer rate of 600 baud.

Data type	Value	Information
UDINT	1200, 2400, 4800, 9600, 19200, 38400	Baud; bus controller default: 9600

HfRepressErrTime

Name:
HfRepressErrTime

This register configures the minimum time that an error code remains in the "HfErrorCode" register. This makes it possible to ensure that the CPU registers every error that occurs.

Data type	Value	Information
UDINT	1 to 20000000	Time in µs, bus controller default setting: 100000

HfRefAdr

Name:
HfRefAdr

This module can manage up to 32 HIPERFACE slaves via its digital interface. High-resolution position sampling, however, requires information from both the digital and analog interfaces. The HIPERFACE address of the station whose sine/cosine track is being read by the module is entered in this register. If there is only one slave on the network, the broadcast address (255) can also be used.

Data type	Value	Information
USINT	0	Operation without sine/cosine track
	64 to 95	Open address range for max. 32 HIPERFACE slaves
	255	Broadcast address; bus controller default

HfRefWidth

Name:
HfRefWidth

This register is used to set the absolute width for the sampled position. The number of bits must be taken from the data provided by the encoder manufacturer and usually consists of three values:

- 5 bits: Resolution of the digital absolute position
- x bits: HIPERFACE data format, number of bits per revolution
- 2^y bits: Number of sine/cosine periods per revolution

The sum of the sampled values results in the HfRefWidth (HfRefWidth = 5+x+y).

Data type	Value	Information
USINT	8 to 32	Bus controller default: 32

4.16.6.9.8.2 HIPERFACE - Read ID

The digital interface provides the option of assigning a HIPERFACE slave a specific ID. Its parameter data can be queried when booting the PLC, for example. Any deviations from the previous hardware constellation can then be handled accordingly in the program.

Configuration

The parameter to be read is specified by 2 registers. One of the registers contains the address of the desired HIPERFACE slave; the other contains a code for the value to be read.

HfAdrIdent

Name:
HfAdrIdent

This register is used to specify the address of the HIPERFACE slave whose parameter should be read by the module.

Data type	Value	Information
USINT	0	Identification disabled; bus controller default: 0
	64 to 95	Open address range for max. 32 HIPERFACE slaves
	255	Broadcast address (when operating with one slave)

HfSelectionIdent

Name:
HfSelectionIdent

This register defines the parameters that should be provided in the slave response and buffered in the module's "HfExtByte" register.

Data type	Value	Value
USINT	0	Serial number; bus controller default
	1	Firmware date
	2	High part of firmware version
	3	Low part of firmware version

Call

After being configured correctly, the selected parameter is transmitted cyclically to the module. There are 8 registers that serve as temporary storage. The module confirms successful receipt by setting the HfIdentOkByte.

HfIdentOk

Name:
HfIdentOk

This register's bits provide information about the validity of the latest ID values in temporary storage.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	HfIdentOk01	0	Parameter 01 invalid
		1	Parameter 01 valid
1 - 7	Reserved	-	

HfRs485Settings

Name:
HfRs485Settings

This register is used to temporarily store the current network configuration expected by the slave. The register value is specifically structured for HIPERFACE.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	Speed code	001	1200 baud
		010	2400 baud
		011	4800 baud
		100	9600 baud; bus controller default
		101	19200 baud
		110	38400 baud
3	Reserved	-	
4	Number of parity bits	0	No parity bit
		1	One parity bit (default)
5	Type of parity bit	0	Even (default)
		1	Odd
6	Behavior if a timeout occurs	0	Timeout 11/baudrate
		1	Timeout 4*11/baud rate (default)
7	Network behavior	0	Bus
		1	Direct connection (default)

HfEncoderType

Name:
HfEncoderType

This register is used to temporarily store the ID of the current encoder. The register value is structured specifically for each slave and must be looked up in the encoder's data sheet.

Data type	Value
USINT	0 to 255

HfEepromSize

Name:
HfEepromSize

This register is used to store the size of the EEPROM being used. The number of 16-byte blocks is specified.

Data type	Value	Value
USINT	0 to 255	16-byte blocks

HfOptionFlags

Name:
HfOptionFlags

This register is used to store slave-specific hardware and software settings.

Data type	Value
USINT	0 to 255

HfFreeMemory

Name:
HfFreeMemory

This register is used to indicate the number of free 16-byte blocks remaining on the HIPERFACE slave.

Data type	Value	Information
USINT	0 to 255	16-byte blocks

HfDataFields

Name:
HfDataFields

This register is used to indicate the number of data fields that have been written thus far.

Data type	Value
USINT	0 to 255

HfExtByte

Name:
HfExtByte01 to HfExtByte10

These registers provide the respective parameters according to how the "HfSelectionIdent" register is configured.

Data type	Value
USINT	0 to 255

4.16.6.9.8.3 HIPERFACE - Reading additional encoder positions

This module can read up to 2 additional position values via the HIPERFACE interface and provide them to the PLC. Each position value is accompanied by a timestamp.

Configuration

The address must be specified in order to read the position value from the respective HIPERFACE interface. One address register is provided for each position value.

AddPosAdr

Name:
AddPosAdr01 to AddPosAdr02

These registers specify the addresses of the HIPERFACE slaves whose position values should be processed in the module.

Data type	Value	Information
USINT	0	Additional encoder position disabled; bus controller default
	64 to 95	Open address range for max. 32 HIPERFACE slaves
	255	Broadcast address (when operating with one slave)

Call

After being configured correctly, the position value is transmitted cyclically to the module. Each slave has five registers that serve as temporary storage. The module automatically generates the timestamp and confirms successful transmission by setting the corresponding AddPosOk0x bit. The HIPERFACE specification does not specify in which format the parameters must be received. The module therefore provides the position value and time in two formats. Which of the position registers should be used for further processing depends on the HIPERFACE slave. The user is free to define the format of the timestamp.

AddPosOk (byte)

Name:
AddPosOk01 to AddPosOk02

This register's bits provide information about the validity of the last position values in temporary storage.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	AddPosOk01	0	Position value 01 invalid
		1	Position value 01 valid
1	AddPosOk02	0	Position value 02 invalid
		1	Position value 02 valid
2 - 7	Reserved	-	

AddPosition

Name:
AddPosition01 to AddPosition02

These registers provide the current position values, depending on the register address, as signed 2-byte or 4-byte values.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647
INT	-32,768 to 32,767

AddPosTime

Name:
AddPosTime01 to AddPosTime02

These registers provide the time stamp of the most recently received position values, depending on the register address, as signed 2-byte or 4-byte values.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	NetTime in µs
INT	-32,768 to 32,767	

4.16.6.9.8.4 HIPERFACE - Reading additional analog values

This module can read up to 4 analog values (16-bit) via the HIPERFACE interface and provide them to the PLC. Each analog value is accompanied by a timestamp.

Configuration

The analog value to be read is specified by 2 registers. One of them contains the address of the desired station, and the other the channel of the parameter to be read. An overview of analog values that can be read is provided in the data sheet for the respective slave.

AnalogAdrCh

Name:
AnalogAdrCh01 to AnalogAdrCh04

These registers specify the addresses of the HIPERFACE slaves whose analog values should be processed in the module. To query multiple values from one HIPERFACE slave, it may make sense to write the same address to different AnalogAdrCh registers.

Data type	Value	Information
USINT	0	Additional analog values disabled; bus controller default
	64 to 95	Open address range for max. 32 HIPERFACE slaves
	255	Broadcast address (when operating with one slave)

AnalogCh

Name:
AnalogCh01 to AnalogCh04

These registers define the channel to be read that is written by the bus station to the module's temporary storage.

Data type	Value
USINT	See encoder data sheet Bus controller default: 0

Call

After being configured correctly, the analog value is transmitted cyclically to the module. There are 5 registers that serve as temporary storage. The module automatically generates the timestamp and confirms successful transmission by setting the corresponding AnalogChOk0x bit. The HIPERFACE specification does not specify in which format the parameters must be received. The module therefore provides the value and time in two formats. Which of the value registers should be used for further processing depends on the peripheral equipment. The user is free to define the format of the timestamp.

AnalogChOk (byte)

Name:
AnalogChOk01 to AnalogChOk04

This register's bits provide information about the validity of the values in temporary storage.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	AnalogChOk01	0	Analog value 01 invalid
		1	Analog value 01 valid
...		...	
3	AnalogChOk04	0	Analog value 04 invalid
		1	Analog value 04 valid
4 - 7	Reserved	-	

AnalogChValue

Name:
AnalogChValue01 to AnalogChValue04

These registers provide the current analog values, depending on the register address, as signed or unsigned 2-byte values.

Data type	Value
UINT	0 to 65,535
INT	-32,768 to 32,767

AnalogChTime

Name:
AnalogChTime01 to AnalogChTime04

These registers provide the time stamp of the most recently received analog values, depending on the register address, as signed 2-byte or 4-byte values.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Time in µs
INT	-32,768 to 32,767	

4.16.6.9.9 FlatStream communication

4.16.6.9.9.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

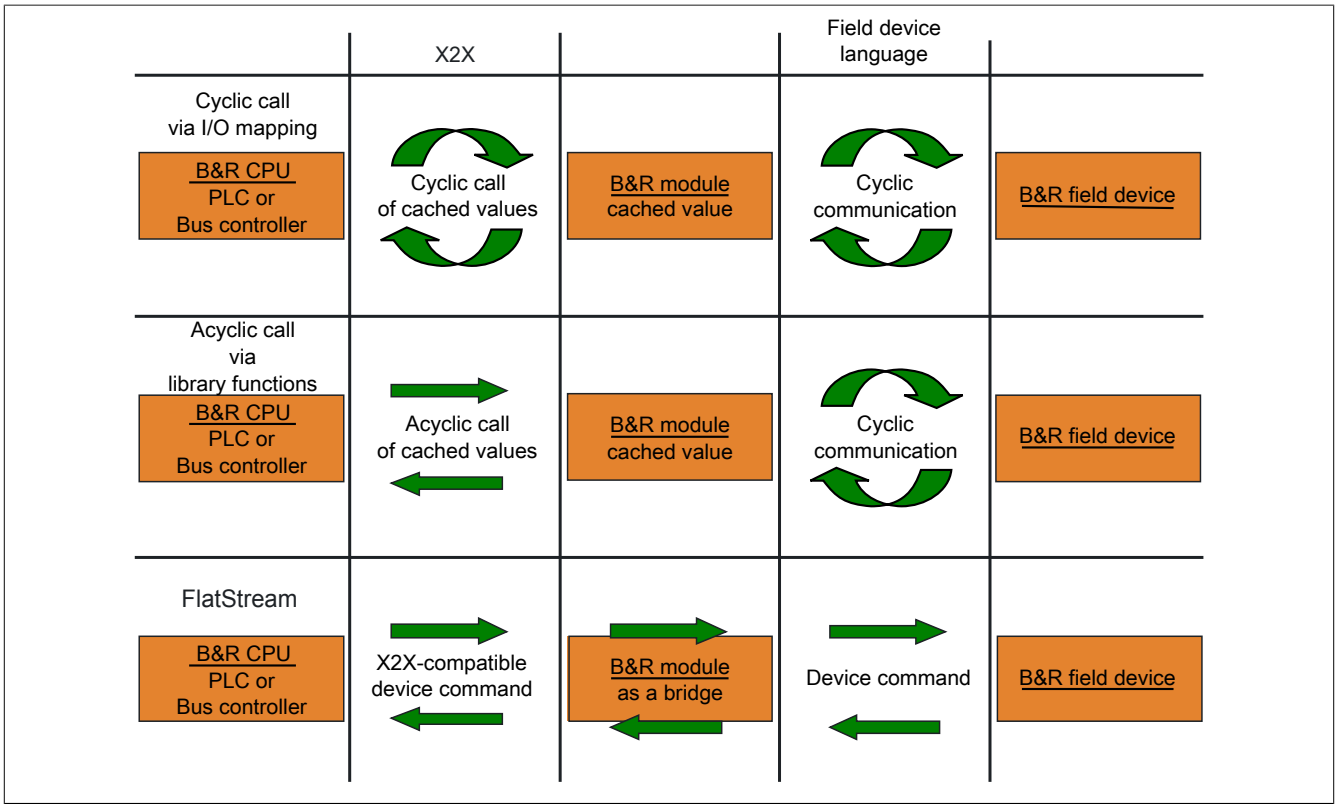


Figure 240: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.16.6.9.9.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.16.6.9.9.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

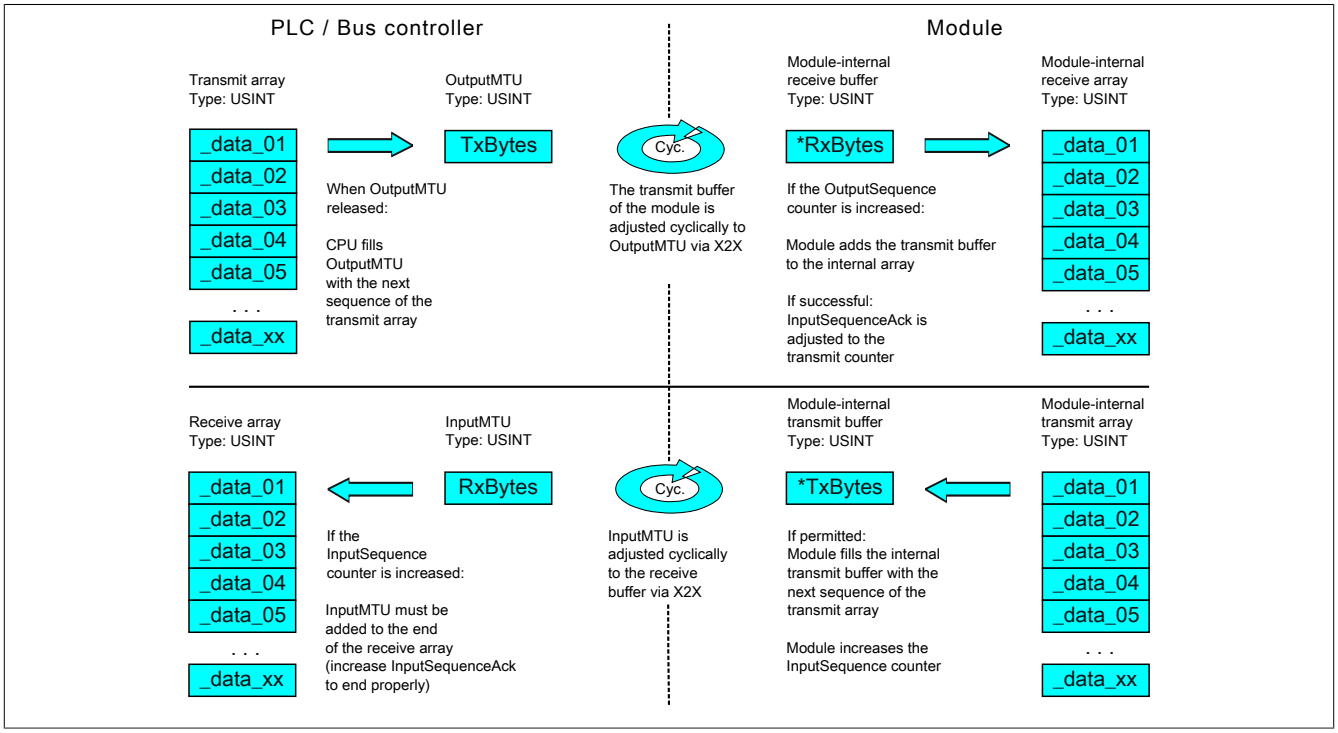

Figure 241: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.16.6.9.9.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

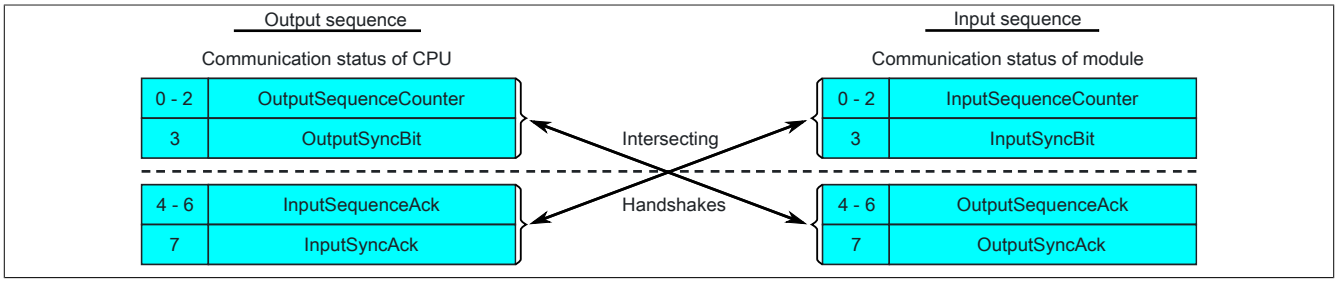

Figure 242: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

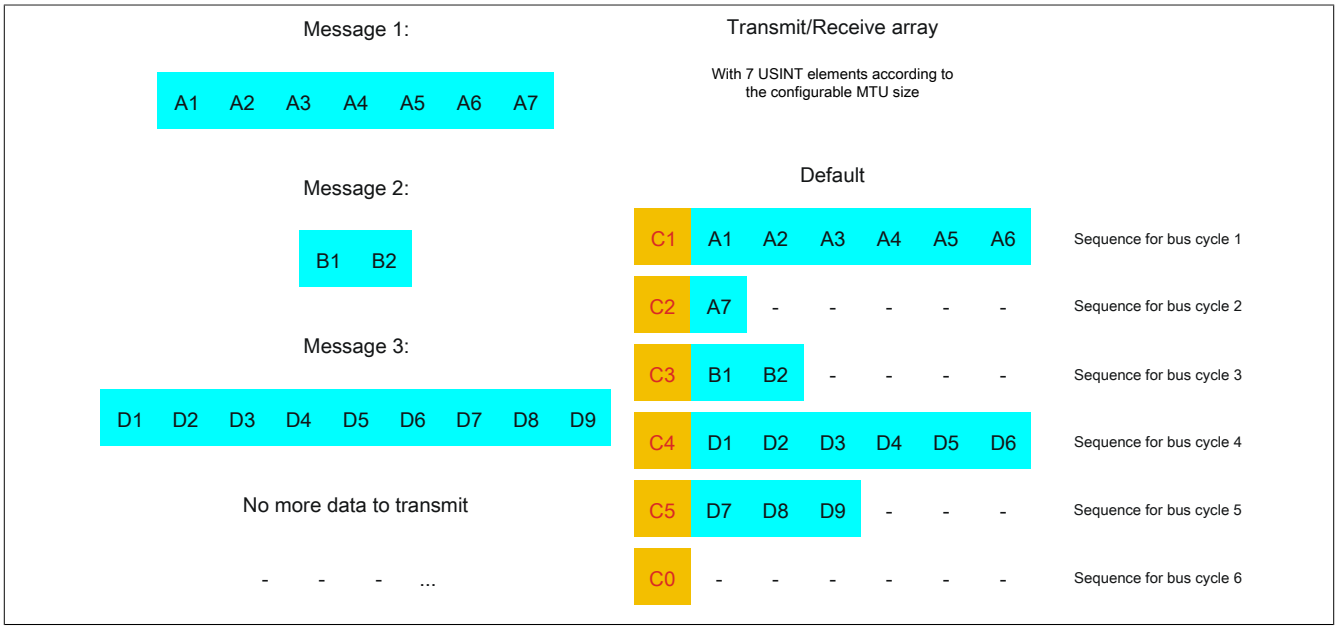

Figure 243: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 363: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 364: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

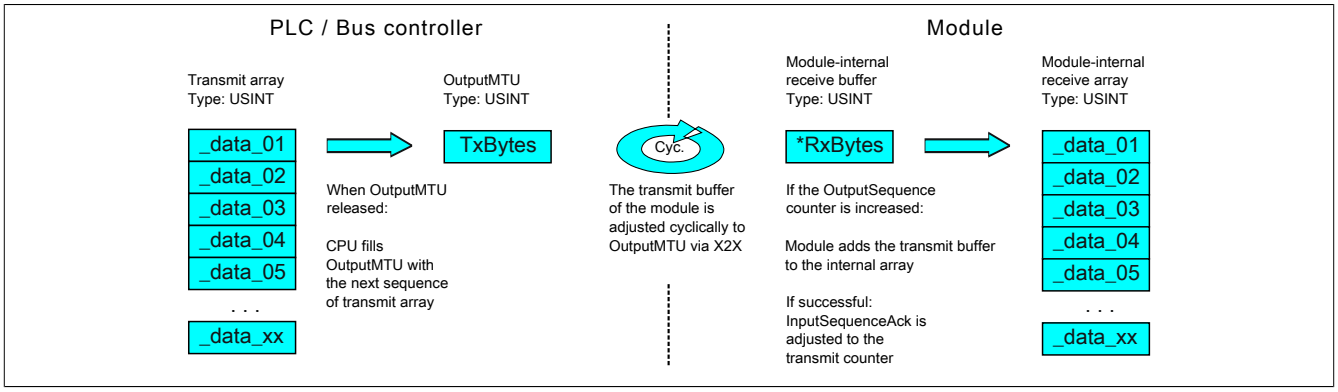

Figure 244: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

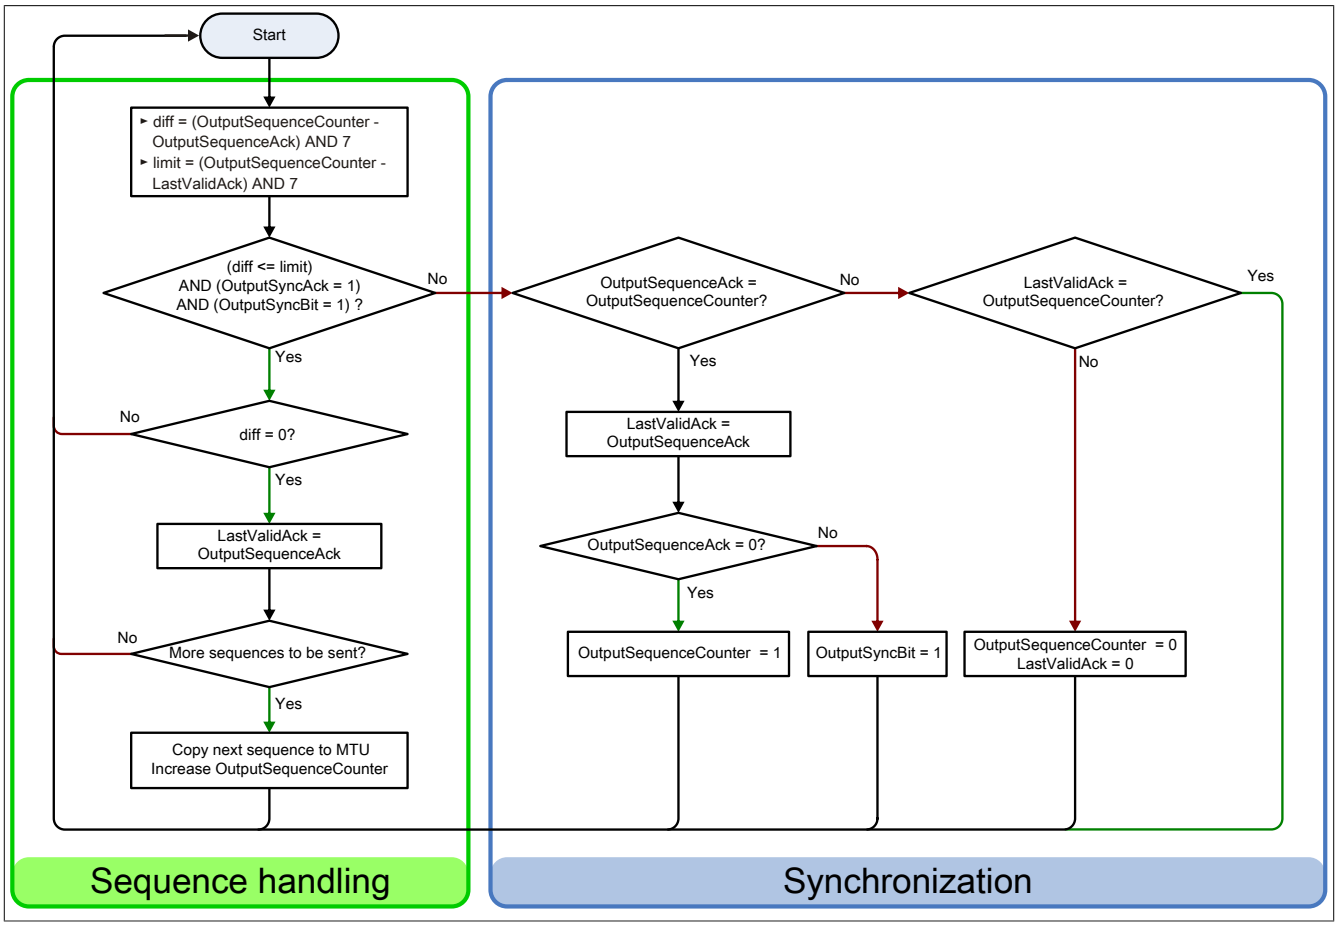

Figure 245: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

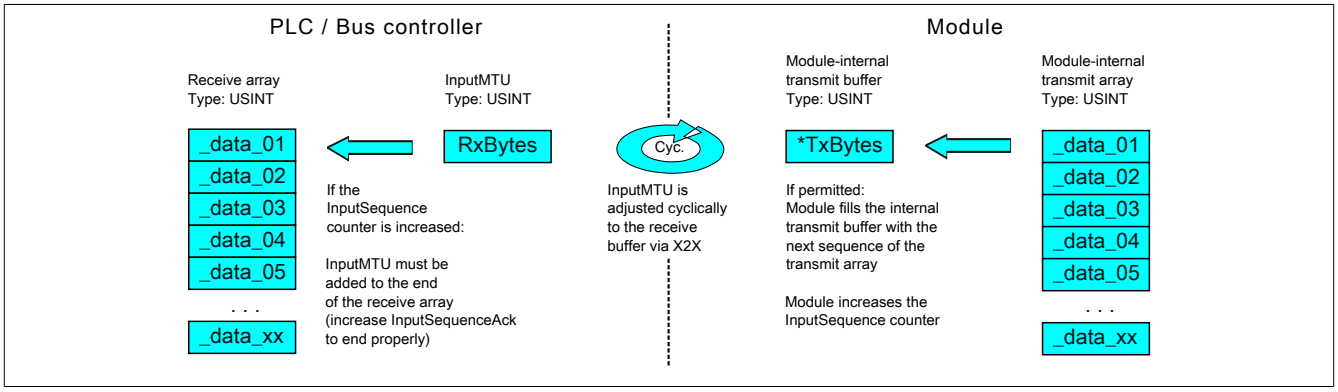

Figure 246: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

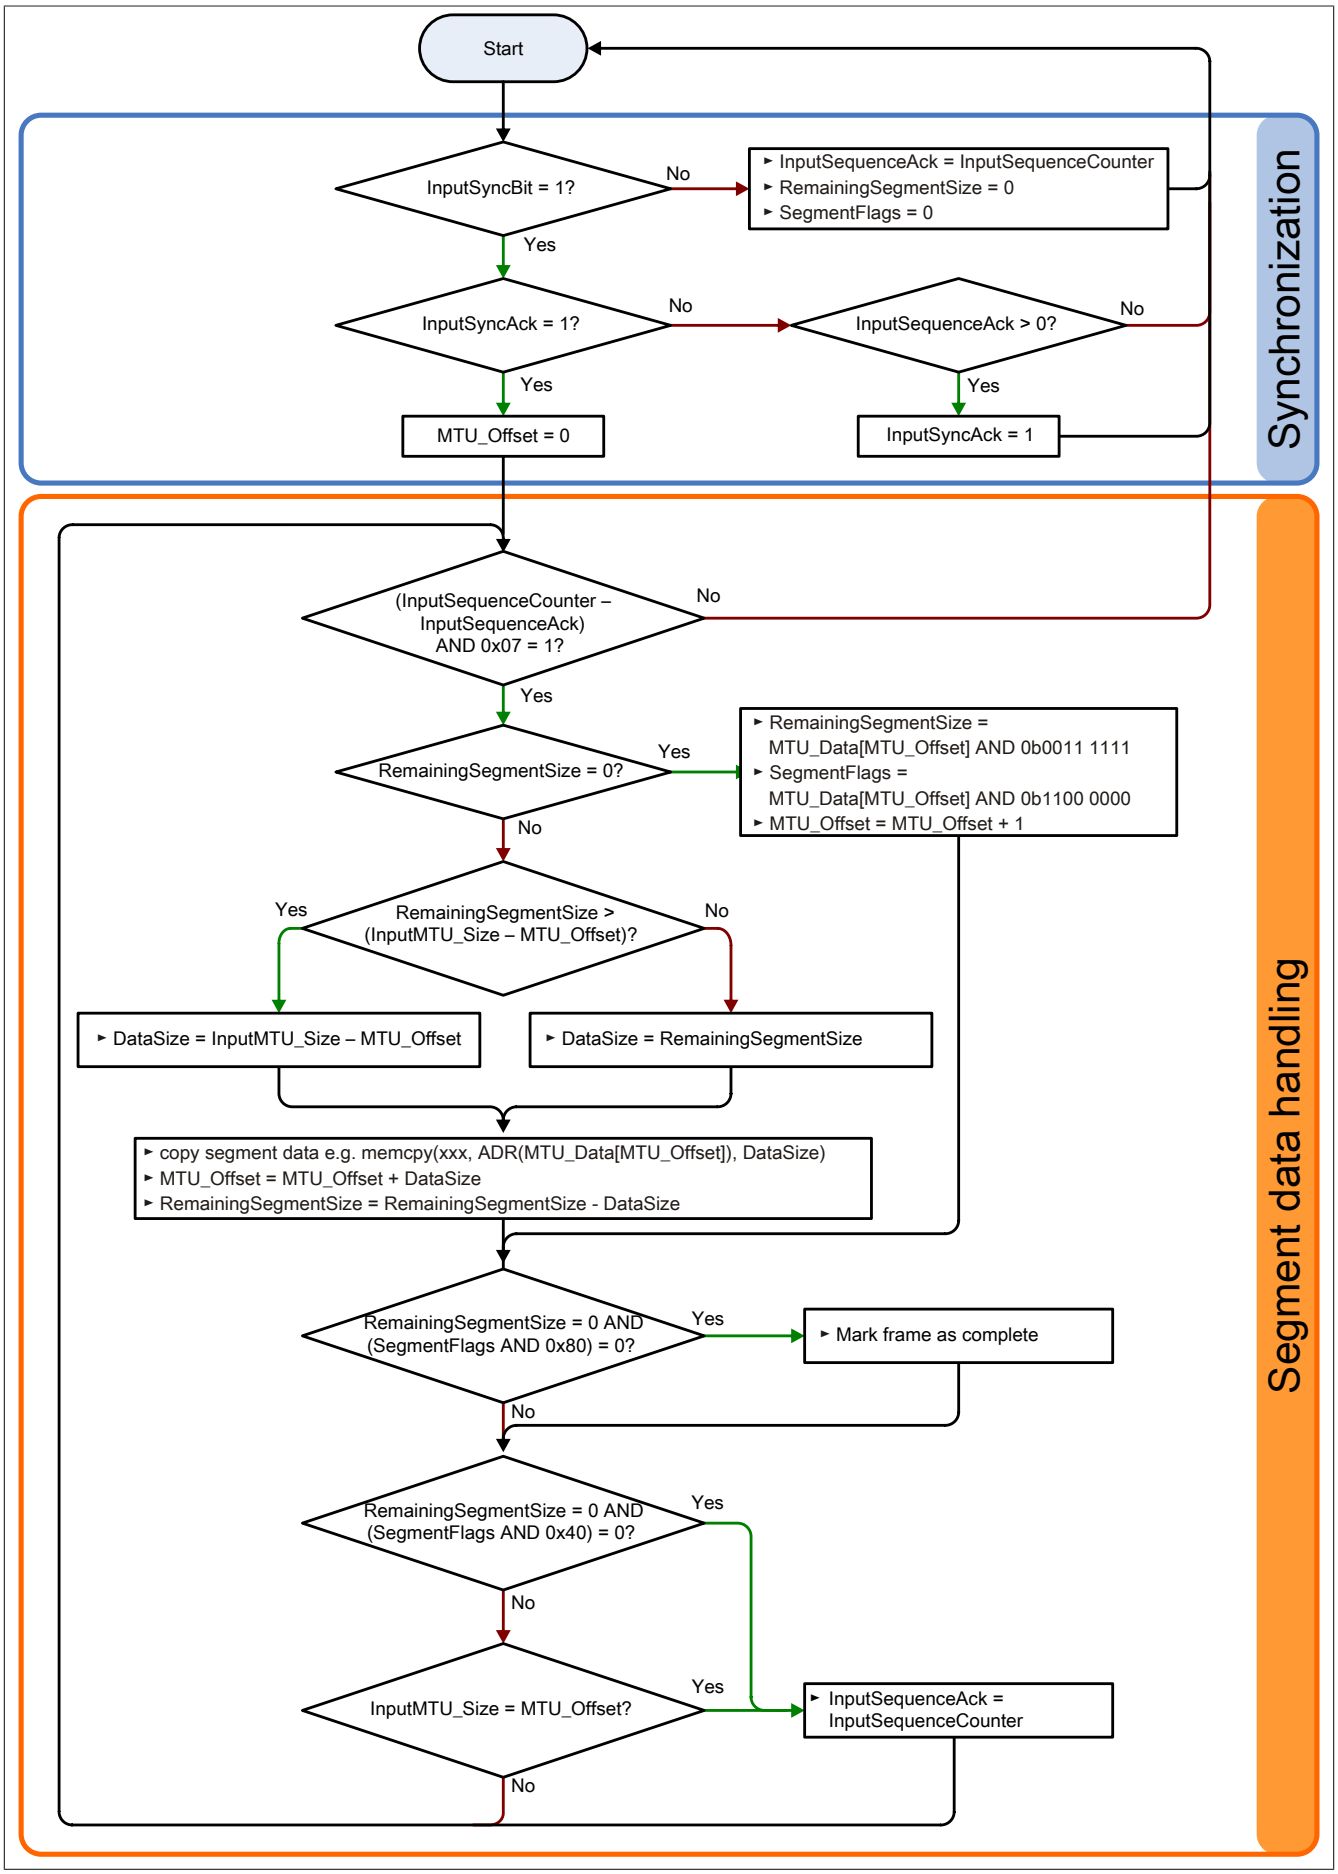

Figure 247: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

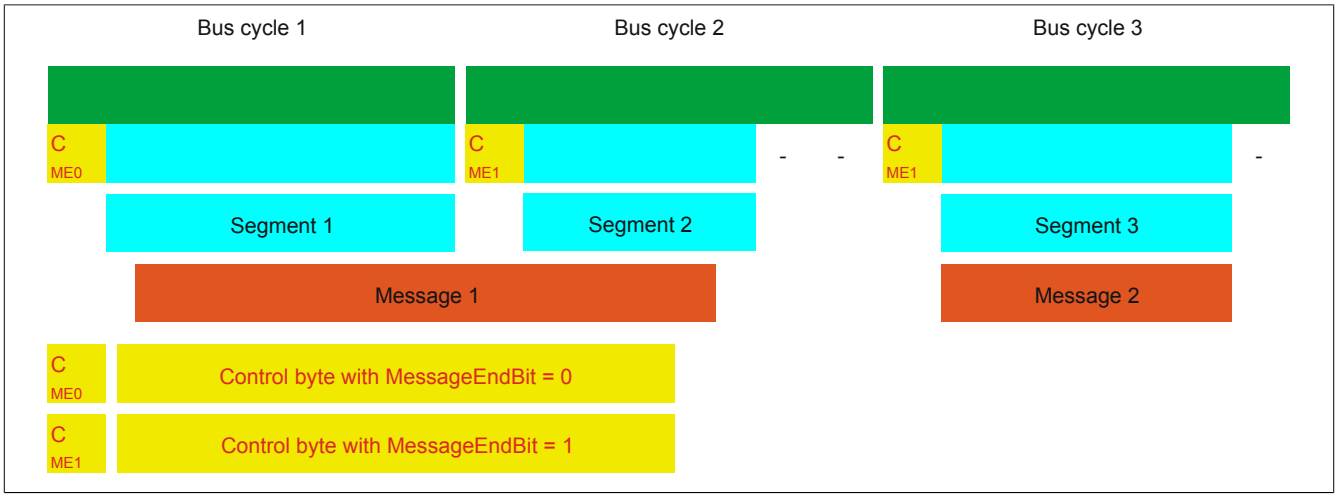

Figure 248: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

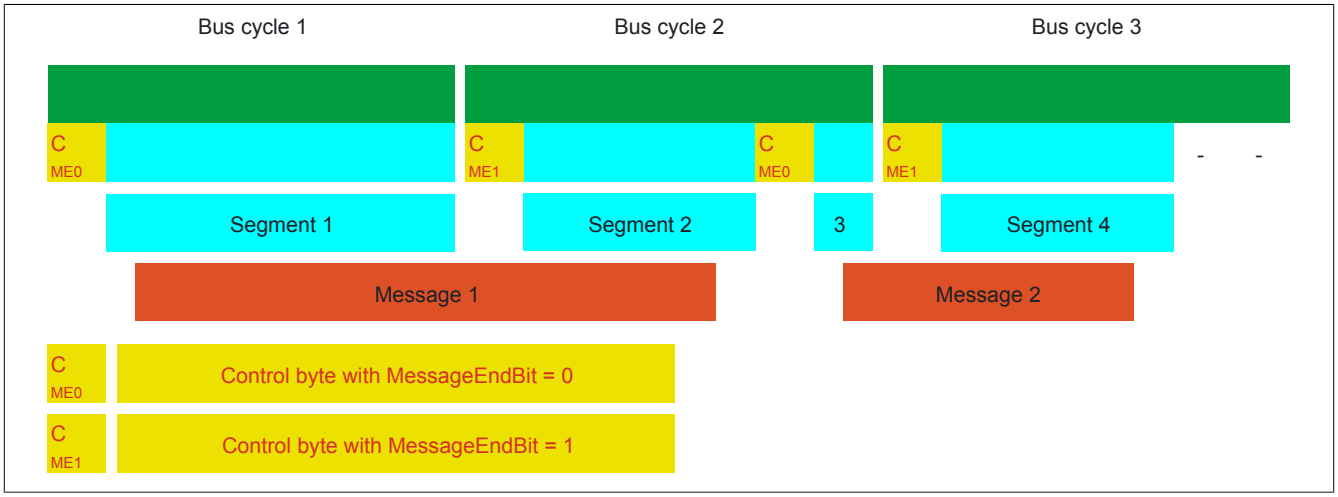

Figure 249: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

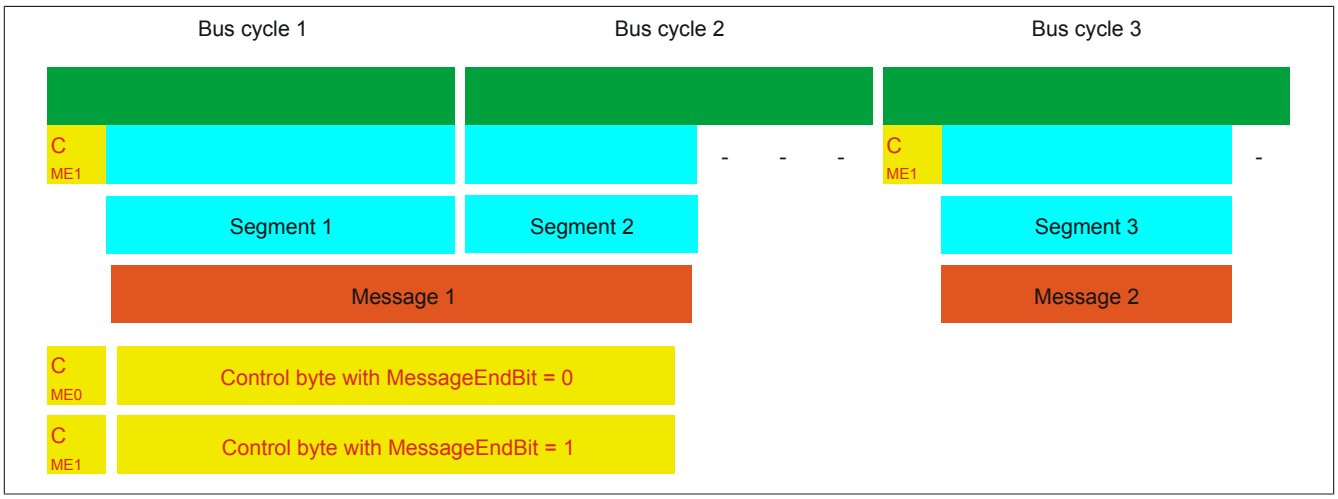

Figure 250: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

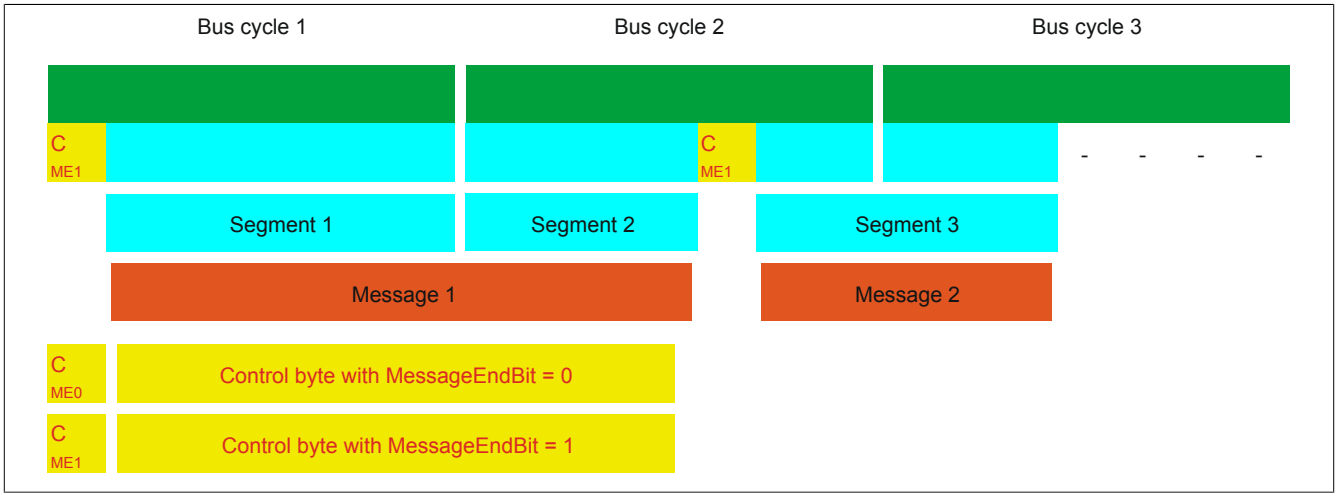

Figure 251: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

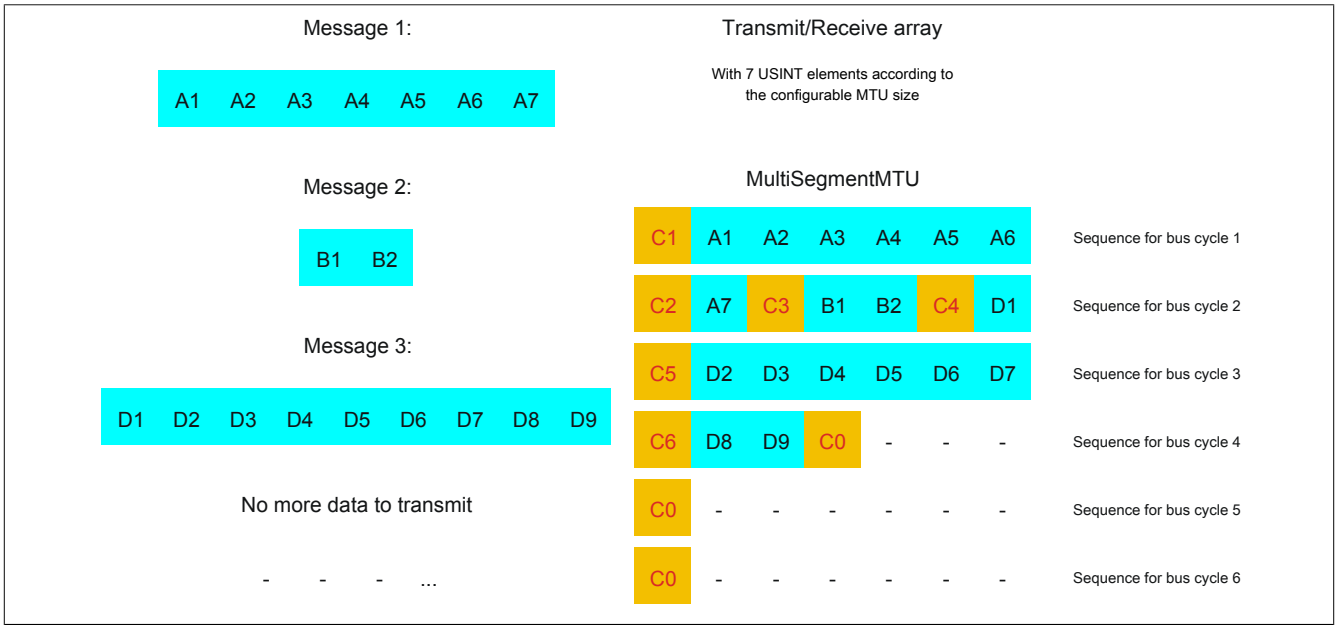

Figure 252: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 365: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 366: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

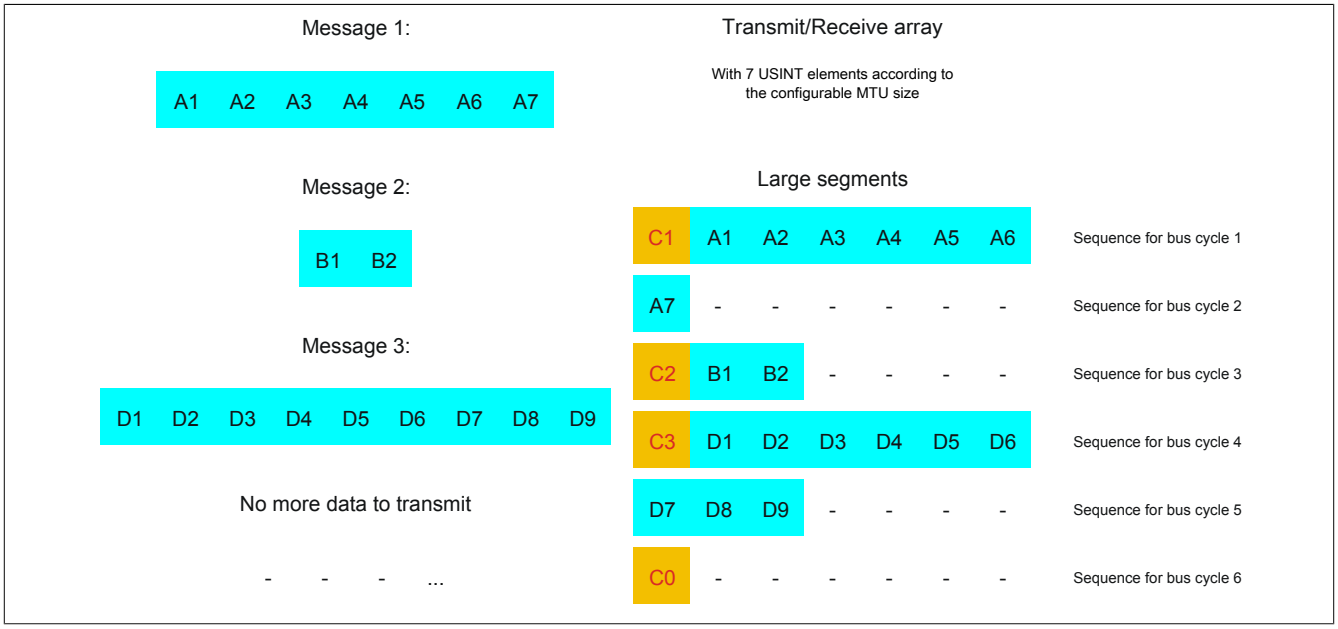

Figure 253: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 367: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

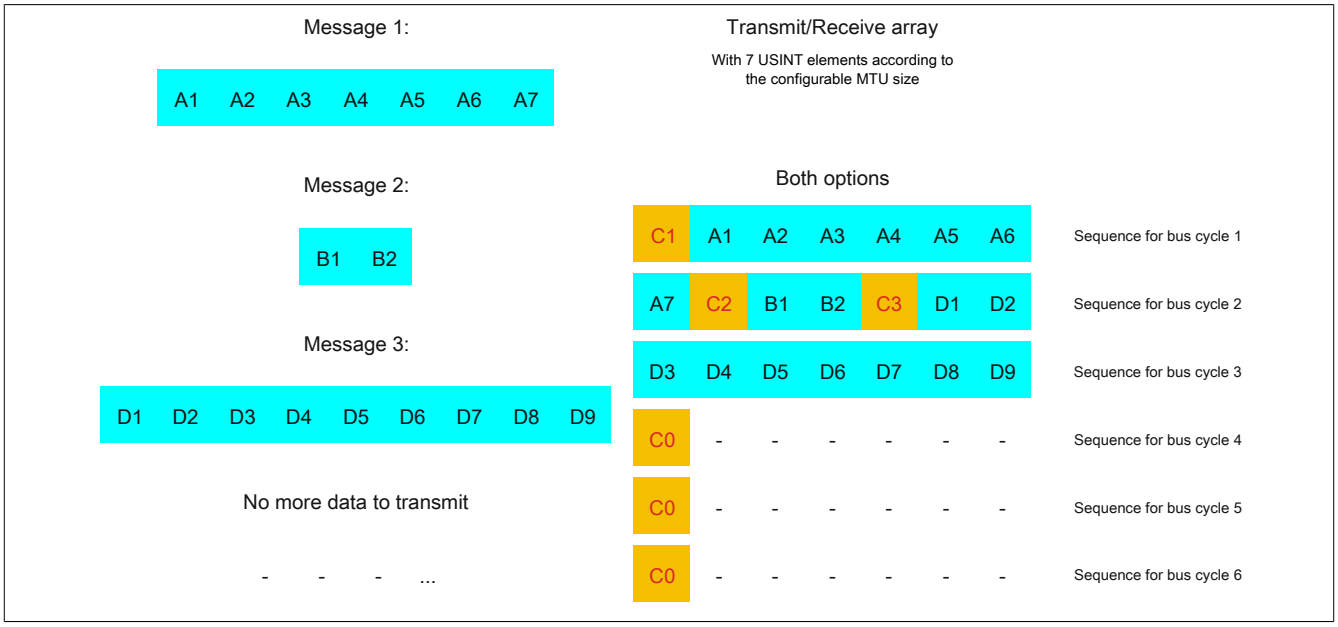

Figure 254: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 368: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.16.6.9.9.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

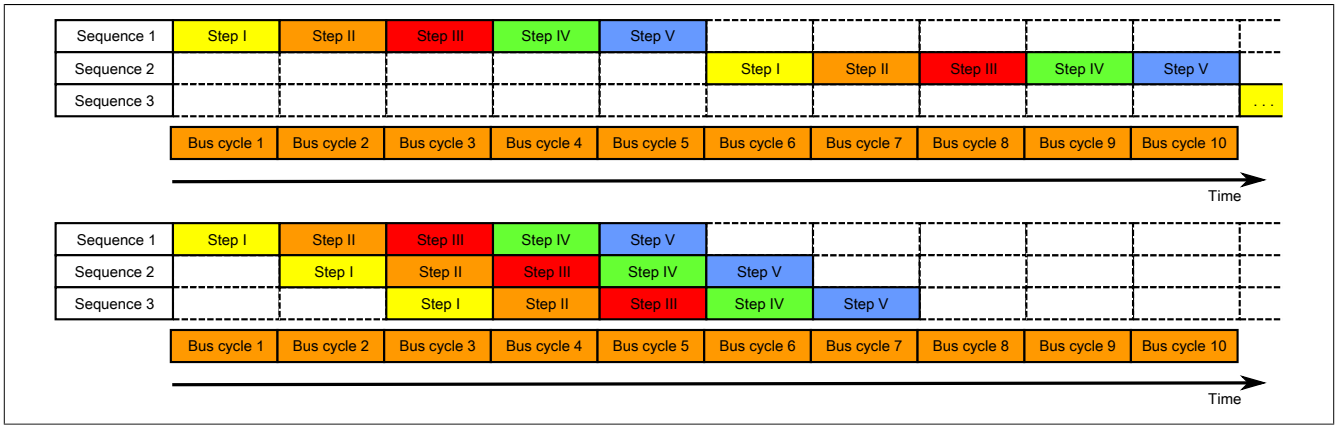

Figure 255: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

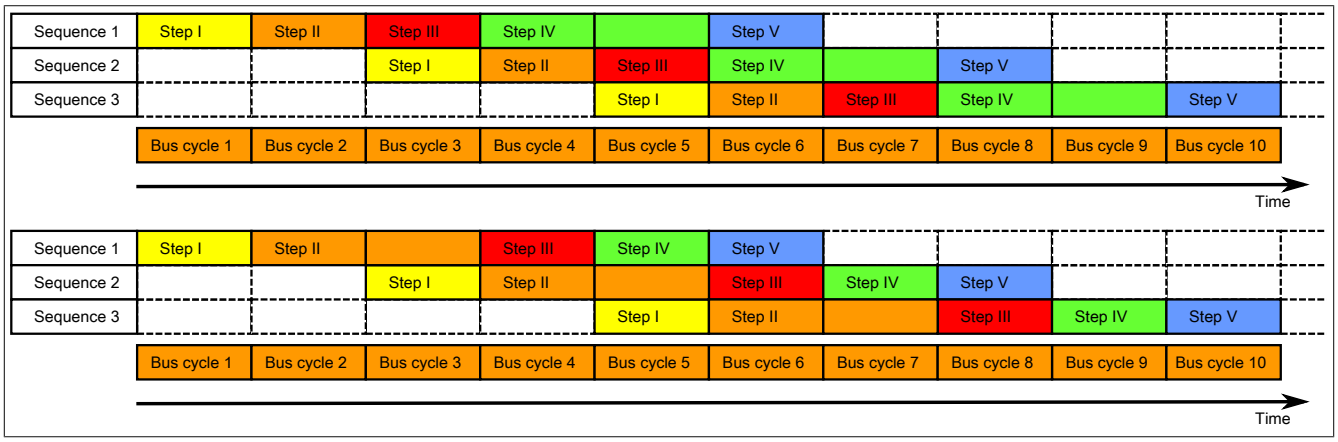

Figure 256: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

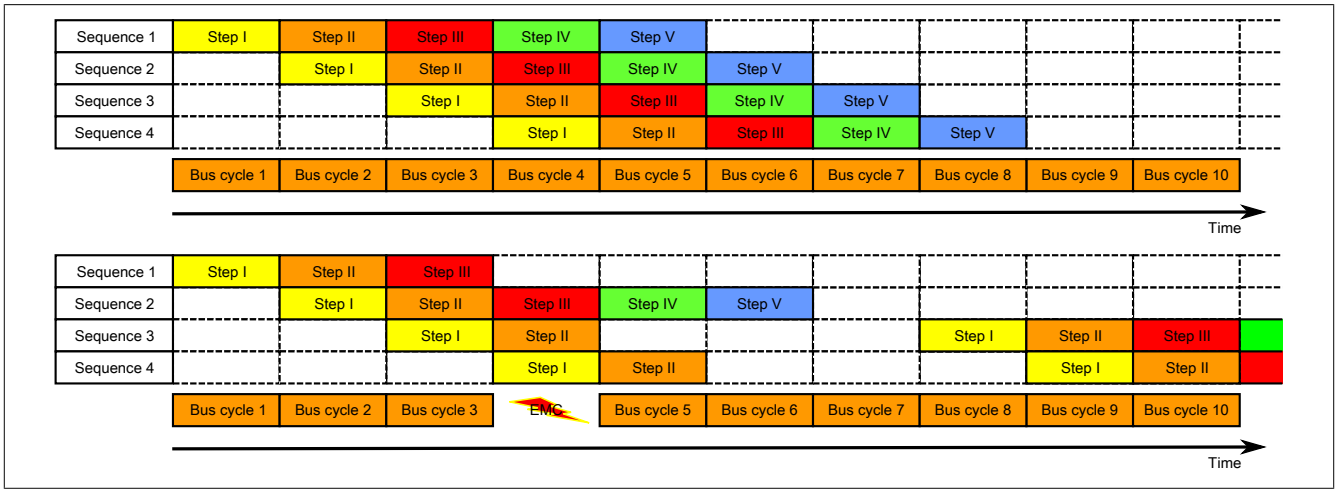

Figure 257: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.16.6.9.10 HIPERFACE with FlatStream

HIPERFACE is an asynchronous interface capable of half-duplex communication. Various features have been included to ensure that signals are transmitted without errors.

- The user can choose to have a parity bit added when transmitting a data block.
- A checksum is sent together with a signal and evaluated by the receiver.
- The command to which the encoder is responding is repeated at the start of a response.

In FlatStream mode, the module acts as a bridge between the CPU and the HIPERFACE slave. HIPERFACE-specific algorithms have been implemented to monitor timeouts and handle checksums. During normal operation, the user does not have access to these details.

Additional information is provided in the "Description of HIPERFACE" document.

4.16.6.9.10.1 Overview of conventional HIPERFACE commands for FlatStream mode

Command byte [hex]	Command	Code0
0x42	Read position	
0x43	Set position	•
0x44	Read analog value	
0x46	Read counter	
0x47	Increment counter	
0x49	Delete counter	•
0x4A	Read data	
0x4B	Save data	
0x4C	Read status of a data field	
0x4D	Create data field	
0x4E	Read available memory area	
0x4F	Change access key	
0x50	Read encoder status	
0x52	Read nameplate	
0x53	Reset encoder	
0x55	Allocate encoder address	•
0x56	Read serial number and program version	
0x57	Configure serial interface	•

Code0 is a byte that was added to the transfer protocol for safety reasons. It protects important system parameters from being overwritten by mistake (default: Code0 = 0x55).

4.16.6.9.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.16.6.9.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.16.7 X20DS1928

4.16.7.1 General information

The module is equipped with an EnDat encoder interface. The module automatically detects whether an encoder is connected with EnDat 2.1 or EnDat 2.2. This module can be used to evaluate encoders installed in B&R servo motors as well as encoders for external axes (encoders that scan any machine movement). The input signals are monitored. This makes it possible to detect open or shorted lines as well as encoder supply failures.

- EnDat 2.1 and EnDat 2.2 encoder interface
- Encoder input monitoring
- 5 VDC and GND for encoder supply
- NetTime function: Time stamp for position

EnDat encoders

EnDat is a standard developed by Johannes Heidenhain GmbH (www.heidenhain.de) that incorporates the advantages of absolute and incremental position measurement and also offers a read/write parameter memory in the encoder. With absolute position measurement, the homing procedure is generally not required. Where necessary a multi-turn encoder should be installed. To save costs, a single-turn encoder and a reference switch can also be used. In this case, a homing procedure must be carried out.

NetTime position timestamp

Highly dynamic positioning tasks require not only the position value, but also the exact time at which the position was determined. The module has a NetTime function for this, which adds a timestamp to the recorded position with microsecond accuracy.

The module provides the PLC with the position value and timestamp as absolute time value. The NetTime mechanisms ensure that the PLC NetTime clock and the local NetTime clock on the module have exactly the same absolute time at all times.

4.16.7.2 Order data

4.16.7.3 Technical data

Product ID	X20DS1928
Short description	
I/O module	1x EnDat interface
General information	
B&R ID code	0xA912
Status indicators	Counting direction, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Counting direction	Yes, using status LED
Power consumption	
Bus	0.01 W
Internal I/O	1.3 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Encoder inputs	
Type	EnDat 2.1/2.2
Angular position resolution	13-bit, with a 1 V_{SS} signal
Encoder monitoring	Yes
Max. encoder cable length	10 m, with a line cross-section 4x 2x 0.14 mm² and 1x 2x 0.5 mm²
Sine/Cosine inputs	
Signal transmission	Differential signals, symmetrical
Signal frequency	DC up to 400 kHz
Differential voltage	1 V_{SS}
Common-mode voltage	Max. ±10 V
Terminating resistor	120 Ω
Encoder supply	
Output voltage	5 V (±5%)
Load capability	300 mA
Protective measures	
Overload protection	Yes
Short circuit protection	Yes
Serial EnDat interface	
Signal transmission	5 VDC differential signal, EiA RS-485 standard
Transmission status	See EnDat specification
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 370: X20DS1928 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.16.7.4 Status LEDs

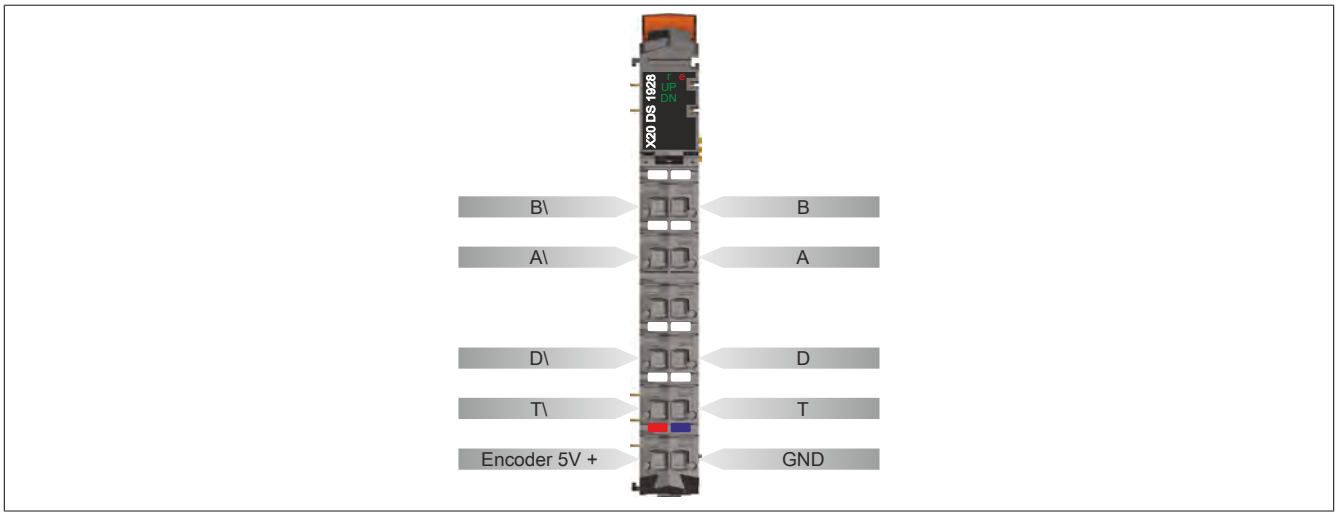
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	Module supply not connected
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything is OK
			On	Error or reset state - Possible cause: • Encoder supply error
			Single flash	I/O error - Possible causes: • Sine/Cosine relative position error (open line) • Sine/Cosine absolute position error (reference)
			Double flash	System error - Possible causes: • EnDat communication error • EnDat position error • EnDat error defining parameters
			Tripple flash	I/O error and system error
			Single flash, inverted	Error or reset state and I/O error
			Double flash, inverted	Error or reset state and system error
			Triple flash, inverted	Error or reset state, I/O error and system error
	UP	Green	On	The "UP/DN" LEDs are lit depending on the rotational direction and the speed of the connected encoder. The "UP" LED indicates when the encoder position changes in the positive direction.
	DN	Green	On	The "DN" LED indicates when the encoder position changes in the negative direction.

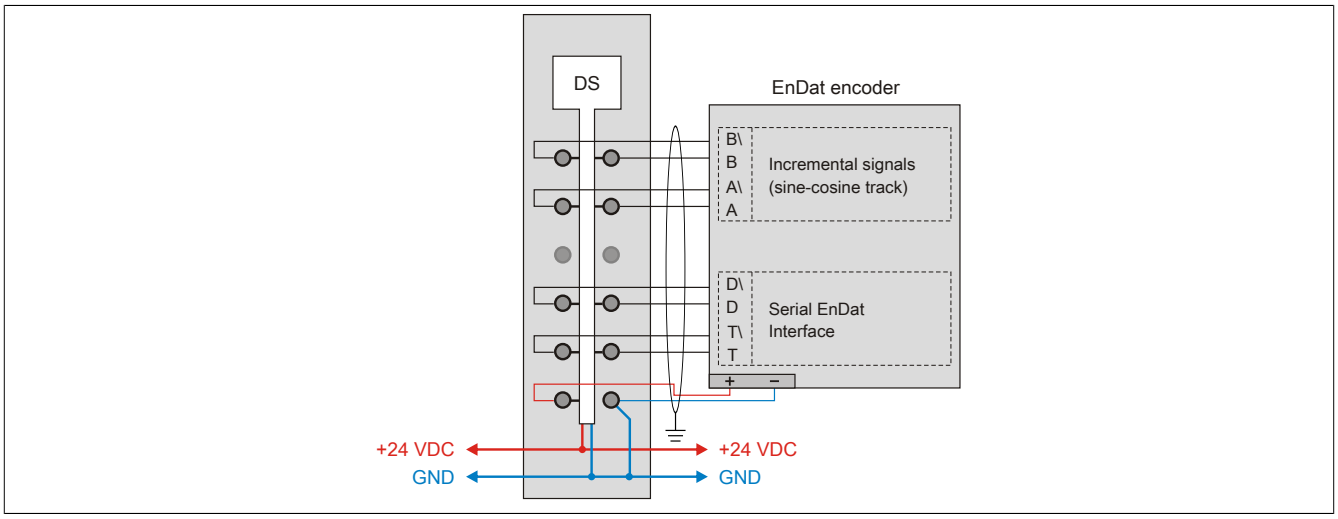
1) Depending on the configuration, a firmware update can take up to several minutes.

4.16.7.5 Pinout

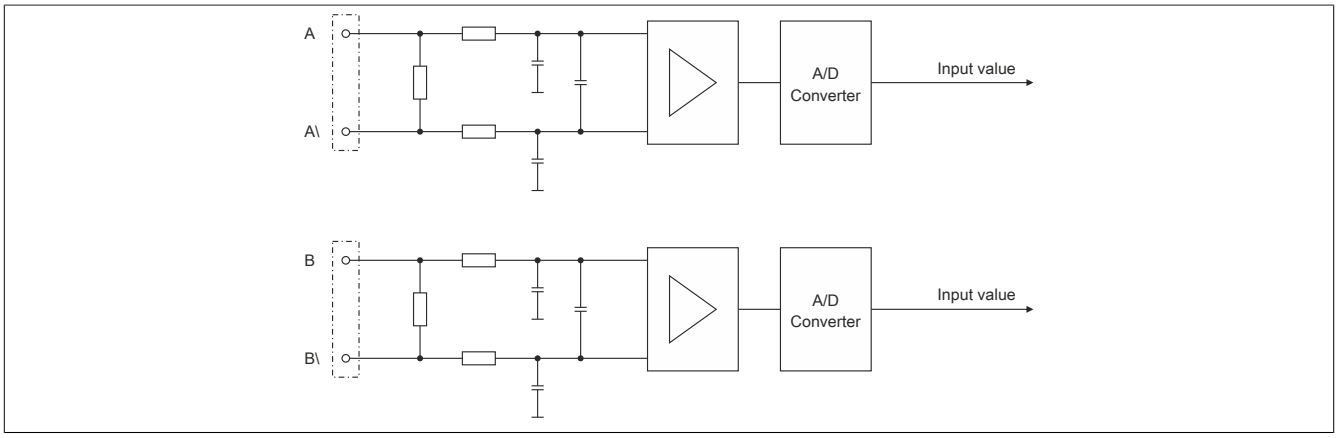
Shielded cables should be used for all signal lines.



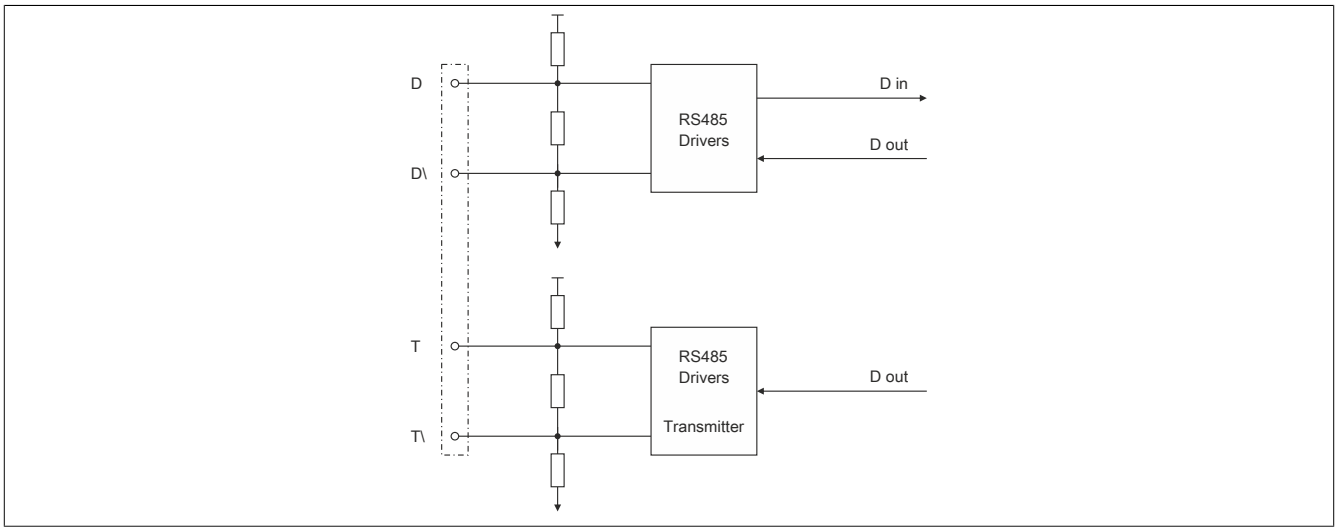
4.16.7.6 Connection example



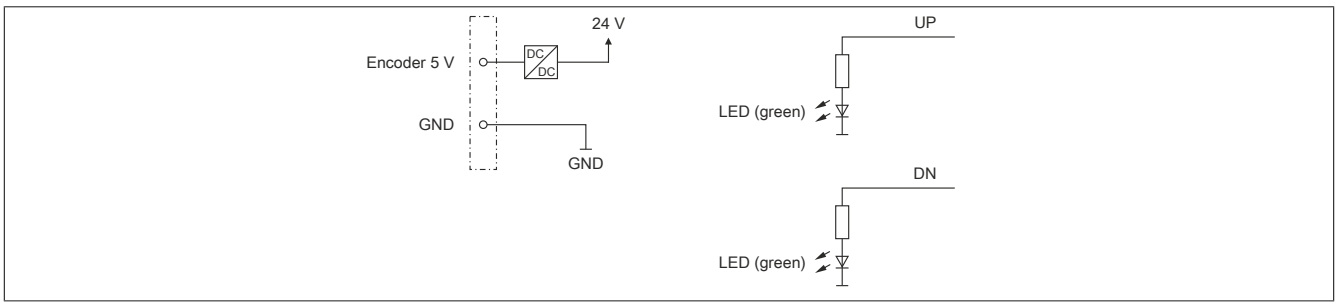
4.16.7.7 Input diagram for the incremental signals (sine-cosine track)



4.16.7.8 Input diagram for the serial EnDat interface



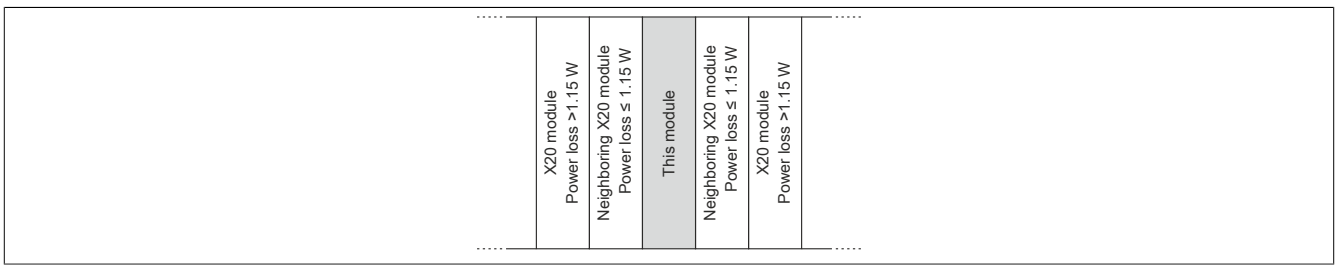
4.16.7.9 Encoder supply scheme and LEDs



4.16.7.10 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.16.7.11 Register description

4.16.7.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.16.7.11.2 Register overview - Function model 0 (standard)

1) The offset specifies the position of the register within the CAN object.

4.16.7.11.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.16.7.11.4 Module configuration

The following configuration registers can be used to define various module settings. They can be used, for example, to modify the module's behavior on an X2X Link network. The user can choose between 2 option registers.

4.16.7.11.4.1 Data query

Name:
CfO_SIframeGenID

This register can be used to define when the synchronous/cyclic input data is generated. "X2X cycle optimized" should be set for jitter-free data acquisition. "Fast reaction" can be set for the best performance.

Data type	Value	Information
USINT	9	Fast reaction
	14	X2X cycle optimized (bus controller default setting)

4.16.7.11.4.2 Prescale factor

Name:
CfO_SystemCyclePrescaler

In order for the module to communicate with the CPU as well as the EnDat encoder, the EnDat cycle time must be at least twice the module cycle time. The actual EnDat cycle time is a result of multiplying the module cycle time by the value in this register.

Data type	Value	Information
UINT	2	EnDat cycle: 200 to 400 µs (bus controller default setting)
	4	EnDat cycle: 400 to 800 µs
	8	EnDat cycle: 800 to 1,600 µs

4.16.7.11.5 Basic functions

This module can import a position when used together with an EnDat encoder. The received data is prepared in 2 different formats and given a time stamp. Six registers are available for further processing. This allows the user to select the format that best fits the application at hand.

4.16.7.11.5.1 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.7.11.5.2 Absolute position values

Name:
PositionHW
PositionLW

The absolute position of the encoder is defined using 64-bit resolution. The position value is stored in the PositionHW and PositionLW registers. The upper 32 bits are stored the PositionHW register, while the lower 32 bits are stored in the PositionLW register.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
2x UDINT	0 to 4,294,967,295

4.16.7.11.5.3 SDC position value

Name:
Position

The SDC library requires a signed 32-bit position value. The position's low word can be accessed separately for this. The value can also be used as default position value, however.

For SinCos signal evaluation, see 4.16.3.11.7.1 "Format of the SinCos signal" for information regarding the data format.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.16.7.11.5.4 NetTime of the position values

Name:
PosTime

This register is used to assign each recorded position of the current NetTime value. The NetTime is recorded with µs accuracy.
The SDC library requires a 16 bit value. The NetTime value is therefore also generated in this format.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	NetTime in µs
INT	-32,768 to 32,767	

4.16.7.11.5.5 Counter for position values

Name:
PosCycle

PosCycle is an integer counter that is incremented as soon as the module has saved a new valid position value.

Data type	Value
SINT	-128 to 127

4.16.7.11.6 Error management

This module can be used to diagnose error states. There are the following ways in which this is done:

- Module-based diagnostics
- EnDat-based diagnostics

4.16.7.11.6.1 Module-based diagnostics

The module diagnoses 7 different errors or warnings. Depending on the settings, the error bits can be called either individually or packed together.

Configuring errors and warnings

Name:
ErrorEnableID_1710

The implemented diagnostic algorithms can be enabled or disabled in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder supply:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
1	Reserved	-	
2	Vss Sin/Cos:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
3	Position error:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
4	EnDat - Communication:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
5	EnDat - Position:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
6	EnDat - Parameters:	0	Error detection disabled
		1	Error detection enabled (Bus Controller default setting)
7	EnDat - Reference warning:	0	Warning disabled
		1	Warning enabled (Bus Controller default setting)

Encoder supply:

The encoder voltage supply is below the permitted limit.

Vss Sin/Cos:

The voltage value for the Sin/Cos track violates the configured limit values.
→ See register 4.16.3.11.7.4 "SinCosVssMin" or 4.16.3.11.7.5 "SinCosVssMax".

Position error:

The determined position value violates the requirements of the application.

EnDat - Communication:

Communication error on the EnDat interface (e.g. incorrect checksum)

EnDat - Position:

Encoder evaluates the determined position value as invalid.

EnDat - Parameters:

Inconsistent register values for encoder identification
→ Countermeasures: Check wiring or rescan (see "EnDatAck")

EnDat - Reference warning:

The digital interface provides an absolute position value that can be used to accurately describe the axis position. The position value is homed to this absolute value at the beginning of a measurement. The analog interface can be used to incrementally sample changes that occur very rapidly. This enables the module to continue sampling the position value at a high resolution. Both the analog and the digital signal are sampled cyclically. If the value determined incrementally deviates from the absolute value during operation then the referencing warning is displayed and the position must be referenced again.

Status of errors and warnings

Name:
ErrorInfo

EncoderSupplyError
VssCheckError
PositionError
EnDatComError
EnDatPosError
EnDatParSetError
EnDatRefWarning

This register indicates which error or warning is currently active. For a description of errors, see "Configuring errors and warnings".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EncoderSupplyError	0	No error
		1	Encoder supply error
1	Reserved	-	
2	VssCheckError	0	No error
		1	Vss error on Sin/Cos track
3	PositionError	0	No error
		1	Position error
4	EnDatComError	0	No error
		1	EnDat communication error
5	EnDatPosError	0	Error detection disabled
		1	Error detection enabled
6	EnDatParSetError	0	Error detection disabled
		1	Error detection enabled
7	EnDatRefWarning	0	Warning disabled
		1	Warning enabled

Acknowledging errors and warnings

Name:
AckErrorInfo

AckEncoderSupplyError
AckVssCheckError
AckPositionError
AckEnDatComError
AckEnDatPosError
AckEnDatParSetError
AckEnDatRefWarning

This register is used to acknowledge an error message that occurred in the "Status of errors and warnings" register. For a description of errors, see "Configuring errors and warnings".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	AckEncoderSupplyError	0	No error acknowledgment
		1	Error acknowledgment
1	Reserved	-	
2	AckVssCheckError	0	No error acknowledgment
		1	Error acknowledgment
3	AckPositionError	0	No error acknowledgment
		1	Error acknowledgment
4	AckEnDatComError	0	No error acknowledgment
		1	Error acknowledgment
5	AckEnDatPosError	0	No error acknowledgment
		1	Error acknowledgment
6	AckEnDatParSetError	0	No error acknowledgment
		1	Error acknowledgment
7	AckEnDatRefWarning	0	No acknowledgment
		1	Acknowledgment

4.16.7.11.6.2 EnDat-based diagnostics

Memory areas are provided in the EnDat standard for error handling. Error management was tailored to utilize error detection according to the EnDat standard. Additional registers were implemented in the module which prepare these areas in the encoder memory.
The module allows access to all previously defined memory areas for error handling. The memory areas are mirrored in the module registers and can be interpreted by the user.
Detailed information regarding the errors that can be detected in this way can be found in the encoder's manual.

EnDat errors

Name:
EnDatError

This register is used to indicate critical conditions on the EnDat encoder. The system has generally ceased to work and requires service.

Data type	Value
UINT	See bit structure.

The bit structure described below is designed according to the general recommendations of the EnDat standard. The specification does not limit which trigger algorithms to use or which of the listed messages must be supported. Please refer to the encoder's manual for further details.

Bit structure:

Bit	Name	Value	Information
0	Illumination	0	OK
		1	Failed
1	Signal amplitude	0	OK
		1	Detected as having errors
2	Position value	0	OK
		1	Detected as having errors
3	Overvoltage	0	No
		1	Yes
4	Undervoltage	0	No
		1	Yes
5	Overcurrent	0	No
		1	Yes
6	Battery	0	OK
		1	Must be changed
7 - 15	Reserved	-	

EnDat warnings

Name:
EnDatWarning

This register is used to indicate critical conditions on the EnDat encoder. Encoder still functional, but must be checked immediately. This generally means that defined tolerances have been exceeded.

Data type	Value
UINT	See bit structure.

The bit structure described below is designed according to the general recommendations of the EnDat standard. The specification does not limit which trigger algorithms to use or which of the listed messages must be supported. Please refer to the encoder's manual for further details.

Bit structure:

Bit	Name	Value	Information
0	Frequency collision	0	No
		1	Yes
1	Temperature exceeded	0	No
		1	Yes
2	Control reserve - Lighting	0	Not required
		1	Required
3	Charge - Battery	0	OK
		1	Low
4	Reference point	0	Reached
		1	Not reached
5 - 15	Reserved	-	

Acknowledging EnDat errors

Name:
EnDatAck

"EnDatAck" acknowledges all errors and warnings from the "EnDatError" and "EnDatWarning" registers. It can also instruct the module to re-import the parameters for identification.

If one of the bits in this register is set, the system automatically resets it and the respective algorithm is run.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EnDatAck	0	No acknowledgment
		1	Acknowledge
1	Rescan - Identification register	0	Imported parameters retained
		1	Reimport parameters
2 - 7	Reserved	-	

4.16.7.11.7 Sin/Cos - Analog interface configuration

In addition to the digital EnDat interface, this module is also equipped with an analog interface for sampling a differential sine-cosine signal. To increase the resolution, the EnDat standard specifies a cooperation between the analog and digital information. This enables a highly dynamic representation of the position while maintaining high resolution.

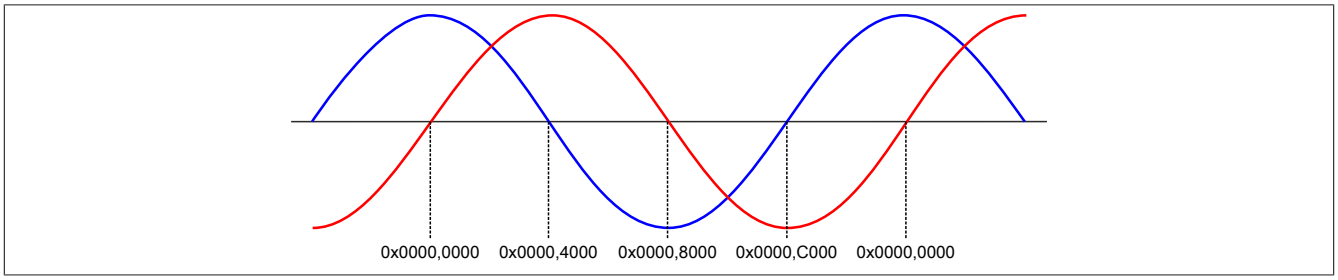
4.16.7.11.7.1 Format of the SinCos signal

The SinCos signal is represented as a position value in the 4.16.3.11.5.2 "Absolute position values" and 4.16.3.11.5.3 "SDC position value" registers. The following relationships apply:

- PositionLW and Position are identical in the function.
- PositionHW extends the integer range of PositionLW by adding multi-turn functionality.

64-bit register	PositionHW (unsigned)	PositionLW (unsigned)	
32-bit register	-	Position (signed)	
Format	Integer extension (to 48-bit)	Integer (16-bit)	Decimal places: (with 13-bit resolution)
Information		A full sine wave corresponds to an increment of the integer.	**15** **14** **13** **12** **11** **10** **9** **8** **7** **6** **5** **4** **3** **2** **1** **0** x x x x x x x x x x x x x 0 0 0 **Important:** The lower 3 bits always contain the value 0.
Word/DWord	DWord	Word 1	Word 0

Relationship between sine curve (red) and decimal places:



4.16.7.11.7.2 Enabling SinCos

Name:
SinCosEnable

This register must always have the value 1 for configuration reasons.

Data type	Value	Information
USINT	1	Bus controller default: 1

4.16.7.11.7.3 Enabling SinCos reference source

Name:
SinCosRefSource

This register must always have the value 1 for configuration reasons.

Data type	Value	Information
USINT	1	Bus controller default: 1

4.16.7.11.7.4 Configuring the lower Vss value

Name:
SinCosVssMin

This register specifies the lower limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value falls below this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 800

4.16.7.11.7.5 Configuring the upper Vss value

Name:
SinCosVssMax

This register specifies the upper limit value for the peak-to-peak voltage of the sine/cosine track. The incoming signal is monitored in this way. If the incoming value exceeds this specified limit, then the module reports the corresponding error.

Data type	Value	Information
UINT	0 to 1500	Values in mV, bus controller default setting: 1200

4.16.7.11.7.6 Configuring the delay time after errors

Name:
SinCosQuitTime

If an error is detected on the analog interface, the last correctly read values remain valid. An interval can be defined in this register at which the module begins receiving correct values again after the error state without processing them further internally. Only then will newly sampled correct analog values be recognized as valid.

Data type	Value	Information
UDINT	0 to 20000000	Values in µs, bus controller default setting: 100000

4.16.7.11.8 EnDat

4.16.7.11.8.1 EnDat - Digital interface configuration

The EnDat interface allows you to establish a point-to-point connection with exactly one EnDat encoder.

There are 2 ways to use the encoder data in the PLC program. One is to store the necessary encoder values temporarily in the module, where they can then be provided to the CPU. The other is to use the module's FlatStream mode, which supports the full range of commands defined in the EnDat specification.

Detailed information about the EnDat specification can be found in the document, "Technical Information – EnDat 2.2".

Configuring EnDat module properties

Name:
EnDatMode

This register is used to define various module properties.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EnDat interface	0	Disabled
		1	Enabled (bus controller default setting)
1	Format of imported position data	0	Unsigned (bus controller default setting)
		1	Signed
2	Fast EnDat cycle (6 MHz)	0	Enabled if encoder compatible (bus controller default setting)
		1	Disabled
3	Sin/Cos track	0	Enabled (bus controller default setting)
		1	Disabled
4 - 7	Reserved	-	

4.16.7.11.8.2 EnDat - Read ID

The EnDat interface does more than just help the user specify axis positions. It can also be used to readout certain data stored in the encoder memory.
The EnDat specification divides the encoder memory into logical groups. These include memory areas for the operating parameters, operating status, manufacturer parameters and manufacturer parameters according to EnDat 2.2.
The 4 most important memory areas are mirrored in the module registers. The information can be accessed in the application and used to identify a particular encoder.

Information:

There are different types of EnDat. Please keep this in mind. EnDat has been continuously expanded to include new technical possibilities while maintaining backward compatibility. Several advancements have been made to the standard, which has resulted in a non-uniform structure.

In general, data is queried from memory for identification purposes when the module is started. In addition, the data can be reimported using the "EnDatAck" register. The module reads the data from the encoder, which is then mapped for the PLC.

Operating Parameters

Name:
OperatingParam_00 to OperatingParam_15

These registers can be used to read out the current operating parameters. The data in these registers correspond exactly to the values on the encoder. More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Data type	Value
16x UINT	See encoder manual

Operating state

Name:
OperatingStatus_00 to OperatingStatus_03

This register can be used to read the encoder's current operating state. The first 2 registers from this group are identical to the "EnDatError" and "EnDatWarning" registers. A special setting is provided because they are update cyclically.
Information about write protection and other configuration settings is managed in registers 02 and 03. The data in these registers correspond exactly to the values on the encoder.
More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Data type	Value
4x UINT	See encoder manual

Manufacturer parameters

Name:
ParamManuf_04 to ParamManuf_47

These registers are used to prepare the manufacturer parameters according to the EnDat standard 2.1. The exact arrangement of information can be found in the documentation "Technical Information - EnDat 2.2".

Data type	Value
44x UINT	see "Technical Information - EnDat 2.2" or encoder manufacturer data

Additional manufacturer parameters according to EnDat 2.2

Name:
ParamManufEnDat22_00 to ParamManufEnDat22_63

These registers are used to prepare the manufacturer parameters according to the EnDat standard 2.2. The exact arrangement of information can be found in the documentation "Technical Information - EnDat 2.2".

Data type	Value
64x UINT	see "Technical Information - EnDat 2.2" or encoder manufacturer data

4.16.7.11.8.3 EnDat - Read additional information

In addition to the identification data, other information can also be accessed from the encoder. However, the following algorithm requires exact knowledge of the encoder's memory structure and the EnDat specification.

Configuration

There are 4 different channels that can be operated during a cycle. One register per channel each is used for configuration, (i.e. determines which data is read from the encoder and mirrored on the respective Info byte).

Transmitting EnDat commands

Name:
EnDatInfoCmd01 to EnDatInfoCmd04

This register controls which data is processed on the corresponding Info byte for each channel. The register consists of up to 4 separate 8-bit values.

Data type	Value
4x UDINT	See bit structure. Bus controller default: 0

Bit structure:

Bit	Name	Information	
0 - 7	Command	Selects the response section	
8 - 15	Memory area codes	MRS code	
		Parameters not in blocks	**Parameters arranged in blocks**
16 - 23	Memory ID	Parameter numbers	Block number
24 - 31	Memory ID	-	Parameter numbers

There is a difference when querying data from an encoder using an EnDat 2.1 command or an EnDat 2.2 command.
When querying encoder data with an EnDat 2.1 command (0x04 and 0x06), the parameter number and (optionally) the block number must be specified in addition to the MRS code.
When querying the memory with an EnDat 2.2 command, the parameter number and block number are not required. The module consecutively transmits all 4 words of the memory area, which was selected using the MRS code. The right command must be selected depending on which of the 4 response bytes is needed.

Memory area codes

The code to be defined is identical to the MRS code for the encoder memory. The EnDat specification has left a few of the encoders memory areas undefined and available for future developments. This is why a clear and reliable explanation cannot be provided here.
More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Parameter numbers

EnDat 2.1 requires the corresponding parameter number to be entered in order to specifically address the desired parameter in the encoder memory. Older EnDat versions did not divide the encoder memory into blocks. This is why there are memory areas that can be selected without specifying a block number. In this case, the parameter number must be entered on the third byte.
More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Block number

To expand the address range of the encoder memory, additional block numbers were added starting at the second section. If the desired parameter is located in this blocked area, then the block number must be specified on the third byte. In this case, the parameter number is entered on the fourth byte.
More detailed information can be found in the encoder's manual or by referring to the latest EnDat specification.

Call

After being configured correctly, the position value is transmitted cyclically to the module. Each channel has 2 registers that serve as temporary storage. The module confirms successful receipt by setting an OK bit. The EnDat specification does not specify in which format the parameters must be received. Therefore, the module provides the information in 2 ways. Which of the two registers should be used for further processing depends on the parameters being read.

Validity of info data

Name:
EnDatInfoOK01 to EnDatInfoOK04

This register's bits provide information about the validity of the current info data in temporary storage.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EnDatInfoOK01	0	Value 01 invalid
		1	Value 01 valid
...	...	...	
3	EnDatInfoOK04	0	Value 04 invalid
		1	Value 04 valid
4 - 7	Reserved	-	

Reading EnDat information

Name:
EnDatInfo01 to EnDatInfo04

These registers provide the corresponding requested information as a signed or unsigned 2-byte value.
The EnDat specification does not specify the format of the received parameters. Which of the two data types should be used for further processing therefore depends on the parameter being read.

Data type	Value
UINT	0 to 65535
INT	-32,768 to 32,767

4.16.7.11.9 FlatStream communication

4.16.7.11.9.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

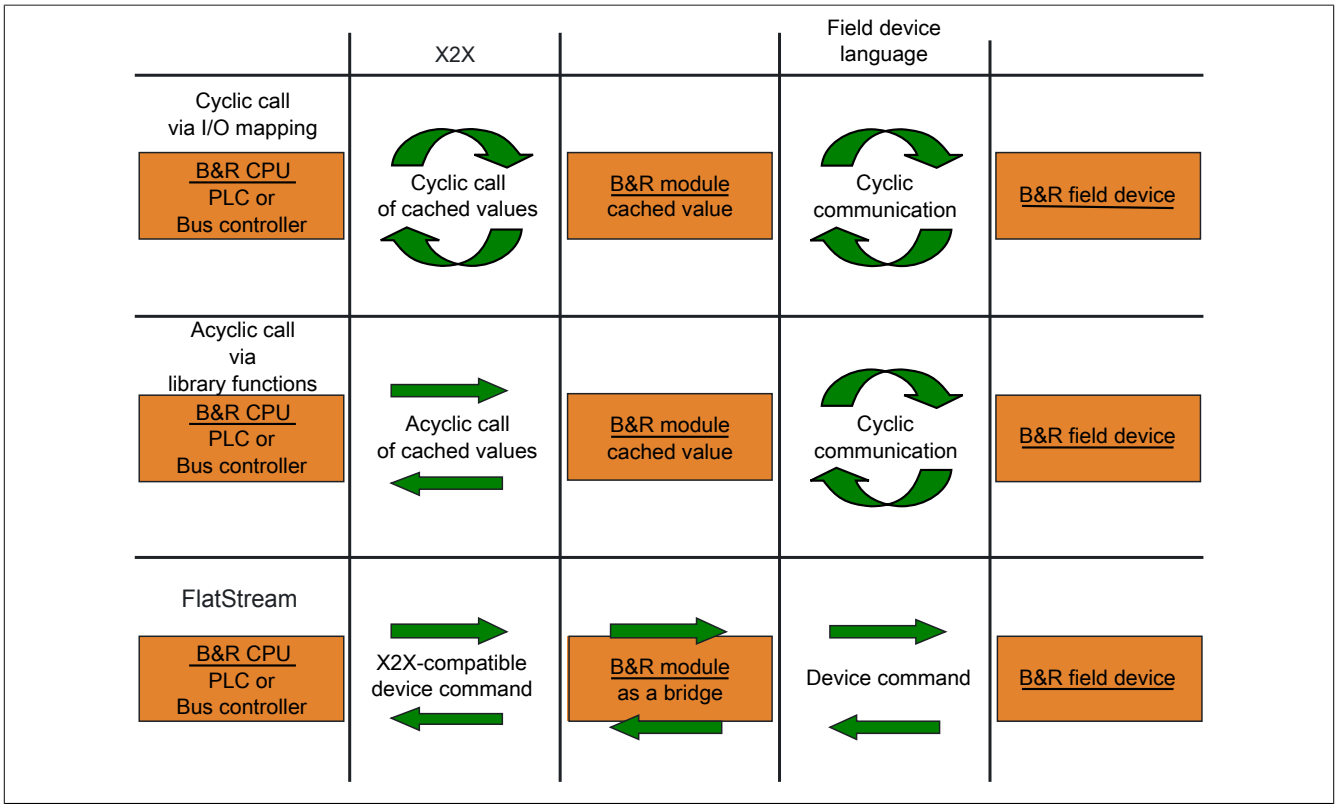


Figure 258: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.16.7.11.9.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.16.7.11.9.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

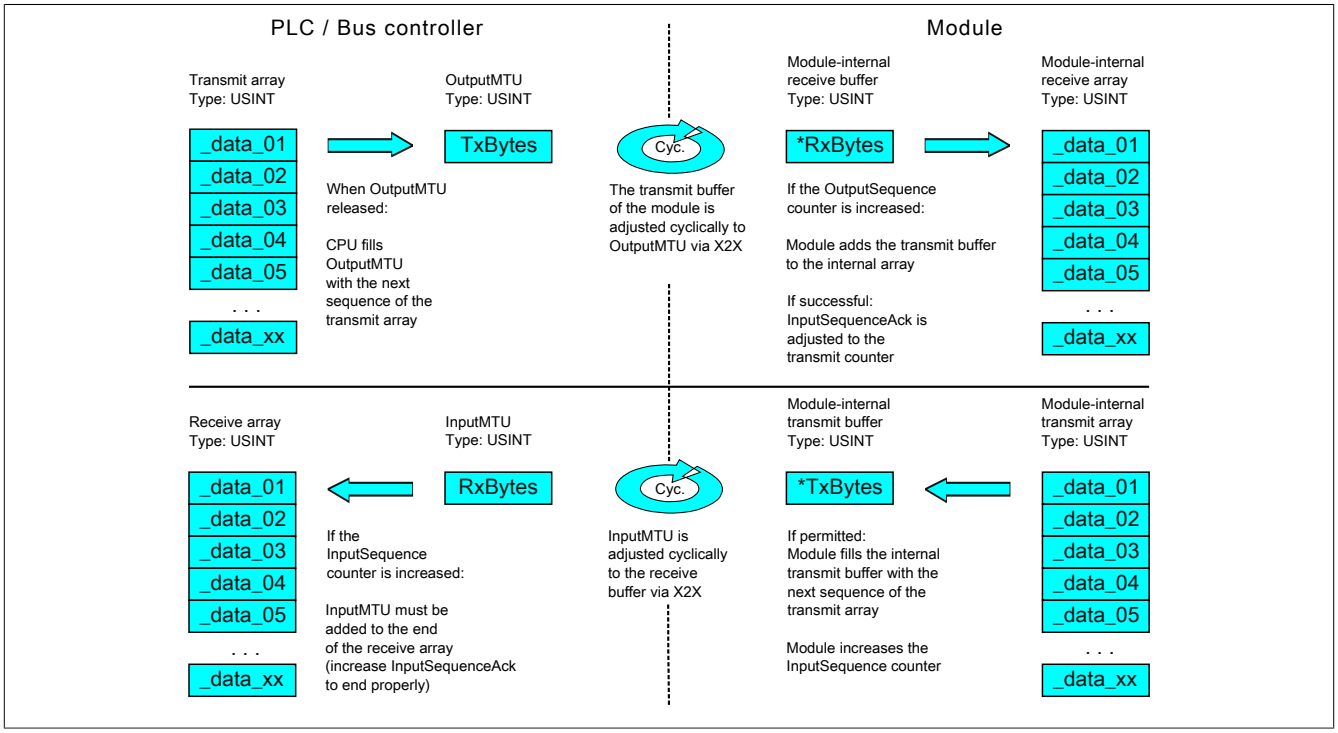

Figure 259: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.16.7.11.9.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

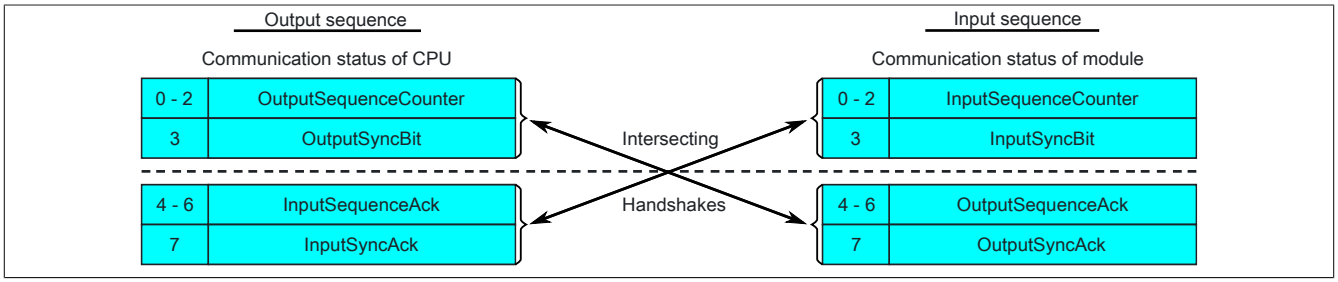

Figure 260: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

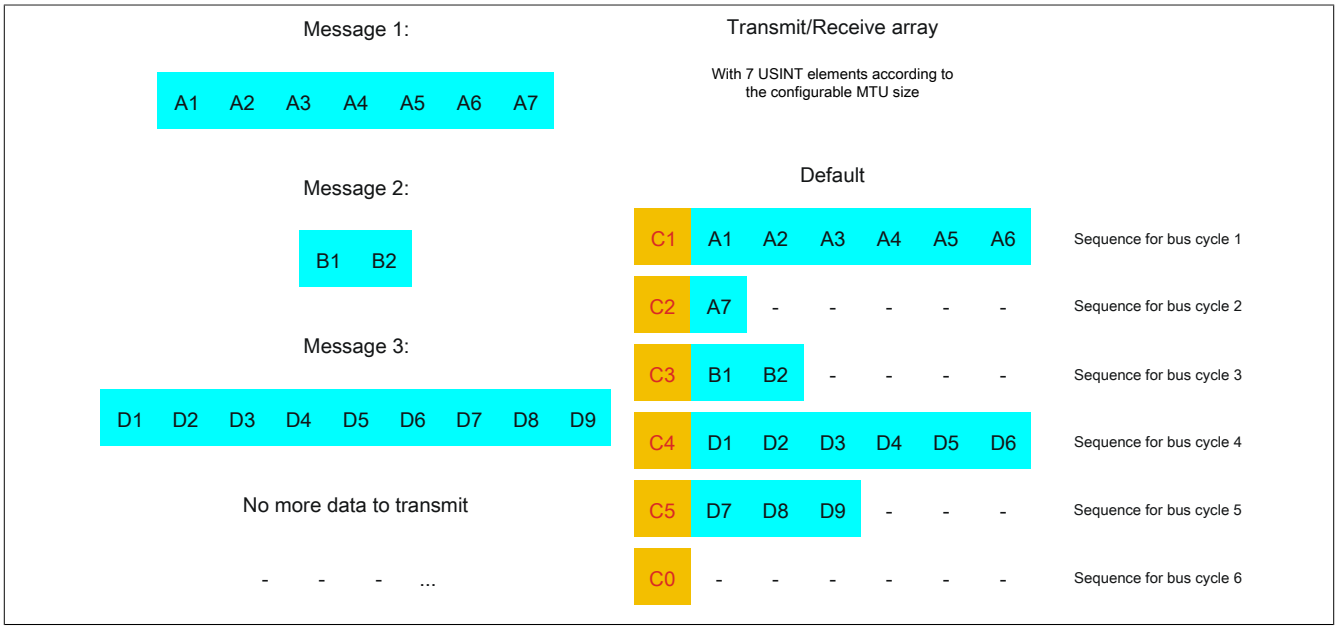

Figure 261: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 371: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 372: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

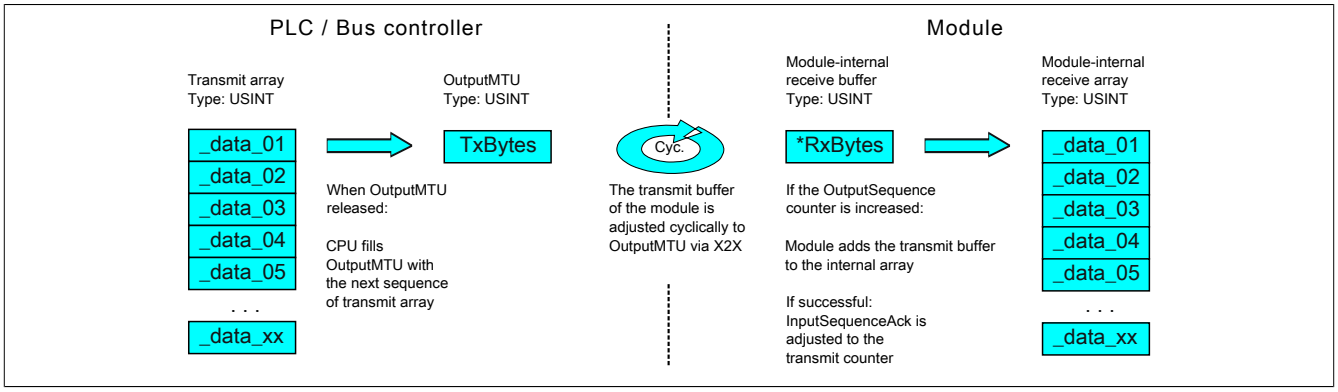

Figure 262: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

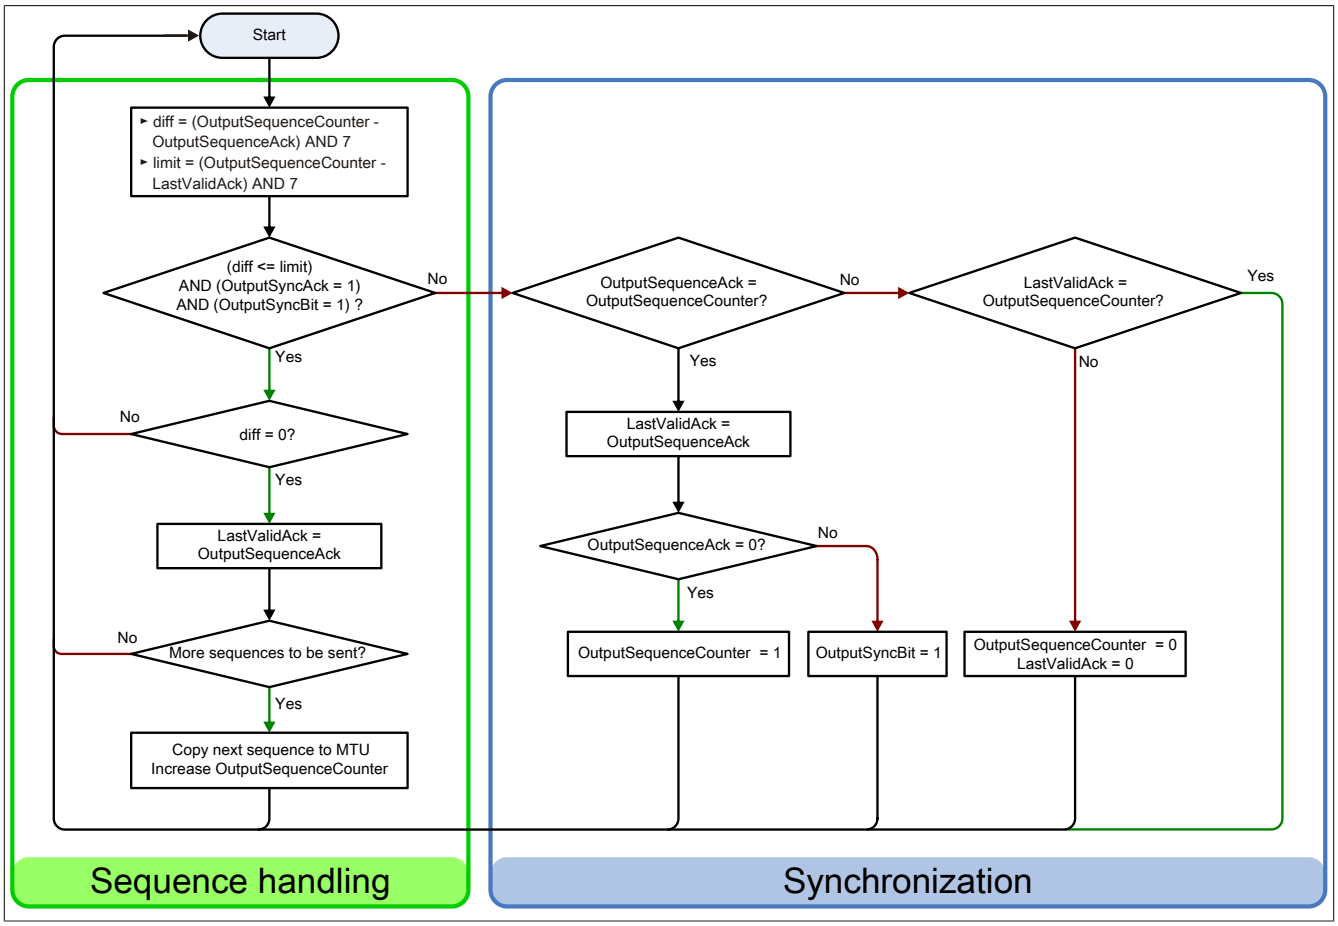

Figure 263: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

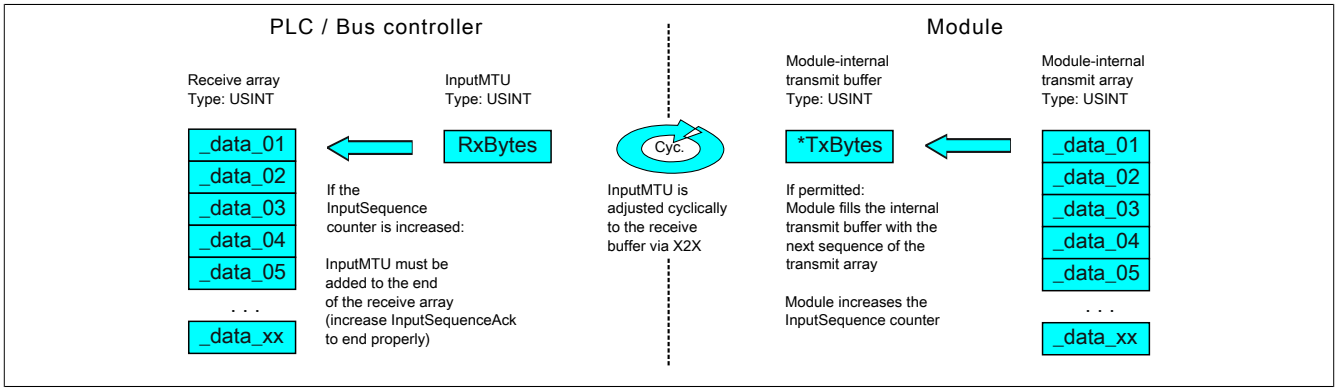

Figure 264: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

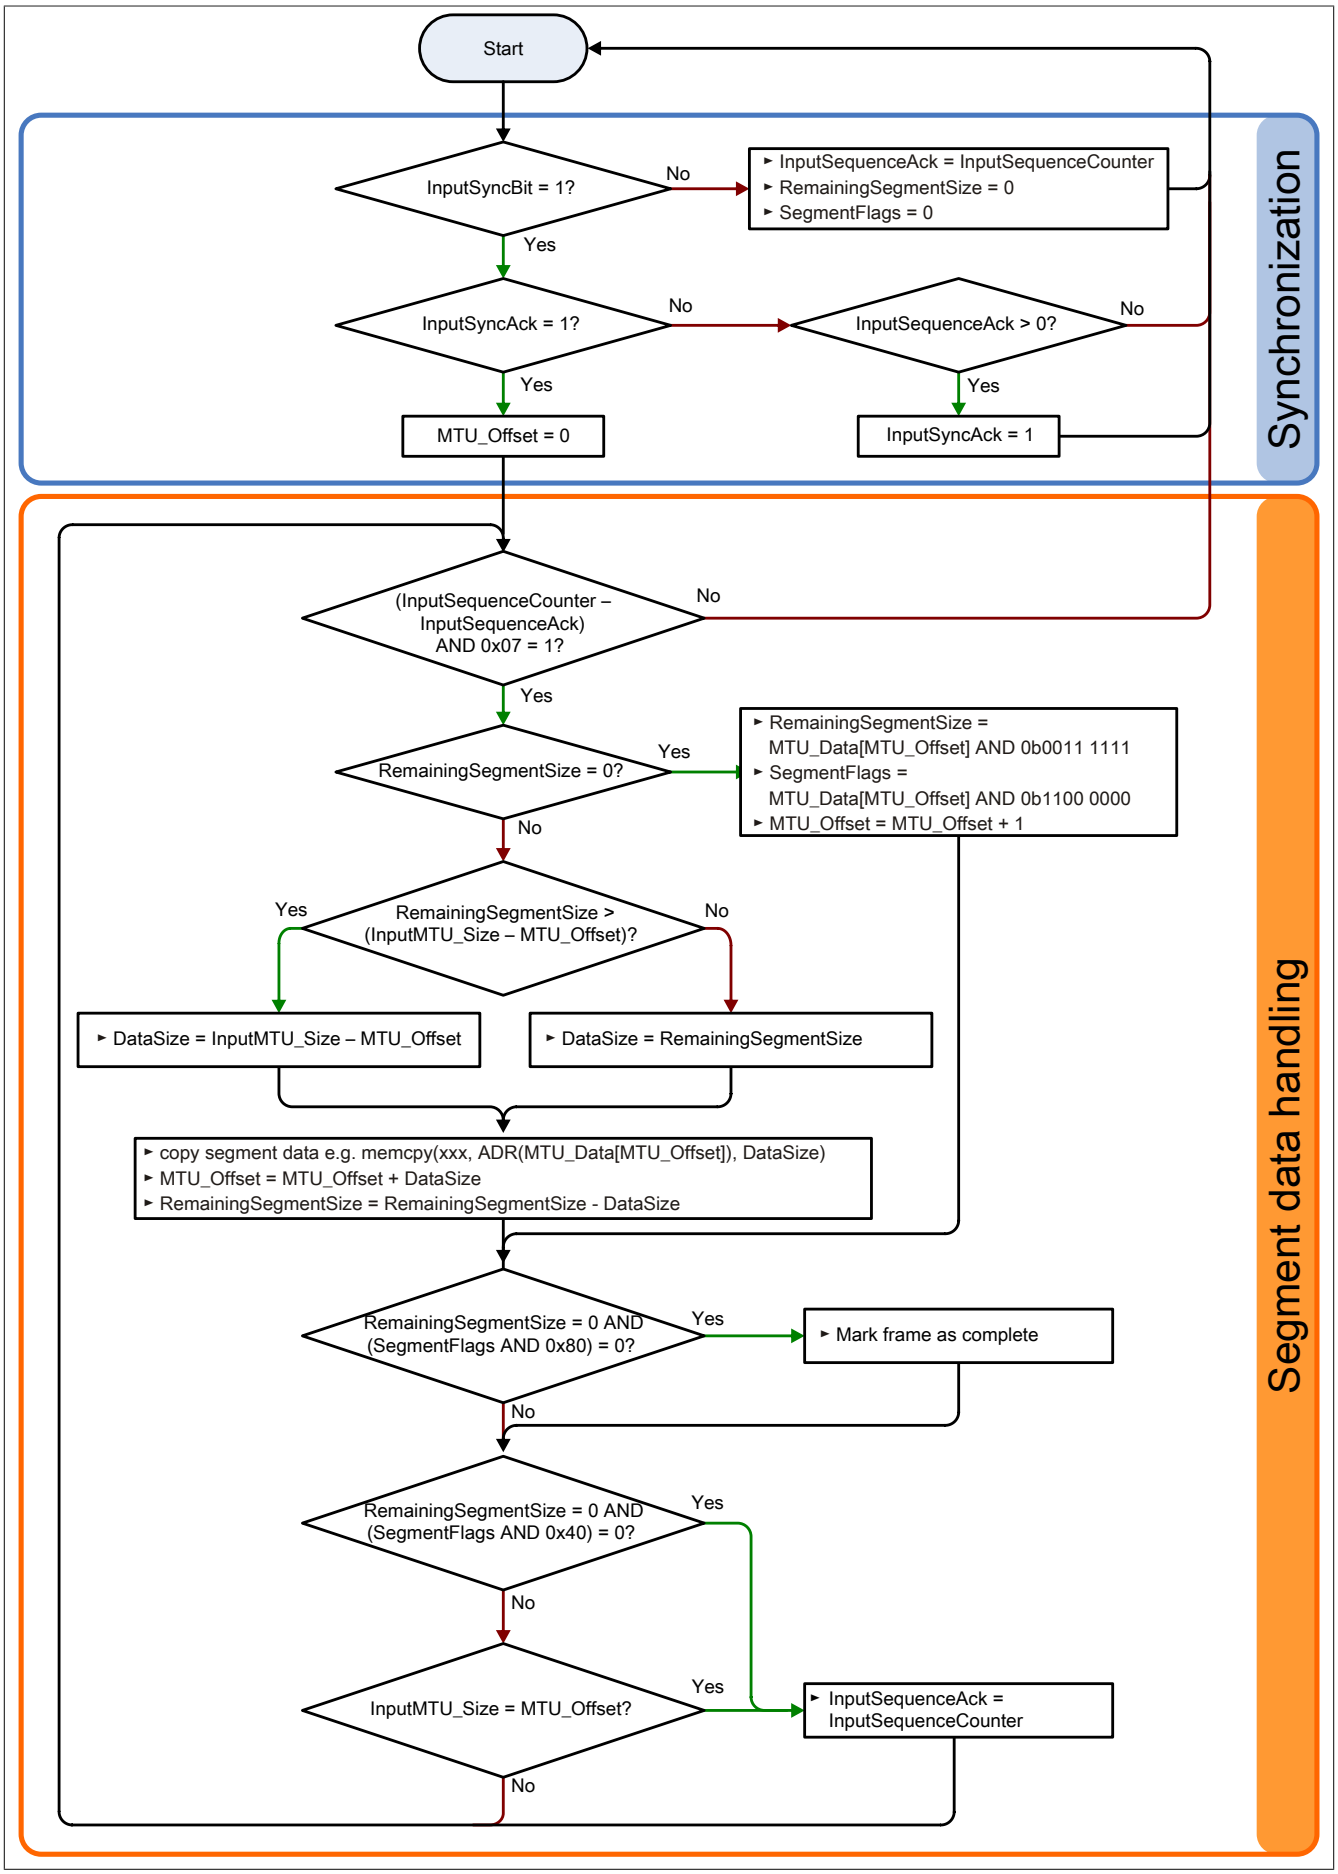

Figure 265: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

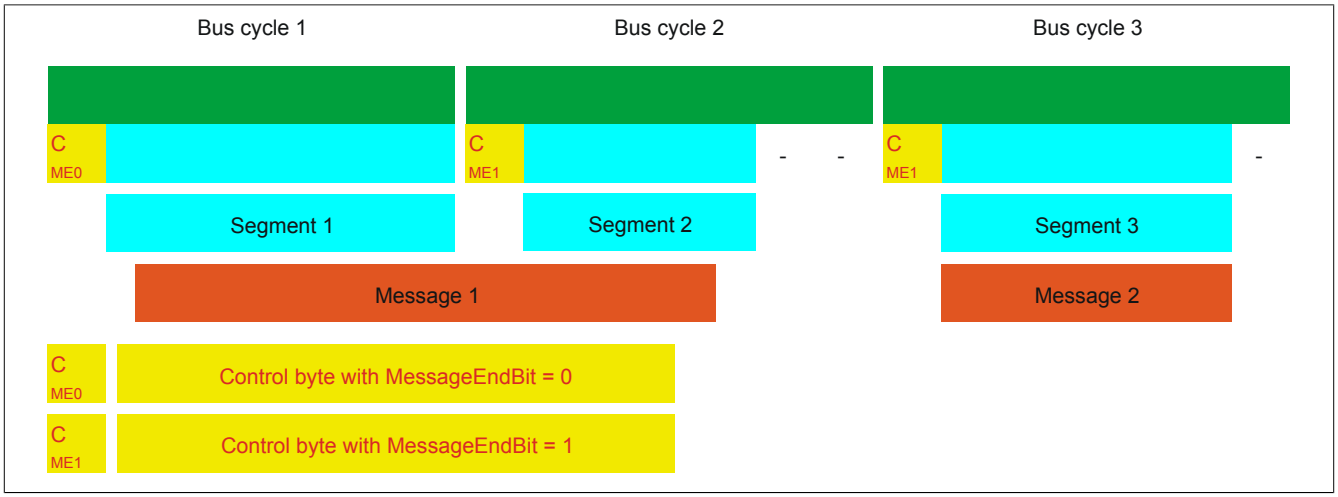

Figure 266: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

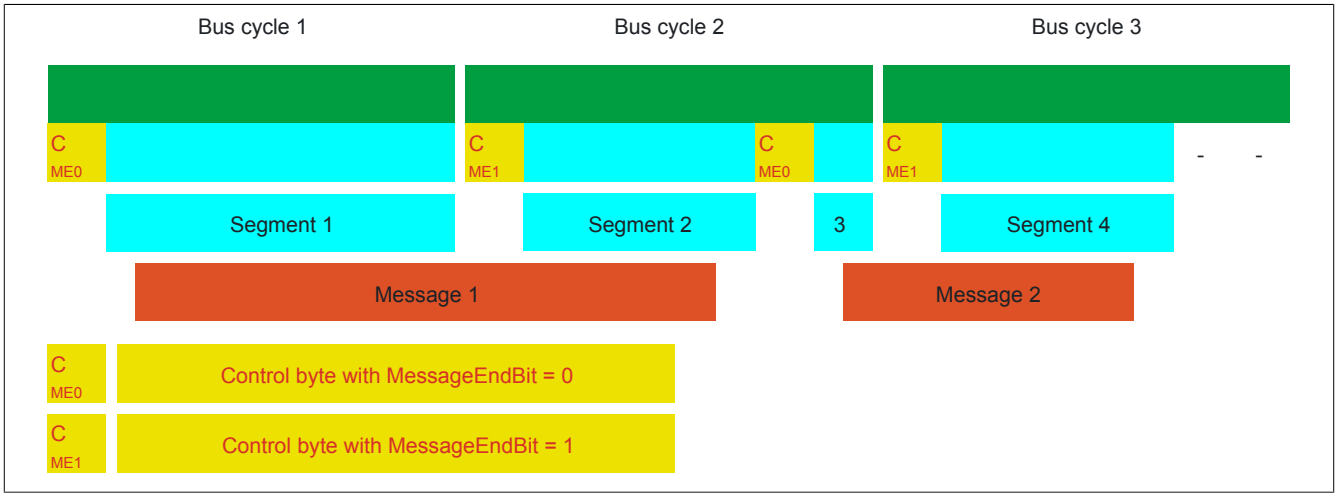

Figure 267: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

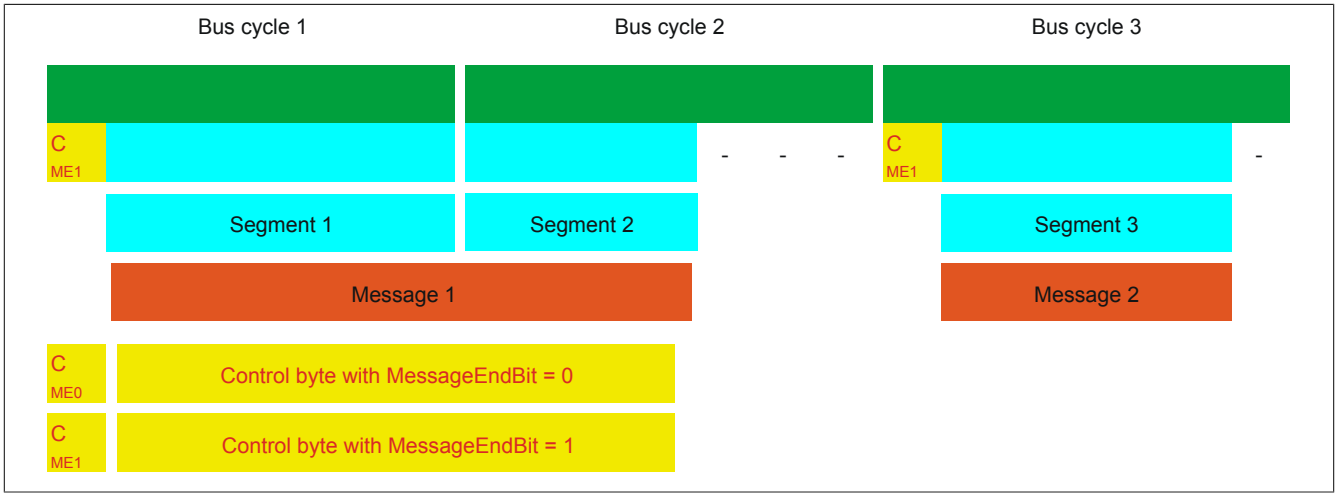

Figure 268: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

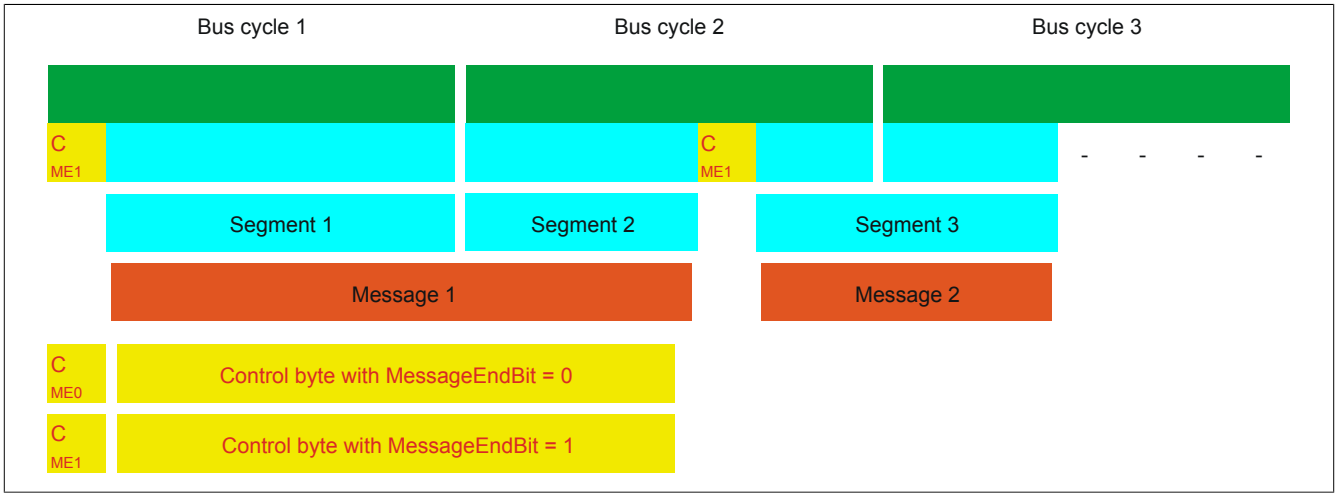

Figure 269: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

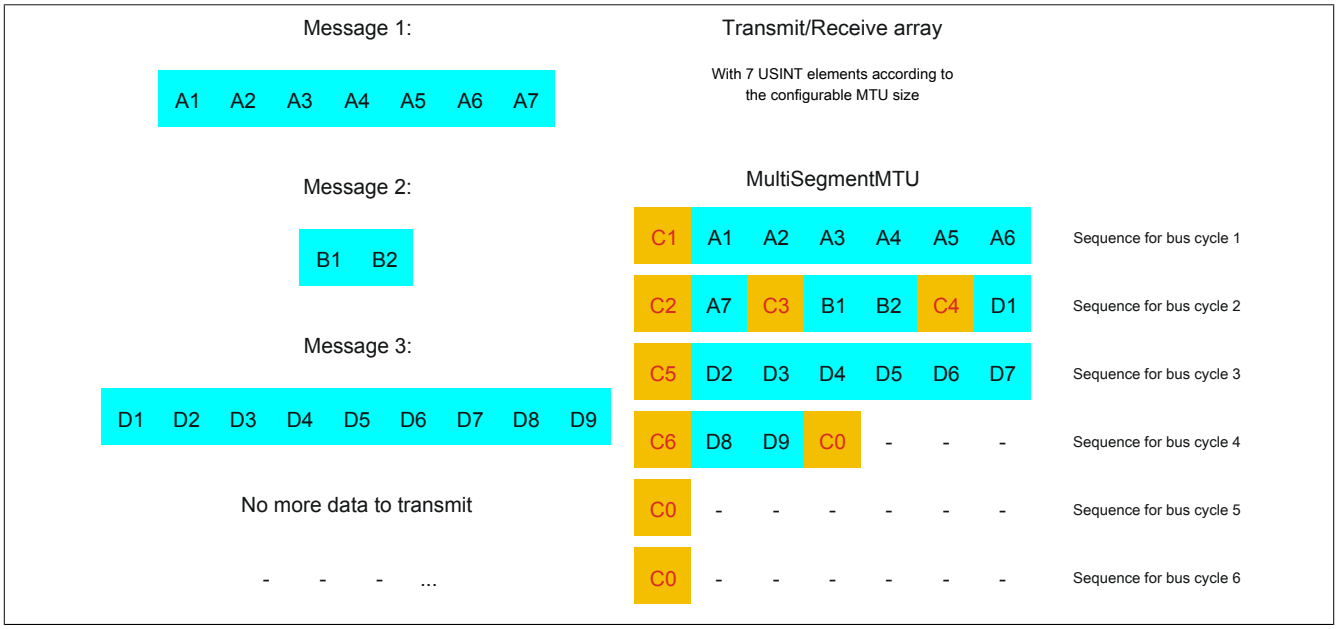

Figure 270: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			**C2 (control byte 2)**			**C3 (control byte 3)**		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 373: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			**C5 (control byte 5)**			**C6 (control byte 6)**		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 374: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

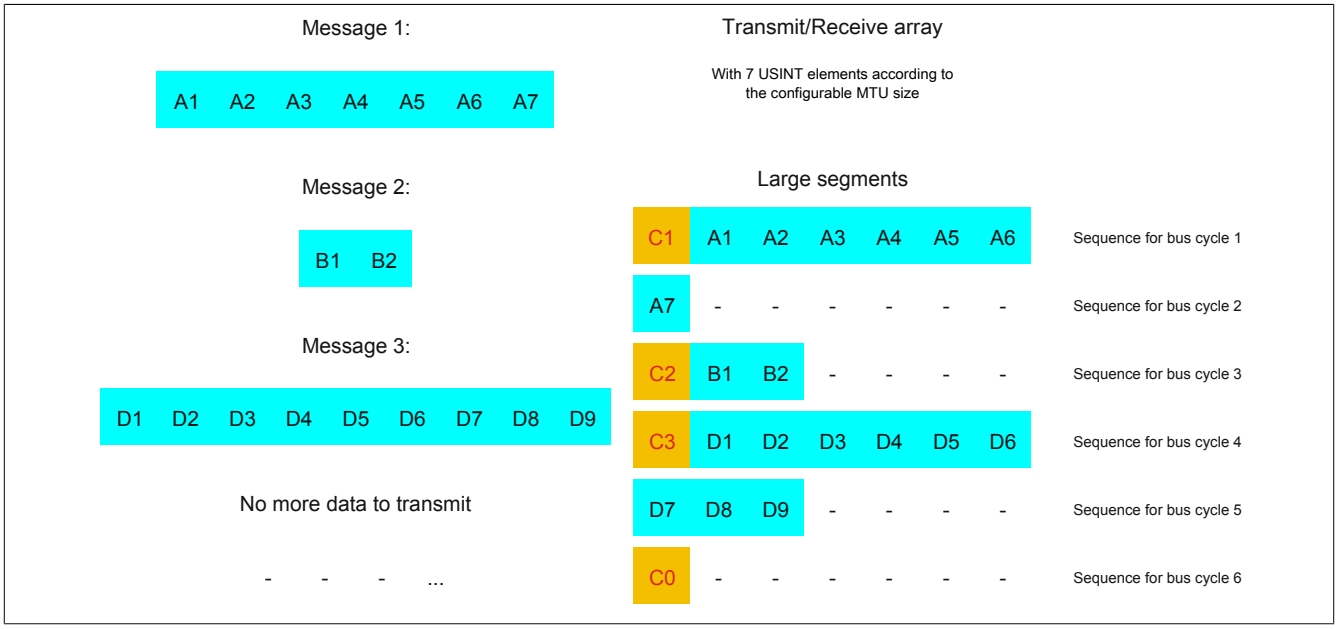

Figure 271: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 375: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

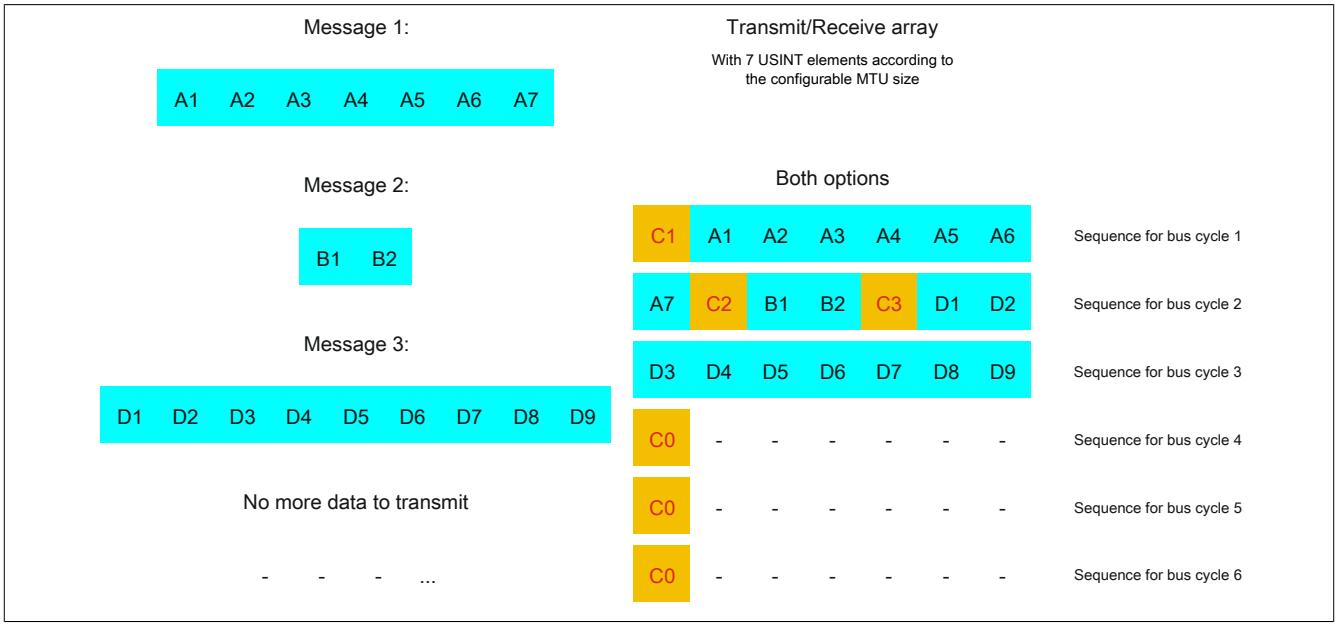

Figure 272: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 376: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.16.7.11.9.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

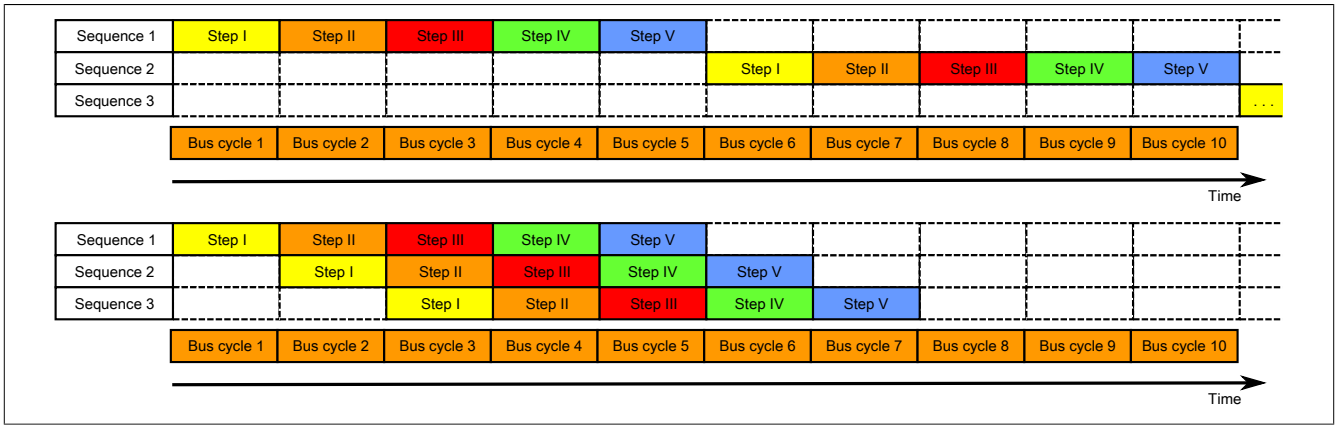

Figure 273: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

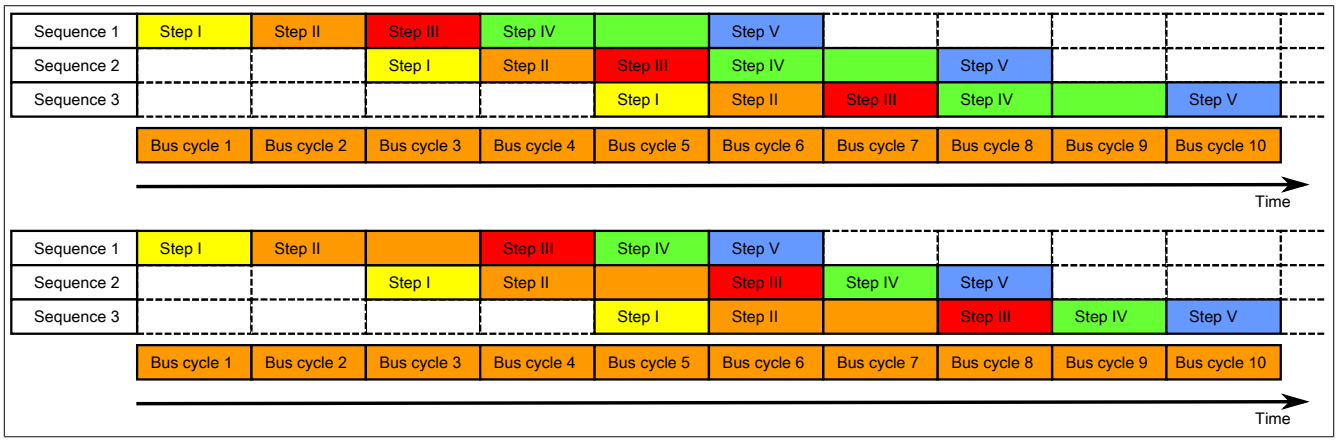

Figure 274: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

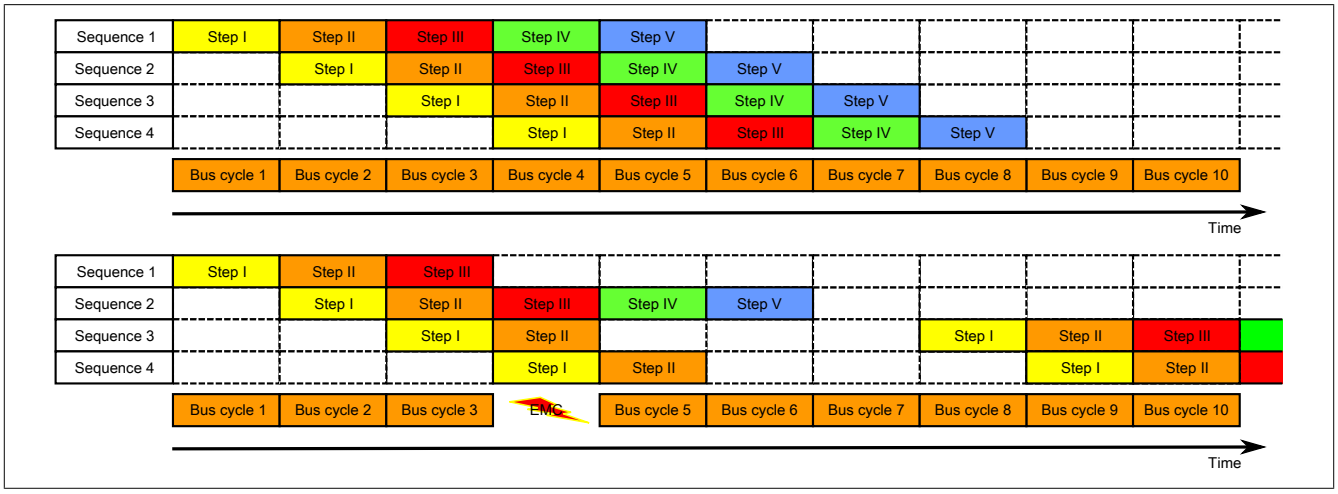

Figure 275: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.16.7.11.10 EnDat with FlatStream

EnDat is a synchronous interface capable of half-duplex communication. Various features have been included to ensure that signals are transmitted without errors.

- An automatically generated checksum is sent together with a signal and evaluated by the recipient.
- The command which the encoder is responding to is repeated at the start of a response.

In Flatstream mode, the module acts as a bridge between the CPU and the EnDat slave. EnDat-specific algorithms were implemented to monitor timeouts and handle checksums. During normal operation, the user does not have access to these details.

More detailed information can be found in the documentation "Technical Information - EnDat 2.2" and the encoder's manufacturer data.

4.16.7.11.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.16.7.11.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.16.8 X20DS4389

4.16.8.1 General information

This module is a digital signal processor module that is used for detecting and evaluating input edges and for creating edges.

High-speed input edges such as registration marks are acquired and given a precise input stamp independently of the X2X Link cycle time of the system. In the other direction, the module sets outputs at precisely defined times. This is done with a resolution of up to 125 ns.

In oversampling mode, the module acquires very short input patters whose low or high phases are shorter than the X2X Link cycle time. Similarly, output patterns (e.g. drum sequencers) can also be output with extremely short high/low times. Oversampling can take place with a scan rate of up to 25 µs.

If necessary, up to 4 events per edge detection unit are stored in a buffer (history elements).

Other functions include pulse duration measuring and differential time measuring.

- 4 digital input channels
- 4 digital channels, configurable as inputs or outputs
- 4 edge detection units with timestamp function (each can be used to measure pulse duration or differential time, 4 history elements per unit)
- 4x precise edge generation down to the µs (up to four edges per unit in each case)
- 4x oversampling (input and output signal)
- 24 VDC and GND for sensor/actuator supply

4.16.8.3 Technical data

Product ID	X20DS4389
Short description	
I/O module	4 digital input channels, 4 digital channels configurable as inputs or outputs, 4 edge detection units with timestamp function (each can be used to measure pulse duration or differential time, 4 history elements per unit), 4x edge generation with µs precision (up to 4 edges per unit), 4x oversampling (input and output signal)
General information	
B&R ID code	0xA93B
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Outputs	Yes, using the status LED and software (output error status)
Power consumption	
Bus	0.01 W
Internal I/O	1.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Quantity	4 + 4, configurable as inputs or outputs using software
Nominal voltage	24 VDC
Input voltage	24 VDC (-15% / +20%)
Input current at 24 VDC	Approx. 1.3 mA
Input circuit	Sink
Additional functions	4 edge detection units with timestamp function, 4x input oversampling
Input resistance	18.4 kΩ
Input frequency	40 kHz
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
Digital outputs	
Design	Push / Pull / Push-Pull
Quantity	Up to 4, configurable as inputs or outputs using software
Nominal voltage	24 VDC
Switching voltage	24 VDC (-15% / +20%)
Nominal output current	0.1 A
Total nominal current	0.4 A
Output circuit	Sink and/or source
Output protection	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
Diagnostic status	Output monitoring
Leakage current when switched off	Max. 25 µA
$R_{DS(on)}$	150 mΩ
Residual voltage	<0.9 V at 0.1 A rated current
Peak short circuit current	<10 A
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Switching delay	
0 -> 1	<2 µs
1 -> 0	<2 µs
Switching frequency	
Resistive load	Max. 24 kHz
Inductive load	See section "Switching inductive loads"
Braking voltage when switching off inductive loads	Switching voltage + 0.6 VDC
Isolation voltage between channel and bus	500 V_{eff}
Additional functions	4x edge generation with µs precision, 4x output oversampling
Edge detection units	
Quantity	4
Operating mode	4 pulse duration measurements, relative or absolute times of input edges in µs resolution, 4 history elements per unit
Counter size	16/32-bit
Input frequency (max.)	40 kHz
Resolution	125 ns timestamp function

Table 378: X20DS4389 - Technical data

Product ID	X20DS4389
Signal form	Square wave pulse
Sensor supply	Module-internal, max. 600 mA
Edge generation units	
Quantity	4
Edge generation	
Absolute	Absolute to NetTime
Relative	Relative to other edges
Offset at relative edge generation	
Range of values	16 or 32 bit value
Resolution	1 µs
Actuator supply	Module-internal, max. 600 mA
Oversampling	
Quantity	4
Sample time	25 to 255 µs
Data volume	Up to 64-bit per X2X Link cycle in input and output direction
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 378: X20DS4389 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.16.8.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	One of the following errors occurred: • Oversample output control error • Oversample output copy error • Edge detect poll cycle violation • Error on edge generator unit 1 - 4
	1 - 8	Green		Status of the corresponding digital signal

1) Depending on the configuration, a firmware update can take up to several minutes.

4.16.8.5 Pinout

Shielded cables must be used for all signal lines.

4.16.8.10 Register description

4.16.8.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.16.8.10.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration - General

4.16.8.10.3 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.16.8.10.4 General

4.16.8.10.4.1 Use with Automation Studio

The module is only supported SG4 target systems via X2X and POWERLINK!

X2X Link supports a up to 28 bytes of synchronous data per module. To optimize use and to prevent needless data transfer, the data points can be adjusted as needed in Automation Studio. Data points that are not needed can be disabled, and the bit width of the data points can be defined.

4.16.8.10.4.2 Timestamp function

The timestamp function is based on synchronized timers. When a timestamp event occurs, the module immediately saves the current net time. After the respective data is transmitted to the CPU, including this precise time, the CPU can then evaluate the data using its own net time (or system time).

Conversely, the CPU can predefine output events, apply a timestamp and transfer them to the module. The module then executes the predefined action at the precise time defined by the CPU.

The resolution of the timestamp is up to 1/8 µs in both directions.

4.16.8.10.4.3 Synchronization jitter

Because the CPU – which determines the X2X net time – and the module have different clocks, the module's internal X2X net time must be synchronized with the CPU's net time. Due to this synchronization, the module's internal X2X net time is corrected by a maximum of 1/8 µs per system cycle if necessary. This synchronization jitter becomes noticeable when using the net time with 1/8 µs resolution (max. ±1/8 µs).

If a 100% exact 1/8 µs resolution without jitter is required, then the "localtime 1/8 µs" must be used (see the 4.16.4.11.11.3 "CfO_EdgeDetectUnitMode" register).

4.16.8.10.5 General registers

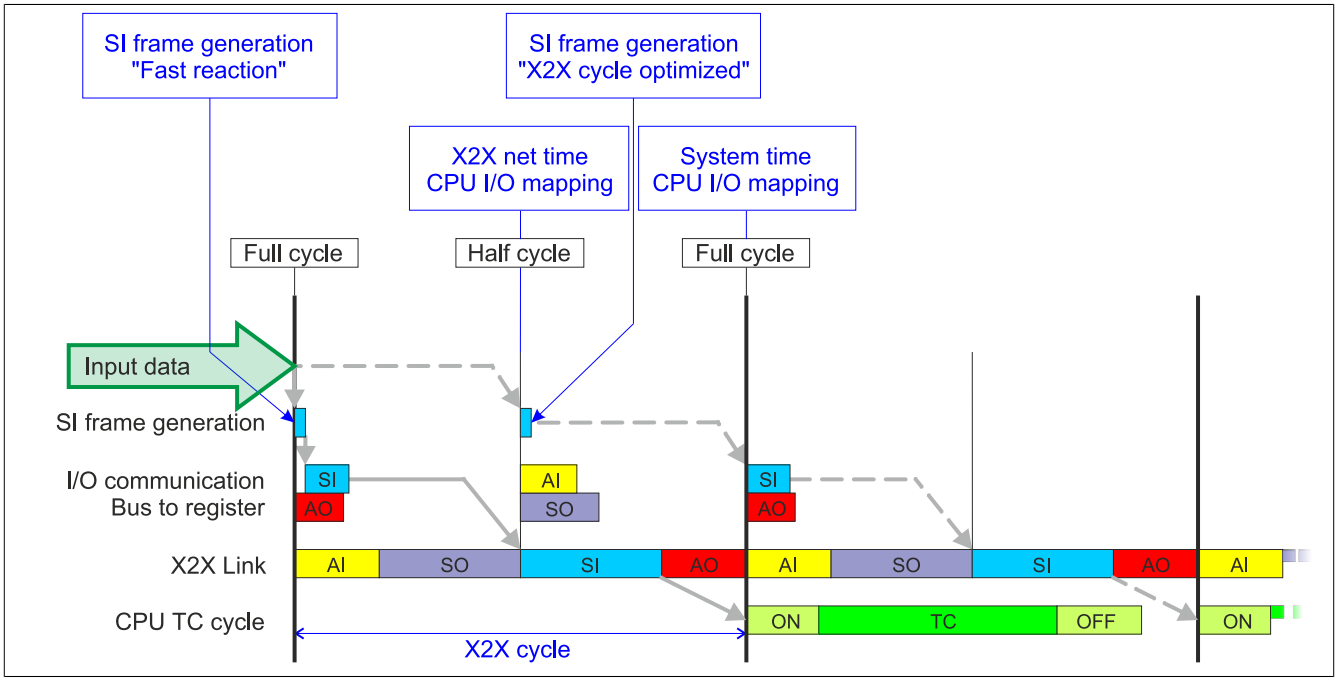
4.16.8.10.5.1 "CfO_SIframeGenID" register

Name:
CfO_SIframeGenID
"SI-frame generation" in the AS I/O configuration.

This register determines when the synchronous input data is generated for transfer. This has a decisive effect on the timing of the input data.

The setting "Fast reaction" causes the input data to be available one X2X cycle sooner in the CPU. However, this setting also has a negative effect on the minimum X2X cycle time.

Data type	Value	Information
USINT	9	X2X cycle optimized
	14	Fast reaction



4.16.8.10.5.2 "ProtocolError" register

Name:
ProtocolError

This register contains an error counter that specifies the number of X2X protocol errors. In the I/O configuration, the "Network information" parameter can be used to help configure a data point for this register with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.8.10.5.3 "ProtocolSequenceViolation" register

Name:
ProtocolSequenceViolation

This register contains an error counter that specifies the number of X2X sequence violations. In the I/O configuration, the "Network information" parameter can be used to help configure a data point with a bit width of 8 or 16 bits in the I/O mapping.

Data type	Value	Information
USINT	0 to 255	Error counter (8-bit)
UINT	0 to 65,535	Error counter (16-bit)

4.16.8.10.5.4 "SDCLifeCount" register

Name:
SDCLifeCount

Counter that is incremented with each system timer cycle. The "SDC information" setting in the AS I/O configuration can be used to activate this register in the I/O mapping as the data point, "SDCLifeCount".

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.16.8.10.6 Error handling

If one of the functions detects an error, then an error bit is set in one of the error state registers. The application is now able to react accordingly and acknowledge the errors by setting a respective bit in the "Acknowledge error message" registers. This causes the bit to be reset in the error state register. If the source of the error persists, then the error bit is set again as soon as the error is detected again (i.e. cannot be reset).

Acknowledging the error does not affect the module's functionality. If possible, the module automatically resumes processing as soon as the source of the error has been corrected.

If an error occurs (not a warning), this is indicated by the red "e" LED on the module (double flash). This signal is automatically acknowledged as soon as the source of the error has been corrected.

4.16.8.10.6.1 Error state register - Output data and edge detection

Name:
OutputControlError
OutputCopyError
EdgeDetectError

Errors in the output data and cycle time settings are indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	OutputControlError	0	No error
		1	The module did not receive new data in time while in the mode "Output control mode = single", meaning that a bit that has already been output would have been output again by the output control buffer.
5	OutputCopyError	0	No error
		1	Oversampling output data could not be copied to the output control buffer. (e.g. an attempt was made to write oversampling output data to an address outside of the OversampleOutputWindow).
6	EdgeDetectError	0	No error
		1	Cycle time violation edge detection: The "EdgeDetectPollCycle" must be smaller than or equal to 255 µs. This error is caused if the cycle defined in the 4.16.4.11.11.1 "CfO_EdgeDetectPollCycleID" register is > 255 µs.
7	Reserved	-	

4.16.8.10.6.2 Error messages register - Edge generator

Name:
EdgeGen01Error to EdgeGen04Error
EdgeGen01Warning to EdgeGen04Warning

This register indicates edge detection errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	EdgeGen01Error	0	No error
		1	Unit 1 error[1)]
1	EdgeGen01Warning	0	No error
		1	Unit 1 warning[2)]
2	EdgeGen02Error	0	No error
		1	Unit 2 error[1)]
3	EdgeGen02Warning	0	No error
		1	Unit 2 warning[2)]
4	EdgeGen03Error	0	No error
		1	Unit 3 error[1)]
5	EdgeGen03Warning	0	No error
		1	Unit 3 warning[2)]
6	EdgeGen04Error	0	No error
		1	Unit 4 error[1)]
7	EdgeGen04Warning	0	No error
		1	Unit 4 warning[2)]

1) **Possible error:**

- Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was not possible to make up for the difference (see: 4.16.8.10.12.7 "CfO_EdgeGenUnitPickupDiff")
- A branched ring-shaped chain of edges in a unit is attempting to set the timestamp for an edge, even though the FIFO of the configured physical channel is already full. (see: 4.16.8.10.12.8 "CfO_EdgeGenUnitConfigEdge"→Ring-shaped chain of edges)

2) Due to "EdgeGenPollCycle", one or more timestamps from the edge generator of a unit were not able to be processed in time, and it was possible to make up for the difference (see: (see: 4.16.8.10.12.7 "CfO_EdgeGenUnitPickupDiff" register)

4.16.8.10.6.3 Acknowledge error message register - Output data and edge detection

Name:
QuitOutputControlError
QuitOutputCopyError
QuitEdgeDetectError

Error messages from the 4.16.4.11.6.1 "Error state - Output data and edge detection" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	QuitOutputControlError	0	No change
		1	Acknowledge error
5	QuitOutputCopyError	0	No change
		1	Acknowledge error
6	QuitEdgeDetectError	0	No change
		1	Acknowledge error
7	Reserved	-	

4.16.8.10.6.4 Acknowledge error message register - Edge generator

Name:
QuitEdgeGen01Error to QuitEdgeGen04Error
QuitEdgeGen01Warning to QuitEdgeGen04Warning

Error messages from the 4.16.8.10.6.2 "Error messages - Edge generator" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	QuitEdgeGen01Error	0	No change
		1	Acknowledge error
1	QuitEdgeGen01Warning	0	No change
		1	Acknowledge warning
2	QuitEdgeGen02Error	0	No change
		1	Acknowledge error
3	QuitEdgeGen02Warning	0	No change
		1	Acknowledge warning
4	QuitEdgeGen03Error	0	No change
		1	Acknowledge error
5	QuitEdgeGen03Warning	0	No change
		1	Acknowledge warning
6	QuitEdgeGen04Error	0	No change
		1	Acknowledge error
7	QuitEdgeGen04Warning	0	No change
		1	Acknowledge warning

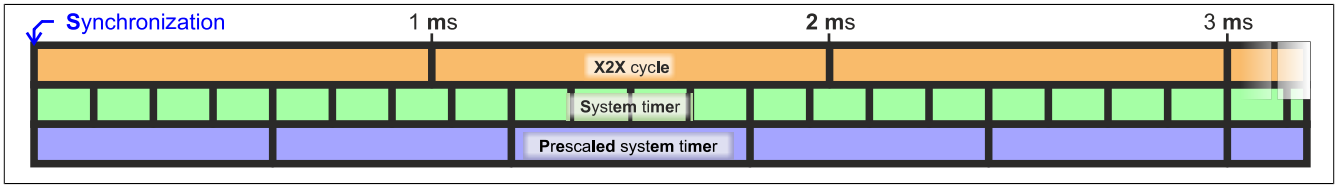
4.16.8.10.7 System timer

The module's individual functions all depend on a system timer. This internal "system cycle time" can be defined from 25 to 255 µs. The functions can also be run with the help of a configurable "prescaled system timer" to minimize the load on the module, thereby making it possible to use the shortest possible X2X cycle time.

The cycle of the "prescaled system timer" (and system timer) is referenced with the X2X Link as soon as the module has been started up and the X2X Link has been initialized. Since the system timer and the module's internal X2X net time use the same clock, the two run synchronously from that point on. An X2X cycle time that is not a multiple of the system cycle time results in an offset, which can be calculated.

The following values apply to the following example:

X2X cycle	1 ms
System timer	150 µs
Prescaled system timer	4



4.16.8.10.7.1 "CfO_SystemCycleTime" register

Name:
CfO_SystemCycleTime
"Cycle time" in the AS I/O configuration.

The cycle time of the system timer can be set in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Information:

A setting < 50 µs has a negative effect on the minimum X2X cycle time!

Data type	Value	Information
UINT	200 to 2047	System timer cycle time in steps of 1/8 µs (25 to 255,875 µs)

4.16.8.10.7.2 "CfO_SystemCycleOffset" register

Name:
CfO_SystemCycleOffset
"Cycle offset" in the AS I/O configuration.

The synchronization time for the system cycle can be offset in this register in steps of 1/8 µs. The value entered in the AS I/O configuration is automatically multiplied by 8.

Data type	Value	Information
INT	-32,768 to 32,767	Cycle offset in steps of 1/8 µs (-4096 to 4095.875 µs)

4.16.8.10.7.3 "CfO_SystemCyclePrescaler" register

Name:
CfO_SystemCyclePrescaler
"Cycle prescaler" in the AS I/O configuration.

The prescaler for setting the "Prescaled system timer" can be configured in this register. The cycle time of the specified system timer is a product of the system timer multiple set in this register.

The "prescaled system timer" can be used as alternative time source for the individual functions. This is useful if a function requires a very short system cycle. To reduce the load on the module in such a situation, other functions can be processed in a slow cycle.

Data type	Value	Information
UINT	2 to 128	Multiple of the system timer

4.16.8.10.8 Physical I/O configuration

4.16.8.10.8.1 "CfO_PhyIOConfigCh" registers

Name:
CfO_PhyIOConfigCh01 to CfO_PhyIOConfigCh08

The physical I/O channels can each be configured individually in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Push driver[1)]	0	Disabled
		1	Enabled
1	Pull driver[1)]	0	Disabled
		1	Enabled
2	Input inverted	0	Not inverted
		1	Inverse
3	Output inverted[1)]	0	Not inverted
		1	Inverse
4 - 7	Output function[1)]	0	Direct I/O
		1 to 15	Reserved

1) Only available for the I/O channels 3, 4, 7 and 8.

4.16.8.10.9 Direct I/O

Direct I/O makes it possible to use the physical I/Os like normal I/Os. Additionally, the application can only set or reset I/Os (e.g. an output channel is set by the edge generator and manually reset by the application).

4.16.8.10.9.1 "EdgeGenTimestamp" register

Name:
CfO_DirectIOClearMask0_7
"Direct control of output channel 03" to "Direct control of output channel 08" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is reset as soon as its direct I/O output channel is reset (4.16.5.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	Output channel 3	0	No change
		1	Reset channel
3	Output channel 4	0	No change
		1	Reset channel
4 - 5	Reserved	-	
6	Output channel 7	0	No change
		1	Reset channel
7	Output channel 8	0	No change
		1	Reset channel

4.16.8.10.9.2 "CfO_DirectIOSetMask0_7" register

Name:
CfO_DirectIOSetMask0_7
"Direct control of output channel 03" to "Direct control of output channel 08" in the AS I/O configuration.

If the bit for the respective channel is set in this register, then the output is set as soon as its direct I/O output channel is set (4.16.5.11.9.3 "output control channel 7_0" or "DigitalOutput0x" register in the AS I/O mapping).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	Output channel 3	0	No change
		1	Set channel
3	Output channel 4	0	No change
		1	Set channel
4 - 5	Reserved	-	
6	Output channel 7	0	No change
		1	Set channel
7	Output channel 8	0	No change
		1	Set channel

4.16.8.10.9.3 "CfO_OutputUpdateCycle" register

Name:
CfO_OutputUpdateCycle

This register sets the time of data output.

Data type	Value	Information
USINT	10	X2X cycle optimized (jitter-free)
	15	Fast reaction (with jitter)

4.16.8.10.9.4 "DigitalOutput" register

Name:
DigitalOutput03 and DigitalOutput04, DigitalOutput07 and DigitalOutput08

This register contains the bits for controlling the direct I/O output channels. Depending on how the 4.16.5.11.9.1 "CfO_DirectIOClearMask0_7" and 4.16.5.11.9.2 "CfO_DirectIOSetMask0_7" registers are configured, the digital outputs are set to the status of the respective bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	-	
2	DigitalOutput03	0 or 1	Output status of channel 3
3	DigitalOutput04	0 or 1	Output status of channel 4
4 - 5	Reserved	-	
6	DigitalOutput07	0 or 1	Output status of channel 7
7	DigitalOutput08	0 or 1	Output status of channel 8

4.16.8.10.9.5 "DigitalInput" register

Name:
DigitalInput01 to DigitalInput08

This register displays the status of the digital input channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalInput01	0 or 1	Input status of channel 1
...	...	...	
7	DigitalInput08	0 or 1	Input status of channel 8

4.16.8.10.10 Oversampled I/O

"Oversampled I/O" is based on input status buffers and output control buffers. Input data acquisition and output control occur in one sample cycle (one sample cycle equals one bit in the buffer). The precise time of an input buffer entry is indicated by its position in the buffer and the net time assigned to the buffer.

In "Output control mode = single" every output buffer entry is marked as invalid once it has been executed. This ensures that the outputs are not supplied with invalid data. In this mode, the application needs to ensure that the module is always supplied with valid data.

When using "Output control mode = continuous" the contents of the buffer are output again if the module is not supplied with new oversample output data.

4.16.8.10.10.1 Addressing the output control buffer

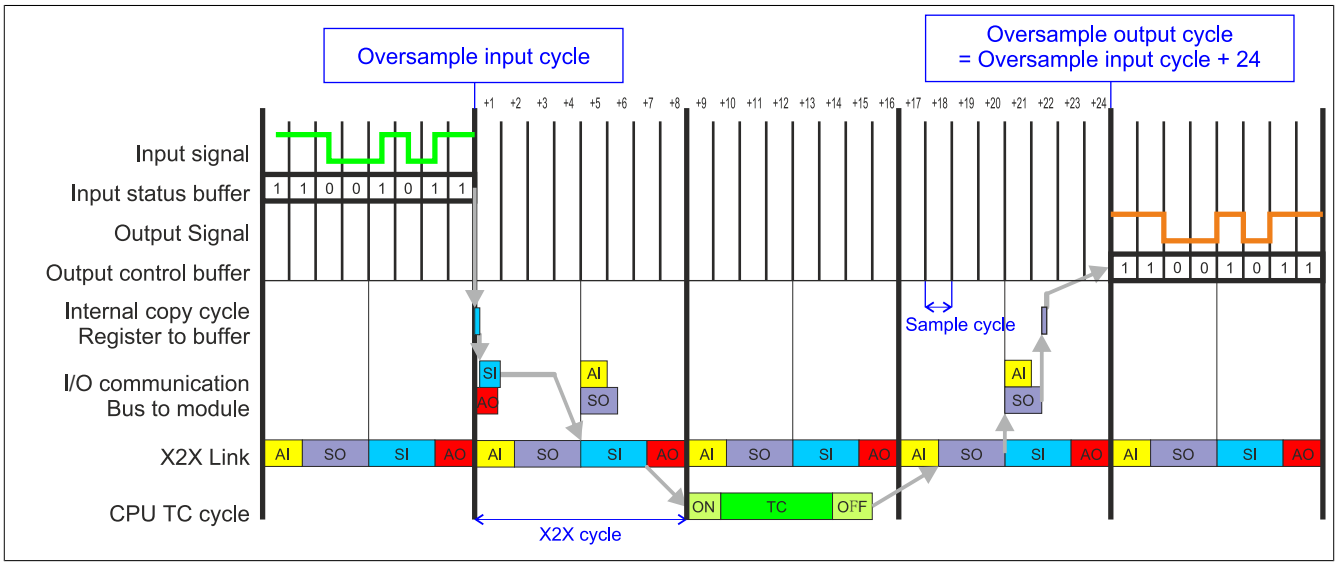
The module has one cyclic 256-bit output control buffer for each oversample channel. One bit is output from these buffers to the configured physical output channels in each "sample cycle". When new data is transferred to one of these buffers, the application must define where in the respective buffer the data should be written to. There are 2 possibilities (absolute or relative "Output mode" in the AS I/O configuration).

4.16.8.10.10.2 Absolute addressing of the output control buffer

With absolute addressing, in each cycle where "OversampleOutputValidate = True", in addition to the oversample output sample data (in the 4.16.4.11.10.15 "OversampleOutput0NSample" registers) an address must also be transferred in the 4.16.4.11.10.13 "OversampleOutputCycle" register. This address determines where in the output control buffer the new data should be copied to. In order to calculate this address, you must account for the contents of the 4.16.4.11.10.17 "OversampleInputCycle" register, which contains the address of the most recently output data, and the transfer time to the module. To help avoid incorrect addressing of the output control buffer, the buffer section that is capable of being written to can be limited using the 4.16.4.11.10.8 "OversampleOutputWindow" register. This window will always be shifted relative to the current sample address. An "OutputCopyError" will be triggered if an attempt is made to write to an address that is outside of this window.

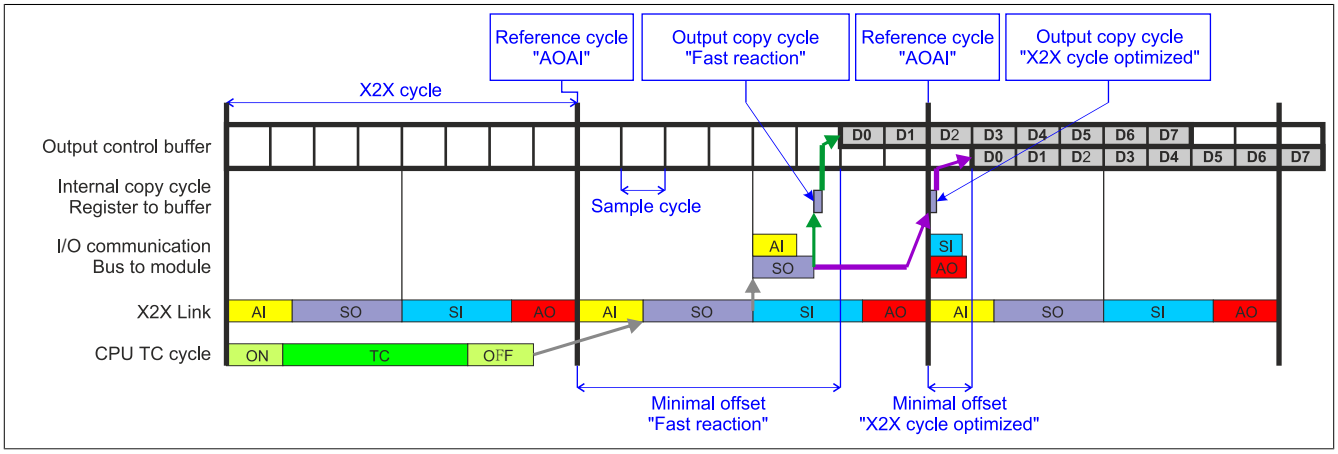
Example

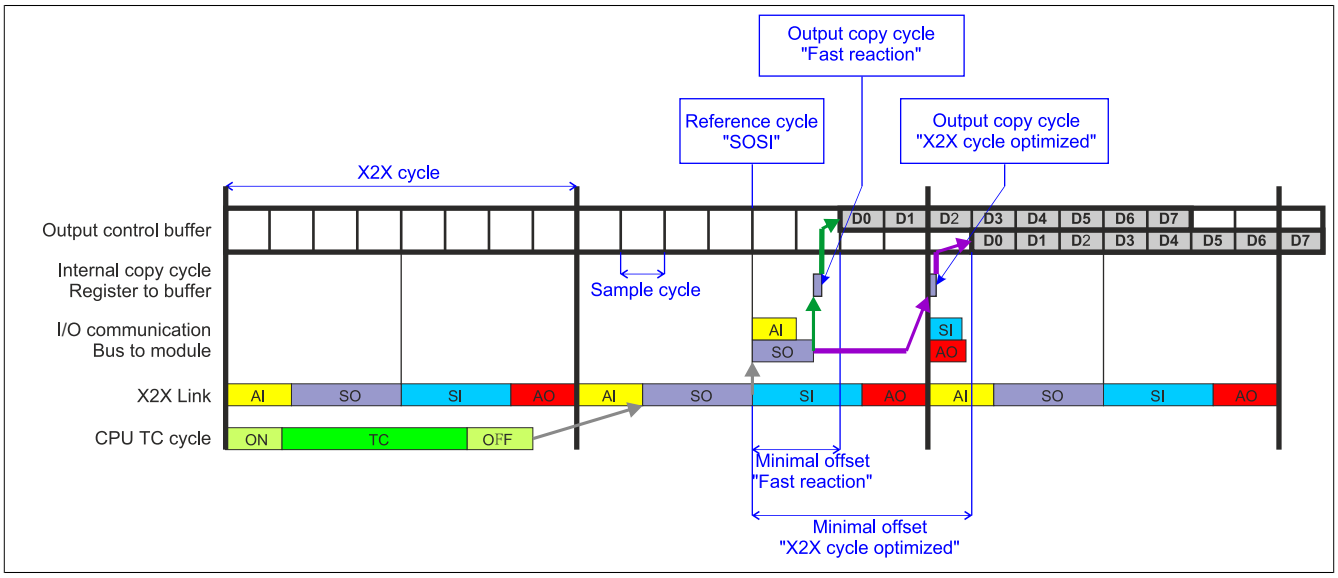
Timing from oversample input cycle to oversample output cycle in absolute output mode ("SI-frame generation = Fast reaction", "Output copy cycle = Fast reaction", 8 samples per X2X cycle):



4.16.8.10.10.3 Relative addressing of the output control buffer

When "OversampleOutputValidate = True", then the oversample output sample data is automatically copied to an address relative to the last referenced address at the defined "output copy cycle" time. The 4.16.4.11.10.14 "OversampleSampleOffset" register serves as the offset. The new data cannot start being output immediately at the "output copy cycle" time because it takes time to copy the data from the registers to the buffer. This means that an offset of 0 is not allowed. The relative output control buffer address + offset must point to an address within the "oversample output window". The "oversample output window" is always offset relative to the current sample address. An "OutputCopyError" is triggered if an attempt is made to write to an address that is outside of this window.





4.16.8.10.10.4 "CfO_OversampleMode" register

Name:
CfO_OversampleMode
"Output mode" in the AS I/O configuration
"Output control mode" in the AS I/O configuration.

The output control buffer can be configured globally for all channels in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Addressing the output control buffer "Output mode" in the AS I/O configuration.	0	Absolute addressing of the output control buffer
		1	Relative addressing of the output control buffer
1	Cyclic output control "Output control mode" in the AS I/O configuration.	0	Single - Output control buffer entry is marked invalid after execution.
		1	Continuous - Output control buffer entry is not changed.
2 - 7	Reserved	-	

Cyclic output control

If cyclic output control is enabled, then all data in the output control buffer is marked invalid as soon as it is output ("Output control mode = single"). An OutputControlError is generated if the module does not receive data in time, thereby causing a situation in which a bit that has already been output would be output in the buffer again. In such a situation, the output assumes the "Output default state" configured in the CfO_OversampleConfigOutput register.

If cyclic output control is disabled, then the data is output again if the output control buffer overflows ("Output control mode = continuous").

Information:

All 256 bits of the output control buffer are always output.

4.16.8.10.10.5 "CfO_OversampleSampleCycleID" register

Name:
CfO_OversampleSampleCycleID
"Sample cycle" in the AS I/O configuration.

The source of the sample cycle can be configured in this register. During each sample cycle, one bit from the output control buffers of the oversampled I/O channels is output to the configured physical output, and the status of the configured inputs is entered in one bit of the respective input status buffer.

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the sample cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is clocked with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is clocked with the SOSI interrupt of the X2X cycle.

4.16.8.10.10.6 "CfO_OversampleRelativeCycleID" register

Name:
CfO_OversampleRelativeCycleID
"Reference cycle" in the AS I/O configuration.

The source of the user interface reference cycle can be configured in this register.

- The input data is referenced at the time of the "reference cycle". The referenced data is then copied to the "oversample input sample register" at the time of "SI frame generation", while taking the "OversampleInputWindow" into account.
- With relative addressing of the output control buffer, the new sample data is copied to an address relative to the output control buffer address current to the "reference cycle".
- The reference cycle is also used to reference the sample cycle, and with it also the output data production and input data acquisition (e.g. to the X2X cycle).

Data type	Value	Information
USINT	2	System timer The value configured in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used as the reference cycle.
	3	Prescaled system timer The "prescaled system timer" is used as sample cycle.
	10	AOAI The sample cycle is referenced with the AOAI interrupt of the X2X cycle.
	14	SOSI The sample cycle is referenced with the SOSI interrupt of the X2X cycle.

4.16.8.10.10.7 "CfO_OversampleConsumeCycleID" register

Name:
CfO_OversampleConsumeCycleID
"Output copy cycle" in the AS I/O configuration.

At the time of the output copy cycle, data is copied from the 4.16.4.11.10.15 "OversampleOutput0NSample" registers into the output control buffer.

When "Output copy cycle = Fast reaction", it is not possible to determine when the data is copied to the output control buffer in either of the two addressing modes. The copy cycles will experience a certain degree of jitter depending on the module load. However, this only affects the moment of the internal copy procedures and therefore the moment of the earliest possible output sample. This will not affect the quality of the output signal. However, "Output copy cycle = Fast reaction" also has a negative effect on the minimum X2X cycle time.

When using the setting "Output copy cycle = X2X cycle optimized", be aware that the sample data cannot start being output immediately at the "Output copy cycle" time due to the internal copy cycle to the output control buffers.

Data type	Value	Information
USINT	10	X2X cycle optimized The output data is copied to the output control buffer with the AOAI interrupt of the X2X cycle.
	15	Fast reaction The output data is copied to the output control buffer immediately after being received.

4.16.8.10.10.8 "CfO_OversampleOutputBits" register

Name:
CfO_OversampleOutputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the 4.16.4.11.10.15 "OversampleOutputONSample" registers to the output control buffers at the time of the "output copy cycle".

Data type	Value	Information
USINT	1 to 64	Output bits

4.16.8.10.10.9 "CfO_OversampleInputBits" register

Name:
CfO_OversampleInputBits
"User interface size" in the AS I/O configuration.

Specifies how many bits are transferred from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register during "SI frame generation".

Data type	Value	Information
USINT	1 to 64	Input bits

4.16.8.10.10.10 "CfO_OversampleOutputWindow" register

Name:
CfO_OversampleOutputWindow
"Output control mode" in the AS I/O configuration.

Determines the area in the output control buffer in which data can be written. The window is always offset relative to the current sample position. (a value of 128, for example, means that the 128 bits following the current sample cycle can be written to). An "OutputCopyError" is triggered if an attempt is made to write output sample data to a location outside of this window.
In AS, with the setting "Output control mode = Single", this register is set to 128 bits and with the setting "Output control mode = Continuous" it is set to 255 bits.

Data type	Value	Information
USINT	0 to 255	Output window

4.16.8.10.10.11 "CfO_OversampleInputWindow" register

Name:
CfO_OversampleInputWindow
"Input mode" in the AS I/O configuration.

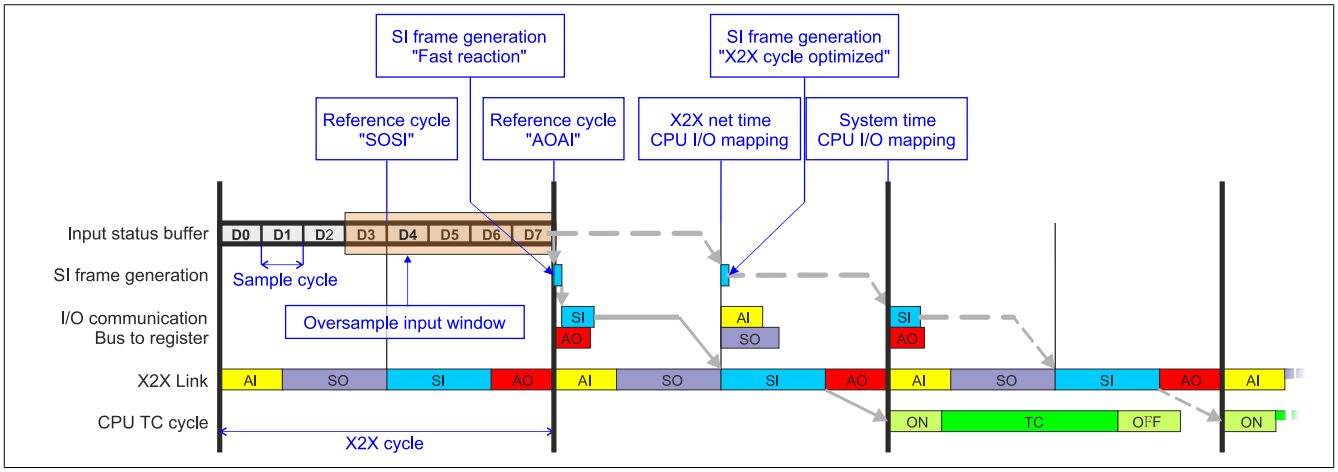
The "OversampleInputWindow" determines when the input data is referenced. It is located chronologically before "SI frame generation". If the reference time ("reference cycle") is within this window, then the referenced data is copied from the input status buffer to the OversampleInput0NSample register. If the time at which the reference occurs is outside the "OversampleInputWindow" then the data that is most recent at the time of "SI frame generation" is copied from the input status buffer to the 4.16.4.11.10.18 "OversampleInput0NSample" register.
This register is limited internally with to the value set in the 4.16.4.11.10.7 "CfO_OversampleInputBits" register.

Information:

As a result, the "OversampleInputTime" and the "OversampleInputCycle" are set either at the reference time or at the time of "SI frame generation".

In Automation Studio, this register is set to 63 when "Input mode = Referenced values" and to 0 when "Input mode = Most recent values".

Data type	Value	Information
USINT	0 to 63	Input window



4.16.8.10.10.12 "CfO_OversampleConfigInput" register

Name:
CfO_OversampleConfigInput
"Oversample I/O 01 →Input" to "Oversample I/O 04 → Input" in the AS I/O configuration

This register determines which physical input channel an oversample I/O input should be linked to.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical input channel	0	Input channel 1
		..	
		7	Input channel 8
4 - 7	Reserved	-	

4.16.8.10.10.13 "CfO_OversampleConfigOutput" register

Name:
CfO_OversampleConfigOutput
"Oversample I/O 01 → Output" to "Oversample I/O 04 → Output" in the AS I/O configuration
"Oversample I/O 01 → Output control" to "Oversample I/O 04 → Output control" in the AS I/O configuration
"Oversample I/O 01 → Output default state" to "Oversample I/O 04 → Output default state" in the AS I/O configuration

This register helps configure the outputs of the individual oversample channels.

The "Output default state" bits determine which level the respective output assumes before oversampling is started. Furthermore, the output is set to the defined "Output default state" in the event of an error.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Number of the physical output channel "Oversample I/O 0x →Output" in the AS I/O configuration	2	Output channel 3
		3	Output channel 4
		6	Output channel 7
		7	Output channel 8
4	Output: Clear "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be reset by the oversample channel.
		1	Output can be reset by the oversample channel.
5	Output: Set "Oversample I/O 0x →Output control" in the AS I/O configuration	0	Output cannot be set by the oversample channel.
		1	Output can be set by the oversample channel.
6	Output default state: Clear "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not cleared by default
		1	Output cleared by default
7	Output default state: Set "Oversample I/O 0x →Output default state" in the AS I/O configuration	0	Output not set by default
		1	Output set by default

4.16.8.10.10.14 Oversample register - Configuration

Name:
OversampleEnable
OversampleOutputValidate

This register can be used to configure oversampling and the copy procedure for the output buffer.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	OversampleEnable	0	Disables oversampling (with the next reference cycle)
		1	Enables oversampling (with the next reference cycle)
1	OversampleOutputValidate	0	Disable the copy procedure to the output control buffer.
		1	Enables the copy procedure to the output control buffer. • Used to synchronize the oversampling procedure at startup. • This makes it possible to prevent new data from being transferred to the 4.16.4.11.10.15 "OversampleOutput0NSample" registers in each X2X cycle.
2 - 7	Reserved	-	

4.16.8.10.10.15 "OversampleOutputCycle" register

Name:
OversampleOutputCycle

When absolute addressing of the output control buffer is being used, this register specifies the address from which the new output sample data should be copied to the output control buffer.

Data type	Value	Information
USINT	0 to 255	Address of the output control buffer

4.16.8.10.10.16 "OversampleSampleOffset" register

Name:
OversampleSampleOffset

When relative addressing of the output control buffer is being used, this register serves as the offset for the new output sample data. (Sample address at the time of the "reference cycle" + Offset = address to which the new output sample data is copied in the output control buffer).

Data type	Value	Information
USINT	0 to 255	Offset of output sample data

4.16.8.10.10.17 "OversampleOutputSample" register

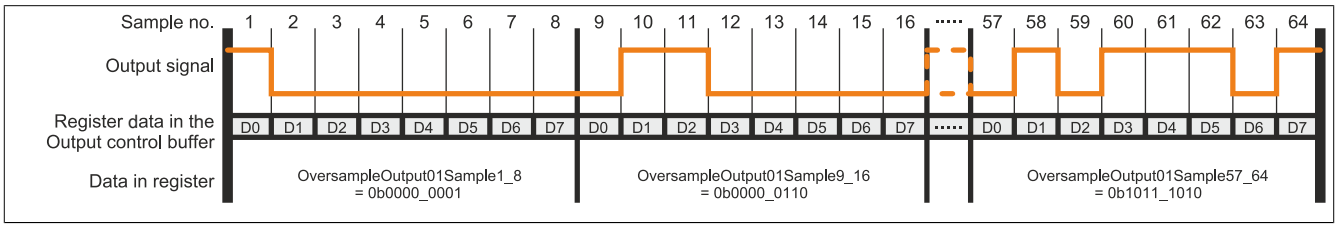
Name:
OversampleOutput01Sample1_8 to OversampleOutput04Sample1_8
OversampleOutput01Sample9_16 to OversampleOutput04Sample9_16
OversampleOutput01Sample17_24 to OversampleOutput04Sample17_24
OversampleOutput01Sample25_32 to OversampleOutput04Sample25_32
OversampleOutput01Sample33_40 to OversampleOutput04Sample33_40
OversampleOutput01Sample41_48 to OversampleOutput04Sample41_48
OversampleOutput01Sample49_56 to OversampleOutput04Sample49_56
OversampleOutput01Sample57_64 to OversampleOutput04Sample57_64

Contains the oversample output sample data. Up to 64 samples (8 bytes) for each oversample I/O channel can be synchronously transferred with a X2X cycle. This data is copied to the specified address (absolute or relative) in the output control buffer during the "output copy cycle". 1 bit of this data is then output during each "sample cycle" to the physical output that is assigned to the oversample I/O channel.
Bit 0 of "OversampleOutputSample8_1" is copied to the output control buffer first, meaning that it is the first bit that is output. "OversampleOutputSample64_57" bit 7 is the last bit to be output.

Data type	Value	Information
USINT	0 to 255	Output sample data

Example

Assignment of "OversampleOutputSample" register data to output signal



4.16.8.10.10.18 "OversampleInputTime" register

Name:
OversampleInputTime

This register contains the 2 low-order bytes of the X2X net time from the moment at which the oversample input data was referenced. This provides an easy way to accurately calculate the time of each individual input sample.

Data type	Value	Information
INT	-32,768 to 32,767	X2X net time of the input data

4.16.8.10.10.19 "OversampleInputCycle" register

Name:
OversampleInputCycle

This register provides the width of the input status buffer address for the input sample data.
Furthermore, the value in this register can be used for referencing an absolute addressing of the output control buffer.

Data type	Value	Information
USINT	0 to 255	Input status buffer address

4.16.8.10.10.20 "OversampleInputSample" register

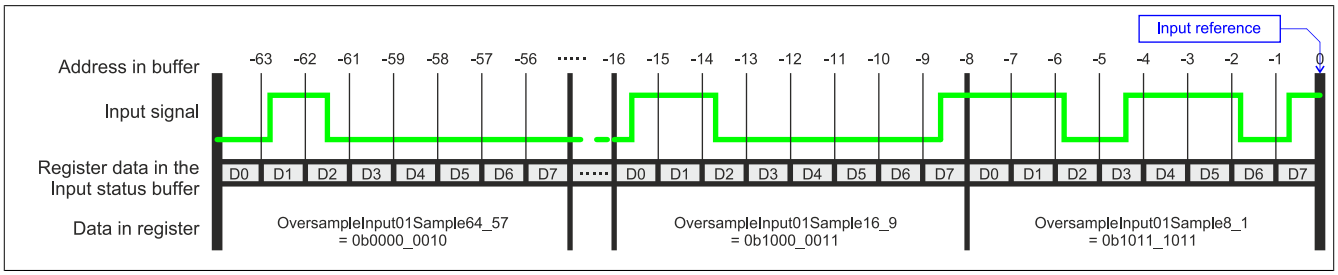
Name:
OversampleInput01Sample8_1 to OversampleInput04Sample8_1
OversampleInput01Sample16_9 to OversampleInput04Sample16_9
OversampleInput01Sample24_17 to OversampleInput04Sample24_17
OversampleInput01Sample32_25 to OversampleInput04Sample32_25
OversampleInput01Sample40_33 to OversampleInput04Sample40_33
OversampleInput01Sample48_41 to OversampleInput04Sample48_41
OversampleInput01Sample56_49 to OversampleInput04Sample56_49
OversampleInput01Sample64_57 to OversampleInput04Sample64_57

The data of the four oversample input status buffers are copied to this register at the time of "SI frame generation". A maximum of 64 samples (8 bytes) per oversample I/O channel can be synchronously retrieved from the oversample input status buffer with each X2X cycle.
The most recent input sample bit is stored in "OversampleInputSample8_1" bit 7. The oldest input sample is stored in "OversampleInputSample64_57" bit 0.

Data type	Value	Information
USINT	0 to 255	Input sample data

Example

Input signal and resulting data in "OversampleInputSample"



4.16.8.10.11 Edge detection

The module's edge detection function identifies edges with µs precision. The concept is based on a maximum of 4 units. A master and a slave edge can be configured for each unit.

At each master edge, the net time of the master edge and the net time of a previous slave edge (if present) are logged. A "master counter" and a "slave counter" can always be used to determine how many edges have been detected since the last X2X cycle.

The module has a history for the timestamp and counters, which can store up to 4 elements per unit. This makes it possible to measure multiple edges precisely within a single X2X cycle.

4.16.8.10.11.1 "CfO_EdgeDetectPollCycleID" register

Name:
CfO_EdgeDetectPollCycleID
"Polling cycle" in the AS I/O configuration.

The source of the polling cycle can be configured in this register.

Information:

The polling cycle must be less than or equal to 255 µs. Setting the cycle > 255 µs causes an EdgeDetectError.

Data type	Value	Information
USINT	2	System timer The time set in the 4.16.4.11.7.1 "CfO_SystemCycleTime" register is used for the polling cycle.
	3	Prescaled system timer The time set in the 4.16.4.11.7.3 "CfO_SystemCyclePrescaler" register is used for the polling cycle.

4.16.8.10.11.2 "CfO_EdgeDetectEventEnable" register

Name:
CfO_EdgeDetectEventEnable
"Edge detection mode" in the AS I/O configuration.

The bits in this register determine at which edges on the individual input channels an interrupt should be triggered for the edge detection.

In "event triggered" mode, the net time of each edge is recorded immediately an interrupt. However, an extremely large amount of interrupts within a short amount of time can prevent the module from being able to process any other operations in time!

In "polling" mode, only the net time of the first edge that occurs within a polling cycle is recorded. This ensures that the module is not overloaded by too many edges.

In the AS IO configuration, this register is initialized with 0x00000000 when "Edge detection mode = polling" and with 0xFFFFFFFF when "Edge detection mode = event triggered".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Physical input 1	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
...		...	
7	Physical input 8	0	No interrupt triggered at falling edge.
		1	Interrupt triggered at falling edge.
8 - 15	Reserved	-	
16	Physical input 1	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
...		...	
23	Physical input 8	0	No interrupt triggered at rising edge.
		1	Interrupt triggered at rising edge.
24 - 31	Reserved	-	

4.16.8.10.11.3 "CfO_EdgeDetectUnitMode" register

Name:
CfO_EdgeDetectUnit01Mode to CfO_EdgeDetectUnit04Mode
"Time base" in the AS I/O configuration.
"Slave edge" in the AS I/O configuration.
"Master edge" in the AS I/O configuration.

When using a "time base" with 1/8 µs resolution, keep in mind that the timestamps produced also have a resolution of exactly 1/8 µs. The respective conversions must be made for calculating in combination with the CPU system time or X2X net time.

Furthermore, synchronization jitter also plays a role when using the setting "time base = net time resolution 1/8 µs" (see: 4.16.4.11.4.3 "Synchronization jitter"). This means that exactly identical input edges can cause slight differences in the results. If a 100% exact 1/8 µs resolution is required, then the "local resolution 1/8 µs" must be used.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	"Time base" in the AS I/O configuration.	0	Local time 1/8 µs (AS: Local resolution 1/8 µs)
		1	Local time 1 µs (AS: Local resolution 1 µs)
		2	Net time 1/8 µs (AS: Net time resolution 1/8 µs)
		3	Net time 1 µs (AS: Net time resolution 1 µs)
2 - 5	Reserved	-	
6	"Slave edge" in the AS I/O configuration.	0	Disabled
		1	Enabled
7	"Master edge" in the AS I/O configuration.	0	Disabled
		1	Enabled

4.16.8.10.11.4 "CfO_EdgeDetectUnitLeading" register

Name:
CfO_EdgeDetectUnit01Leading to CfO_EdgeDetectUnit04Leading
"Slave leading" in the AS I/O configuration.

When a slave edge occurs, the current net time is always saved within the module. A FIFO is provided inside the module which always stores the last 16 slave stamps (even when a master edge occurs).

This value determines from which position the slave time should be retrieved from the FIFO when a master edge occurs. This can be used to measure average periodic signals over multiple cycles.

Data type	Value	Information
USINT	0 to 15	Position in the slave edge FIFO

4.16.8.10.11.5 "CfO_EdgeDetectUnitMaster" register

Name:
CfO_EdgeDetectUnit01Master to CfO_EdgeDetectUnit01Master
"Master edge" in the AS I/O configuration.

This register is used to select the source of the master edge for the respective "edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	...	...
	7	Rising edge on physical input 8
	16	Falling edge on physical input 1
	...	...
	23	Falling edge on physical input 8

4.16.8.10.11.6 "CfO_EdgeDetectUnitSlave" register

Name:
CfO_EdgeDetectUnit01Slave to CfO_EdgeDetectUnit04Slave
"Slave edge" in the AS I/O configuration.

This register is used to select the source of the slave edge for the respective "edge detection unit".

Data type	Value	Information
USINT	0	Rising edge on physical input 1
	...	...
	7	Rising edge on physical input 8
	16	Falling edge on physical input 1
	...	...
	23	Falling edge on physical input 8

4.16.8.10.11.7 "EdgeDetectSlavecount" register

Name:
EdgeDetect01Slavecount to EdgeDetect04Slavecount

The reference pulses of the detected slave edges are counted continuously in this register. The contents of this register are only updated when a master edge occurs. Up to 4 history elements can be enabled for these counters in the AS I/O configuration. These counters can detect if multiple slave edges occur before a master edge.

Data type	Value	Information
SINT	-128 to 127	Number of detected slave edges (8-bit)
INT	-32,768 to 32,767	Number of detected slave edges (16-bit)

4.16.8.10.11.8 "EdgeDetectDifference" register

Name:
EdgeDetect01Difference to EdgeDetect04Difference

Contains the time difference between a master edge and the last slave edge addressed via "Slave leading".

Data type	Value	Information
INT	-32,768 to 32,767	Time difference between master/slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Time difference between master/slave edge (32-bit)

4.16.8.10.11.9 "EdgeDetectMastercount" register

Name:
EdgeDetect01Mastercount to EdgeDetect04Mastercount

The reference pulses of the detected master edges are counted in this register.

Data type	Value	Information
SINT	-128 to 127	Number of detected master edges (8-bit)
INT	-32,768 to 32,767	Number of detected master edges (16-bit)

4.16.8.10.11.10 "EdgeDetectMastertime" register

Name:
EdgeDetect01Mastertime to EdgeDetect04Mastertime

The exact net time is copied in this register when a master edge occurs.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of master edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of master edge (32-bit)

4.16.8.10.11.11 "EdgeDetectSlavetime" register

Name:
EdgeDetect01Slavetime to EdgeDetect04Slavetime

When a master edge occurs, the exact net time of any slave edge that may have occurred prior to the master edge and addressed by "Slave leading" is copied in this register. Only one slave time can be taken from the "Slave leading FIFO" for each master edge. Only EdgeDetectSlavecount can indicate if multiple edges have occurred before a master edge.

Data type	Value	Information
INT	-32,768 to 32,767	Net time of the slave edge (16-bit)
DINT	-2,147,483,648 to 2,147,483,647	Net time of the slave edge (32-bit)

History:

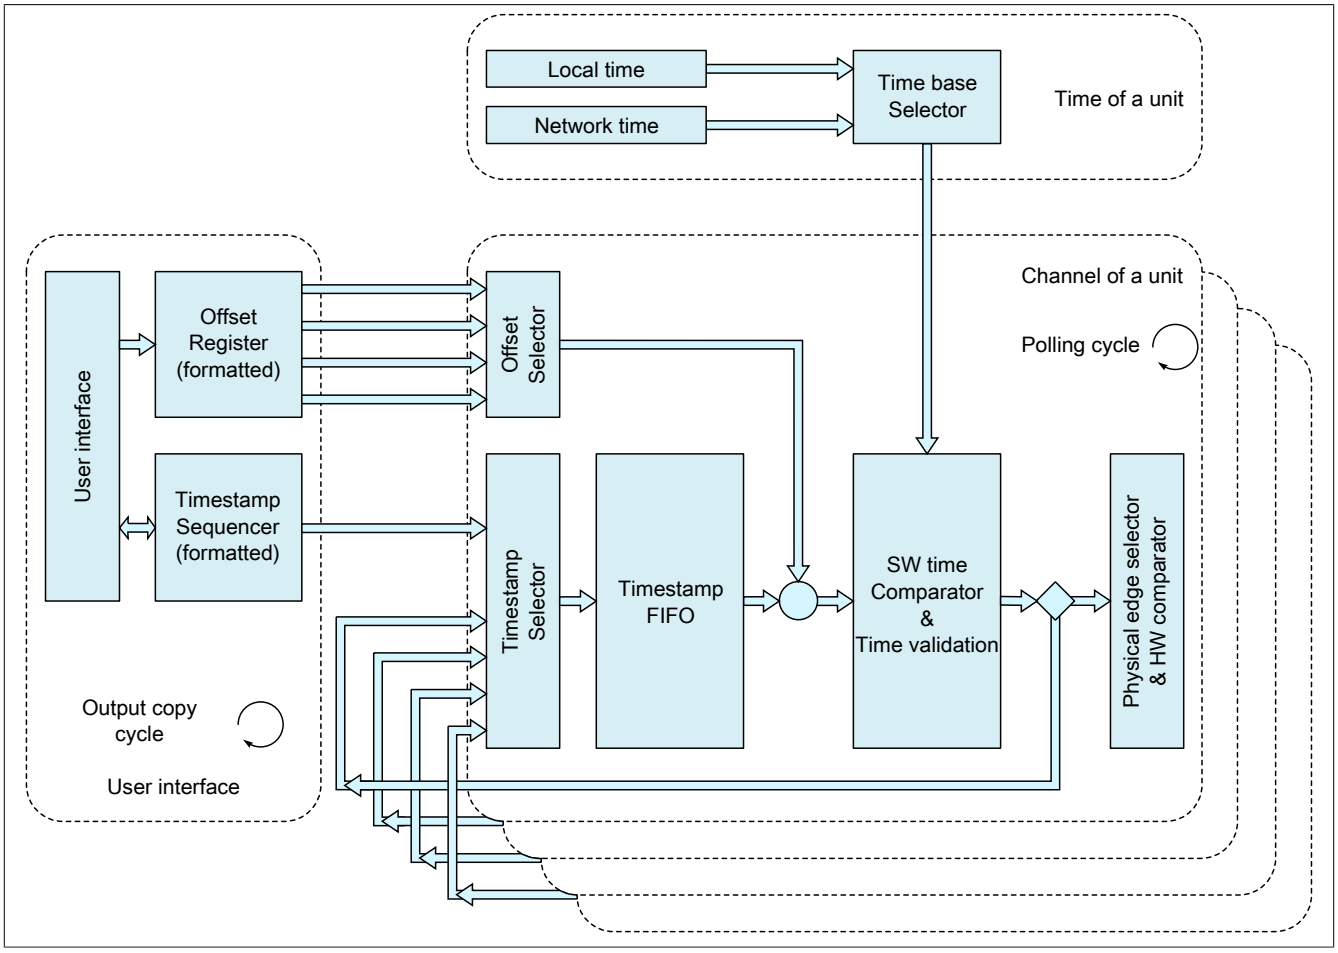
In AS, a history of up to 4 elements can be enabled in the I/O configuration for the following registers: 4.16.8.10.11.7 "EdgeDetectSlavecount", 4.16.8.10.11.8 "EdgeDetectDifference", 4.16.4.11.11.10 "EdgeDetectMastertime" and 4.16.8.10.11.11 "EdgeDetectSlavetime". Configured history elements are all transferred synchronously with each X2X cycle. This makes it possible to measure multiple edges precisely within a single X2X cycle.

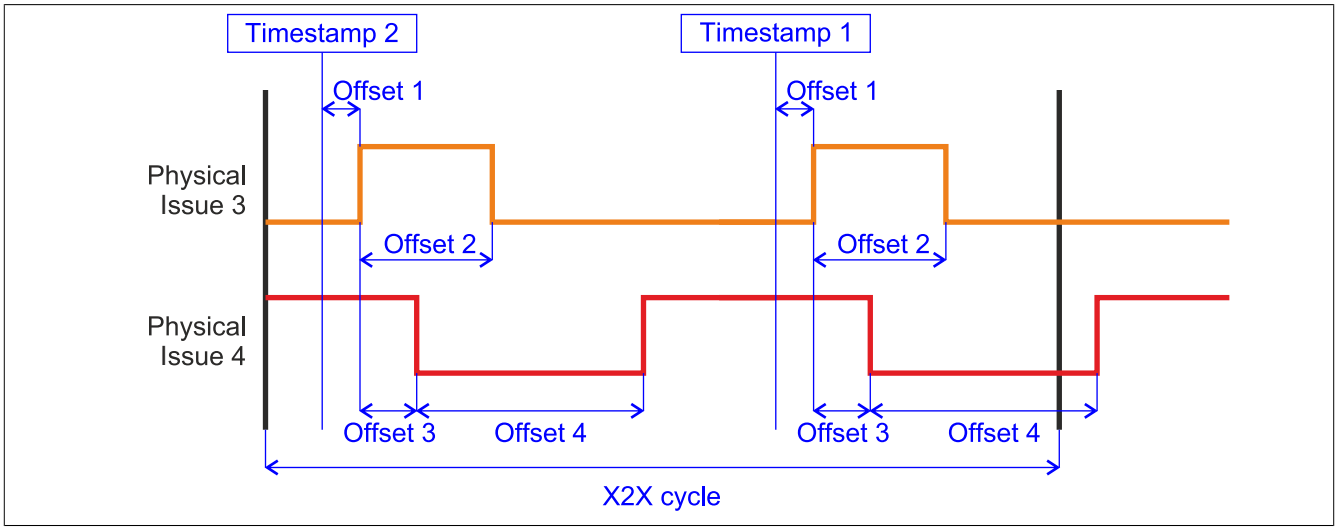
Information:

When the history is enabled, the maximum number of data bytes (28 bytes) that can be transferred synchronously via the X2X Link is reached quickly (especially if 32-bit data points are used).

4.16.8.10.12 Edge generator

The edge generator is based on 4 units. The units are able to generate edges independently of the X2X cycle. For each unit, up to 4 timestamps can be set per X2X cycle. The individual edges can then be referenced to this timestamp or to other edges using an offset.





4.16.8.10.12.1 Mode "DigitalCamSwitch"

"Unit 0x" in AS I/O configuration.

Starting with upgrade 1.1.0.2, "DigitalCamSwitch" mode can also be selected for each unit when configuring the edge generator in AS Studio.
In this mode, the entire configuration and operation take place exclusively with the function blocks from the "ASMcDcs" motion library. For more information, see the corresponding ASMcDcs function block descriptions.

4.16.8.10.12.2 "CfO_EdgeGenPollCycleEventID" register

Name:
CfO_EdgeGenPollCycleEventID
"Generation cycle" in the AS I/O configuration.

To ensure edge output with µs precision, edge generation is based on internal hardware components. One such comparator is available for one rising and one falling edge respectively for each physical output channel. The data for the comparators is prepared in "EdgeGenPollCycle". Therefore, a maximum of one rising and one falling edge can be generated for each physical output channel per "EdgeGenPollCycle". If timestamps are set that cannot be processed in time due to this limitation, then an "EdgeGen0Warning" is generated. Processing of such timestamps is made up for as quickly as possible, as long as they are within "EdgeGenUnit0PickupDiff".
A shorter "Generation cycle" means that an enabled edge generator function has a less negative effect on the minimum X2X cycle time.

Data type	Value	Information
USINT	2	System timer
	3	Prescaled system timer

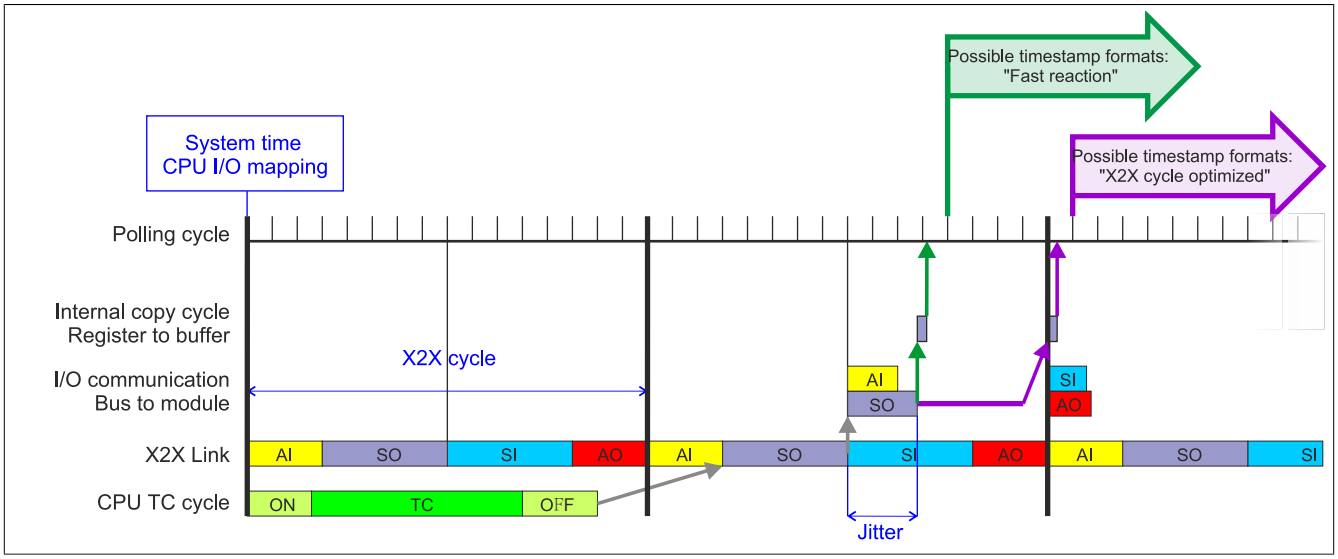
4.16.8.10.12.3 "CfO_EdgeGenConsumeCycleEventID" register

Name:
CfO_EdgeGenConsumeCycleEventID

This register determines when the output data for edge generation is applied within the X2X cycle.

Data type	Value	Information
USINT	10	"X2X cycle optimized" The data is force-applied between the periods ASYNC IN (AI) and ASYNC OUT (AO).
	15	"Fast reaction (with jitter)" The data is applied immediately after SYNC OUT (SO) processing.

The "Fast reaction" setting results in jitter because the copy cycle of the SYNC OUT data can take different amounts of time. However, this only affects the moment at which the internal copy cycle takes place and therefore possibly also the earliest possible timestamp. Timestamps that are set outside of this jitter range are not affected by this.



4.16.8.10.12.4 "CfO_EdgeGenUnitMode" register

Name:
CfO_EdgeGenUnit01Mode to CfO_EdgeGenUnit04Mode
"Time base" in the AS I/O configuration.
"Timestamp format" in the AS I/O configuration.
"Offset format" in the AS I/O configuration.
"Unit 01" to "Unit 04" in the AS I/O configuration

These registers contain the configuration bits for the respective units.

If "timestamp resolution = 1/8 µs" is used, be aware that the timestamp data must also have a resolution of 1/8 µs. Because the CPU system time and the X2X net time only have µs resolution, the system time or the net time must be offset by 3 bits to the left or multiplied by 8 in the application. This value can then be used as reference for timestamps with a resolution of 1/8 µs. It is also possible to use 1/8 µs timestamps from input edges as a reference.

When using the net time with 1/8 µs resolution, the synchronization jitter affects the output results (see: 4.16.4.11.4.3 "Synchronization jitter").

Because the local time is not synchronized with the CPU system time or the X2X net time, this can only be used effectively together with a time source from the module (e.g. input edge timestamp on "local time").

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Resolution of the timestamp "Time base" in the AS I/O configuration.	0	1 µs
		1	1/8 µs
1	Number of bits in the timestamp register "Timestamp format" in the AS I/O configuration.	0	16-bit
		1	32-bit
2	Offset resolution "Time base" in the AS I/O configuration.	0	1 µs
		1	1/8 µs
3	Number of bits in the offset register "Offset format" in the AS I/O configuration.	0	16-bit
		1	32-bit
4	Time base "Time base" in the AS I/O configuration.	0	Net time
		1	Local time
5 - 6	Reserved	-	
7	Enable/disable units "Unit 0x" in the AS I/O configuration.	0	Disabled
		1	Enabled

4.16.8.10.12.5 "CfO_EdgeGenUnitTimestampFifoLim" register

Name:
CfO_EdgeGenUnit01TimestampFifoLim to CfO_EdgeGenUnit04TimestampFifoLim

Specifies how many timestamps in the FIFO a unit can be transferred to. The FIFO serves as a memory buffer for timestamps in the future. The timestamps must be entered in the FIFO in the same order in which they should be output. This means it is not possible to set a timestamp in the future followed by an earlier timestamp. The 4.16.8.10.12.11 "EdgeGenSequenceReadback" register can be used to indicate if the defined limit has been reached.

Data type	Value	Information
USINT	1 to 12	FIFO limit (AS default: 12)

4.16.8.10.12.6 "CfO_EdgeGenUnitTimestampRegCount" register

Name:
CfO_EdgeGenUnit01TimestampRegCount to CfO_EdgeGenUnit04TimestampRegCount
"Timestamp elements" in the AS I/O configuration.

This register determines how many timestamps can be transferred per X2X cycle.

Data type	Value	Information
USINT	1 to 4	Number of timestamps per X2X cycle

4.16.8.10.12.7 "CfO_EdgeGenUnitPickupDiff" register

Name:
CfO_EdgeGenUnit01PickupDiff to CfO_EdgeGenUnit04PickupDiff

This register determines how far in the past timestamps can go so that the difference in time can be regained. Timestamps in the past are processed as quickly as possible as long as they are located within the difference specified in this register. EdgeGenWarning is triggered if a timestamp was not able to be processed in time and its difference had to be regained. If the difference in time for a timestamp was not able to be regained because it is outside of the specified difference value, then "EdgeGenError" is also reported in addition to "EdgeGenWarning".

In AS, if "Timestamp format = 16-bit" this register is initialized with 65535 (0xFFFF), and if "Timestamp format = 32-bit" it is initialized with 134,217,728 (0x8000000).

Data type	Value	Information
UDINT	0 to 65,535	Difference to be regained in µs when "Offset format = 16-bit"
	0 to 134217728	Difference to be regained in µs when "Offset format = 32-bit"

4.16.8.10.12.8 "CfO_EdgeGenUnitConfigEdge" register

Name:
CfO_EdgeGenUnit01ConfigEdge to CfO_EdgeGenUnit04ConfigEdge
"Unit 01→ Edge" to "Unit 04→ Edge" in the AS I/O configuration.
"Unit 01→ Mode" to "Unit 04→ Mode" in the AS I/O configuration.
"Unit 01→ Offset" to "Unit 04→ Offset" in the AS I/O configuration.
"Unit 01→ Unit 01" to "Unit 04→ Unit 04" in the AS I/O configuration.

The properties of each of the 4 edges of a unit can be configured in this register.

Ring-shaped chain of edges:

If the individual edges are linked together in a ring shape (e.g. edge 2 is relative to edge 1 and edge 1 is relative to edge 2) then a header must be determined for the ring using bit 11 "ring head enable" bit so that this type of cycle can start without timestamp. In AS, the "ring head enable" bit (bit 11) is set for edge 1 in all units by default. If this type of ring is branched (e.g. a third edge is relative to an edge within the ring) then you must make sure that the internal FIFO, which is available to every physical I/O edge, does not overflow. This happens if more than 12 edges are created by the ring, but should not be output until much later. If this situation occurs, whereby a ring creates edges even though the FIFO is full, then an EdgeGenError error is generated.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Physical edge "Unit 0x →Edge" in the AS I/O configuration.	2	Channel 3 rising edge
		3	Channel 4 rising edge
		6	Channel 7 rising edge
		7	Channel 8 rising edge
		18	Channel 3 falling edge
		19	Channel 4 falling edge
		22	Channel 7 falling edge
		23	Channel 8 falling edge
5 - 7	Reserved	-	
8 - 10	Timestamp of FIFO source "Unit 0x →Mode" in the AS I/O configuration.	0	User interface, absolute
		1 to 3	Reserved
		4	Edge 1, relative
		5	Edge 2, relative
		6	Edge 3, relative
		7	Edge 4, relative
11	Ring-shaped chain Default in AS for "Edge 01 = 1", "Edge 02 = 0", "Edge 03 = 0", "Edge 04 = 0"	0	Disabled
		1	Enabled
12 -13	Offset register numbers "Unit 0x →Offset" in the AS I/O configuration.	0	Offset register 0
		1	Offset register 1
		2	Offset register 2
		3	Offset register 3
14	Reserved	-	
15	Switch edge on/off. "Unit 0x →Unit 0x" in the AS I/O configuration.	0	Disabled
		1	Enabled

4.16.8.10.12.9 "EdgeGenEnable" register

Name:
EdgeGen01Enable to EdgeGen04Enable
EdgeGen01EnableReadback to EdgeGen04EnableReadback
"Unit 01" to "Unit 04" in the AS I/O configuration

The units of the edge generator can be enabled/disabled using this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	EdgeGen0NEnable EdgeGen0NEnableReadback	0	Disabled
		1	Enabled
1 - 7	Reserved	-	

4.16.8.10.12.10 "EdgeGenSequence" register

Name:
EdgeGen01Sequence to EdgeGen04Sequence

If new timestamp data is to be applied to the module, then the sequence number must be increased by the number of timestamp elements that have to be applied. If multiple elements are transferred within one X2X cycle, then you must make sure that the individual timestamps are placed in the FIFO in the same order in which they occur chronologically. This means that data from "EdgeGenTimestamp4" arrives first in the FIFO, and data from "EdgeGenTimestamp1" arrives last.

Data type	Value	Information
SINT	-128 to 127	Sequence number for generating switching edges

4.16.8.10.12.11 "EdgeGenSequenceReadback" register

Name:
EdgeGen01SequenceReadback to EdgeGen04SequenceReadback

This register reads back the sequence number. Like the 4.16.8.10.12.10 "EdgeGenSequence" register, this register is increased when the transferred timestamps are able to be accepted by the module. If the module is not able to accept any new stamps (e.g. because EdgeGenUnitTimestampFifoLim has been reached), then this register indicates the number of the last sequence accepted by the module.

Data type	Value	Information
SINT	-128 to 127	Last sequence number accepted by the module for edge generation.

4.16.8.10.12.12 Offset formats

Automation Studio provides 3 different parameters for setting offsets.

- **Offset format:** This parameter allows you to select the file type (16 or 32-bit) for cyclic transfer, and only affects the "EdgeGenOffset" register.
  Acyclic transfer of offset values with the "CfO_EdgeGenOffset_32bit" register is not affected by this parameter and always remains 32 bits wide.
- **Offset 01 to Offset 04:** This parameter has 2 possible settings:
  - Initial configuration: The offset value is only written once during configuration.
  - Cyclic data: A data point is created in the AS I/O mapping and the offset value is written cyclically.
- **Offset 01 value to Offset 04 value:** The actual offset value.

"EdgeGenOffset" register

Name:
EdgeGen01Offset1 to EdgeGen04Offset1
...
EdgeGen01Offset4 to EdgeGen04Offset4
"Offset 01 value" to "Offset 04 value" in the AS I/O configuration

The 4 offsets of an edge generator unit are written in this register. Depending on the configuration in the 4.16.8.10.12.4 "Edge generator unit mode" register, the offset values are handled as µs or in 1/8 µs.

For information regarding how to use the register and set the offset formats in Automation Studio, see 4.16.8.10.12.12 "Offset formats".

Data type	Value	Information
UINT	0 to 65535	16-bit offset
UDINT	0 to 134217728	Offset when "Offset format = 32-bit" and "Time base" = 1 µs
	0 to 1,073,741,824	Offset when "Offset format = 32-bit" and "Time base" = 1/8 µs

"CfO_EdgeGenOffset_32bit" register

Name:
CfO_EdgeGen01Offset_32bit1 to CfO_EdgeGen04Offset_32bit1
...
CfO_EdgeGen01Offset_32bit4 to CfO_EdgeGen04Offset_32bit4

The 4 offsets of an edge generator unit can be written acyclically using this register. Depending on the configuration in the 4.16.8.10.12.4 "Edge generator unit mode" register, the offset values are handled as µs or in 1/8 µs.

For information regarding how to use the register and set the offset formats in Automation Studio, see 4.16.8.10.12.12 "Offset formats".

Data type	Value	Information
UDINT	0 to 134217728	Offset when "Offset format = 32-bit" and "Time base" = 1 µs
	0 to 1,073,741,824	Offset when "Offset format = 32-bit" and "Time base" = 1/8 µs

4.16.8.10.12.13 "EdgeGenTimestamp" register

Name:
EdgeGen01Timestamp1 to EdgeGen04Timestamp1
...
EdgeGen01Timestamp4 to EdgeGen04Timestamp4

Registers for the timestamps to which edges pending generation are referenced. Up to 4 timestamp elements (net times) can be transferred per X2X cycle. Between 1 and 4 of these timestamp elements are placed in the FIFO, depending on how much the sequence number is increased by. If an attempt is made to set timestamps to a time that has already passed, then a EdgeGenWarning is generated (see: 4.16.8.10.12.7 "CfO_EdgeGenUnitPickupDiff" register).

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.16.8.10.13 Minimum X2X cycle time

The minimum X2X cycle time is strongly dependent on the configured functions and the resulting load on the module. In general, a "Fast reaction" setting and a very short system cycle (50 µs) have a negative influence on the minimum X2X cycle time. This can lead to errors when the X2X cycle time is short.

4.17 Dummy modules

The dummy module is used as a placeholder to prevent configuration errors caused by empty slots.

4.17.1 Brief information

Product ID	Short description	on page
X20IF0000	X20 dummy interface module (non-functional)	1869
X20ZF0000	Dummy X20 module (non-functional)	1870
X20ZF000F	Dummy X20 module (non-functional)	1872

4.17.2 X20IF0000

4.17.2.1 General information

Covers for unused interface module slots are included with X20 CPUs. If an X20 system is used in a maritime environment, then the system will be subjected to increased vibration fatigue. In order to achieve the stability necessary for operation, the X20IF0000 dummy interface module from the X20 series is used instead of the covers.

- Cover for unused interface module slots
- IF dummy modules required if the X20 system is subjected to increased vibration fatigue
- Module with no electrical function

4.18.2 X20CS1011

4.18.2.1 General information

SmartWire from the company Moeller makes it possible to very easily integrate switching devices such as contactors or motor protection switches in the X20 system without extensive wiring. It replaces the control circuit wiring between the controller and switching devices with pluggable, pre-assembled connection cables.

Although SmartWire is an intelligent connection, this changes almost nothing for the machine programmer. Integration in the X20 system via the interface module cuts down on overall communication. The individual switching devices can simply be viewed as digital inputs and outputs.

Practical applications

SmartWire allows up to 16 switching devices to be connected using pre-assembled cables and attached to the X20 SmartWire interface module. The system can configure itself completely at the push of a button without additional intervention or effort. This replaces the wiring test that was previously necessary.

At the same time, the device configuration is known to the system. If a device is no longer available due to an error or intervention, it will be detected immediately. Once corrected, the system continues to run.

The interface module is designed as a normal electronic module, which means it can be placed anywhere on the remote backplane.

- X2X SmartWire master for controlling up to 16 SmartWire slaves
- Simple connection using pre-assembled connection cables
- Moeller SmartWire modules for Moeller standard switching devices
- Replaces control circuit wiring
- Contactor activation
- Contactor switching status
- Motor circuit breaker status
- 24 VDC control voltage via SmartWire connection cable

4.18.2.2 Order data

Model number	Short description	Figure
	X20 electronics module communication

4.18.2.3 Technical data

Product ID	X20CS1011
Short description	
Communication module	1 SmartWire master for controlling up to 16 slaves
General information	
B&R ID code	0xA38D
Status indicators	SmartWire bus function, external supply voltage, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
SmartWire operating state	Yes, using status LED and software
U Aux	Yes, using status LED
Power output	
Internal I/O	6.8 W for supplying external slaves (equal to 16 slaves each with 0.425 W)
Power consumption	
Bus	0.01 W
Internal I/O	1.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
SmartWire bus - X2X Link	Yes
SmartWire supply (17 VDC) - I/O supply	No
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Interfaces	
Interface	
Type	SmartWire (LIN bus)
Design	Connection made using 12-pin X20TB12 terminal block
Transfer rate	19200 bit/s
SmartWire	
Data format	1 start bit, 8 data bits, no parity bit, 1 stop bit
Max. distance	4 m
Configuration button	
Internal	Integrated in the module on the bottom of the housing.
External	Connection via 12-pin terminal block N.O. contact, not electrically isolated (use potential-free contact)
SWIRE terminal 1 (24 VDC)	
Voltage drop for reverse polarity protection at 3 A	Max. 0.1 VDC
Voltage range	Voltage and supply
Current load	Max. 3 A
Short circuit protection	No, only with external fuse
Monitoring	20 VDC < 24 VDC Aux < 29.4 VDC (via firmware)
SWIRE terminal 2	
Daisy chain signal	5 VDC, CMOS level
SWIRE terminal 5 (bus level)	
Dominant	<2 VDC
Recessive	>14.85 VDC
SWIRE terminal 6 (17 VDC)	
Voltage range	Typ. 16.6 VDC (16.3 VDC to 16.8 VDC)
Summation current	Max. 400 mA for 16 SmartWire slaves
Short circuit protection	Yes
Monitoring	14.2 VDC < 17 VDC Aux < 17.9 VDC (via firmware)
U-Aux (24 VDC aux supply)	
Connection	Externally via 12-pin terminal block [2)]
Input voltage	24 VDC -15 % / +20 %
Fuse	Recommended line fuse: 3 A, slow-blow
Summation current	Max. 3 A for 16 SmartWire slaves
Reverse polarity protection	Yes
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20

Table 386: X20CS1011 - Technical data

Product ID	X20CS1011
Environmental conditions	
Temperature	
Operation	
Horizontal installation	0 to 55°C
Vertical installation	0 to 50°C
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order SmartWire attachment cable X20CA4S00.00xx separately Order 1x X20BM11 bus module separately
Spacing	12.5$^{+0.2}$ mm

Table 386: X20CS1011 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions
2) Using an external feed makes it possible to shut down via E-stop or switching relay

4.18.2.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)1)
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Warning/Error on an I/O channel
	e + r	Red on / Green single flash		Invalid firmware
	S + R	Green		The "S" and "R" LEDs indicate the status of the SmartWire interface.
	A	Green	Off	U-Aux supply missing or too low
			On	U-Aux supply OK

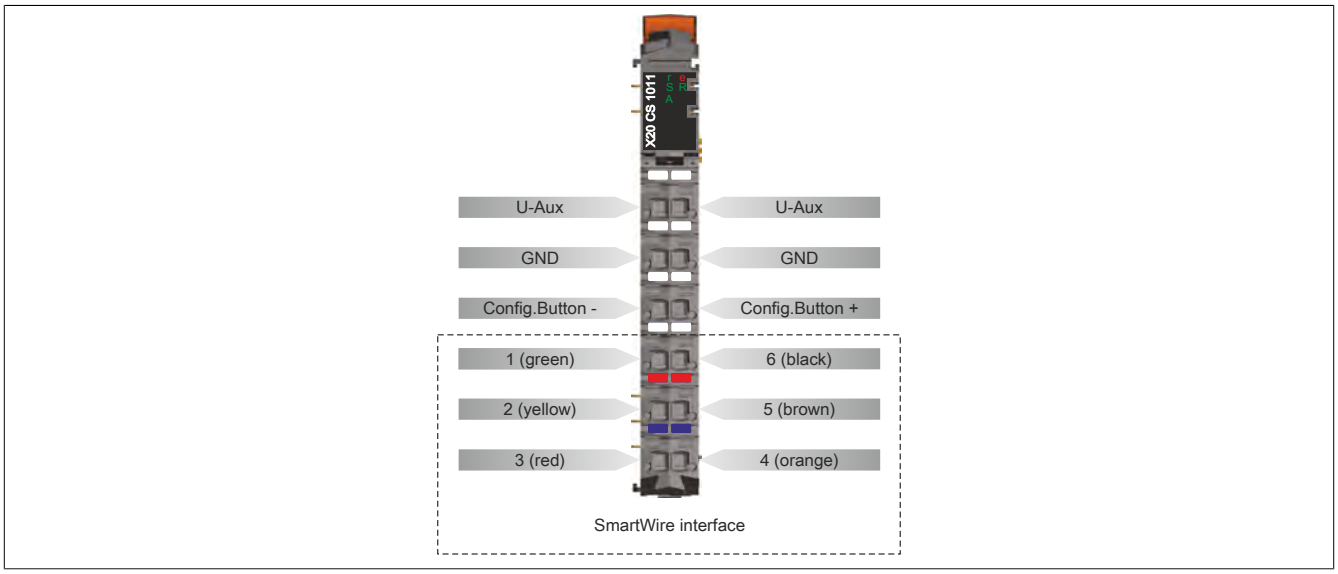
1) Depending on the configuration, a firmware update can take up to several minutes.

"S" and "R" LEDs

The status of the SmartWire interface is indicated by the "S" and "R" LEDs.

S	R	Firmware status	Description
Off	Off	CHECK_INT_FRAM	Initialization
		CHECK_LIN_SUPPLY	Wait until 17 VDC bus is OK
		INT_ERROR_STATE	Internal error has occurred (remains)
Off	On	SET_TRANSCEIVER_MODE	Initialization of transceiver
		RESET_UART	Initialization of UART + 10 ms delay
		READ_REVISION_CNT	Initialization (revision counter from FLASH)
Blinking slowly	Blinking slowly	INIT_LIN_SCAN	Initialization for bus scan
		RUN_LIN_SCAN	Perform bus scan
		INIT_LIN_SETUP	Initialization for RUN_LIN_SETUP
		RUN_LIN_SETUP	Perform bus setup
		STORE_REVISION_CNT	Revision counter in FLASH
		WAIT_FOR_PUSHBUTTON	Wait for configuration button after bus scan and difference with existing configuration
Blinking slowly	Blinking quickly	TIME_DELAY	4 s optical confirmation signal after pressing the configuration button
On	Blinking slowly	DP_CFG_CHECK	Check of the configuration by the higher-level CPU (not currently used)
		SET_SLAVES_TO_OP	Switch SmartWire stack to Operational
		SET_SLAVES_TO_PREOP	Switch SmartWire stack to Preoperational
		INIT_LIN_SCHED	Initialization for RUN_LIN_SCHED
		RUN_LIN_SCHED (PREOP)	RUN SmartWire scheduler (in PREOP)
On	On	RUN_LIN_SCHED (OP)	RUN SmartWire scheduler (in OP)
Blinking slowly	On	IDLE_STATE	RUN SmartWire without scheduler (no slaves connected)
Blinking quickly	On	LIN_ERROR_STATE	ERROR LIN-BUS has occurred (remains)

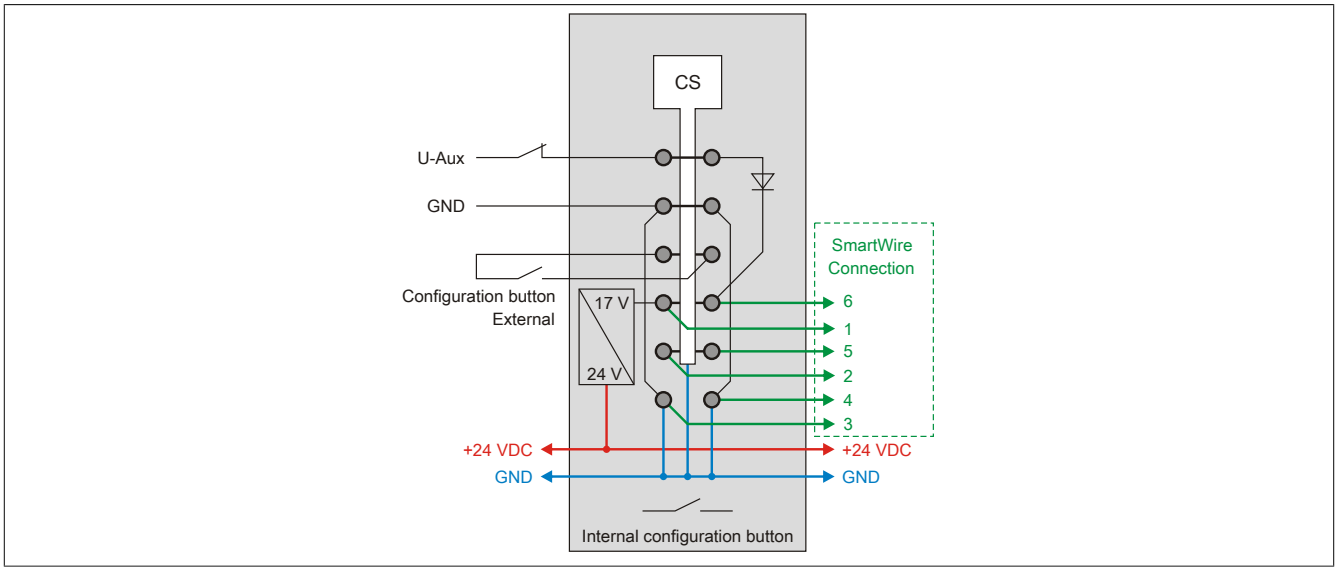
4.18.2.5 Pinout



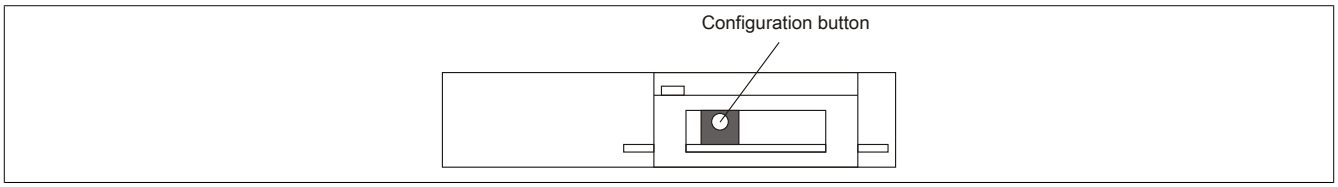
Information:

X20CA4S00.00xx SmartWire cables are delivered with the X20TB12 terminal block fully installed.

4.18.2.6 Connection example



4.18.2.7 Configuration button



A configuration button is integrated on the underside of the interface module housing. It can be used to completely configure the entire system.

After adding or removing SmartWire sensors/actuators, pressing the configuration button rescans the SmartWire bus and saves the new configuration in the X20 SmartWire interface module.

In addition to the internal configuration button, it is also possible to connect an external configuration button to the terminal block.

4.18.2.8 Register description

4.18.2.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.2.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
5121	FastOutput01_02	USINT			●	
5123	FastOutput03_04	USINT			●	
...	...					
5133	FastOutput13_14	USINT			●	
5135	FastOutput15_16	USINT			●	
257	SmartWireEnable	USINT				●
259	Smart WireMode	USINT				●
8193 + (N-1) * 32	VendorNCfg (Index N = 1 to 16)	USINT				●
8195 + (N-1) * 32	DeviceNCfg (Index N = 1 to 16)	USINT				●
Communication						
557	MasterOperatingState	USINT	●			
550	MasterStatus	UINT	●			
546	SlaveStatus	UINT	●			
4097 + (N-1) * 32	InputN (Index N = 01 to 16)	USINT	●			
513 + (N-1) * 2	SlaveStatusN (Index N = 01 to 16)	USINT		●		
8193 + (N-1) * 32	VendorN (Index N = 1 to 16)	USINT		●		
8195 + (N-1) * 32	DeviceN (Index N = 1 to 16)	USINT		●		

4.18.2.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
5121	0	FastOutput01_02	USINT			●	
5123	1	FastOutput03_04	USINT			●	
...	...	...					
5133	6	FastOutput13_14	USINT			●	
5135	7	FastOutput15_16	USINT			●	
257	-	SmartWireEnable	USINT				●
259	-	Smart WireMode	USINT				●
8193 + (N-1) * 32	-	VendorNCfg (Index N = 1 to 16)	USINT				●
8195 + (N-1) * 32	-	DeviceNCfg (Index N = 1 to 16)	USINT				●
Communication							
77	-	MasterOperatingState	USINT		●		
70	-	MasterStatus	UINT		●		
66	-	SlaveStatus	UINT		●		
4097 + (N-1) * 32	N - 1	InputN (Index N = 01 to 16)	USINT	●			
513 + (N-1) * 2	-	SlaveStatusN (Index N = 01 to 16)	USINT		●		
8193 + (N-1) * 32	-	VendorN (Index N = 1 to 16)	USINT		●		
8195 + (N-1) * 32	-	DeviceN (Index N = 1 to 16)	USINT		●		

1) The offset specifies the position of the register within the CAN object.

4.18.2.8.3.1 CAN I/O bus controller

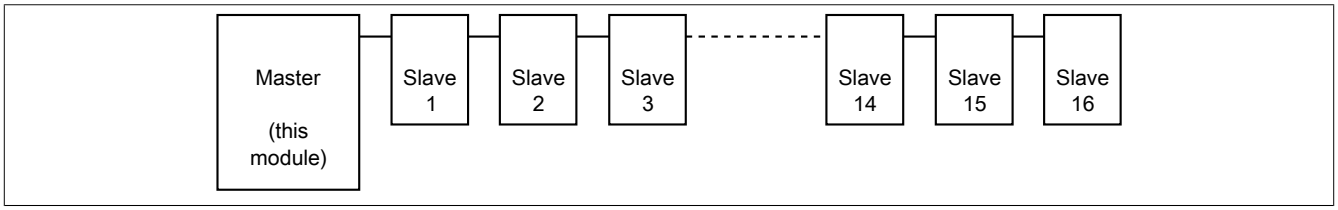
The module occupies 2 analog logical slots on CAN-I/O.

4.18.2.8.4 Communication module Basic Master for SmartWire

SmartWire is essentially a master-slave system.

- All data traffic is initiated by the master, but the system can only contain one master.
- The SmartWire master can control up to 16 SmartWire slaves.
- The total scheduling time is 160 ms (i.e. after 160 ms, all 16 slaves have been queried one time).
- The maximum allowed bus extension is 2.6 m.
- Due to the automatic bus configuration, the numbering of the individual slaves is determined by the line structure of the bus.

This results in the following order:



Node address = Physical position in the bus line

4.18.2.8.5 Functions

4.18.2.8.5.1 Scan SmartWire

Automatically started and run after the system is turned on (default settings).

This procedure terminates if

- the set and actual configuration of the bus are identical: system changes to normal operation (i.e cyclic data exchange)
- or if there is a deviation between the set and actual configuration: error present, cyclic data transfer is not started

4.18.2.8.5.2 Setup SmartWire

Can be activated by pressing the configuration button or using a software command:

- if no configuration is saved
- if a SmartWire scan was just terminated due to error

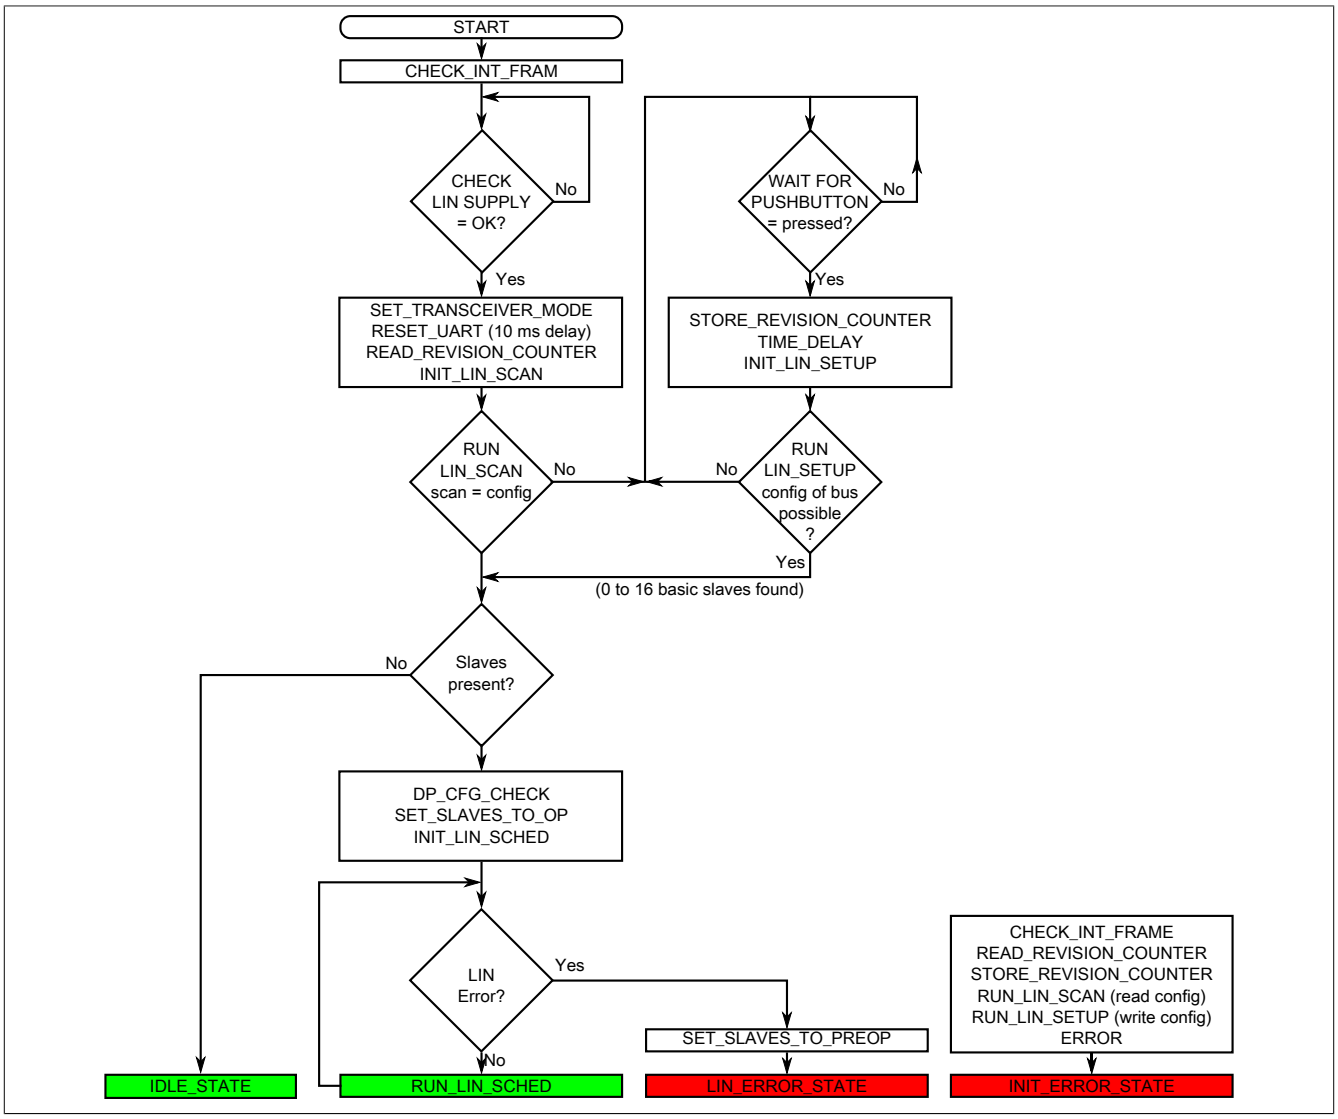
During setup, all connected stations are saved remanently in the master as new set configuration. Valid stations are uniquely identified by the two parameters 4.18.2.8.14.3 "Device ID" and 4.18.2.8.14.2 "Vendor ID".

4.18.2.8.6 Show operating state of the master

The current state of the master state machine is indicated in this register.

Data type	Value	Code	Description
USINT	1	CHECK_INT_FRAM	Init State
	2	CHECK_LIN_SUPPLY	Waiting for 17 V voltage OK
	3	SET_TRANSCEIVER_MODE	Turn on transceiver
	4	RESET_UART UART	Reset
	6	INIT_LIN_SCAN	Init before bus scan
	7	RUN_LIN_SCAN	Bus scan is running
	8	WAIT_FOR_PUSHBUTTON	Scan != Configuration, waiting for Config button
	9	TIME_DELAY	Delay before bus setup
	10	INIT_LIN_SETUP	Init before bus setup
	11	RUN_LIN_SETUP	Bus setup is running (new configuration)
	12	DP_CFG_CHECK	PLC has set "Wait for configuration"
	15	SET_SLAVES_TO_OP	Sets slaves to OP mode (after successful scan or setup)
	16	SET_SLAVES_TO_PREOP	Sets slaves to PREOP mode (after errors have occurred, before LIN_ERROR or INT_ERROR)
	19	INIT_LIN_SCHED	Init bus scheduling
	20	RUN_LIN_SCHED	Bus scheduler is running
	21	LIN_ERROR_STATE	A fatal bus error has occurred (permanent)
	22	INT_ERROR_STATE	A fatal internal error has occurred (permanent)
	23	IDLE_STATE	Idle because there is no slave connected (permanent)

4.18.2.8.6.1 Flow chart of SmartWire master operating status



The register receives the following value after successfully starting:

Value	Code	Description
20	RUN_LIN_SCHED	Bus scheduler is running

4.18.2.8.7 Status of the master

Name:
MasterStatus

The current status information for the master is shown in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	LIN_BUS_SETUP_COMPLETE	0	Saved configuration does not match the actual hardware on the bus
		1	Setup finished: SCAN or SETUP after config button is valid
1	LIN_FATAL_ERROR	0	No error on the bus
		1	SmartWire bus is defective: e.g. short circuit, no echo → more than 10 consecutive communication errors have occurred. **Information:** **The failure of a slave is not a communication error. Instead it is indicated in the slave status and the scheduler continues to run!**
2	LIN_MASTER_PREOP	0	SmartWire stack not in PREOP mode
		1	SmartWire stack in PREOP mode
3	LIN_MASTER_OP	0	SmartWire stack not in OP mode
		1	SmartWire stack in OP mode
4	LIN_GLOBAL_CONTROL	0	No command sent
		1	Set SmartWire stack to OP mode: Bit is written to the enable bit and can be read back
5	Reserved	0	
6	LIN_POWER_SUPPLY_STATE	0	Bus voltage supply is not OK
		1	Bus voltage supply is OK
7	Reserved	0	
8	DP_CHECK_COMPLETED	0	Not a valid configuration
		1	Configuration check completed (Not Used) (could optionally be written by the PLC, if the SCAN (configuration) is OK and was able to be read back from here)
9	Reserved	0	
10	DP_RECONFIGURATION	0	X2X Reconfiguration → X2X configuration button not pressed
		1	X2X Reconfiguration → X2X configuration button can be read back
11 - 15	Reserved	0	

The register receives the following value after successfully starting:

Equal to the decimal value: 345

Bit	Description	Value	Information
0	LIN_BUS_SETUP_COMPLETE	1	SmartWire setup complete: SCAN or SETUP after config button is valid
3	LIN_MASTER_OP	1	SmartWire stack in OP mode
4	LIN_GLOBAL_CONTROL	1	Set SmartWire stack to OP mode - Command set
6	LIN_POWER_SUPPLY_STATE	1	Bus voltage supply is OK
7	DP_CHECK_COMPLETED	1	Configuration is Ok

4.18.2.8.8 Status of all slaves

Name:
SlaveStatus

The current state of the slave is indicated collectively in this register.

In the event of an error, the failed slaves are indicated in the respective bits, and in the status registers individually set up for the slaves (see 4.18.2.8.14.1 "SlaveStatus1 to SlaveStatus16").

Data is exchanged cyclically as long as none of these bits are set. If an error does error, then I/O transfer is stopped. The bus can be started again after the error has been corrected or a setup has been performed again (see 4.18.2.8.13 "Basic application registers "SmartWireEnable" and "SmartWireMode"").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Slave 1	0	Ok
		1	Errors
...		...	
15	Slave 16	0	Ok
		1	Errors

4.18.2.8.9 Transfer control bits to slaves

Name:
FastOutput01_02 to FastOutput15_16

In these registers, the control bits are transferred to 2 consecutive slaves. Each slave receives 4 control bits, that must be selected from the 8 data bytes depending on the node address (1 to 16). These 4 control bits are assigned fixed values and utilization of the bits by the slave is optional.

All of the slaves evaluate this telegram. It must be sent cyclically by the master so that the slaves can ensure that the master is still functioning without any problems within the monitoring time (lifeguarding time = 400 ms).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Slave N	0	Digital output 1 reset
		1	Digital output 1 set
...		..	
3	Slave N	0	Digital output 4 reset
		1	Digital output 4 set
4	Slave N + 1	0	Digital output 1 reset
		1	Digital output 1 set
...		..	
7	Slave N + 1	0	Digital output 4 reset
		1	Digital output 4 set

4.18.2.8.10 Read input data from slave

Name:
Input01 to Input16

Each slave sends its input data and/or its status to the master.

The data volume consumes 1 byte per slave. Each slave has one diagnostics bit, which it sends to the master with the cyclic data. This bit is a message bit if an application error occurs (on the module). It is always located in the highest value bit.

The master can constantly evaluate this bit. The diagnostic bit is set on the slave if the status of the slave is "Error". Slaves that do not have any input data will still send a byte that is used to make their status data available. This is required because the master also monitors the slaves for proper functionality through the receipt of this byte.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Input state - Digital input 1	0 or 1	
...		...	
3	Input state - Digital input 4	0 or 1	
4 - 6	Reserved	0	
7	Error status	0	No error on the slave
		1	Error on the slave

4.18.2.8.11 Configure the function breakpoints on the master

Name:
SmartWireEnable

This register can be used to configure function breakpoints that may be implemented in master state machine.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Enable SmartWire stack	0	Disabled
		1	Enabled
1	Set SmartWire stack mode	0	Sets PREOP mode (scheduler is already running, output data will still be output with 0)
		1	Sets OP mode
2	Reserved	0	
3	Software "Config button"	0	Not pressed
		1	Pressed (necessary so that slaves can also be reconfigured)
4 - 7	Reserved	0	

4.18.2.8.12 Configure the operating mode of the master

Name:
SmartWireMode

This register can be used to configure the master operating mode.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Operating mode	00	CONFIG from RAM (controller)
		01	Read CONFIG from flash (default)
		10	Write CONFIG to flash
		11	Reserved
2 - 7	Reserved	0	

4.18.2.8.13 Basic application registers "SmartWireEnable" and "SmartWireMode"

By default, the SmartWire bus is started automatically and must at least be configured using an external method (e.g. external button or push-button).

If sensors / actuators are added to or removed from the SmartWire bus, then the configuration procedure must be restarted so that the SmartWire bus will be rescanned and the new configuration saved remanently in the master.

These registers can and must be used for special conditions and for acknowledging errors.

The library commands are sent asynchronously via X2X Link. The following conditions could cause errors on the module and are therefore not permitted:

- The command register SmartWireMode is written to first. It is possible to write to the SmartWireEnable register once the function block reports that it is finished.
- The function block status response is checked in the application
- The specified response from the master status information must arrive in order for the master state machine to function properly

4.18.2.8.13.1 Starting the bus when Manual Start has been configured

Status information after startup:

Value (decimal)	Register	Information
1	MasterOperatingState	Init State
0	MasterStatus	
0	SlaveStatus	

If Manual start is selected for the bus in the configuration, then the AsIOAccWrite() function from the AsIOAcc library must be used to write to the two registers in the specified order.

Value (decimal)	Register	Information
1	SmartWireMode	Configuration from rem. memory
3	SmartWireEnable	Command for STACK ON / OPERATIONAL

Status information after error-free startup of the bus:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
345	MasterStatus	"RUN without error if SlaveStatus = 0"
0	SlaveStatus	No slave errors

4.18.2.8.13.2 Starting the bus after slave error

Status information after slave error

In this case, a change to MasterOperatingState and MasterStatus cannot be detected at first, although the respective error bits are set in the SlaveStatus. The slaves have failed, and data is no longer being exchanged.

Value (decimal)	Register	Information
20	MasterOperatingState	
345	MasterStatus	
x	SlaveStatus	Bits for the faulty slaves have been set

To set the master to a defined state, the bus must first be stopped with the following write commands.

Value (decimal)	Register	Information
0	SmartWireMode	All off
0	SmartWireEnable	All off

Wait until the commands have been completed successfully, which is indicated in the MasterStatus. Bit 4 is cleared: Response indicating that the bus is no longer operational.

Value (decimal)	Register	Information
20	MasterOperatingState	
329	MasterStatus	
0	SlaveStatus	

The bus can be restarted using the write commands after the errors have been corrected:

Value (decimal)	Register	Information
1	SmartWireMode	Configuration from rem. memory
3	SmartWireEnable	Command for STACK ON / OPERATIONAL

Status information after error-free startup of the bus:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
345	MasterStatus	"RUN without error if SlaveStatus = 0"
0	SlaveStatus	No slave errors

Different status information can result depending on the present error situation (see 4.18.2.8.6 "MasterOperatingState").

Typical situation when there are hardware configuration differences:

Value (decimal)	Register	Information
0	MasterOperatingState	
80	MasterStatus	
0	SlaveStatus	

Information:

A stop command must be sent before a new start command can be applied!

4.18.2.8.14 Advanced applications

The following registers are used for advanced diagnostics, for reading back the current configuration and for creating a configuration from the application. The registers that have already been written and their respective contents are, of course, valid.

4.18.2.8.14.1 Status of the individual slaves

Name:
SlaveStatus1 to SlaveStatus16

These registers display the respective slave status.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0		0	Slave integrated on the bus
		1	Slave failure on the bus
1 - 7	Reserved	0	

4.18.2.8.14.2 Read slave vendor ID

Name:
Vendor1 to Vendor16

These registers display the respective slave Vendor ID.

Data type	Value	Information
USINT	x	Slave vendor ID

4.18.2.8.14.3 Read slave device ID

Name:
Device1 to Device16

These registers display the respective slave device ID.

Data type	Value	Information
USINT	x	Slave device ID

4.18.2.8.14.4 Write slave vendor ID

Name:
Vendor1Cfg to Vendor16Cfg

The desired vendor ID for the slave can be written in these registers.

Data type	Value	Information
USINT	x	Slave vendor ID

4.18.2.8.14.5 Write slave device ID

Name:
Device1Cfg to Device16Cfg

The desired device ID for the slave can be written in these registers.

Data type	Value	Information
USINT	x	Slave device ID

Import the configuration without starting the bus

For safety reasons, it is possible to import the configuration for the connected bus without starting cyclic data transfer. This actual configuration can be compared with the set configuration stored in the application. Cyclic data transfer can be started if the configurations are the same. An error is reported if they are not the same.

Manual start is configured, status information after startup:

Value (decimal)	Register	Information
1	MasterOperatingState	Init State
0	MasterStatus	
0	SlaveStatus	

The function AsIOAccWrite() from the library AsIOAcc must be used to write the two registers in the specified order.

Value (decimal)	Register	Information
0	SmartWireMode	RAM memory configuration
9	SmartWireEnable	Command for STACK ON / PREOPERATIONAL and CONFIG-BUTTON

Status information after error-free import of the bus configuration:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
1349	MasterStatus	"PREOP and no errors"
0	SlaveStatus	No slave errors

Once these commands have been completed, the connected slave modules are imported and stored in the remanent memory for subsequent startups.

The function AsIOAccRead() from the library AsIOAcc must now be used to read all corresponding registers Vendor1 to Vendor16 and Device1 to Device 16 . If the configuration matches, then the bus can now be started using the standard command:

Value (decimal)	Register	Information
1	SmartWireMode	Configuration from rem. memory
3	SmartWireEnable	Command for STACK ON / OPERATIONAL

Status information after error-free startup of the bus:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
345	MasterStatus	"RUN without error if SlaveStatus = 0"
0	SlaveStatus	No slave errors

Bus configuration settings

Manual start is configured, status information after startup:

Value (decimal)	Register	Information
1	MasterOperatingState	Init State
0	MasterStatus	
0	SlaveStatus	

A running bus can, of course, also be stopped with the standard command and re-configured!

The function AsIOAccWrite() from the library AsIOAcc must now be used to write the respective data to all registers Vendor1Cfg to Vendor16Cfg and Device1Cfg to Device16Cfg. All vendor and device registers that are not being used must be set to zero. This does not cause a change in the status registers.

To save the data in remanent memory, the function AsIOAccWrite() from the library AsIOAcc must be used to write to the two registers in the specified order.

Value (decimal)	Register	Information
2	SmartWireMode	WRITE rem. memory configuration
1	SmartWireEnable	Command for STACK ON / OPERATIONAL

Status information after error-free configuration:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
325	MasterStatus	"PREOP without errors"
0	SlaveStatus	No slave errors

The bus can now be started using the standard command for the bus:

Value (decimal)	Register	Information
1	SmartWireMode	Configuration from rem. memory
3	SmartWireEnable	Command for STACK ON / OPERATIONAL

Status information after error-free startup of the bus:

Value (decimal)	Register	Information
20	MasterOperatingState	"RUN without error if SlaveStatus = 0"
345	MasterStatus	"RUN without error if SlaveStatus = 0"
0	SlaveStatus	No slave errors

4.18.2.8.15 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.3 X20CS1012

4.18.3.1 General information

The X20 system is now being expanded to include a new M-Bus master communication slice. This single-width module can be placed anywhere in an X20 I/O system and can therefore be used as a decentralized solution in distributed topologies. The M-Bus master supports transfer rates of 300, 2400 and 9600 Bit/s and up to 64 slaves can be connected and supplied via the M-Bus.

The M-Bus (meter bus) is a relatively simple fieldbus for collecting consumption data, such as from electricity or heat meters. It is based on reverse polarity proof two-wire connections and uses the master-slave principle.

- Supply for up to 64 slaves on the M-Bus
- Decentralized use of the communication interface

4.18.3.2 Order data

Model number	Short description	Figure
	X20 electronics module communication	
X20CS1012	X20 interface module, 1 M-Bus master interface, integrated slave supply	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous

4.18.3.3 Technical data

Product ID	X20CS1012
Short description	
Communication module	1 M-Bus master for controlling up to 64 slaves
General information	
B&R ID code	0xCABF
Status indicators	Data transfer, M-Bus supply, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Data transfer	Yes, using status LED
M-Bus supply	Yes, using status LED and software
Power consumption	
Bus	0.2 W
Internal I/O	0.35 W + (number of slaves * 0.08 W)
Module power dissipation	0.55 W + (number of slaves * 0.006 W)
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
M-Bus - X2X Link	Yes
M-Bus - I/O supply	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1]	Yes
GOST-R	Yes
Isolation voltage between M-Bus and X2X Link	500 VDC, 1 min
Interfaces	
Interface	
Type	M-Bus master
Design	Connection made using 12-pin X20TB12 terminal block
Transfer rate	300, 2400 or 9600 bit/s
Max. distance	See section "M-Bus"
Number of slaves	Max. 64
Internal resistance of the master	Max. 6 Ω
Bus voltage mark at 0 mA	I/O supply voltage (+ 11.5 to 13.5 V)
Bus voltage drop with space	12 to 13.5 V
Overload cutoff	250 mA ±10%
Bit threshold	6 to 9 mA
Collision threshold	24 to 36 mA
Received readjustment time	Max. 10 s [2]
Bus cable	Shielded or unshielded
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 388: X20CS1012 - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) Dependent on the changes to the load on the M-Bus (e.g. switching slaves on and off)

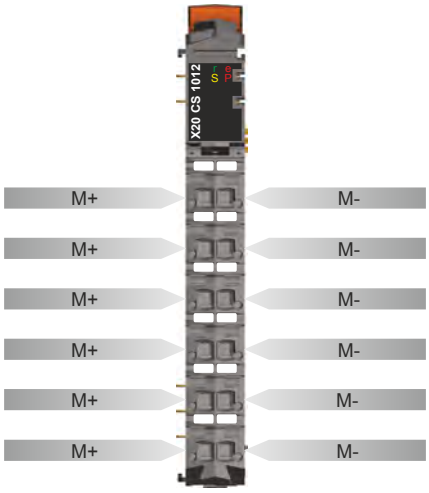
4.18.3.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

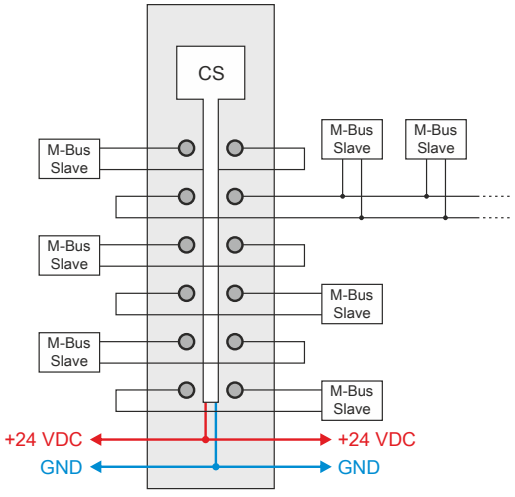
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	S	Yellow	Off	No slaves sending data
			On	At least one slave is sending data via the M-Bus
	P	Red	Off	M-Bus supply ok
			On	Short-circuit or overload on M-Bus

1) Depending on the configuration, a firmware update can take up to several minutes.

4.18.3.5 Pinout



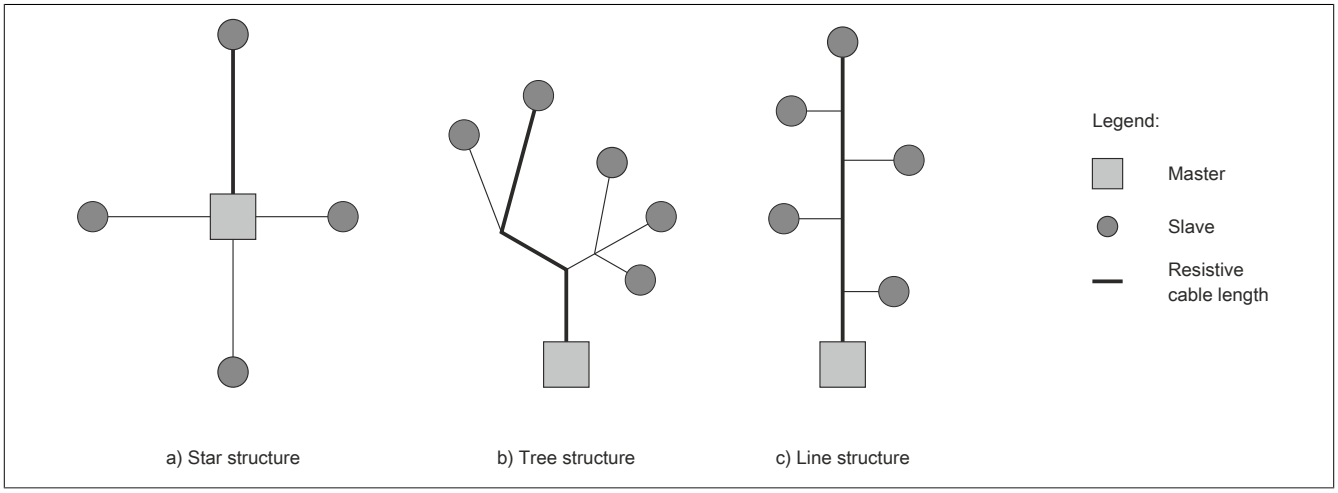
4.18.3.6 Connection example



4.18.3.7 M-Bus

4.18.3.7.1 Bus topology

The bus topology has a significant influence on the maximum load of an M-Bus network. In general a star structure is preferred over a tree structure and in turn a tree structure is preferred over a line structure. Furthermore, connecting the slaves to the bus the same way provides better values than connecting them all at the end of the branches after all other parameters have been determined.



4.18.3.7.2 Cable cross section

The cable being used has a specific capacity and resistance, which in turn has an effect on the operation of the bus. The resistive influence of the cable means a loss of voltage on the line, which is subsequently not available for supplying the bus. In order to guarantee sufficient power, the voltage on the slaves must never be less than 12 V neither when sending from the master to the slave, nor in the opposite direction. The deciding factor in this case is the longest branch of the network whose length is referred to as the resistive cable length.

The cable's capacity causes signal distortion during data transfer because the slew rates of the rising and falling edges are slowed down. For example, replacing a 3 km branch in a network with two 1.5 km branches will improve the signal. The total distance of the network is referred to as the capacitive cable length (the sum of all segment lengths).

Information:

The maximum permissible line resistance (for the longest loop) is 250 Ω.

The maximum permissible line capacitance for the entire bus is 500 nF.

4.18.3.7.3 Transmission current and bit threshold

The bit threshold on the master is typically 7.5 mA. Therefore, a slave transmission current of 15 mA results in the least amount of signal distortion while the highest amount occurs at 11 or 20 mA.

4.18.3.7.4 Transfer rate

A lower transfer rate decreases the influence of the signal distortion caused by cable capacity and bit threshold.

Information:

Starting with a total bus length >1 km, the slaves must be operated at a baud rate <9600 bit/s.

4.18.3.7.5 Calculating the resistive bus length

The resistive cable length must be calculated in order to ensure a sufficient power supply of 12 V on the M-Bus. What matters most here is the longest segment between the master and slave.

The resistive bus length is calculated using the following formula without taking an increased bus current caused by a defective receiver into account:

$$L_{res} = \frac{V_{I/O} - (n * 0.0015 + 0.02) * 6 - 12.6}{(n * 0.0015 + 0.02) * R_L} * 1000$$

L_{res} ... Resistive bus length [m]
n ... Number of slaves (all at end of line)
R_L ... Line resistance (loop resistance [Ω/km])
$V_{I/O}$ ... I/O supply voltage [V]

Examples for calculating the maximum resistive bus length:

No.	Example	Maximum resistive bus length
1	• 64 slaves (all at end of line) • 19.2 V I/O supply voltage • 0.5 mm² wire cross-section	675 m
2	• 64 slaves (all at end of line) • 28.8 V I/O supply voltage • 1.5 mm² wire cross-section	5340 m

4.18.3.7.6 Accounting for the capacitive bus length

The total distance of the network is referred to as the capacitive bus length (the sum of all segment lengths). The capacitive bus length depends on two factors:

- Distributed capacitance of cable
- Transfer rate

Distributed capacitance of cable

A lower distributed capacitance on a cable means a higher capacitive bus length.

Transfer rate

A lower transfer rate on an M-Bus system means a higher capacitive bus length.

Example of a cable with a distributed capacitance of 50 nF/km:

Transfer rate	Capacitive bus length
9600 bit/s	1 km
2400 bit/s	4 km
300 bit/s	10 km

4.18.3.7.7 Bus installation

Cables with twisted pair wires and a cross-section of 0.5 mm² to 1.5 mm² are normally used for bus installation (according to standard: J-Y(ST)Y nx2x0.8). The shield on shielded cables only has to be grounded to the module on one side. On the slaves, the shielding must be high resistance for DC and low frequency signals.

4.18.3.7.8 Repeater

Repeaters can be used to further expand the M-Bus network.

4.18.3.8 Register description

4.18.3.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.3.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic

1) The offset specifies the position of the register within the CAN object.

4.18.3.8.3.1 CAN I/O bus controller

The module occupies 3 analog logical slots on CAN-I/O.

4.18.3.8.4 General information

The M-Bus standard is a serial bus system that handles half-duplex or asynchronous communication. The high level of variability provided by this protocol enables a wide range of information to be handled via the same interface. In basic M-Bus networks, the master communicates with up to 250 slaves via the "primary address". In later stages of development, the secondary address (4 bytes) was then also specified. This made it possible to significantly increase the number of slaves in a network.

Important information about the module

- Generally: Primary address used (1 to 250)
- Secondary address only supported via FlatStream
- Bus can supply 64 slaves with power

4.18.3.8.5 Module configuration

The flexible design of the M-Bus protocol can quickly add up to a lot of configuration work. That's why B&R offers two different user interfaces for the module: "Standard" and "FlatStream". The user-friendly B&R Standard interface allows users to view up to eight values requested cyclically from the M-Bus network. In FlatStream mode, the module acts as a bridge between the PLC and the M-Bus slave, which makes all M-Bus functions available.

Information:

The B&R Standard interface is statically configured and based on cyclic registers. Because X2X Link can only transfer a certain number of values cyclically, the user must make his selection accordingly.

4.18.3.8.5.1 Settings for operation

Name:
CfO_FunctionModel

This register can be used to enable either the Standard or FlatStream interface, which makes the module much more efficient.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	B&R Standard Interface	0	Disabled
		1	Enabled
1	FlatStream	0	Disabled
		1	Enabled
3 - 7	Reserved	0	

4.18.3.8.6 M-Bus - Configuration

Separate configuration registers are provided for each value to read. These must be configured correctly in order to call up a counter value from the M-Bus network. The user must know the following values from the slave:

- Transfer rate configured on the slave
- Primary address configured on the slave (value: 1 to 250, otherwise only point-to-point connection is possible)
- Data type / data length of value
- How the slave's memory is structured

Information:

The following section "M-Bus - Configuration" is based solely on the B&R Standard interface.

4.18.3.8.6.1 Data length

Name:
CfO_LengthData1 to CfO_LengthData8

The Standard interface is able to request data from the M-Bus slave with different lengths. When using Automation Studio the value of the "Length" register is a result of the data type defined for the X2X Link. All common data types with up to 4 bytes in length are supported.

Data type	Value
USINT	0 to 7

Bit structure:

Bit	Name	Value	Information
0 - 5	Data length code	00 0000	USINT
		00 0001	SINT
		00 0010	UINT
		00 0100	UINT
		00 1000	UDINT
		01 0000	UDINT
		10 0000	REAL
6 - 7	Reserved	0	

4.18.3.8.6.2 Transfer rate

Name:
CfO_BaudData1 to CfO_BaudData8

This register can be used to define the transfer rate for retrieving the desired values.

Data type	Value
USINT	1 to 8

Bit structure:

Bit	Name	Value	Information
0 - 3	Baud rate (Code)	0000	Reserved!
		0001	300 bit/s
		0010	600 bit/s
		0011	1200 bit/s
		0100	2400 bit/s
		0101	4800 bit/s
		0110	9600 bit/s
		0111	19200 bit/s
		1000	38400 bit/s
4 - 7	Reserved	0	

4.18.3.8.6.3 Address

Name:
CfO_PAdrData1 to CfO_PAdrData8

This register can be used to define the address where the desired values will be requested from.

Data type	Value
USINT	1 to 250 (254)

Special addresses:

Value	Information
251 to 253	Reserved (in accordance with M-Bus specification)
254	Broadcast address (response from all connected slaves - risk of collision)

4.18.3.8.6.4 Index

Name:
CfO_IndexData1 to CfO_IndexData8

This register is used to specify the ordinal number of the value (independent of the medium). This value results from the order of values in the slave. The value is then transferred to the data register.

Data type	Value
USINT	1 to 255

4.18.3.8.6.5 Specifies the refresh time

Name:
CfO_ReqTimeData1 to CfO_ReqTimeData8

Slave value requests can be triggered manually or time-based. Time-based request requires the refresh time value to be specified in the "RequestTime" register. The respective unit is specified in the "MBusMode" register.

Data type	Value
USINT	1 to 255 [s, min]

4.18.3.8.6.6 M-Bus mode

Name:
CfO_MBusModeData1 to CfO_MBusModeData8

To speed up the module's boot procedure, various configuration details that define the module's behavior have been combined in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	Byte offset	0 - 7	See "Byte Offset" section
3 - 4	Reserved	0	
5	InitFrame	0	No extra frame
		1	Send extra frame
6	ApplicationResetFrame	0	No extra frame
		1	Send extra frame
7	Replacement value strategy	0	Retain last valid value
		1	Replace with static value
8	Time-based reading out	0	Disabled
		1	Enabled
9	Manually triggered reading	0	Disabled
		1	Read via the "MBusCommand" register (see 4.18.3.8.7.1 "M-Bus commands" on page 1901)
10	Unit of periodic read	0	[s] - Second
		1	[min] - Minute
11 - 15	Reserved	0	

Byte offset

The M-Bus specification allows for many individual data types. In order to also read these counter values with up to 64 bits, a slave value may have to be read using two data registers. The byte offset can be defined to read a specific part of the value.

4.18.3.8.6.7 Timeout offset

Name:
CfO_ToutOffData1 to CfO_ToutOffData8

The timeout for the M-Bus communication generally depends on the currently defined transfer rate. The user can also define an offset value in addition to the calculated standard timeout.

Timeout = standard timeout + (timeout offset * 10 ms)

Data type	Value
USINT	0 to 255: Resolution: 10 ms

4.18.3.8.6.8 Static replacement value

Name:
CfO_ReplData1 to CfO_ReplData8

This register is used to define the static replacement value if the replacement value strategy "Replace with static value" was enabled in "M-Bus mode". The data register takes on this value if an invalid input value is detected.

Data type	Value
(U)SINT (U)INT (U)DINT REAL	According to data type

4.18.3.8.7 M-Bus - Communication

Three important control and status bytes are provided in the B&R interface for communication with the M-Bus slaves. For example the "MBusCommand" register can be used to switch UART on/off to increase the system's energy efficiency.

Up to 8 cyclic input registers are registered depending on the configuration. Manually configured data must be requested via the "MBusCommand" register. The "ValidDataByte" and "InvalidDataByte" registers can be used to determine the quality of the value currently read.

Information:

The following section "M-Bus - Communication" is based solely on the B&R Standard interface.

4.18.3.8.7.1 M-Bus commands

Name:
MBusCommand

This register can be used to apply different commands to the module. The module only responds to positive edges.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Activate UART	0 → 1	Execute command
1	Read manually triggered values	0 → 1	Execute command
2	Acknowledge the "MBusState" register	0 → 1	Execute command
3 - 6	Reserved	0	
7	Deactivate UART	0 → 1	Execute command

Bit 0 and 7

The level converter is switched on by default when the module boots. These bits can be used to switch it on or off from the application to save electricity, for example.

4.18.3.8.7.2 M-Bus operation

Name:
MBusOperation

This register shows the user which task the module is currently processing. The LSB is always set when the UART is active. Manual commands are indicated by an increase of one in this byte while being processed.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	UART	0	Inactive
		1	Active
1	Read values	0	-
		1	Command being processed
2	Refresh/reset the "MBusState" register	0	-
		1	Command being processed[1)]
3 - 6	Reserved	0	
7	UART	0	Inactive
		1	Active

1) Bit 2 is only set for one X2X cycle. Requesting this bit is not recommended when operating the module behind a bus controller.

4.18.3.8.7.3 M-Bus status

Name:
MBusState

This register contains the current M-Bus network error state. All bits are managed in non-volatile memory. This means they must be reset via the "MBusCommand" register (see 4.18.3.8.7.1 "M-Bus commands" on page 1901).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Kollisionserkennung	0	Addressing OK
		1	Address repeated on bus
1	Read error (at least one)	0	Configured values OK
		1	Unable to read value
2	Checksums	0	Received checksum OK
		1	Error in input direction
3	M-Bus load	0	Power supply OK
		1	Load too high on M-Bus network
4	Communication aborted due to overflow	0	Communication OK
		1	The master is overloaded and cannot take on any additional requests. Measures taken: Repeat the request![1)]
5	Communication aborted due to level converter	0	Communication OK
		1	Level converter is OFF (aborted at runtime or not started).
6	Data exchange since startup	0	Valid data not yet received
		1	Valid data received at least one time
7	UART off MBUS ENABLE	0	M-Bus drive, level converter not active
		1	Module ready for communication

1) Communication is reestablished automatically as soon as the pending communication jobs have been processed.

4.18.3.8.7.4 Valid data

Name:
ValidDataByte

ValidData1 to ValidData8

This register indicates (by bit) which of the max. eight read values are valid.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	ValidData1	0	Value 1 invalid
		1	Value 1 valid
...	...	...	...
7	ValidData8	0	Value 8 invalid
		1	Value 8 valid

4.18.3.8.7.5 Invalid data

Name:
InvalidDataByte

InvalidData1 to InvalidData8

Validity of the read values can be checked redundantly. This register indicates (by bit) which of the max. eight read values are invalid.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	InvalidData1	0	Value 1 valid
		1	Value 1 invalid
...	...	...	...
7	InvalidData8	0	Value 8 valid
		1	Value 8 invalid

4.18.3.8.7.6 Data

Name:
Data1 to Data8

Each cyclic data register contains the respective pre-configured value from the M-Bus network. The data type of the data register was designed to be variable and must be specified by the user during configuration.

Information:

Because X2X Link can only transfer a certain number of bytes cyclically, the user must make his selection accordingly.

Data type	Value
(U)SINT (U)INT (U)DINT REAL	According to data type

4.18.3.8.7.7 Change the serial number of an M-bus slave

Name:
ChangedSNByte

This register indicates (by bit) whether one of the M-Bus slave serial numbers on the bus has changed. Only the serial numbers of the slaves accessed via the B&R interface are checked. The respective bit is toggled if a change is detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	SN (Slave 1)	0 -> 1	Slave1: Serial number changed
		1 -> 0	
...	...	...	...
7	SN (Slave 8)	0 -> 1	Slave8: Serial number changed
		1 -> 0	

4.18.3.8.7.8 M-Bus slave serial numbers

Name:
SNData1 to SNData8

These registers contain the serial numbers of the M-Bus slaves that are accessed via the B&R interface. They are implemented acyclically and can be read using the AsIOAcc library.

Data type	Value
UDINT	0 to 4,294,967,295

4.18.3.8.8 FlatStream communication

4.18.3.8.8.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

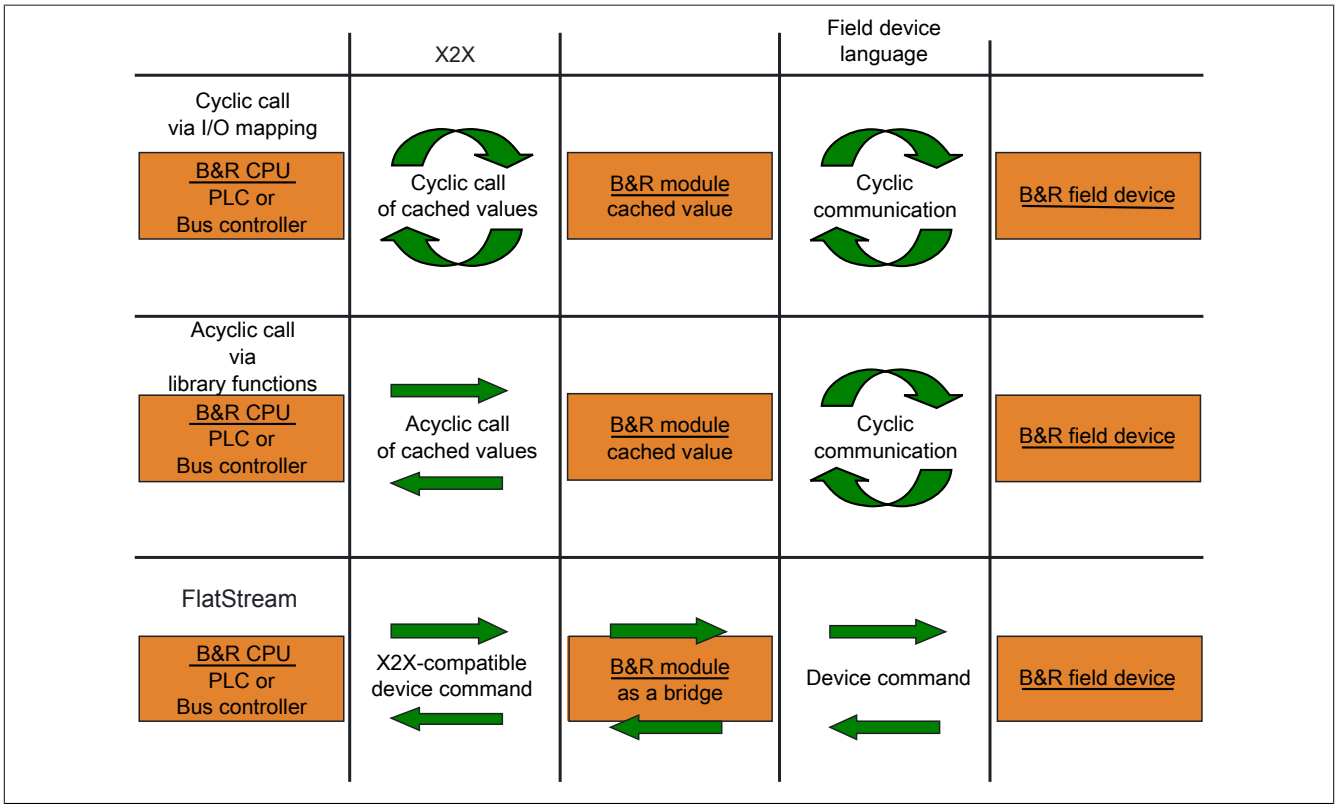

Figure 276: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.18.3.8.8.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.18.3.8.8.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

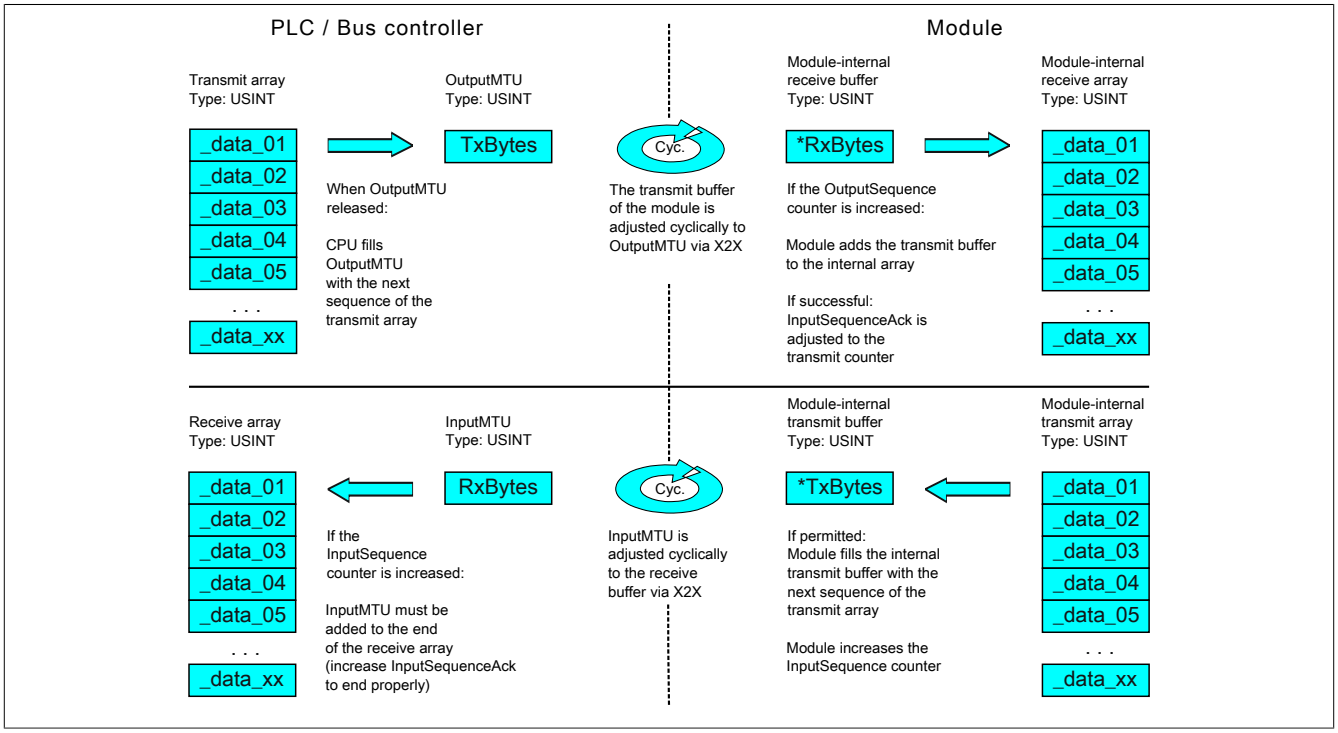

Figure 277: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.18.3.8.8.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

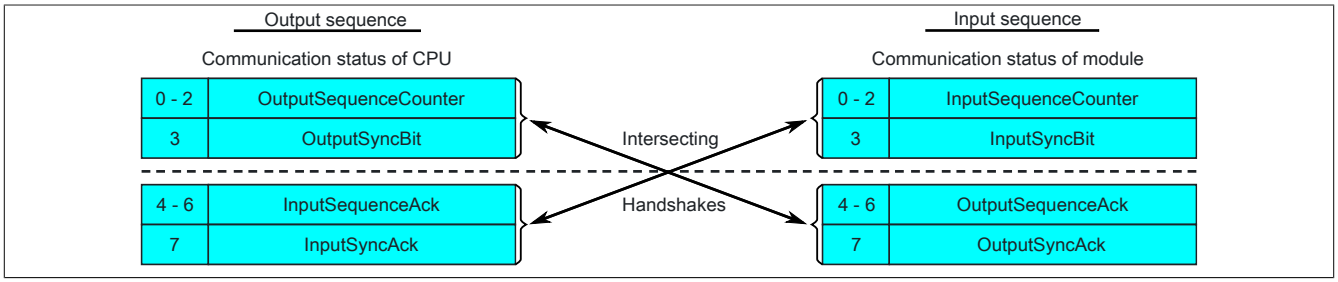

Figure 278: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

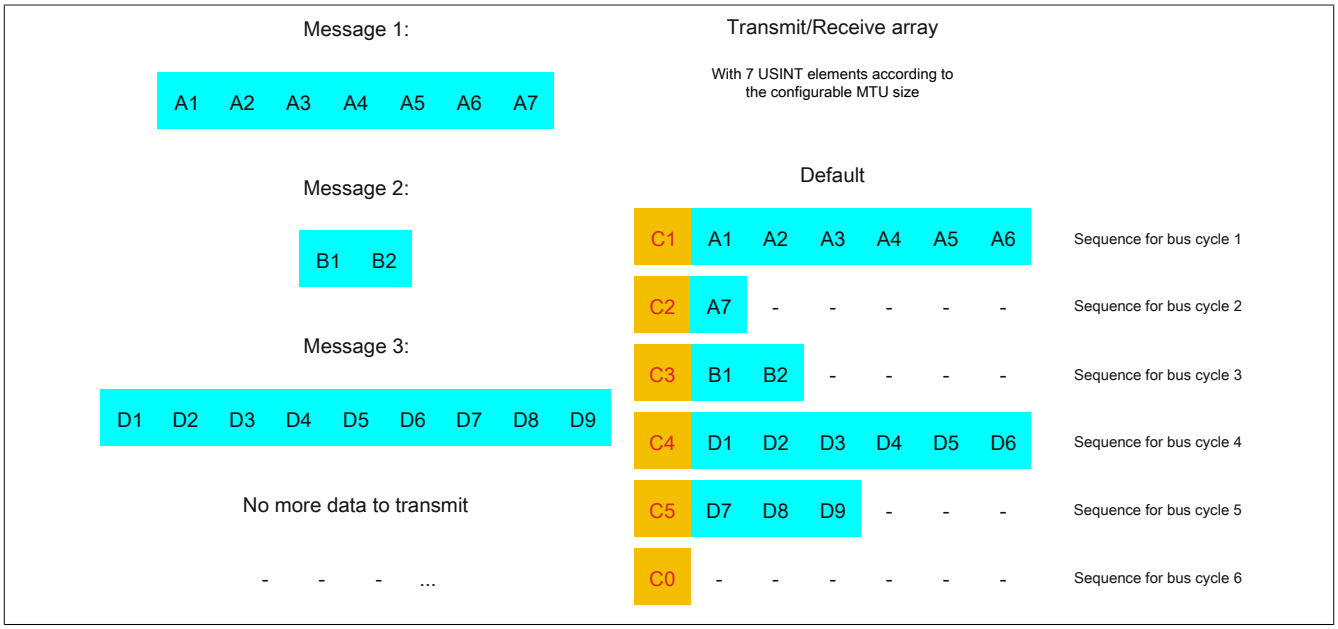

Figure 279: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 389: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 390: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

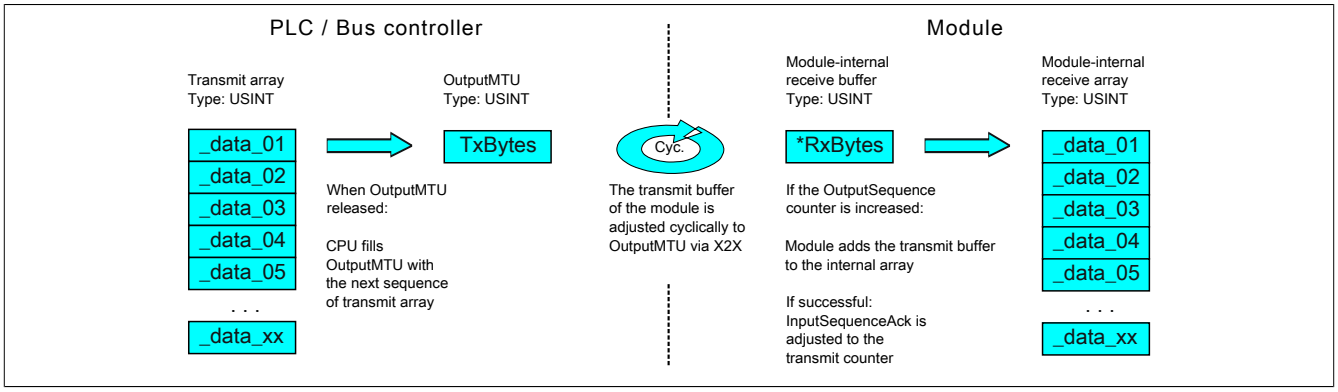

Figure 280: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

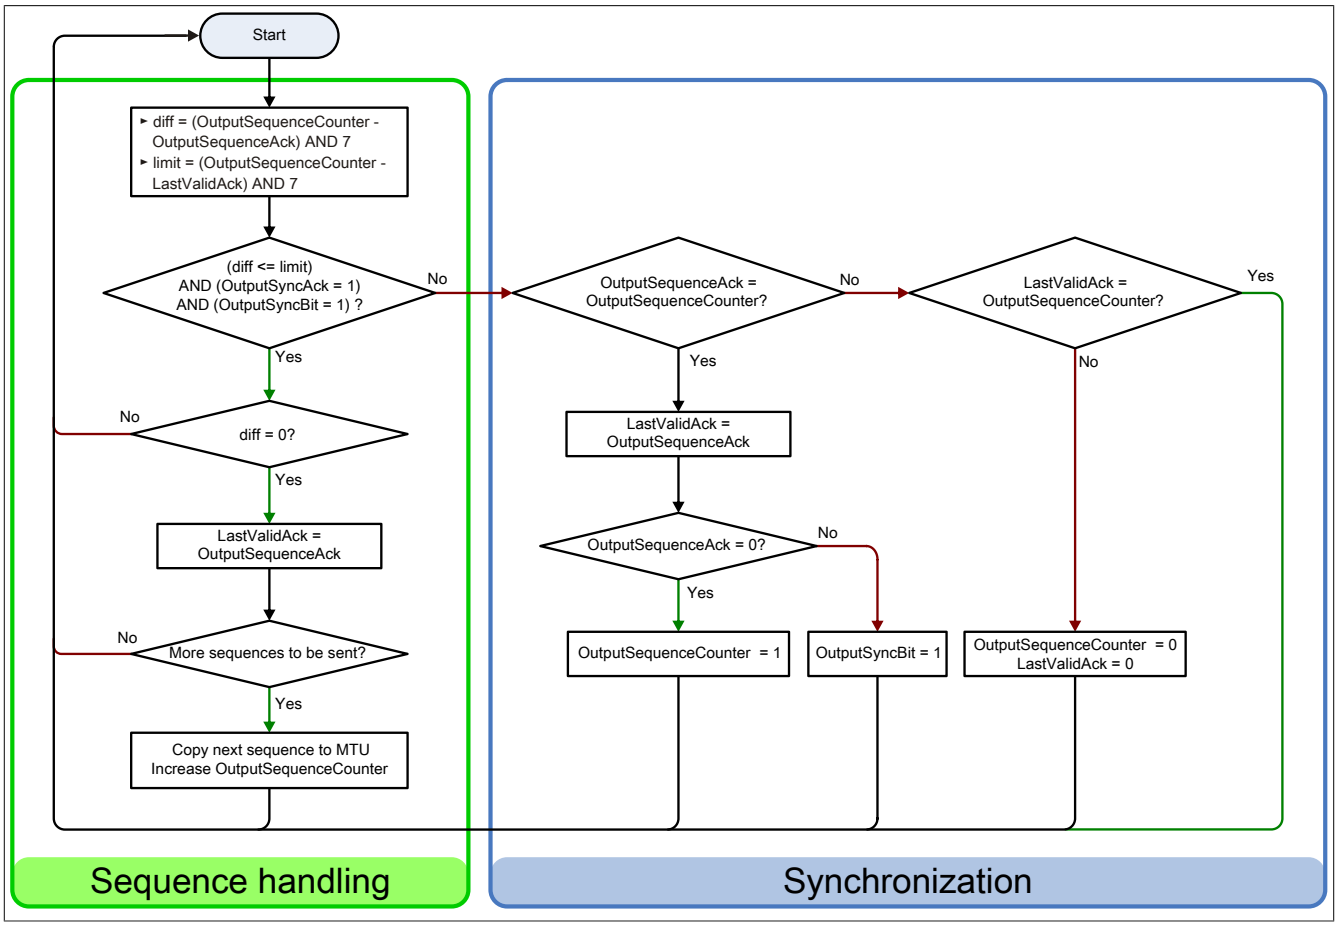

Figure 281: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

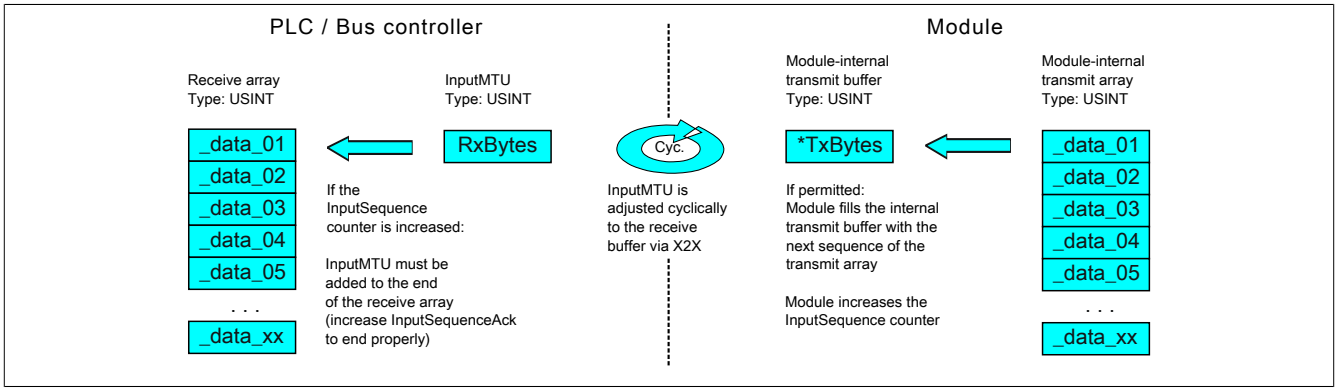

Figure 282: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

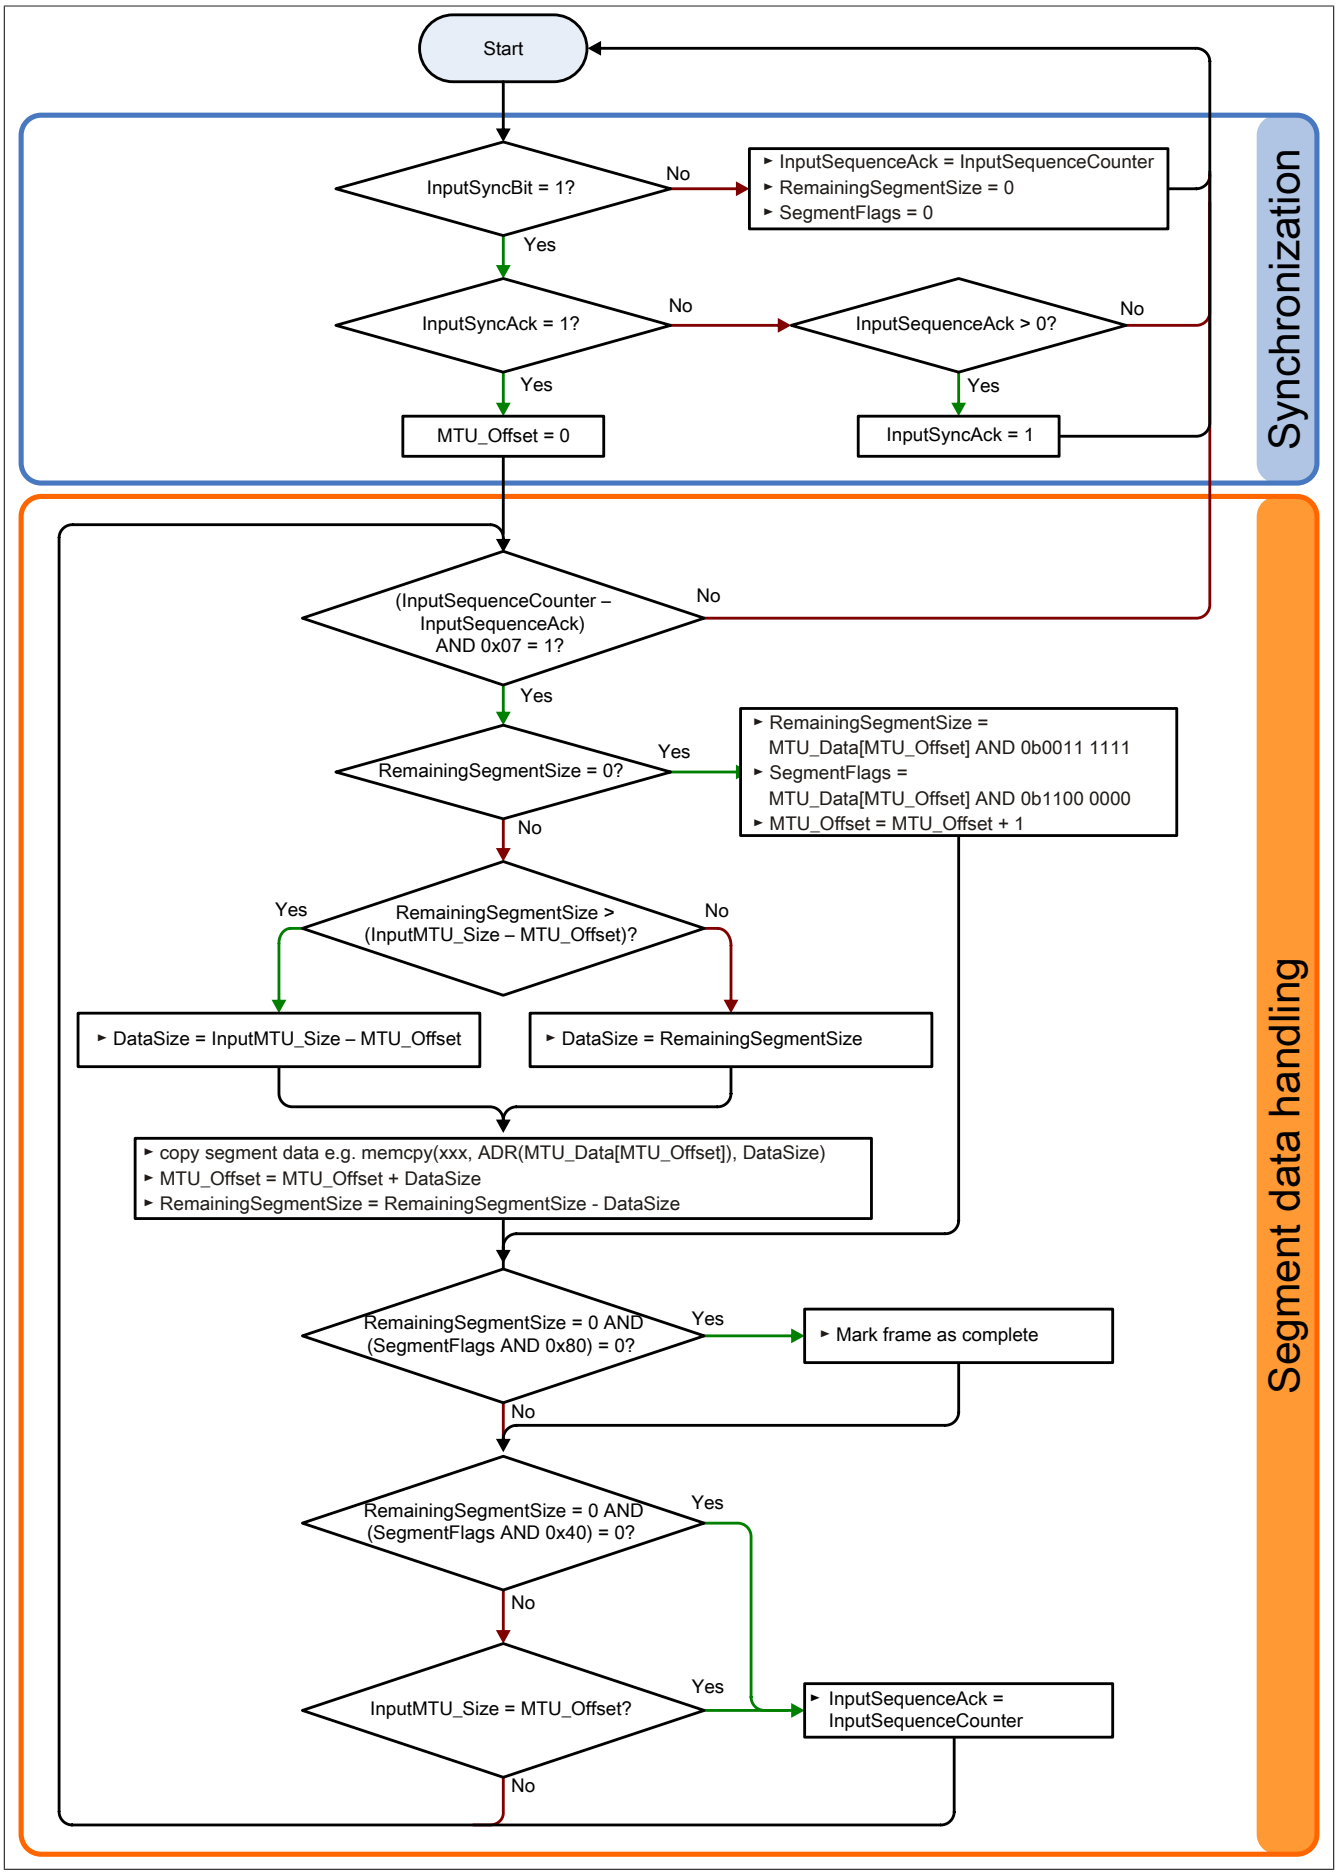

Figure 283: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

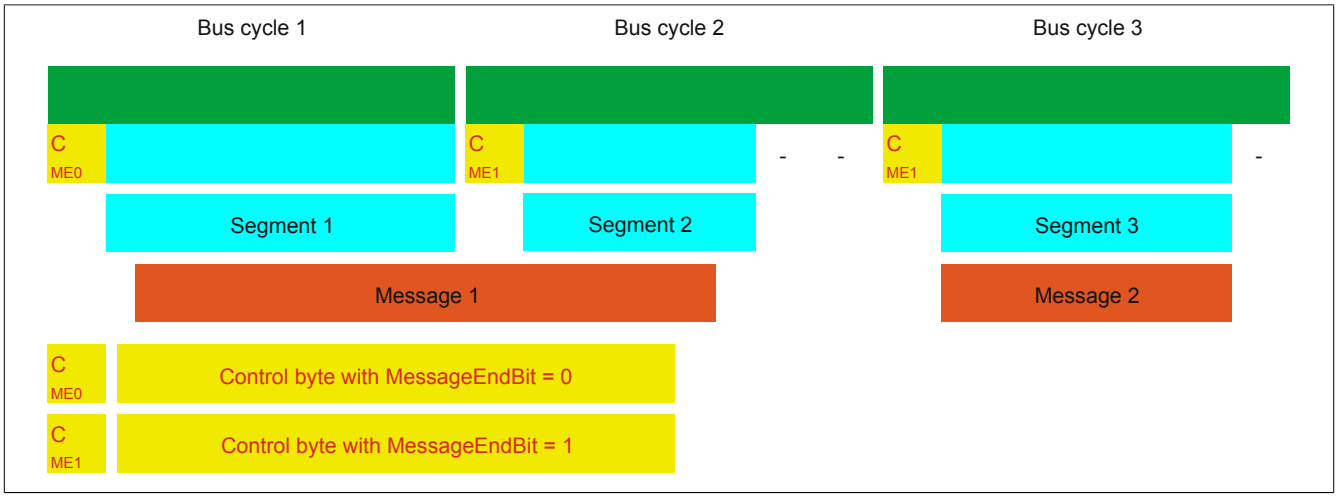

Figure 284: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

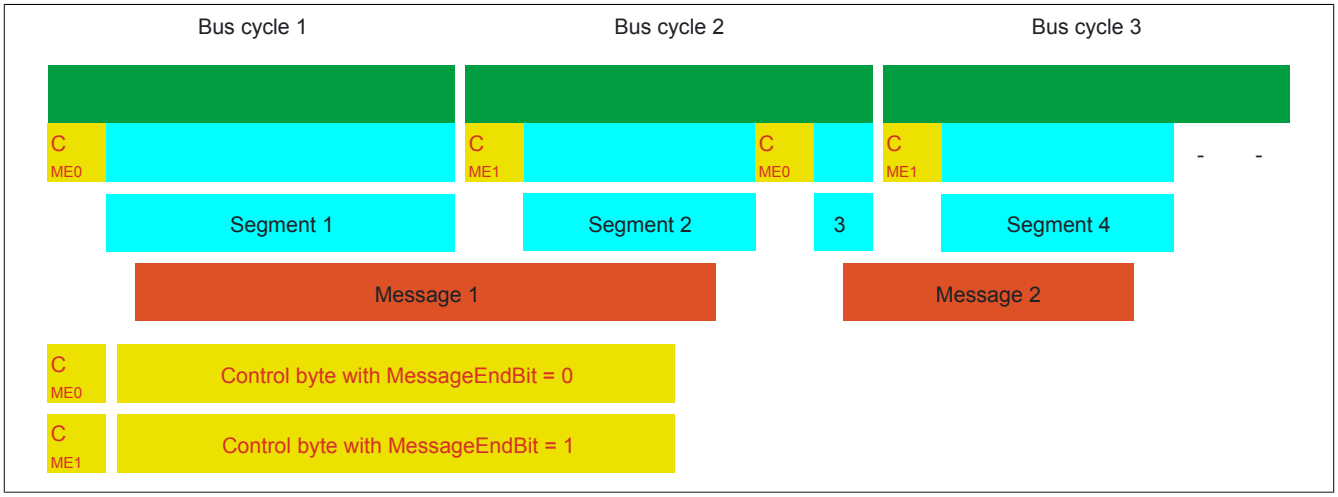

Figure 285: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

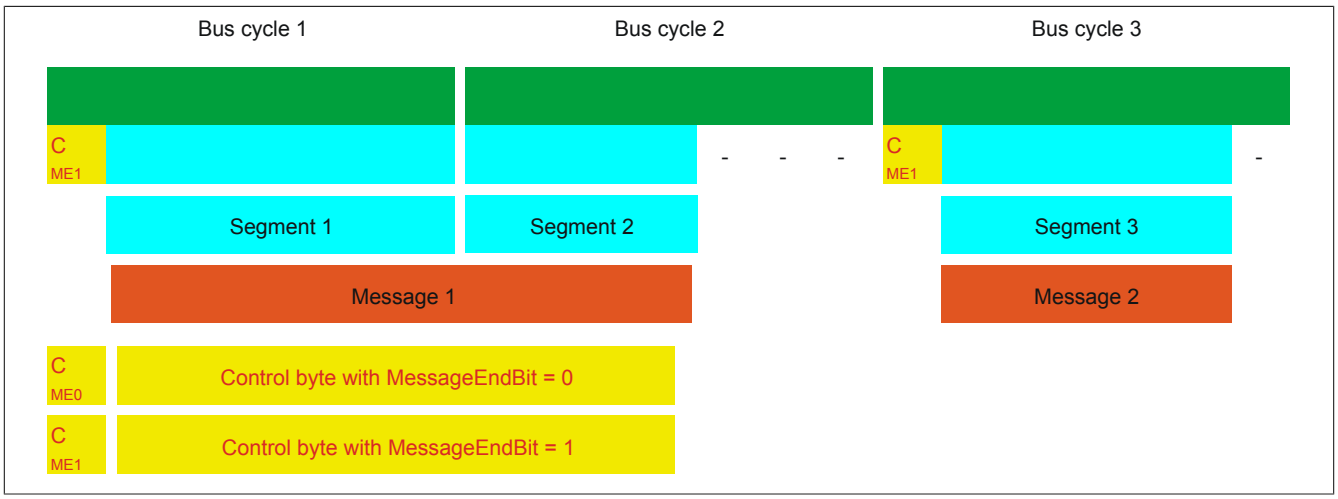

Figure 286: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

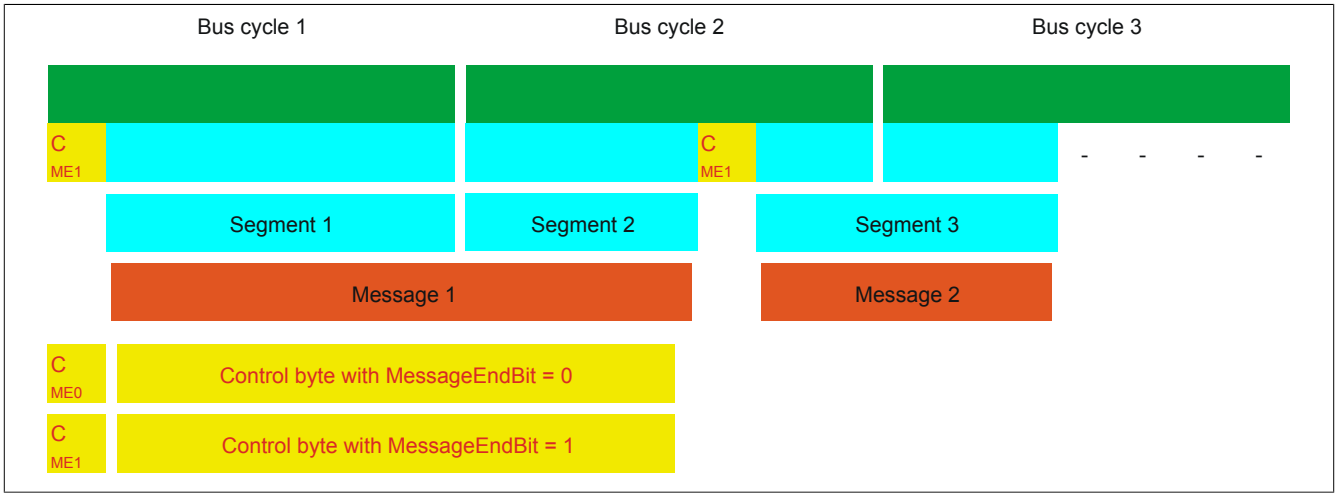

Figure 287: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

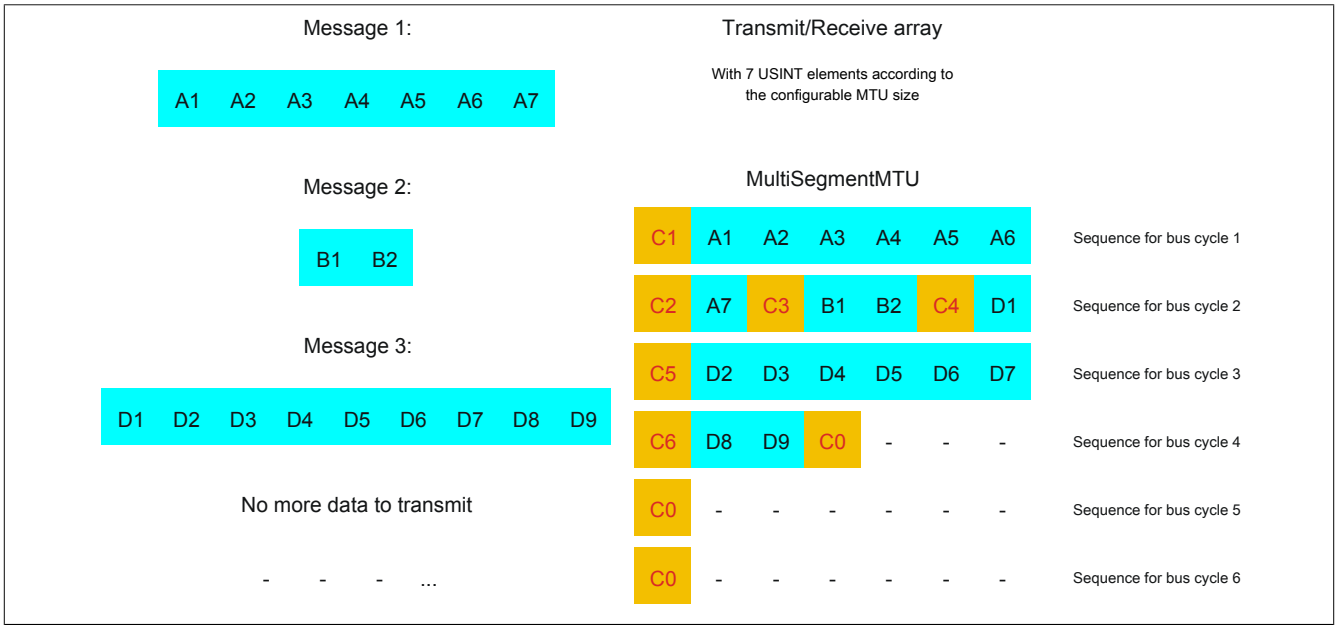

Figure 288: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 391: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 392: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

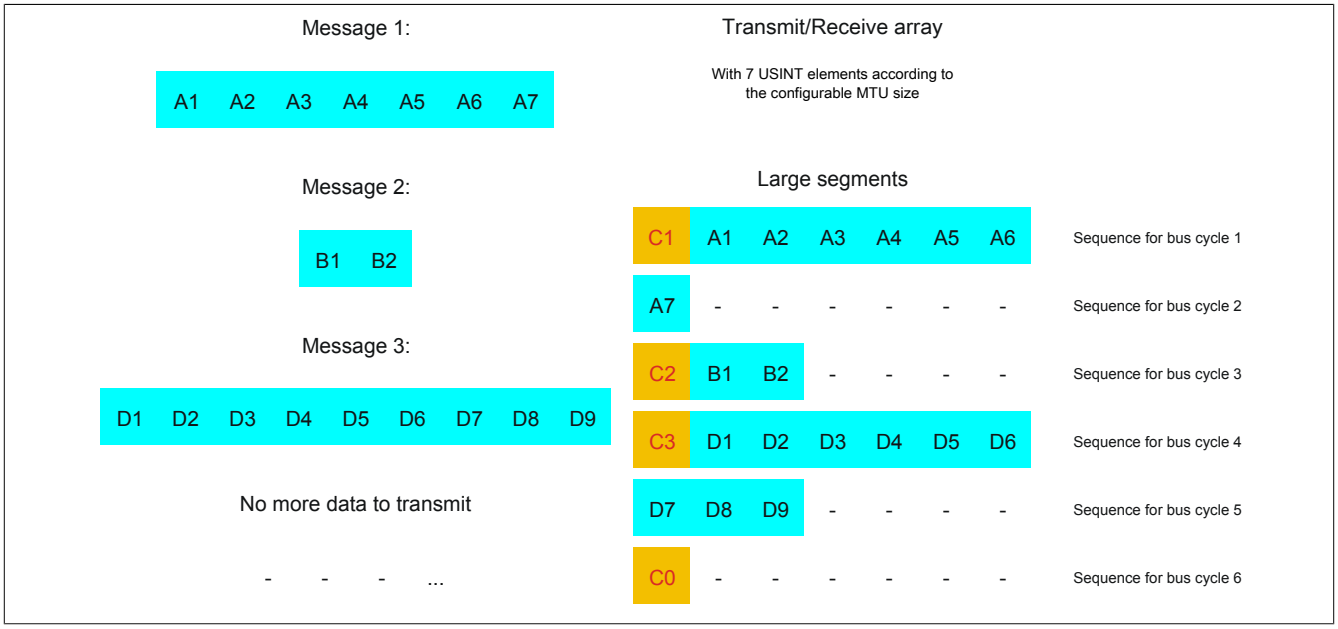

Figure 289: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 393: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

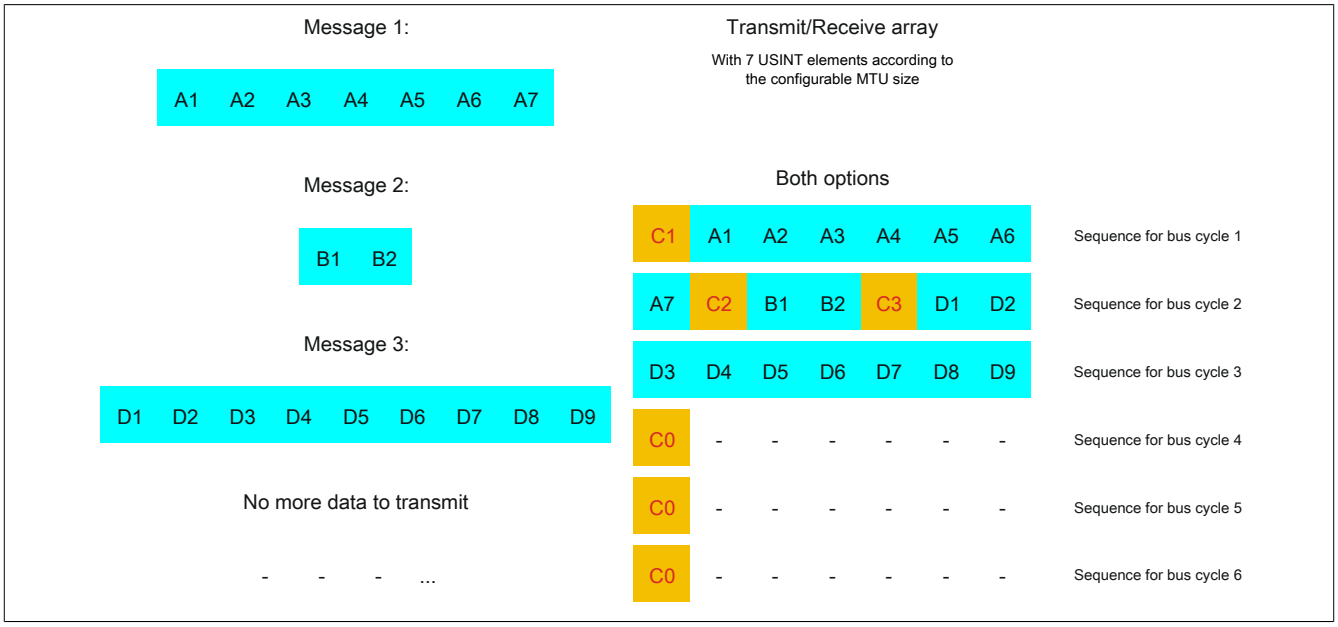

Figure 290: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 394: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.18.3.8.8.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

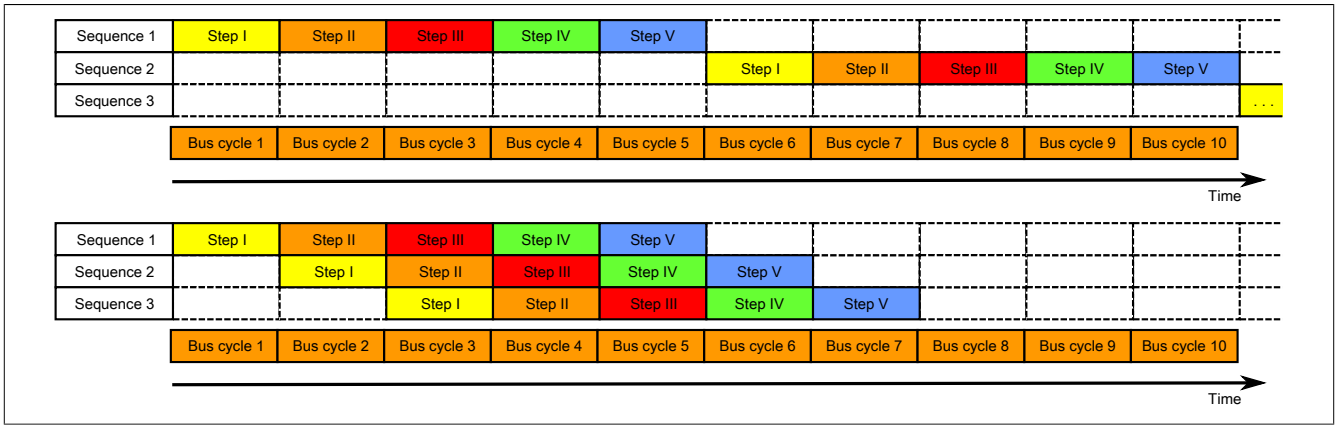

Figure 291: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

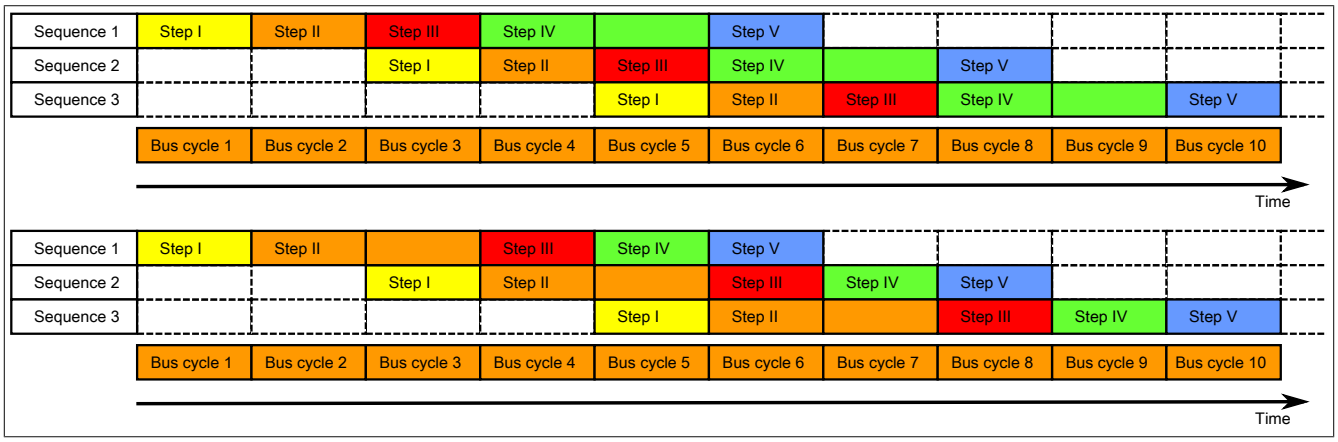

Figure 292: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

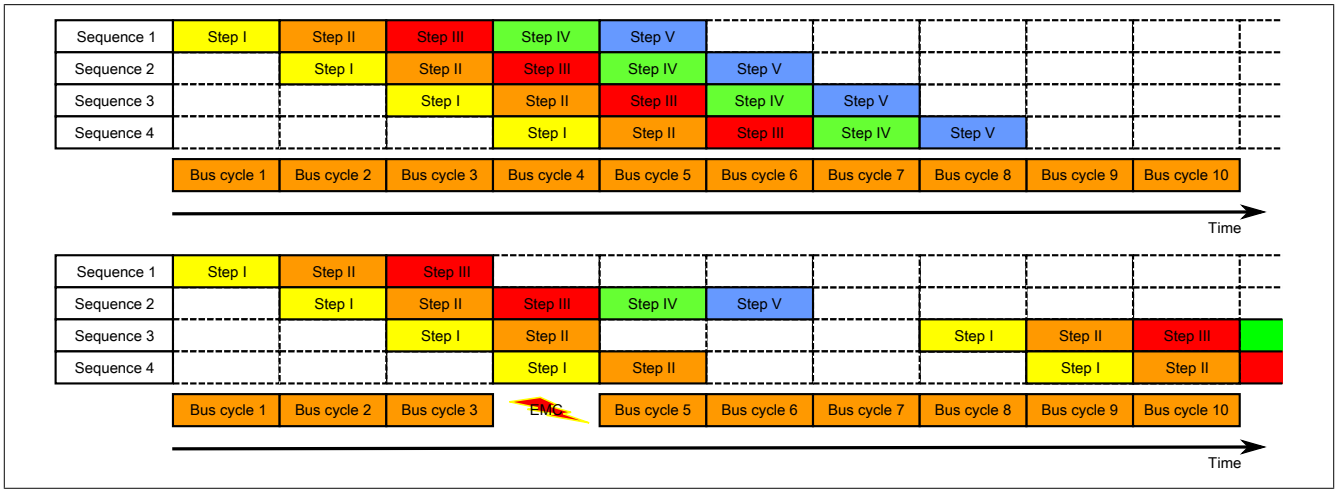

Figure 293: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.18.3.8.9 M-Bus with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for bus systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have direct access to these details.

Operation

The M-Bus specification recognizes four different frame types. From the application standpoint, only "long frames" are generated and transferred when using the M-Bus via FlatStreams. Due to the flexible design of the M-Bus protocol, the user must include the corresponding slave configuration with each request.

FlatStream structure		
In-/OutputSequence	Rx-/TxBytes	
(unchanged)	Control byte (unchanged)	M-Bus data (FlatStream)

4.18.3.8.9.1 FlatStream in output direction

FlatStream query

This standard protocol specifies that a data query via FlatStream consists of a main part and two index records. An index record is made up of an introduction containing various information and followed by a parameter block.

Introduction

The primary role of the main part is to assign a synchronization number and register the protocol type.

Note 1
When registering an undefined protocol type, the module works with the standard protocol.

Note 2
Because there is currently only one protocol type defined, the corresponding configuration bytes should be set to 1. This will allow the protocol to be expanded later without becoming incompatible with existing projects.

Bytes	Name	Value	Description
1	Frame number: For synchronization in the application	0 - 255	The frame number is repeated in the module's response. This allows the later response from the module to be distinctly attributed to the request.
2	Index Record Count "i"	2!	Number of subsequent index records
3	Protocol type	0	Native M-Bus (level converter mode) - see "Native M-Bus"
		1	Data query (raw data / parameters)
4	Reserved	1!	
...	Index record (configuration)		
...	Index record (data query)		

Native M-Bus

The "Native M-Bus" protocol type provides universal communication within the M-Bus network. It can be used to assemble and send M-Bus frames in the application.

A conventional data query is possible using a raw data or parameter query.

Index record 0

Configuration block

The interface parameters for defining the module's behavior in the M-Bus network must be chosen configuration part.

Information:

With the standard protocol, the index record must be resent with each request for configuration.

Introduction

Bytes	Name	Value	Description
1	Index record type	0!	Module interface configuration
2	Counter (config parameter)	5!	Number of subsequent M-Bus parameters
3	Length of parameter block - Low	19!	Length of index record description
4	Length of parameter block - High	0!	Length of index record description

Parameter block

Configuration parameter 0 - Addressing type

Bytes	Name	Value	Description
1	Parameter number	0!	
2	Length	1!	
3	Addressing type	1	Addressing via primary address
		2	Addressing via secondary address

Configuration parameter 1 - Address

Bytes	Name	Value	Description
4	Parameter number	1!	
5	Length	4!	
6	Address - LowLow	1 - 255	Primary address
7	Address - LowHigh	0 - 255	0!, if primary addressing
8	Address - HighLow	0 - 255	0!, if primary addressing
9	Address - HighHigh	0 - 255	0!, if primary addressing

Configuration parameter 2 - Transfer rate

Bytes	Name	Value	Description
10	Parameter number	2!	
11	Length	2!	
12	Transfer rate Low	0 - 255	Verified transfer rates 300 bit/s, 2400 bit/s, 9600 bit/s
13	Transfer rate High	0 - 255	

Configuration parameter 3 - Timeout offset

Bytes	Name	Value	Description
14	Parameter number	3!	
15	Length	1!	
16	TimeoutOffset	0 - 255	Additional time for timeout monitoring on the M-Bus (Resolution: 10 ms)

Configuration parameter 4 - Extra frames

Bytes	Name	Value	Description
17	Parameter number	4!	
18	Length	1!	
19	M-Bus options	Bit 0 … 1	Send Init frame
		Bit 1 … 1	Send application reset
		Bit 6 … 1	Set frame count bit[1)]
		Bit 7 … 1	Request media and version

1) Some M-Bus slaves use this bit to switch to a another data set.

Index record 1

Data query block

The M-Bus parameters to be retrieved from the memory of the M-Bus slaves are requested in the request part. The user can request certain parameters from the slave or the entire slave memory.

Introduction

Bytes	Name	Value	Description
1	Index record type	1!	Data request for M-Bus slave
2	Counter (data parameter) = (d + 1)	0	• Communication via native M-Bus • Read out M-Bus raw data
		1 - 20	Number of parameters to read out
3	Length of subsequent block - Low	0 - 255	• Length of M-Bus frame to be sent • Length of parameter block • 0! with raw data query
4	Length of subsequent block - High	0 - 255	• Length of M-Bus frame to be sent • Length of parameter block • 0! with raw data query
...	Depending on request: • Native M-Bus frame • Parameter block		*Not needed if raw data query = 0*

M-Bus frame

M-Bus frame to be sent

Bytes	Name	Value	Description
1	TxByte 1	0 - 255	Byte 1 in output direction
2	TxByte 2	0 - 255	Byte 2 in output direction
n	TxByte n	0 - 255	Byte n in output direction

Parameter block

Data parameter 0

Bytes	Name	Value	Description
1	Parameter number	0!	
2	Data index	1 - 255	Data index in the M-Bus frame

Data parameter 1

Bytes	Name	Value	Description
2	Parameter number	1!	
3	Data index	1 - 255	Data index in the M-Bus frame

Data parameter d

Bytes	Name	Value	Description
...	Parameter number	d!	
...	Data index	1 - 255	Data index in the M-Bus frame

4.18.3.8.9.2 FlatStream in input direction

FlatStream response

The standard protocol has three different responses according to the request.

Response error

The error response is sent when the module receives an invalid or incomplete request.

Bytes	Name	Value	Description
1	Frame number: For synchronization in the application	0 - 255	The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request.
2	Error code - LowLow	0 - 255	See error code table
3	Error code - LowHigh	0 - 255	See error code table
4	Error code - HighLow	0 - 255	See error code table
5	Error code - HighHigh	0 - 255	See error code table
6	Additional information - LowLow	0 - 255	Optional
7	Additional information - LowHigh	0 - 255	Optional
8	Additional information - HighLow	0 - 255	Optional
9	Additional information - HighHigh	0 - 255	Optional

Error codes

Error code and name	Error description
0x11111111	An M-Bus counter not responding to a data request. This can be caused by many different things: • Counter not connected • Counter defective • Counter with selected addressing parameters not found on bus
0x22222222	This error code is sent if the secondary address is addressed and the selected counter does not respond.
0x33333333	An invalid transfer rate sent via stream will not be evaluated. An M-Bus frame is not sent, the FlatStream interface responds directly with this error code.
0x44444444	If an occur occurs when querying data on the bus, the data query is terminated and this error code returned.
0x55555555	Communication aborted due to overflow (See bit 4 in section 4.18.3.8.7.3 "M-Bus status")
0x66666666	The M-Bus frame's checksum is checked before the data is evaluated by the M-Bus counter. If it does not match up, then the error code is sent right to the CPU and processing of the received data is stopped.
0x77777777	Stream (CPU -> IOM) error. The number of parameters may be incorrect. The stream undergoes very careful examination (i.e. a stream with errors will never be used).
0x88888888	Overload during M-Bus communication
0x99999999	Communication aborted due to level converter (See bit 5 in section 4.18.3.8.7.3 "M-Bus status")
0xAAAAAAAA	It is not possible to interpret the slave data. The MBus slave being used is not compatible with the parameter query. The MBus slave must be implemented using the native MBus protocol or a raw data query.

Additional information

Additional information	Error description
0x00000001	Number of index records is lower than 2
0x00000002	Stream length doesn't match
0x00000004	Index numbers don't match
0x00000008	Incorrect number of parameters per index record
0x00000010	Index length too short
0x00000020	Incorrect parameter number for index record 0
0x00000040	Incorrect parameter length for index record 0
0x00000080	Invalid addressing type
0x00000100	Invalid address
0x00000200	Invalid transfer rate
0x00000400	Invalid TimeoutOffset
0x00000800	Invalid extra frame configuration

Response - native M-Bus

This response corresponds with a successfully transferred M-Bus frame created within the application.

Bytes	Name	Value	Description
1	Frame number: For synchronization in the application	0 - 255	The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request.
2	Reserved	0	
...	Response		

Response

Bytes	Name	Value	Description
1	RxByte 1	0 - 255	Byte 1 in input direction
2	RxByte 2	0 - 255	Byte 2 in input direction
n	RxByte n	0 - 255	Byte n in input direction

Response - Raw data

The raw data response is sent if the M-Bus slave's entire memory is requested.

Bytes	Name	Value	Description
1	Frame number: For synchronization in the application	0 - 255	The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request.
2	M-Bus status	0 - 255	Status info from M-Bus header
3	Raw data frame	0 - 255	Includes all bytes sent by the M-Bus slave.
...		0 - 255	

Response - Parameters

The parameter response is sent if one or more parameters from an M-Bus slave have been requested.

Bytes	Name	Value	Description
1	Frame number: For synchronization in the application	0 - 255	The frame number is repeated in the module's response. This allows the response from the module to be distinctly attributed to the request.
2	M-Bus status	0 - 255	Status info from M-Bus header
3	Parameter count "p"	0 - 255	Number of parameters received
4	M-Bus address	0 - 255	Primary address
5	Serial number - LowLow	0 - 255	Secondary address
6	Serial number - LowHigh	0 - 255	Secondary address
7	Serial number - HighLow	0 - 255	Secondary address
8	Serial number - HighHigh	0 - 255	Secondary address
9	VendorID – Low \ Version	0 - 255	See "MBus option (IndexRecord 0)"
10	VendorID – High \ Medium	0 - 255	See "MBus option (IndexRecord 0)"
11	Data structure (M-Bus)	1	Fixed data structure
		2	Variable data structure
...	Received parameter 1 through p		*Not needed if parameter count = 0*

Received parameter

Bytes	Name	Value	Description
1	Medium	0 - 255	Medium of subsequent counter value
2	Index	0 - 255	Index of subsequent counter value
3	Data length	1 - 8	Length of the counter value
		255	If the parameter number is invalid
4	DIF	0 - 255	0!, if fixed data structure
5	VIF	0 - 255	0!, if fixed data structure
6	Counter value	0 - 255	LowLowLowLowLowLowLowLow
...		...	...
13		0 - 255	HighHighHighHighHighHighHigh

4.18.3.8.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.3.8.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 s

4.18.4 X20CS1013

4.18.4.1 General information

The module is a DALI control device with an integrated power supply. Up to 64 operating devices can be connected.

DALI stands for Digital Addressable Lighting Interface and enables easy and safe control of light fixtures using a standardized digital operating device interface. The DALI bus conforms with IEC EN 62386 and is now supported by many electronic ballast manufacturers.

- Integrated power supply
- Up to 64 operating devices (individual addresses)
- Up to 16 groups (group addresses)
- Up to 16 scenes (scene lighting values)

Product ID	X20CS1013
Short description	
Communication module	DALI master
General information	
B&R ID code	0xDE85
Diagnostics	
Module status	Yes, with status LED and software
Bus status	Yes, with status LED and software
Power consumption	
24 VDC	Max. 2.8 W
Bus	Max. 0.25 W
Thermal loss	
24 VDC	0.6 W
Bus	0.4 W
Electrical isolation	
PLC - Terminal block	Yes
Isolation voltage	
Terminal block - PLC	510 VAC / 1 minute
PLC - Ground	510 VAC / 1 minute
Certification	
CE	Yes
Dali bus	
Insulation system	Basic insulation
No load voltage	16.5 V ±5%
Signal voltage	
Low	-6.5 V to 6.5 V (typically 0 V)
High	11.5 V to 20.5 V (typically 16 V)
Signal current	
Low	≤250 mA (internally limited)
High	≤130 mA at voltages ≥11.5 V
Transfer rate	1200 baud
Maximum number of slaves	64
Data signal slew rate (Manchester bi-phase)	
Negative edge	10 µs ≤ t_{fall} ≤ 100 µs
Positive edge	10 µs ≤ t_{rise} ≤ 100 µs
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at altitudes above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
Protection in accordance with EN 60529	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB06 or X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5 $^{+0.2}$ mm

Table 396: X20CS1013 - Technical data

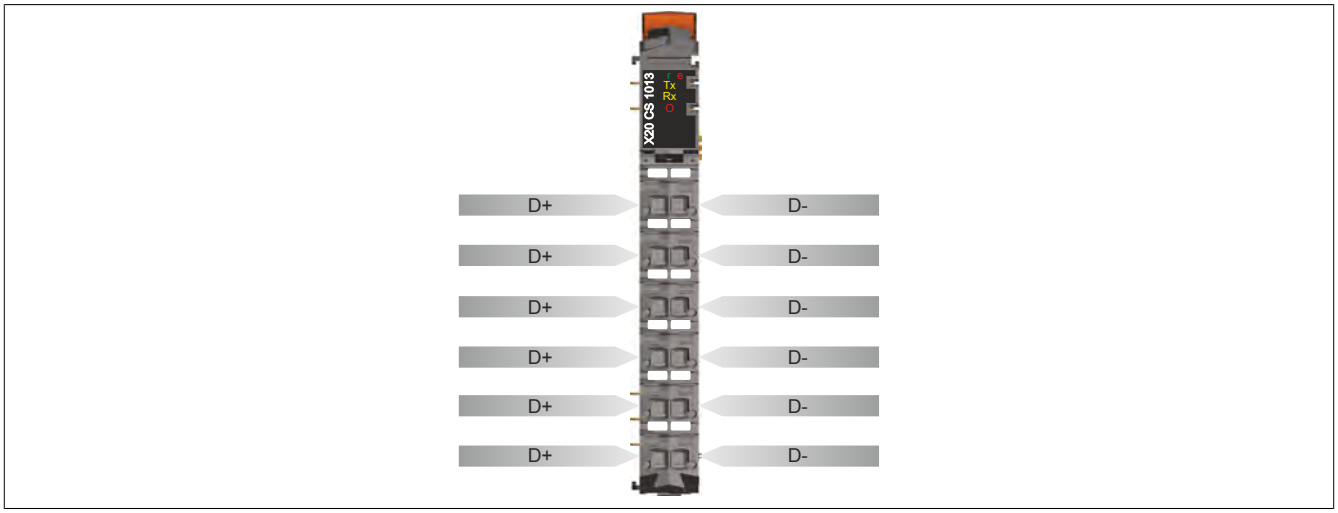
4.18.4.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			On	RUN mode
			Double flash	BOOT mode (during firmware update)[1)]
	e	Red	Off	No power to module or everything OK
			On	Error status
	Tx	Yellow		Control device (master) transmitting
	Rx	Yellow		Operating device (slave) responding
	O	Red		Error status: Overload or short circuit

1) Depending on the configuration, a firmware update can take up to several minutes.

4.18.4.5 Pinout



4.18.4.6 Using an external power supply

Since the internal DALI power supply provides sufficient power for a configuration with up to 64 slaves, the module is not designed for an external power supply.

Warning!

Using an additional DALI power supply may result in damage to the module.

4.18.4.7 Register description

4.18.4.7.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.4.7.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
258	Dali_State	UINT	•			
263	Dali_RequestCounter	USINT	•			
261	Dali_AnswerCounter	USINT	•			
265	Dali_Answer	USINT	•			
257	Dali_Enable	USINT			•	
262	Dali_Control	UINT			•	
265	Dali_Address	USINT			•	
267	Dali_Command	USINT			•	

4.18.4.7.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
258	0	Dali_State	UINT	•			
263	3	Dali_RequestCounter	USINT	•			
261	2	Dali_AnswerCounter	USINT	•			
265	4	Dali_Answer	USINT	•			
257	0	Dali_Enable	USINT			•	
262	2	Dali_Control	UINT			•	
265	4	Dali_Address	USINT			•	
267	5	Dali_Command	USINT			•	

1) The offset specifies the position of the register within the CAN object.

4.18.4.7.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.18.4.7.4 General information

DALI stands for Digital Addressable Lighting Interface and is mainly used to control lighting systems. The communication standard is intended for building automation systems and described in the IEC 62386 standard.

4.18.4.7.4.1 The DALI protocol

The DALI standard specifies bidirectional communication based on the "request and answer" principle. A DALI network may contain multiple masters. The serial asynchronous interface transmits voltage signals at a transfer rate of 1200 bits/s.
According to the DALI standard, up to 64 individual addresses can be assigned on the network. In addition, all of the slaves in the network can be addressed via broadcast and group addresses. 16 different group addresses can be assigned independently of the individual slave addresses. This makes it possible to send a command to multiple slaves at the same time.

4.18.4.7.5 DALI - Communication

The module provides the user with a channel for communicating with and controlling DALI slaves in a DALI network.

The multi-master mode described in the DALI standard is accepted by the module but not actively supported.

4.18.4.7.5.1 Communication in the DALI network

The module supports all commands defined in the DALI standard.

Communication in the DALI network takes place using the 2 bytes of the following registers:

- "Address of the DALI slave"
- "Direct or indirect command for receiver"

Some commands are described in the DALI specification with the structure "YAAA AAAS XXXX XXXX". In order to translate this representation to the B&R interface, the two registers "DALI_Address" and "DALI_Command" must be viewed with "Byte" as the unit.

Dali_Address								Dali_Command							
MSB	6	5	4	3	2	1	LSB	7	6	5	4	3	2	1	0
↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓
Y	A	A	A	A	A	A	S	X	X	X	X	X	X	X	X

Key

Y	Address type
A	Address
S	Command type
X	Command

Address of the DALI slave

Name:
Dali_Address

This register provides the module with the address of the DALI slave being addressed. It also defines the address type (single or group address) and command type (direct or indirect command).

Data type	Value	
USINT	0 to 159	Single or group address for direct or indirect command
	254	Broadcast address for direct DALI command
	255	Broadcast address for indirect DALI command

Bit structure:

Bit	Name	Value	Information
0	Type of the subsequent command	0	Direct DALI command
		1	Indirect DALI command
1 - 6	Address	0 to 63	Address of an individual slave
		0 to 15	Address of a group of slaves
7	Type of the subsequent address	0	Addressing of an individual slave
		1	Addressing of a group of slaves

Direct or indirect command for receiver

Name:
Dali_Command

This register provides the module with the direct or indirect command for the receiver in the DALI network.

Data type	Value	Information
USINT	0 to 255	DALI or slave-specific command

4.18.4.7.5.2 Status in the DALI network

Name:
Dali_State

This register is used to indicate the current status of the DALI network.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enables/Disables the level converter	0	Communication off
		1	Communication on
1	Status of the last request	0	Valid request not yet sent
		1	Transmit procedure successful
2	Status of the last response	0	No response since the last request
		1	Receive procedure successful
3	Collision (multi-master)	0	No collision
		1	Collision in the DALI network
4 - 7	Reserved	-	
8	Transmit error	0	No error
		1	Transmit procedure failed
9	Receive error	0	No error
		1	Invalid response received
10	TX busy	0	No transmission activity
		1	Transmission taking place
11	RX busy	0	No receiving activity
		1	Receiving taking place
12 - 15	Reserved	-	

4.18.4.7.5.3 Transmission counter

Name:
Dali_RequestCounter

This register provides the user with information about how many DALI messages have already been sent by the module.

Data type	Value
USINT	0 to 255

4.18.4.7.5.4 Response counter

Name:
Dali_AnswerCounter

This register provides the user with information about how many DALI messages have already been received by the module.

Data type	Value
USINT	0 to 255

4.18.4.7.5.5 Response from DALI network

Name:
Dali_Answer

This register provides the user with access to the last valid response from the downstream DALI network.

Data type	Value
USINT	0 to 255

4.18.4.7.5.6 Enabling the communication channel

Name:
Dali_Enable

This register is used to enable or disable the communication channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Turn communication on/off (via software)	0	Turn communication channel off
		1	Turn communication channel on
1	Turn power saving mode on/off	0	Supply DALI network
		1	Turn internal power supply for the module off
2 - 7	Reserved	-	

Information:

for communication in the DALI network, the internal power supply in the module must be turned on.

4.18.4.7.5.7 Controlling the DALI module

Name:
Dali_Control

This register is used to control the module. The respective command is transported via X2X Link and then executed by the module. The register is edge-triggered (i.e. this type of command is only triggered if the state of the respective bit changes).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Requests command (pos. edge)	0	No action
		1	Transmits request in the DALI network
1	Reserved	-	
2	Acknowledges the status byte (pos. edge)	0	No action
		1	Resets the status byte
3	Acknowledges the transmission counter (pos. edge)	0	No action
		1	Resets the transmission counter
4	Acknowledges the response counter (pos. edge)	0	No action
		1	Resets the response counter
5 - 15	Reserved	-	

4.18.4.7.6 Excerpt from the DALI specification

4.18.4.7.6.1 General

The DALI standard involves 2 different command types. Direct commands control the brightness of the lights on the DALI slave being addressed. This type of communication runs only from the master to the slave.

Setting the LSB in the address register will use the included command for independent digital communication. The commands are also transferred from the master to the slave. Some requests require a response from the slave. In this case, communication from the slave to the master must also be possible.

4.18.4.7.6.2 Direct DALI commands (ARC)

These commands can be used to directly set the brightness of each DALI slave. The statements 1 to 254 correspond to a brightness of the connected DALI slave based on the following formula:

$$P = 10^{\frac{Value - 1}{253 / 3}} * \frac{P_{max}}{1000}$$

Command 0 can also be transmitted to switch off a DALI slave. In this case, the brightness decreases slowly at first and then shuts off when a critical power level is crossed.

Command 255 serves as an internal mask value. It is not applied by the DALI slave, which means it has no effect on its behavior.

4.18.4.7.6.3 Indirect DALI commands for lamp wattage

Indirect commands make digital communication possible on the DALI network. In addition to the commands defined in the DALI standard, some manufacturers of DALI slaves also define their own commands.

Selected standardized DALI commands

Source: EN 62386-102:2009

Code (dec.)	Function
Indirect control commands	
0	Switches off the light immediately – No smooth transition
1	200 ms dimming up – Possible to configure the dimming speed separately – No further change once maximum is reached – Command ignored when light is off
2	200 ms dimming down – Possible to configure the dimming speed separately – No further change once minimum is reached – Command does not turn light off
3	Increases the brightness by one step – No smooth transition – No further change once maximum is reached – Command ignored when light is off
4	Decreases the brightness by one step – No smooth transition – No further change once minimum is reached – Command does not turn light off
5	Maximum brightness – No smooth transition – Turns the light on
6	Minimum brightness – No smooth transition – Turns the light on
7	Decrease brightness by one step (including switching off) – No smooth transition – Command can turn light off
8	Increase brightness by one step (including switching on) – No smooth transition – Turns the light on
9	Commence DACP sequence – Starts direct power control – Dimming speed adjusted dynamically by the control device – DACP sequence required at the end
10 - 15	Reserved
16 - 31	Enables scene 0 to 15 – Power regulated to the level stored in the scene

4.18.4.7.6.4 Indirect DALI commands for configuration

Indirect commands make digital communication possible on the DALI network. In addition to the commands defined in the DALI standard, some manufacturers of DALI slaves also define their own commands.

Information:

Some indirect DALI commands must be repeated within 100 ms. The module does not evaluate specified addresses and commands, which means this repetition must be ensured by the application.

Selected standardized DALI commands

Source: EN 62386-102:2009

Code (dec.)	Function	Response
Configuration commands[1)]		
32	Resets nonvolatile memory – DALI slave requires up to 300 ms for execution	
33	Reads out the current power level – Stores the current power value in the DTR – Command code 152 required	
34 - 41	Reserved	
Save DTR value[1)]		

Code (dec.)	Function	Response
42	Save as maximum power value	
43	Save as minimum power value	
44	Save power value as value for event of error	
45	Save power value as switch-on value	
46	Save value as dimming time	
47	Save value as dimming speed	
48 - 63	Reserved	
Used for setting system parameters[1)]		
64 - 79	Save DTR value as selected scene 0 to 15 – Scene number = Command number - 64	
80 - 95	Removes DALI slave from scene 0 to 15 – Scene number = Command number - 80	
96 - 111	Adds DALI slave to group 0 to 15 – Group number = Command number - 96	
112 - 127	Removes DALI slave from group 0 to 15 – Group number = Command number - 112	
128	Save DTR value as short address	
129 - 143	Reserved	
Request commands		
144	Checks the general status	**Bit / Value / Function** 0 / 0 / DALI slave status OK 0 / 1 / DALI slave status not OK 1 / 0 / Light status OK 1 / 1 / Light status not OK 2 / 0 / Light off 2 / 1 / Light on 3 / 0 / Last requested power level permissible 3 / 1 / Last requested power level not permissible 4 / 0 / Last dimming procedure complete 4 / 1 / Dimming procedure not yet complete 5 / 0 / DALI slave not in reset state 5 / 1 / DALI slave in reset state 6 / 0 / DALI slave has short address 6 / 1 / DALI slave has no short address 7 / 0 / Reset or control command not yet received by DALI slave 7 / 1 / Reset or control command received by DALI slave
145	Checks communication readiness	Yes/No
146	Checks for light failure	Yes/No
147	Checks whether light is currently on	Yes/No
148	Checks whether the last requested power value was applied	Yes/No
149	Checks whether the DALI slave is in reset state	Yes/No
150	Checks whether the DALI slave has a short address	Yes/No
151	Checks whether the DALI slave has a version number	The response depends on the DALI slave: • Yes/No (DALI slave has a version number or not) • Version number
152	Checks the DTR value	DTR value
153	Checks the device type	DALI-specific code for categorizing DALI slaves
154	Checks the physical minimum level (greater than 0)	Value of physical minimum level
155	Checks for power failure	Yes/No
156 - 159	Reserved	
160	Checks the current power level	Current power level or 255 if the light is being warmed up
161	Checks the maximum value	Maximum value
162	Checks the minimum value	Minimum value
163	Checks the switch-on power level	Switch-on power level
164	Checks the power level in the event of error	Power level in the event of error
165	Checks the dimming time and dimming speed	**Bit / Function** 0 - 3 / Dimming speed 4 - 7 / Dimming time
166 - 175	Reserved	
176 - 191	Checks the light level for scene 0 to 15	
192	Checks whether the DALI slave member is part of group 0 to 7	**Bit / Value / Function** 0 / 0 / Slave not in group 0 0 / 1 / Slave in group 0 ... / / 7 / 0 / Slave not in group 7 7 / 1 / Slave in group 7

<table>
<tr><th>Code (dec.)</th><th>Function</th><th>Response</th></tr>
<tr><td>193</td><td>Checks whether the DALI slave member is part of group 8 to 15</td><td>
<table>
<tr><th>Bit</th><th>Val-ue</th><th>Function</th></tr>
<tr><td rowspan="2">0</td><td>0</td><td>Slave not in group 8</td></tr>
<tr><td>1</td><td>Slave in group 8</td></tr>
<tr><td>...</td><td></td><td></td></tr>
<tr><td rowspan="2">7</td><td>0</td><td>Slave not in group 15</td></tr>
<tr><td>1</td><td>Slave in group 15</td></tr>

<tr><td>224 - 255</td><td>Checks application-specific defined commands</td><td></td></tr>
</table>

1) Any command in the range 32 to 129 must be repeated within the next 100 ms. No other commands can be transmitted to the DALI slave being addressed during this time.

4.18.4.7.6.5 DALI special commands

In the DALI standard, special commands are described as a bit structure represented by the arrangement YAAAAAAS XXXXXXXX (see also section 4.18.4.7.5.1 "Communication in the DALI network"). This chapter contains information about he most important special commands from the DALI specification.

Leave special modes

TERMINATE

YAAAAAAS XXXXXXXX 10100001 00000000

Switches all DALI slaves on the bus in normal mode

Write DTR

DATA TRANSFER REGISTER (DTR)

YAAAAAAS XXXXXXXX 10100011 xxxxxxxx

Writes the bit pattern xxxxxxxx to the Data Transfer Register (DTR)

Special addressing for address assignment

INITIALISE

YAAAAAAS XXXXXXXX 10100101 xxxxxxxx

Allows commands for special addressing within the next 15 minutes.

Information:

- **The command must be sent twice within 100 ms.**
- **"TERMINATE" can be used to exit initialization early.**
  Reinitializing (before the 15 minutes is completed) extends initialization by a further 15 minutes.

RANDOMISE

YAAAAAAS XXXXXXXX 10100111 00000000

Information:

The command must be sent twice within 100 ms.

SEARCHADDRH
SEARCHADDRM
SEARCHADDRL

YAAAAAAS XXXXXXXX 10110001 hhhhhhhh
10110011 mmmmmmmm
10110101 llllllll

"hhhhhhhh", "mmmmmmmm" and "llllllll" represent the currently "selected" 24-bit address in the DALI network.

COMPARE

YAAAAAAS XXXXXXXX 10101001 00000000

All slaves in the DALI network with a 24-bit address less than or equal to hhhhhhhh mmmmmmmm llllllll respond with YES. By repeatedly assigning new search addresses and using "COMPARE", it is possible to select the currently initialized slave with the smallest 24-bit address.

PROGRAM SHORT ADDRESS

YAAAAAAS XXXXXXXX 10110111 0aaaaaa1

The selected slave takes on the short address assigned to aaaaaa.

QUERY SHORT ADDRESS

YAAAAAAS XXXXXXXX = 10111011 00000000

The selected slave responds with its current short address. If no short address has been assigned, it responds with 255. This can be used to check the possible success of address assignment.

VERIFY SHORT ADDRESS

YAAAAAAS XXXXXXXX 10111001 0aaaaaa1

The selected slave responds with YES if the value specified on aaaaaa corresponds to its short address. This can be used to check the possible success of address assignment.

WITHDRAW

YAAAAAAS XXXXXXXX 10101011 00000000

The selected slave is excluded from the subsequent search with "COMPARE" statements but remains initialized and can be selected.

PHYSICAL SELECTION

YAAAAAAS XXXXXXXX = 10111101 00000000

The selected slave is excluded from the subsequent search with "COMPARE" statements, no longer initialized and can no longer be selected.

Additional special commands

Additional special commands can be found in the DALI standard.

4.18.4.7.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.18.4.7.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
30 ms

4.18.5 X20(c)CS1020

4.18.5.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are designed precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- RS232 interface for serial, remote connection of complex devices to the X20 system

4.18.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.18.5.3 Order data

Model number	Short description	Figure
	X20 electronics module communication	
X20CS1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s	
X20cCS1020	X20 interface module, coated, 1 RS232 interface, max. 115.2 kbit/s	
	Required accessories

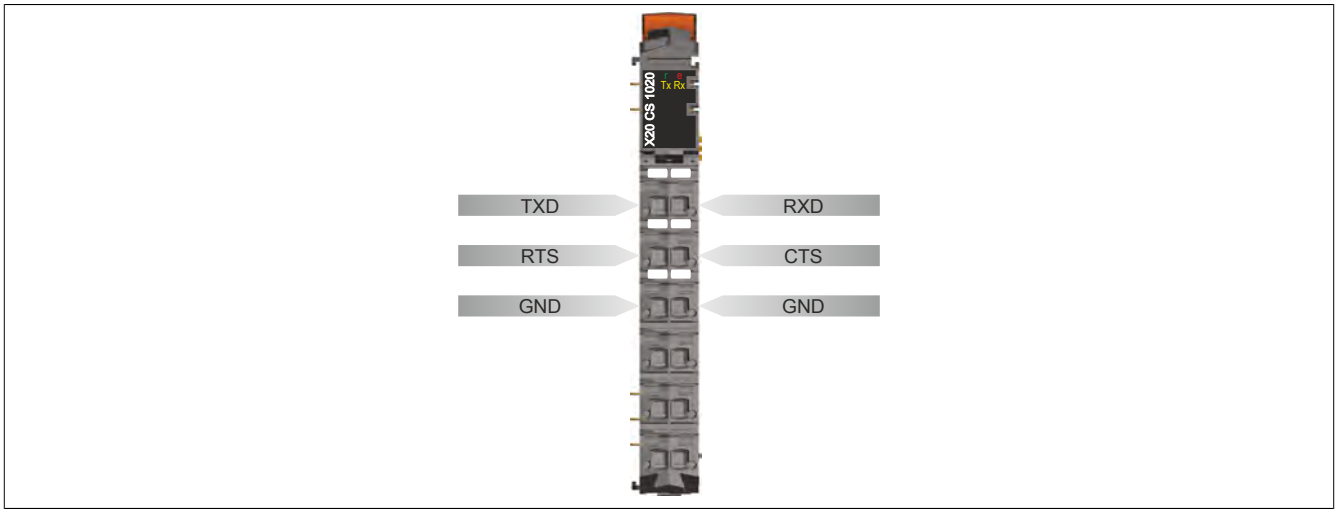
4.18.5.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	An I/O error has occurred, see 4.18.5.8.9.1 "Error message status bits"
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	Tx	Yellow	On	The module transmits data via the RS232 interface.
	Rx	Yellow	On	The module receives data via the RS232 interface.

1) Depending on the configuration, a firmware update can take up to several minutes.

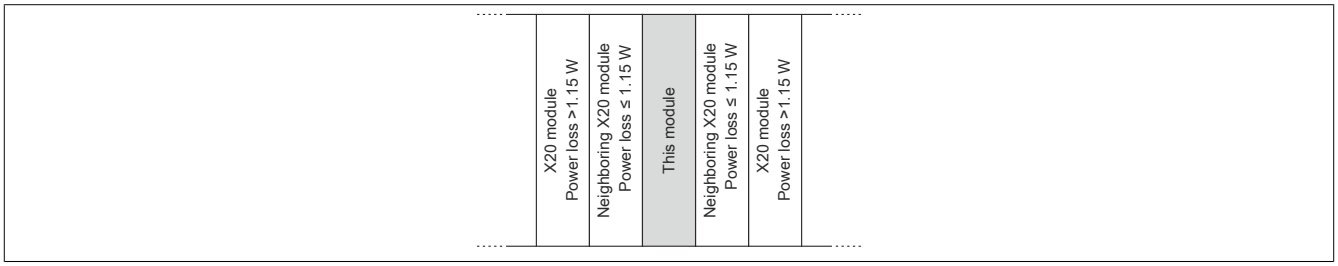
4.18.5.6 Pinout



4.18.5.7 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.18.5.8 Register description

4.18.5.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.5.8.2 Function model 2 - Stream and Function model 254 - Cyclic stream

The "Stream" and "Cyclic stream" function models use a module-specific driver for the operating system. The interface can be controlled using the "DVFrame" library and be reconfigured at runtime.

Function model - Stream

In the "Stream" function model, the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

The "Cyclic stream" function model was implemented later. From the application's point of view, there is no difference between the "Stream" and "Cyclic stream" function models. Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- **In order to use the "Stream" and "Cyclic stream" function models, you must be using B&R controllers of the type "SG4".**

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Module – Configuration						
-	AsynSize	-				
Status messages – Configuration						
50	CfO_RxStateIgnoreMask	UINT				•
6273	CfO_ErrorID0007	USINT				•

	QuitStartBitError	Bit 0				
	QuitStopBitError	Bit 1				
	QuitParityError	Bit 2				
	QuitRXoverrun	Bit 3				

4.18.5.8.3 Function model 254 - FlatStream

The "FlatStream" function model provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the module. Serial information is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see 4.3.7.10.8 "FlatStream communication").

When using the Flatstream function model, the user can choose whether to use the "AsFltGen" library in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

4.18.5.8.4 Function model 254 - Bus controller

The "Bus controller" function model is a reduced form of the "FlatStream" function model. Instead of up to 27 Tx / Rx bytes, a maximum of 7 Tx / Rx bytes can be used.

Register	Offset[1)]	Name	Data type	Read		Write

1) The offset specifies the position of the register within the CAN object.

4.18.5.8.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.18.5.8.5 Serial interface – Configuration

The user has to configure 5 registers to operate the serial interface.

4.18.5.8.5.1 Mode_IF

Name:
phyMode
phyMode_CANIO

This register is used to determine the current operating mode of the interface.

Enabling the interface is only permitted after complete configuration of the other registers. If parameters need to be changed, the interface must first be disabled.

Data type	Value	Description
USINT	0	RS232 interface disabled (default)
	2	RS232 interface enabled

4.18.5.8.5.2 Baudrate_IF

Name:
phyBaud
phyBaud_CANIO

This register is used to set the baud rate of the interface in bit/s.

Data type	Value	Description
UDINT	1200	1.2 kbaud
	2400	2.4 kbaud
	4800	4.8 kbaud
	9600	9.6 kbaud
	19200	19.2 kbaud
	38400	38.4 kbaud
	57600	57.6 kbaud
	115200	115.2 kbaud

4.18.5.8.5.3 Databit_IF

Name:
phyData
phyData_CANIO

This register is used to specify the number of bits to be transferred for each character.

Data type	Value	Description
USINT	7	7 data bits
	8	8 data bits (default)

4.18.5.8.5.4 Stoppbit_IF

Name:
phyStop
phyStop_CANIO

This register is used to define the number of stop bits.

Data type	Value	Description
USINT	2	1 stop bit (default)
	4	2 stop bits

4.18.5.8.5.5 Parity_IF

Name:
phyParity
phyParity_CANIO

This register is used to define the parity check type. Possible values are ASCII coded.

Data type	Value	Description
USINT	48	"0" - (low) bit is always 0
	49	"1" - (high) bit is always 1
	69	"E" - (even) even parity (default)
	78	"N" - (no) no bit
	79	"O" - (odd) odd parity

4.18.5.8.6 Handshake - Configuration

In order to guarantee that serial communication runs smoothly, the size of the receive buffer in the module must be known. In addition, the user can configure a software or hardware handshake algorithm.

4.18.5.8.6.1 Locking the receive buffer

Name:
rxlLock
rxlLock_CANIO

This register is used to configure the upper threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the "Lock" register value, flow control switches to the "passive" state. To return to the "active" or "ready" state, the amount of data in the receive buffer must fall under the default value of the "Unlock" register.

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of the "Lock" register must be greater than the value of the "Unlock" register.

Data type	Value	Description
UINT	0 to 4095	Upper threshold of the receive buffer (default = 1024)

4.18.5.8.6.2 Unlocking the receive buffer

Name:
rxlUnlock
rxlUnlock_CANIO

This register is used to configure the lower threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the "Lock" register value, flow control switches to the "passive" state. To return to the "active" or "ready" state, the amount of data in the receive buffer must fall under the default value of the "Unlock" register.

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of the "Lock" register must be greater than the value of the "Unlock" register.

Data type	Value	Description
UINT	0 to 4095	Lower threshold of the receive buffer (default = 512)

4.18.5.8.6.3 RTS evaluation

Name:
hshRxF
hshRxF_CANIO

These registers can be used to configure how the hardware handshake line RTS is controlled depending on the fill level of the receive buffer.

The two registers "TxF" and 'RxF" can be used to enable flow control for the input or output direction. Communication takes place here via a ring buffer.

Information:

Only one hsh register can be configured for controlling the RTS line.

Data type	Value	Description
USINT	0	RTS line freely available for other flow control methods (default)
	16	RTS line is controlled by the fill level of the receive buffer

4.18.5.8.6.4 CTS evaluation

Name:
hshTxF
hshTxF_CANIO

This register is used to configure how the CTS hardware handshake line is evaluated. Make sure wiring to the peer station is correct when CTS query is enabled.

The two registers "TxF" and 'RxF" can be used to enable flow control for the input or output direction. Communication takes place here via a ring buffer.

Data type	Value	Description
USINT	0	CTS line ignored, data can be sent at any time (default)
	1	CTS line active and is being used for flow control, transmit enable from the peer station

4.18.5.8.6.5 Turn on software handshake

Name:
hssXOn
hssXOn_CANIO

This register can be used to configure the XOn character. The value 17 is the default, but any other value can also be configured.

The two registers "XOn" and "XOff" can be used to initiate a software handshake for flow control. When doing so, a valid ASCII character must be configured in both registers.

Data type	Value	Description
UINT	0 to 255	XOn ASCII character
	65535	No software handshake (default)

4.18.5.8.6.6 Turn off software handshake

Name:
hssXOff
hssXOff_CANIO

This register can be used to configure the XOff character. The value 19 is the default, but any other value can also be configured.

The two registers "XOn" and "XOff" can be used to initiate a software handshake for flow control. When doing so, a valid ASCII character must be configured in both registers.

Data type	Value	Description
UINT	0 to 255	XOff ASCII character
	65535	No software handshake (default)

4.18.5.8.6.7 Handshake repetition

Name:
hssPeriod
hssPeriod_CANIO

When using a software handshake, some applications require periodic repetition of the current status. The repeat time can be defined in this register in ms for this purpose.

Data type	Value	Description
UINT	0	Automatic status repeat disabled
	500 to 10000	Repeat time in ms (default = 5000)

4.18.5.8.6.8 Enable handshake manually

Name:
hshSet
hshSet_CANIO

The two registers "Set" and "Clr" can be used to manually manage the handshake via the application.

These registers can be used to force the output level of the RTS hardware handshake line to remain active.

Information:

Only one hsh register can be configured for controlling the RTS line.

Data type	Value	Description
USINT	0	RTS line freely available for other flow control methods (default)
	16	RTS line enabled

4.18.5.8.6.9 Disable handshake manually

Name:
hshClr
hshClr_CANIO

The two registers "Set" and "Clr" can be used to manually manage the handshake via the application.

These registers can be used to force the output level of the RTS hardware handshake line to remain passive.

Information:

Only one hsh register can be configured for controlling the RTS line.

Data type	Value	Description
USINT	0	RTS line freely available for other flow control methods (default)
	16	RTS line disabled

4.18.5.8.6.10 Frame detection

Name:
hshFrm
hshFrm_CANIO

This register is used to generally enable hardware-based frame detection. The RTS line is enabled as long as data is being sent. This Tx-Framing mode can be used to control external interface converters.

Information:

Only one hsh register can be configured for controlling the RTS line.

Data type	Value	Description
USINT	0	RTS line freely available for other flow control methods (default)
	80	RTS line Tx-Framing switched on

4.18.5.8.6.11 Inverting RTS/CTS

Name:
hshInv
hshInv_CANIO

This register can be used to create a logical inverse of the RTS/CTS signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	RTS signal	0	Inverse off (default)
		1	Inverse on
1	CTS signal	0	Inverse off (default)
		1	Inverse on
2 - 7	Reserved	0	

4.18.5.8.7 Frame - Configuration

Different message termination codes can be specified in order to correctly create transmitted Tx frames and correctly interpret received Rx frames.

4.18.5.8.7.1 Terminating when a receive timeout occurs

Name:
rxCto
rxCto_CANIO

This register is used to set the duration until a receive timeout is triggered.

The message is considered to be terminated when nothing is transfered for the specified duration.
The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

Data type	Value	Description
UINT	0	Function disabled
	1 to 65535	Receive timeout in characters (default = 4)

4.18.5.8.7.2 Terminating when a transmit timeout occurs

Name:
txCto
txCto_CANIO

This register is used to set the duration until a transmit timeout is triggered.

The message is considered to be terminated when nothing is transfered for the specified duration.
The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

Data type	Value	Description
UINT	0	Function disabled
	1 to 65535	Transmit timeout in characters (default = 5)

4.18.5.8.7.3 Maximum number of bytes received

Name:
rxEomSize
rxEomSize_CANIO

These registers configure the maximum number of bytes in the receive frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte receive buffer. Larger frames cause the Receive Overrun error.

Data type	Value	Description
UINT	0	Function disabled
	1 to 4096	Configurable receive frame length in characters (default = 256)

4.18.5.8.7.4 Maximum number of bytes transmitted

Name:
txEomSize
txEomSize_CANIO

These registers configure the maximum number of bytes in the transmit frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte transmit buffer. The configured transmit timeout is maintained after the frame has been sent.

Data type	Value	Description
UINT	0	Function disabled
	1 to 4096	Configurable transmit frame length in characters (default = 4096)

4.18.5.8.7.5 Define receive terminator

Name:
rxEomChar0 to rxEomChar3
rxEomChar0_CANIO to rxEomChar3_CANIO

It is possible to configure a receive terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

Data type	Value	Description
UINT	0 to 255	Frame terminator (ASCII code)
	65535	Function disabled (default)

4.18.5.8.7.6 Define transmit terminator

Name:
txEomChar0 to txEomChar3
txEomChar0_CANIO to txEomChar3_CANIO

It is possible to configure a transmit terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

Data type	Value	Description
UINT	0 to 255	Frame terminator (ASCII code)
	65535	Function disabled (default)

4.18.5.8.8 Status messages - Configuration

The status messages provide the user with information about the current situation in the downstream serial network.

4.18.5.8.8.1 Error detection setting

Name:
CfO_RxStateIgnoreMask
CfO_RxStateIgnoreMask_CANIO

This register has a direct effect on UART operation. Error detection in general can be disabled using the low byte. If error detection is not disabled, the high byte can be used to specify that a detected error should be interpreted as the end of the message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Reserved	0	
4	StartBitError	0	Detecting a faulty start bit
		1	Ignore
5	StopBitError	0	Detecting a faulty stop bit
		1	Ignore
6	ParityError	0	Detecting a faulty parity bit
		1	Ignore
7	RXoverrun	0	Detecting an overflow in the receive direction
		1	Ignore
8 - 11	Reserved	0	
12	StartBitError corresponds to the end of the frame (if bit 4 = 0)	0	Only display error inside the module
		1	Also signal end of frame
13	StopBitError corresponds to the end of the frame (if bit 5 = 0)	0	Only display error inside the module
		1	Also signal end of frame
14	ParityError corresponds to the end of the frame (if bit 6 = 0)	0	Only display error inside the module
		1	Also signal end of frame
15	RXoverrun corresponds to the end of the frame (if bit 7 = 0)	0	Only display error inside the module
		1	Also signal end of frame

4.18.5.8.8.2 Forward error to the application

Name:
CfO_ErrorID0007

If the UART inside the module reports an error, this byte can be used to specify which error messages are forwarded to the application.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name		Information
0	StartBitError	0	Ignore
		1	Indicating a faulty start bit
1	StopBitError	0	Ignore
		1	Indicating a faulty stop bit
2	ParityError	0	Ignore
		1	Indicating a faulty parity bit
3	RXoverrun	0	Ignore
		1	Indicating an overflow in the receive direction
4 - 7	Reserved	0	

4.18.5.8.9 Status messages - Communication

After configuration is completed, up to four status messages can be evaluated in the application.

4.18.5.8.9.1 Error message status bits

Name:
StartBitError
StopBitError
ParityError
RXoverrun

This register is used to transfer the individual bits that indicate an error. If a error occurs, the corresponding bit is set and maintained until it is acknowledged.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StartBitError	0	No error
		1	Start bit error occurred[1)]
1	StopBitError	0	No error
		1	Stop bit error occurred[1)]
2	ParityError	0	No error
		1	Parity bit error occurred[1)]
3	RXoverrun	0	No error
		1	Receive buffer overflow occurred[2)]
4 - 7	Reserved	0	

1) This error can result from things such as mismatched interface configurations or problems with the wiring.
2) This data point reports a receive buffer overrun. The buffer capacity on the module is exhausted and all subsequent data arriving at the interface is lost. An overrun always means that the data received on the module is not read fast enough by the higher-level system.
The solution here is to optimize the cycle times of all transfer routes and task classes involved and utilize the available handshake options.

4.18.5.8.9.2 Acknowledging the status bits

Name:
QuitStartBitError
QuitStopBitError
QuitParityError
QuitRXoverrun

This register is used to transfer the individual bits that acknowledge an indicated error state. After one of the bits has been set, it can be reset using the corresponding acknowledgment bit.
If the error is still actively pending, the error status bit is not deleted. The acknowledgment bit can only be reset if the error status bit is no longer set.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	QuitStartBitError	0	No acknowledgment
		1	Acknowledge start bit error
1	QuitStopBitError	0	No acknowledgment
		1	Acknowledge stop bit error
2	QuitParityError	0	No acknowledgment
		1	Acknowledge parity bit error
3	QuitRXoverrun	0	No acknowledgment
		1	Acknowledge receive buffer overflow error
4 - 7	Reserved	0	

4.18.5.8.10 FlatStream communication

4.18.5.8.10.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

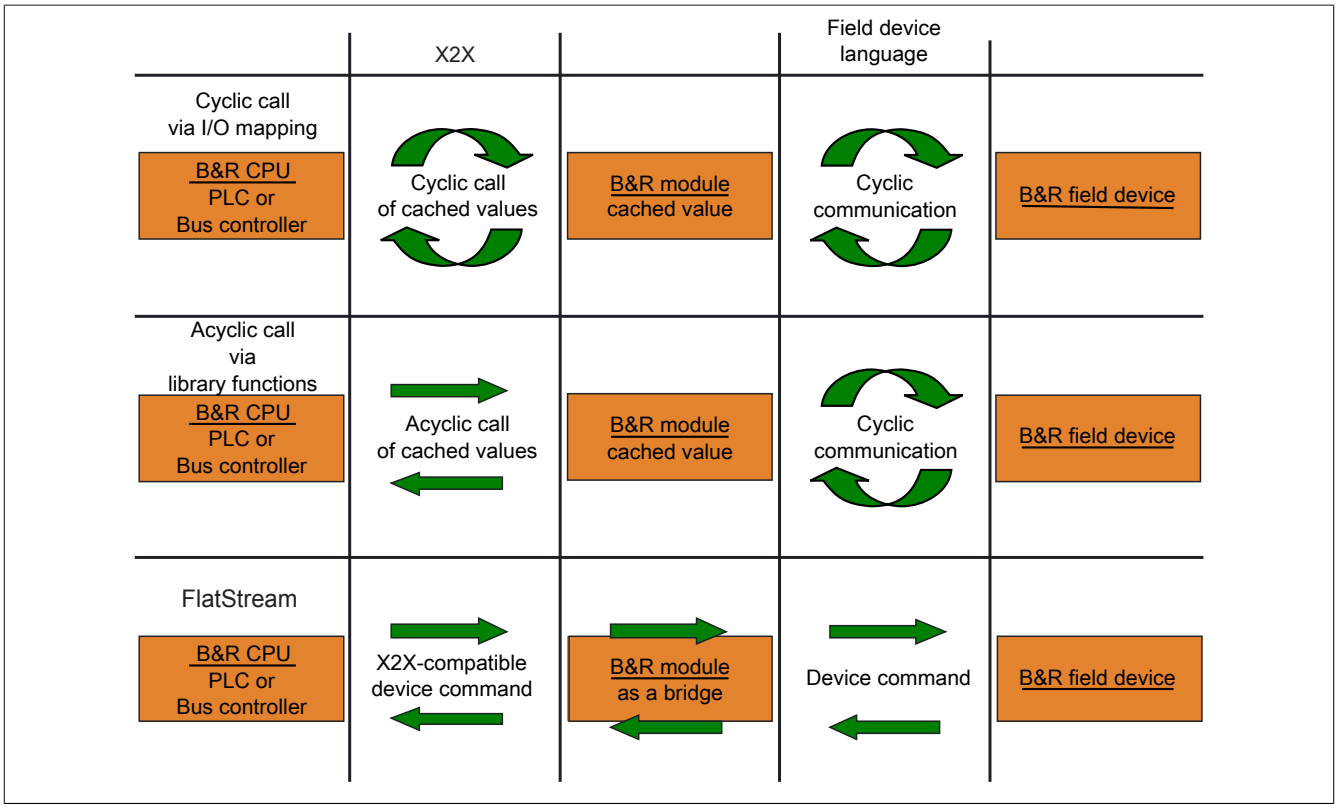

Figure 294: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.18.5.8.10.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.18.5.8.10.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

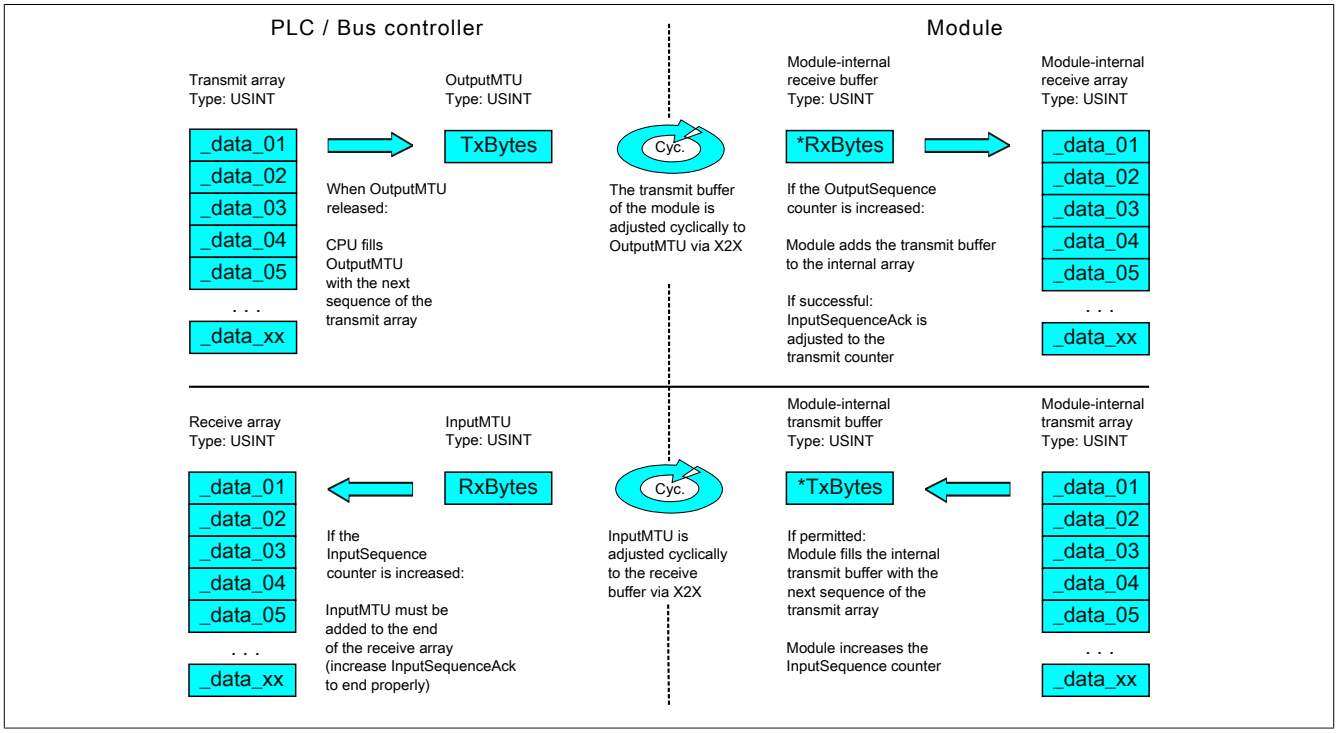

Figure 295: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.18.5.8.10.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Format of input and output bytes

Name:

"Format of Flat stream" in Automation Studio

This function sets how the Flatstream input and output bytes (Tx or Rx bytes) are transferred.

- **packed variable:** Transfers data as an array
- **byte variables:**Transfers data as individual bytes

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

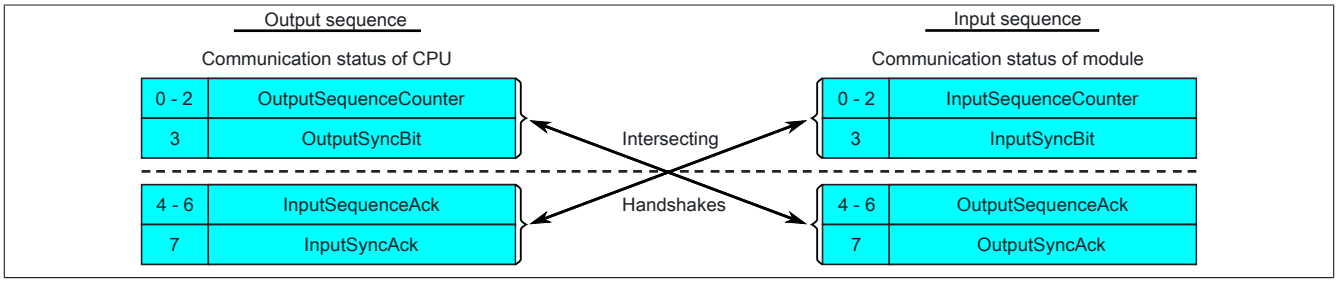

Figure 296: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

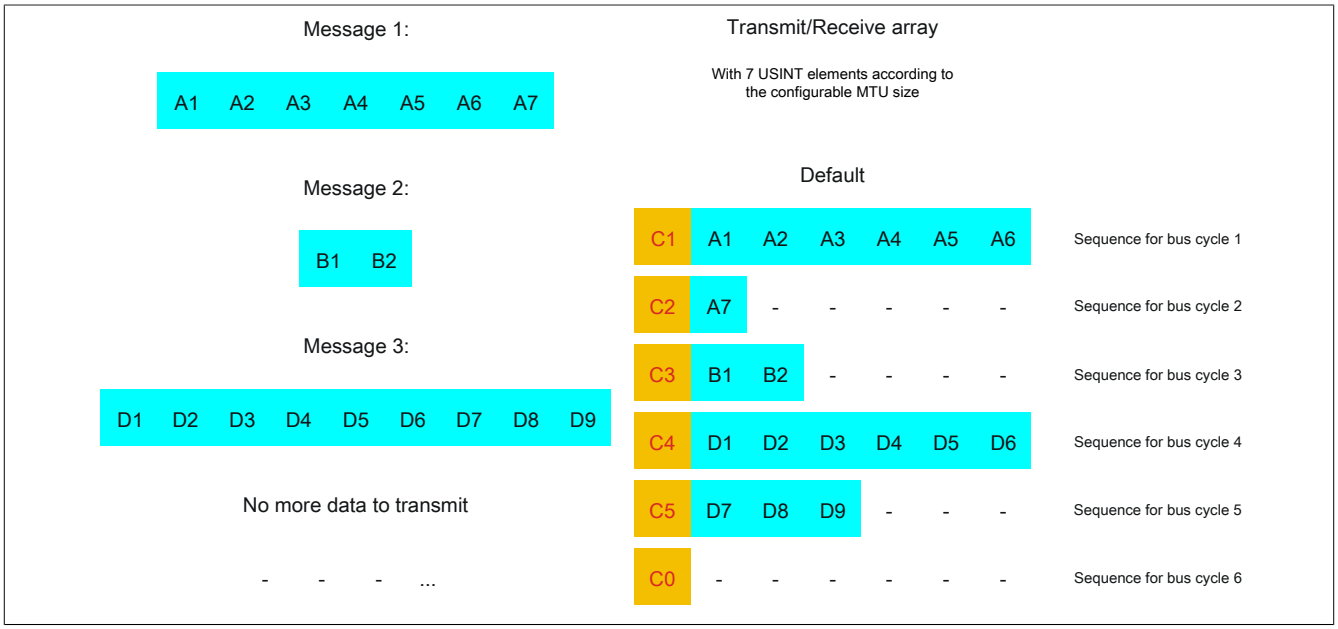

Figure 297: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 399: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 400: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

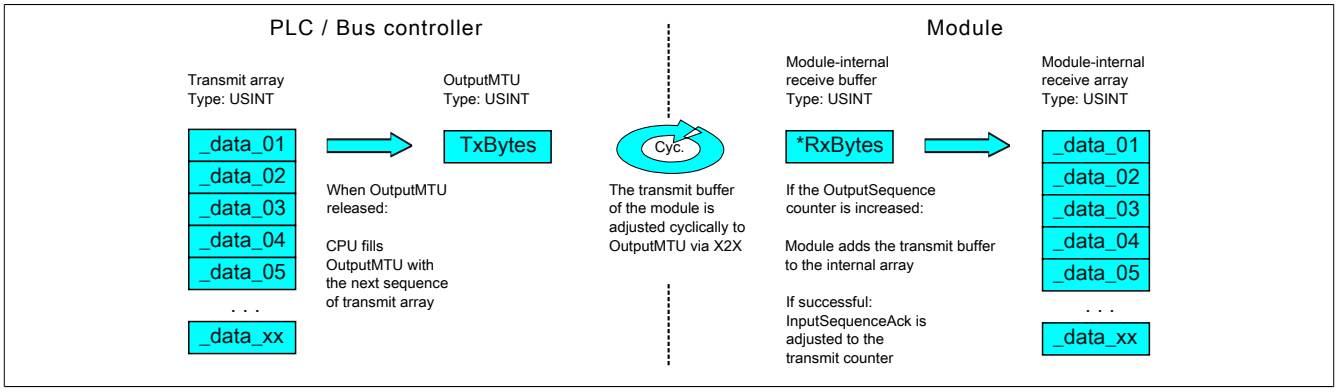

Figure 298: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

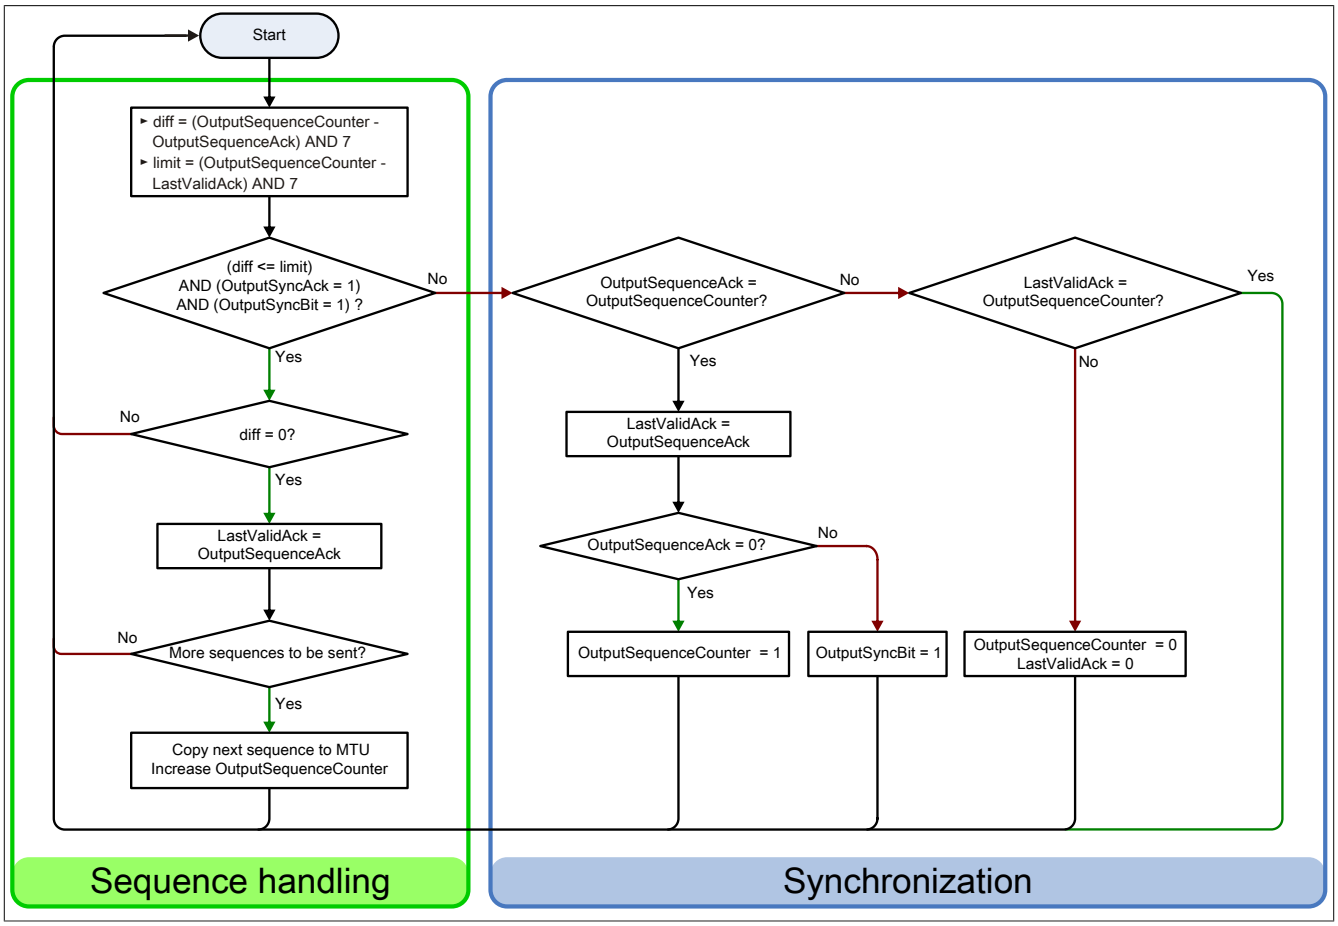

Figure 299: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

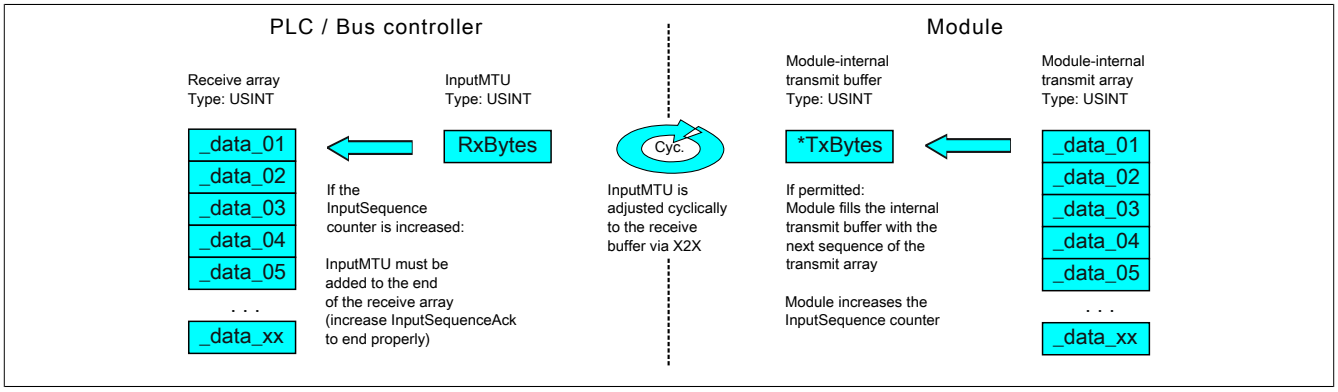

Figure 300: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

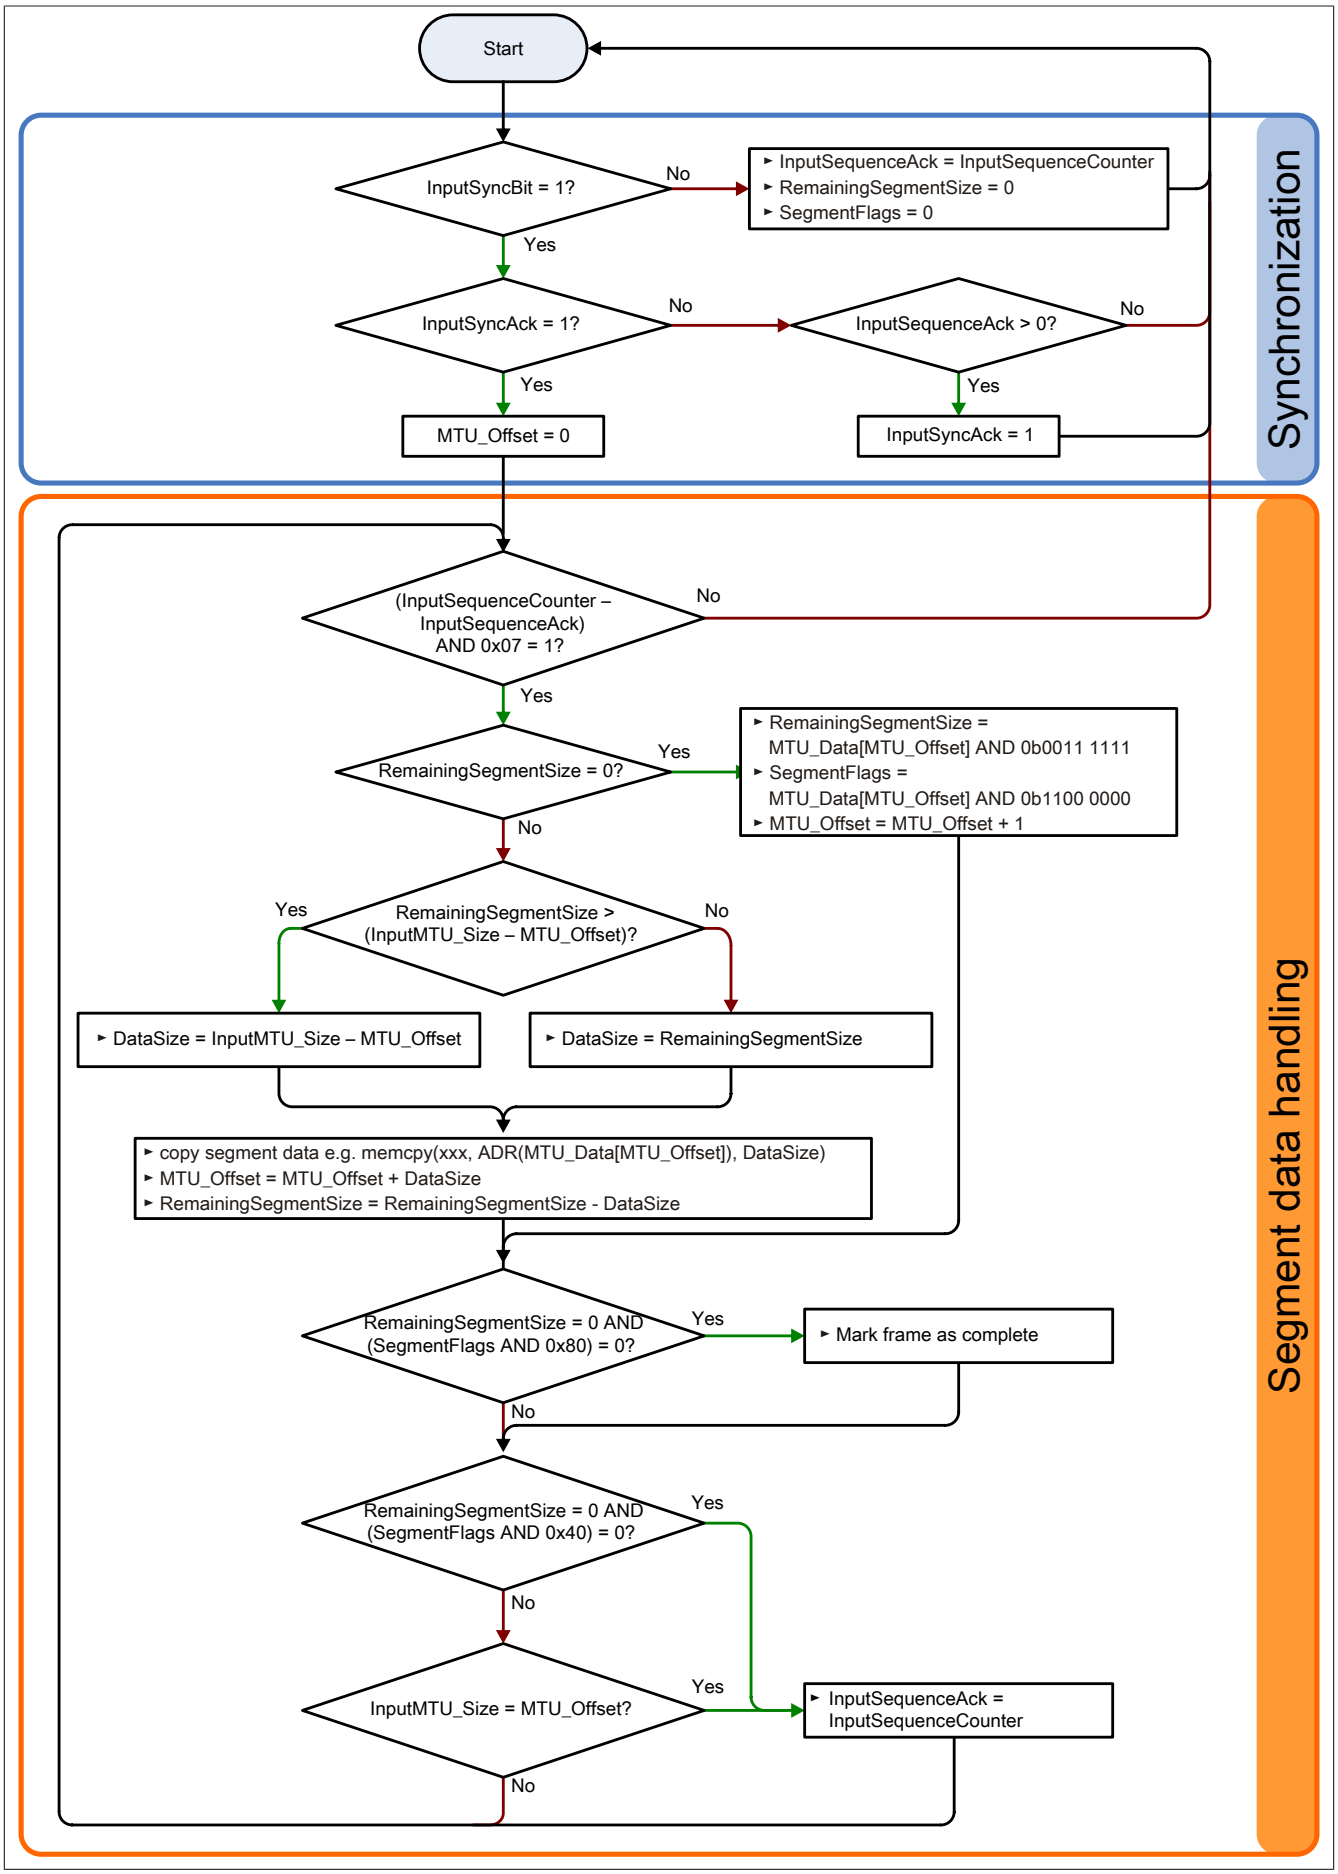

Figure 301: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

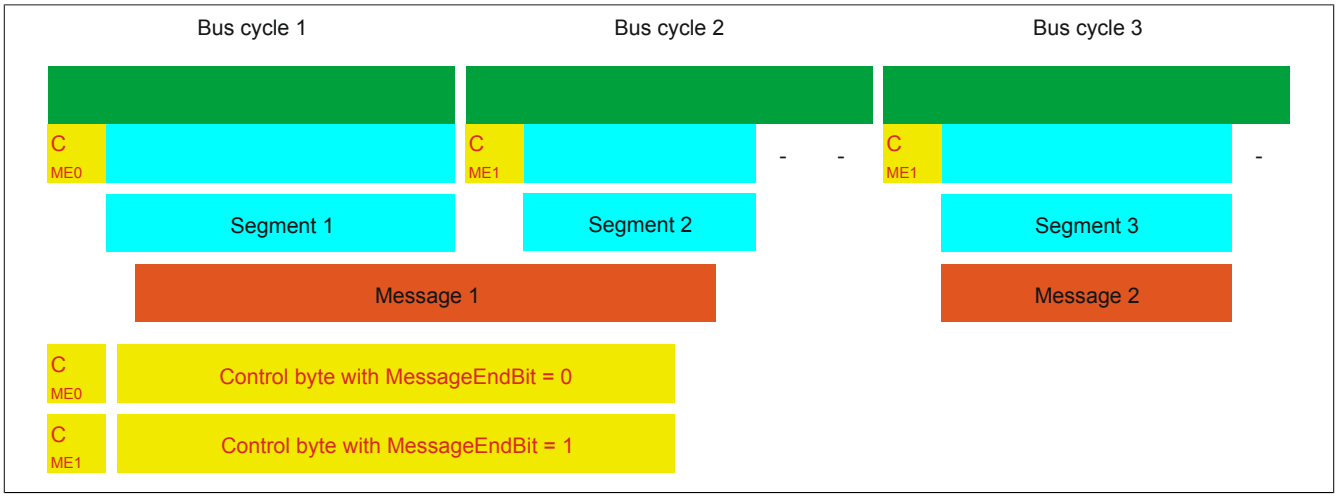

Figure 302: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

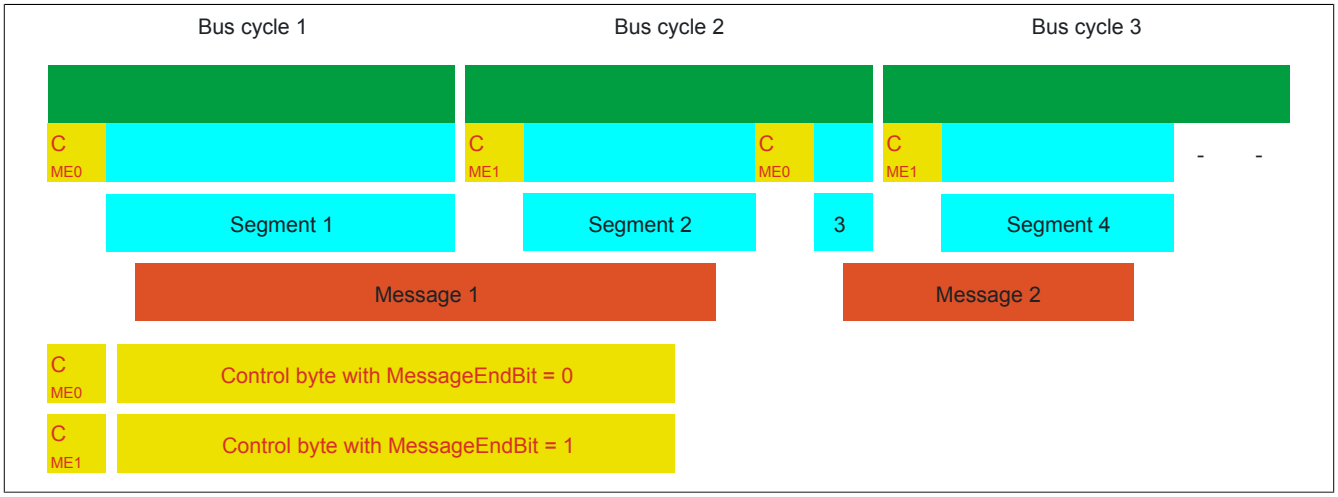

Figure 303: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

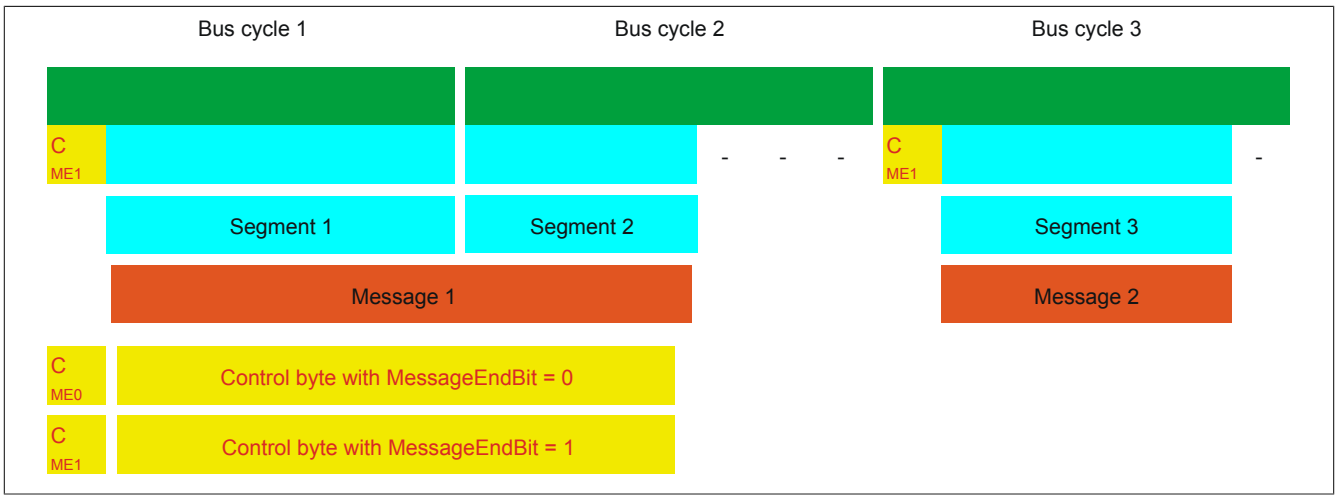

Figure 304: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

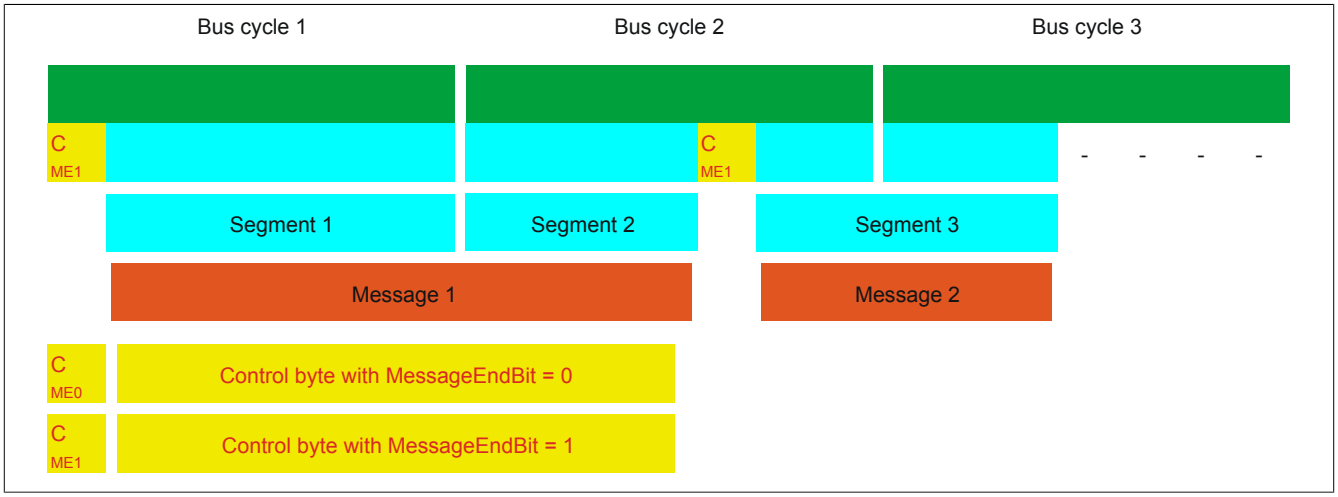

Figure 305: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

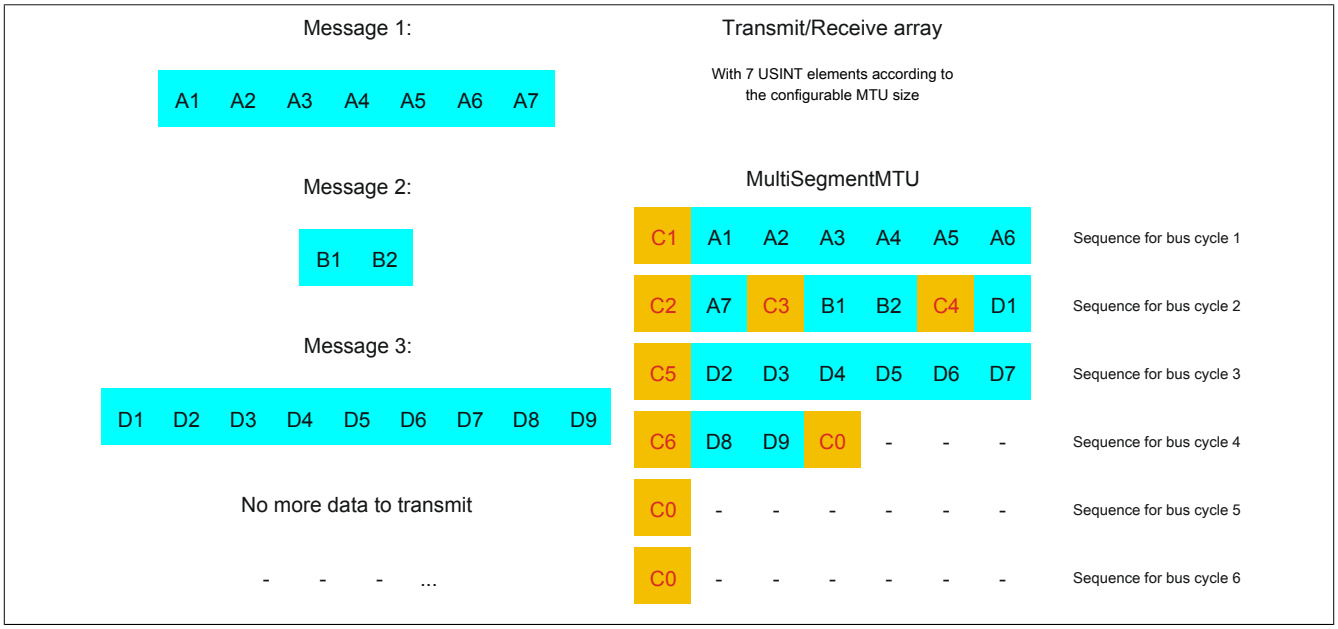

Figure 306: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 401: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 402: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

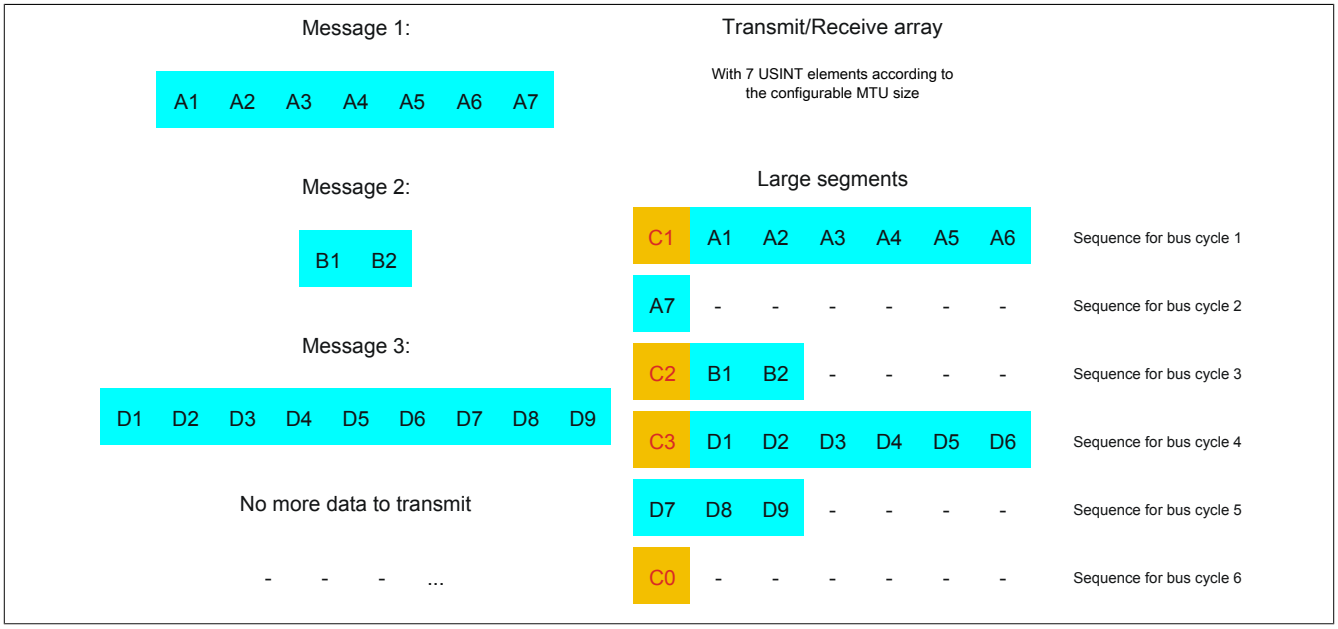

Figure 307: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 403: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

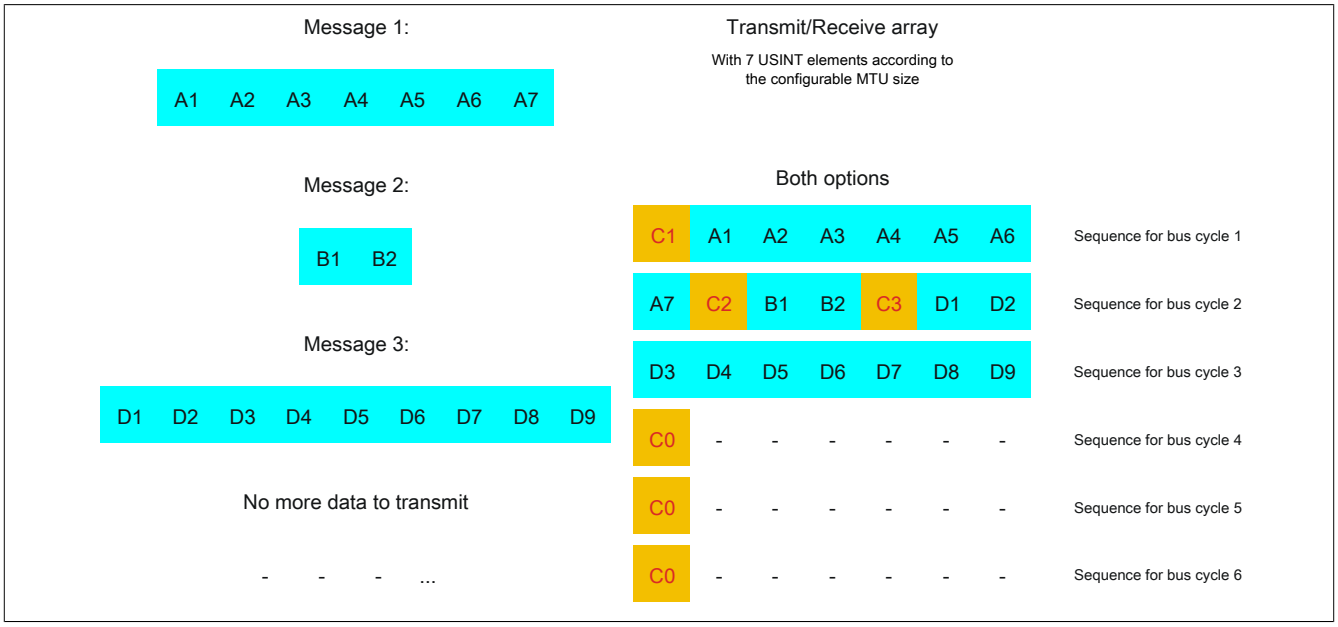

Figure 308: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 404: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.18.5.8.10.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

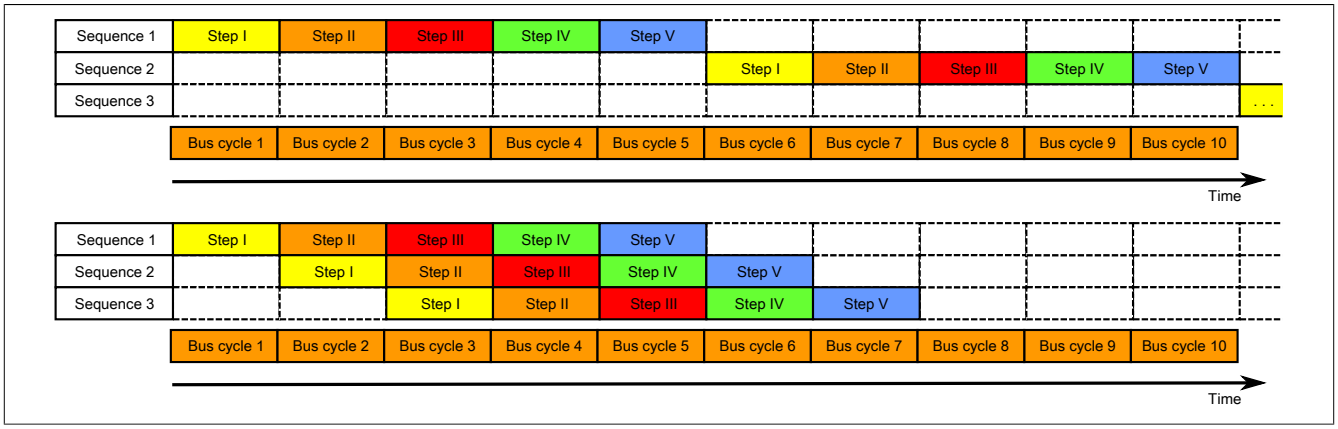

Figure 309: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

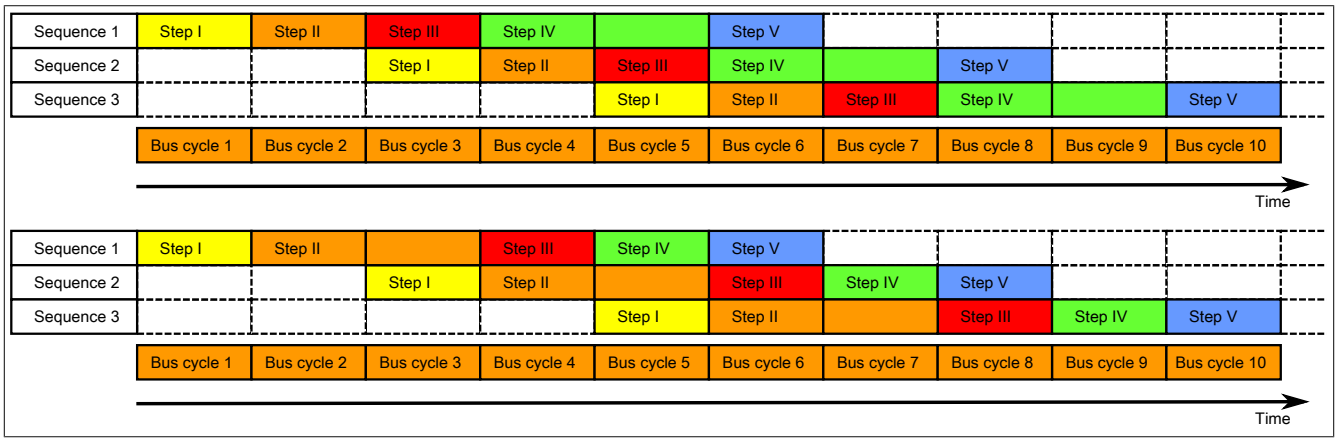

Figure 310: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

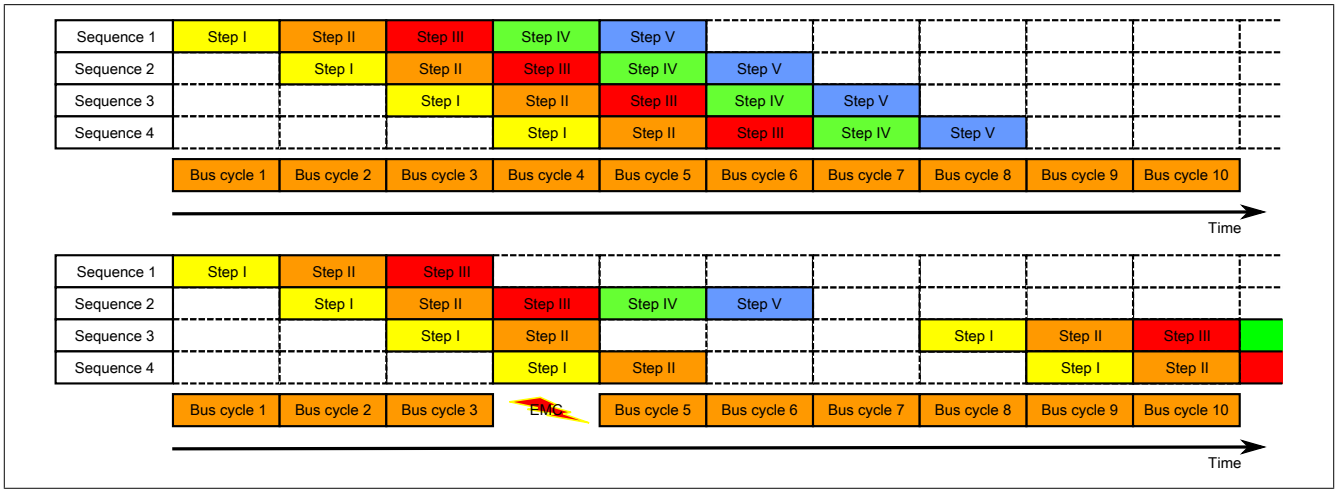

Figure 311: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.18.5.8.11 Serial with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X Link master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

In a serial network, the module is always the master (DTE). Various adjustments can be made to ensure that signals are transmitted without errors.
The user can, for example, define a handshake algorithm or set the baud rate in order to adapt the transmission quality to the requirements of the application.

Operation

When using FlatStream, the general structure of the FlatStream frame must be maintained.

Input/Output sequence	Tx/Rx bytes	
(unchanged)	Control byte (unchanged)	Serial frame (without hand-shake or similar measures)

4.18.5.8.12 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.18.5.8.13 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.5.8.14 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.18.6 X20(c)CS1030

4.18.6.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- RS485/RS422 interface for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistor

4.18.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.18.6.3 Order data

Model number	Short description	Figure

4.18.6.5 LED status indicators

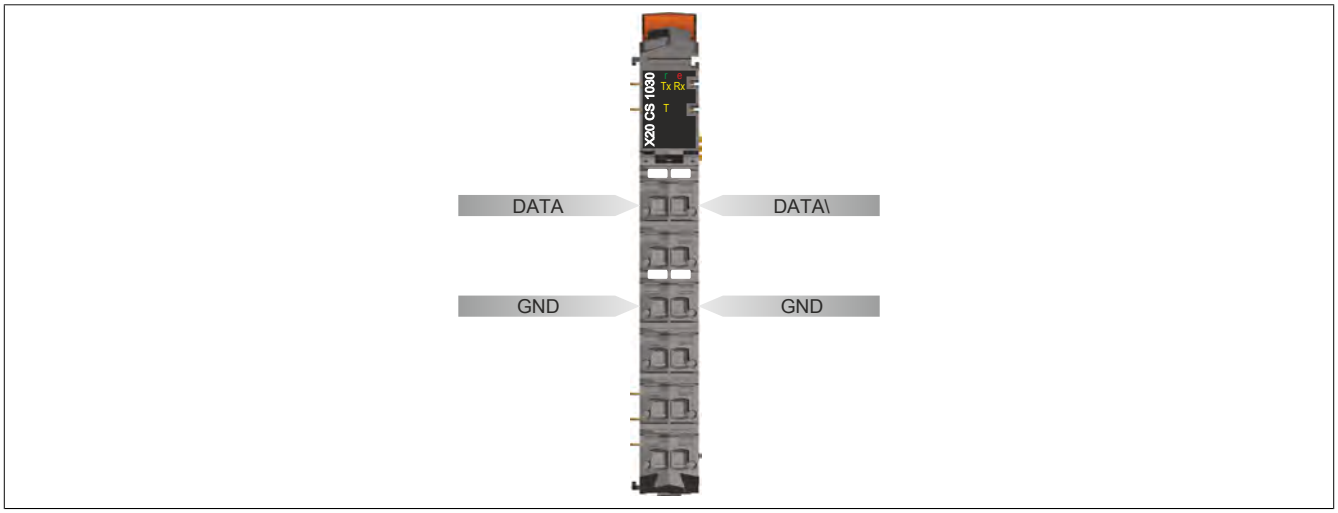
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	An I/O error has occurred, see 4.18.5.8.9.1 "Error message status bits"
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	Tx	Yellow	On	The module transmits data via the RS485/RS422 interface
	Rx	Yellow	On	The module receives data via the RS485/RS422 interface
	T	Yellow	On	Terminating resistor integrated in the module switched on

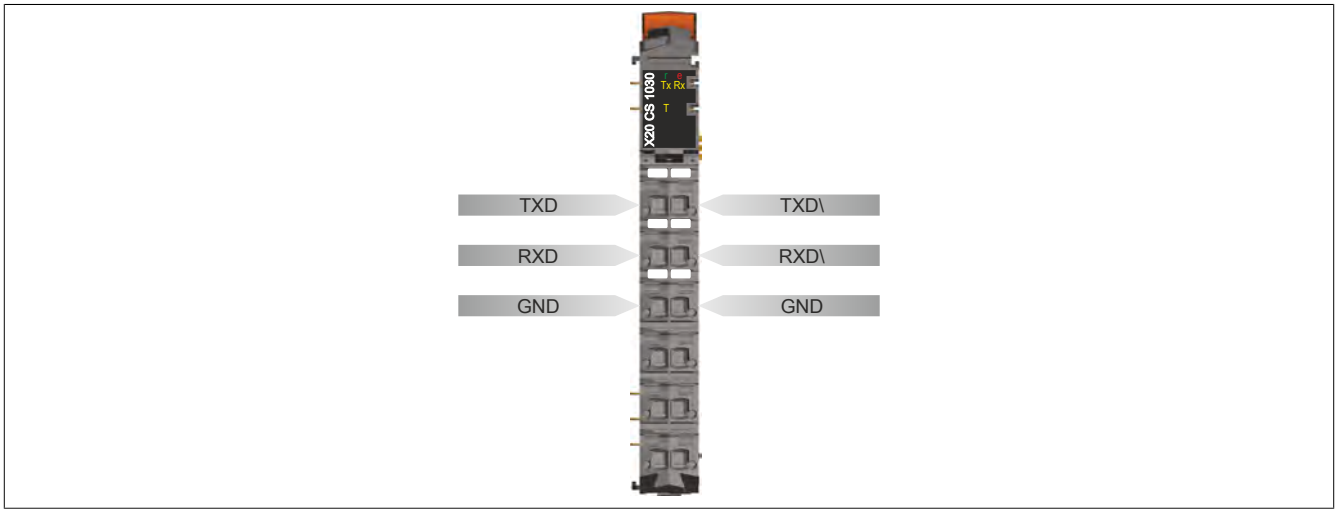
1) Depending on the configuration, a firmware update can take up to several minutes.

4.18.6.6 Pinout

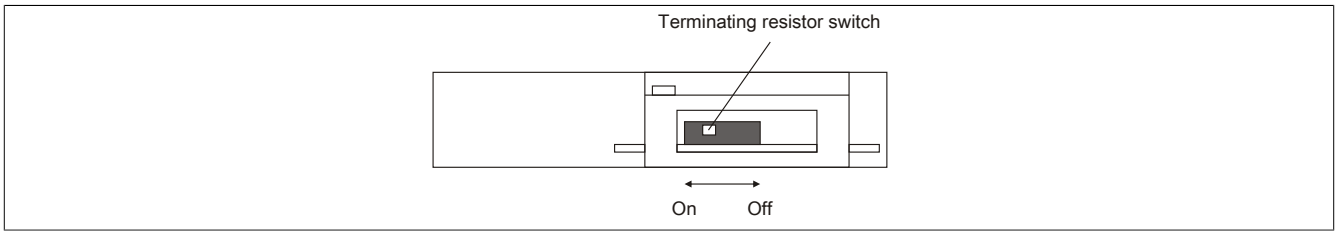
RS485 mode



RS422 mode



4.18.6.7 Terminating resistor

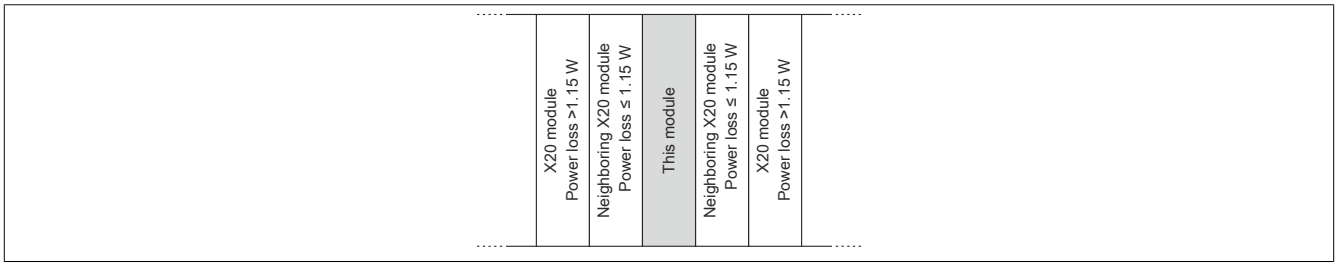


A terminating resistor is integrated in the communication module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T" LED.

4.18.6.8 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.18.6.9 Register description

4.18.6.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.6.9.2 Function model 2 - Stream and Function model 254 - Cyclic stream

The "Stream" and "Cyclic stream" function models use a module-specific driver for the operating system. The interface can be controlled using the "DVFrame" library and be reconfigured at runtime.

Function model - Stream

In the "Stream" function model, the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

The "Cyclic stream" function model was implemented later. From the application's point of view, there is no difference between the "Stream" and "Cyclic stream" function models. Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- **In order to use the "Stream" and "Cyclic stream" function models, you must be using B&R controllers of the type "SG4".**

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic

	QuitRXoverrun	Bit 3				

4.18.6.9.3 Function model 254 - FlatStream

The "FlatStream" function model provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the module. Serial information is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see 4.3.7.10.8 "FlatStream communication").

When using the Flatstream function model, the user can choose whether to use the "AsFltGen" library in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

1) The offset specifies the position of the register within the CAN object.

4.18.6.9.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.18.6.9.5 Serial interface – Configuration

The user has to configure 5 registers to operate the serial interface.

4.18.6.9.5.1 Mode_IF

Name:
phyMode
phyMode_CANIO

This register is used to determine the current operating mode of the interface.

Enabling the interface is only permitted after complete configuration of the other registers. If parameters need to be changed, the interface must first be disabled.

Data type	Value	Description
USINT	0	Interface disabled (default)
	4	RS422 interface enabled[1)]
	5	RS422 interface enables as a bus[2)]
	6	RS485 interface enabled with echo
	7	RS485 interface enabled without echo

1) Connection between 2 stations
2) Connections between multiple stations possible. Transmit lines connected as with RS485 TriState.

4.18.6.9.5.2 Baudrate_IF

Name:
phyBaud
phyBaud_CANIO

This register is used to set the baud rate of the interface in bit/s.

Data type	Value	Description
UDINT	1200	1.2 kbaud
	2400	2.4 kbaud
	4800	4.8 kbaud
	9600	9.6 kbaud
	19200	19.2 kbaud
	38400	38.4 kbaud
	57600	57.6 kbaud
	115200	115.2 kbaud

4.18.6.9.5.3 Databit_IF

Name:
phyData
phyData_CANIO

This register is used to specify the number of bits to be transferred for each character.

Data type	Value	Description
USINT	7	7 data bits
	8	8 data bits (default)

4.18.6.9.5.4 Stoppbit_IF

Name:
phyStop
phyStop_CANIO

This register is used to define the number of stop bits.

Data type	Value	Description
USINT	2	1 stop bit (default)
	4	2 stop bits

4.18.6.9.5.5 Parity_IF

Name:
phyParity
phyParity_CANIO

This register is used to define the parity check type. Possible values are ASCII coded.

Data type	Value	Description
USINT	48	"0" - (low) bit is always 0
	49	"1" - (high) bit is always 1
	69	"E" - (even) even parity (default)
	78	"N" - (no) no bit
	79	"O" - (odd) odd parity

4.18.6.9.6 Handshake - Configuration

In order to guarantee that serial communication runs smoothly, the size of the receive buffer in the module must be known. In addition, the user can configure a software or hardware handshake algorithm.

4.18.6.9.6.1 Locking the receive buffer

Name:
rxlLock
rxlLock_CANIO

This register is used to configure the upper threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the "Lock" register value, flow control switches to the "passive" state. To return to the "active" or "ready" state, the amount of data in the receive buffer must fall under the default value of the "Unlock" register.

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of the "Lock" register must be greater than the value of the "Unlock" register.

Data type	Value	Description
UINT	0 to 4095	Upper threshold of the receive buffer (default = 1024)

4.18.6.9.6.2 Unlocking the receive buffer

Name:
rxlUnlock
rxlUnlock_CANIO

This register is used to configure the lower threshold of the receive buffer.

The two registers "Lock" and "Unlock" can be used for "flow control" monitoring of the communication. If the amount of data from the module input exceeds the "Lock" register value, flow control switches to the "passive" state. To return to the "active" or "ready" state, the amount of data in the receive buffer must fall under the default value of the "Unlock" register.

Information:

These registers simulate the behavior of a Schmitt trigger, so the value of the "Lock" register must be greater than the value of the "Unlock" register.

Data type	Value	Description
UINT	0 to 4095	Lower threshold of the receive buffer (default = 512)

4.18.6.9.6.3 Turn on software handshake

Name:
hssXOn
hssXOn_CANIO

This register can be used to configure the XOn character. The value 17 is the default, but any other value can also be configured.

The two registers "XOn" and "XOff" can be used to initiate a software handshake for flow control. When doing so, a valid ASCII character must be configured in both registers.

Data type	Value	Description
UINT	0 to 255	XOn ASCII character
	65535	No software handshake (default)

4.18.6.9.6.4 Turn off software handshake

Name:
hssXOff
hssXOff_CANIO

This register can be used to configure the XOff character. The value 19 is the default, but any other value can also be configured.

The two registers "XOn" and "XOff" can be used to initiate a software handshake for flow control. When doing so, a valid ASCII character must be configured in both registers.

Data type	Value	Description
UINT	0 to 255	XOff ASCII character
	65535	No software handshake (default)

4.18.6.9.6.5 Handshake repetition

Name:
hssPeriod
hssPeriod_CANIO

When using a software handshake, some applications require periodic repetition of the current status. The repeat time can be defined in this register in ms for this purpose.

Data type	Value	Description
UINT	0	Automatic status repeat disabled
	500 to 10000	Repeat time in ms (default = 5000)

4.18.6.9.7 Frame - Configuration

Different message termination codes can be specified in order to correctly create transmitted Tx frames and correctly interpret received Rx frames.

4.18.6.9.7.1 Terminating when a receive timeout occurs

Name:
rxCto
rxCto_CANIO

This register is used to set the duration until a receive timeout is triggered.

The message is considered to be terminated when nothing is transfered for the specified duration.
The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

Data type	Value	Description
UINT	0	Function disabled
	1 to 65535	Receive timeout in characters (default = 4)

4.18.6.9.7.2 Terminating when a transmit timeout occurs

Name:
txCto
txCto_CANIO

This register is used to set the duration until a transmit timeout is triggered.

The message is considered to be terminated when nothing is transfered for the specified duration.
The time is specified here in characters to ensure that it is independent of the transfer rate. The number of characters is then multiplied by the time needed to transfer a character.

Data type	Value	Description
UINT	0	Function disabled
	1 to 65535	Transmit timeout in characters (default = 5)

4.18.6.9.7.3 Maximum number of bytes received

Name:
rxEomSize
rxEomSize_CANIO

These registers configure the maximum number of bytes in the receive frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte receive buffer. Larger frames cause the Receive Overrun error.

Data type	Value	Description
UINT	0	Function disabled
	1 to 4096	Configurable receive frame length in characters (default = 256)

4.18.6.9.7.4 Maximum number of bytes transmitted

Name:
txEomSize
txEomSize_CANIO

These registers configure the maximum number of bytes in the transmit frame.

The message is considered to be ended as soon as a frame with the specified size in bytes is transferred. The longest possible frame length is the size of the 4096-byte transmit buffer. The configured transmit timeout is maintained after the frame has been sent.

Data type	Value	Description
UINT	0	Function disabled
	1 to 4096	Configurable transmit frame length in characters (default = 4096)

4.18.6.9.7.5 Define receive terminator

Name:
rxEomChar0 to rxEomChar3
rxEomChar0_CANIO to rxEomChar3_CANIO

It is possible to configure a receive terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

Data type	Value	Description
UINT	0 to 255	Frame terminator (ASCII code)
	65535	Function disabled (default)

4.18.6.9.7.6 Define transmit terminator

Name:
txEomChar0 to txEomChar3
txEomChar0_CANIO to txEomChar3_CANIO

It is possible to configure a transmit terminator for all registers.

The message is considered to be terminated as soon as one of the defined characters is transferred.

Data type	Value	Description
UINT	0 to 255	Frame terminator (ASCII code)
	65535	Function disabled (default)

4.18.6.9.8 Status messages - Configuration

The status messages provide the user with information about the current situation in the downstream serial network.

4.18.6.9.8.1 Error detection setting

Name:
CfO_RxStateIgnoreMask
CfO_RxStateIgnoreMask_CANIO

This register has a direct effect on UART operation. Error detection in general can be disabled using the low byte. If error detection is not disabled, the high byte can be used to specify that a detected error should be interpreted as the end of the message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Reserved	0	
4	StartBitError	0	Detecting a faulty start bit
		1	Ignore
5	StopBitError	0	Detecting a faulty stop bit
		1	Ignore
6	ParityError	0	Detecting a faulty parity bit
		1	Ignore
7	RXoverrun	0	Detecting an overflow in the receive direction
		1	Ignore
8 - 11	Reserved	0	
12	StartBitError corresponds to the end of the frame (if bit 4 = 0)	0	Only display error inside the module
		1	Also signal end of frame
13	StopBitError corresponds to the end of the frame (if bit 5 = 0)	0	Only display error inside the module
		1	Also signal end of frame
14	ParityError corresponds to the end of the frame (if bit 6 = 0)	0	Only display error inside the module
		1	Also signal end of frame
15	RXoverrun corresponds to the end of the frame (if bit 7 = 0)	0	Only display error inside the module
		1	Also signal end of frame

4.18.6.9.8.2 Forward error to the application

Name:
CfO_ErrorID0007

If the UART inside the module reports an error, this byte can be used to specify which error messages are forwarded to the application.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name		Information
0	StartBitError	0	Ignore
		1	Indicating a faulty start bit
1	StopBitError	0	Ignore
		1	Indicating a faulty stop bit
2	ParityError	0	Ignore
		1	Indicating a faulty parity bit
3	RXoverrun	0	Ignore
		1	Indicating an overflow in the receive direction
4 - 7	Reserved	0	

4.18.6.9.9 Status messages - Communication

After configuration is completed, up to four status messages can be evaluated in the application.

4.18.6.9.9.1 Error message status bits

Name:
StartBitError
StopBitError
ParityError
RXoverrun

This register is used to transfer the individual bits that indicate an error. If a error occurs, the corresponding bit is set and maintained until it is acknowledged.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StartBitError	0	No error
		1	Start bit error occurred[1)]
1	StopBitError	0	No error
		1	Stop bit error occurred[1)]
2	ParityError	0	No error
		1	Parity bit error occurred[1)]
3	RXoverrun	0	No error
		1	Receive buffer overflow occurred[2)]
4 - 7	Reserved	0	

1) This error can result from things such as mismatched interface configurations or problems with the wiring.
2) This data point reports a receive buffer overrun. The buffer capacity on the module is exhausted and all subsequent data arriving at the interface is lost. An overrun always means that the data received on the module is not read fast enough by the higher-level system.
The solution here is to optimize the cycle times of all transfer routes and task classes involved and utilize the available handshake options.

4.18.6.9.9.2 Acknowledging the status bits

Name:
QuitStartBitError
QuitStopBitError
QuitParityError
QuitRXoverrun

This register is used to transfer the individual bits that acknowledge an indicated error state. After one of the bits has been set, it can be reset using the corresponding acknowledgment bit.
If the error is still actively pending, the error status bit is not deleted. The acknowledgment bit can only be reset if the error status bit is no longer set.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	QuitStartBitError	0	No acknowledgment
		1	Acknowledge start bit error
1	QuitStopBitError	0	No acknowledgment
		1	Acknowledge stop bit error
2	QuitParityError	0	No acknowledgment
		1	Acknowledge parity bit error
3	QuitRXoverrun	0	No acknowledgment
		1	Acknowledge receive buffer overflow error
4 - 7	Reserved	0	

4.18.6.9.10 FlatStream communication

4.18.6.9.10.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

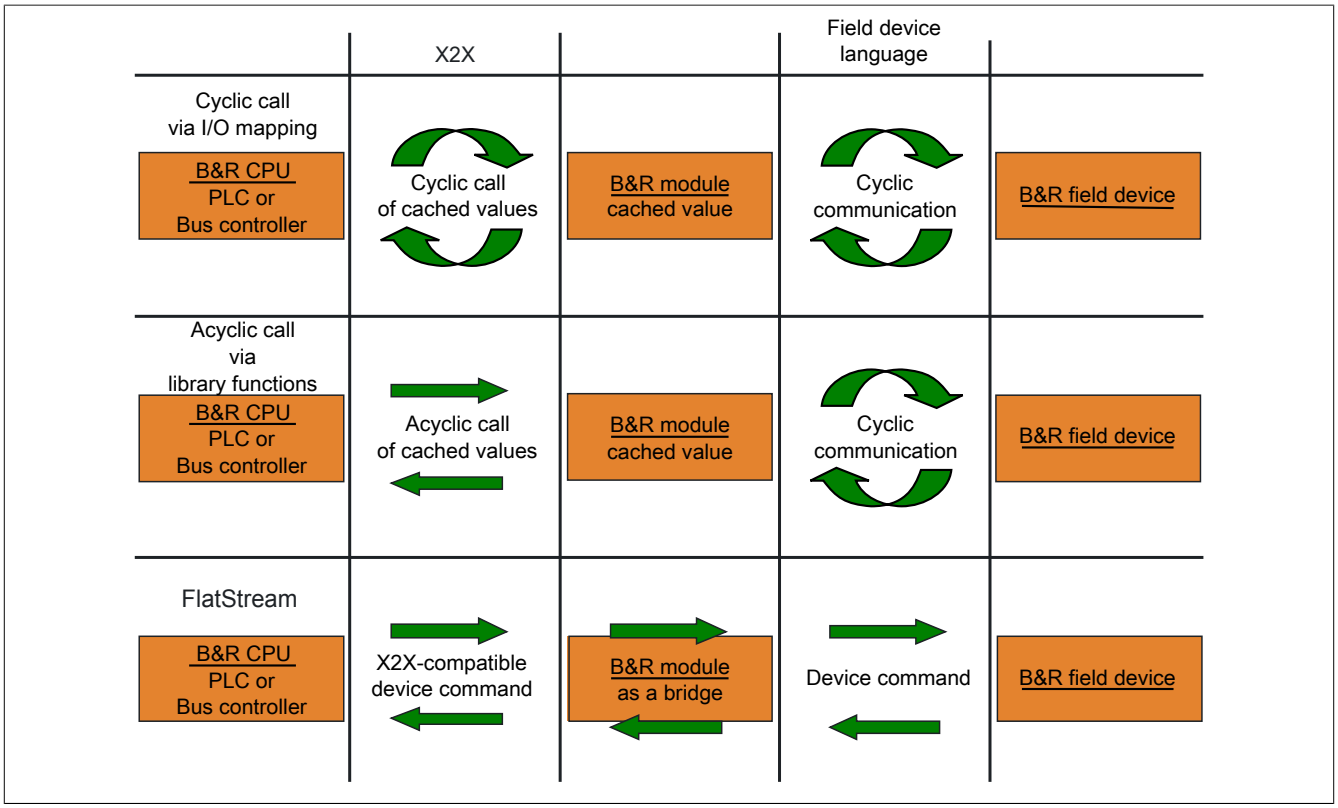

Figure 312: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.18.6.9.10.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.18.6.9.10.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

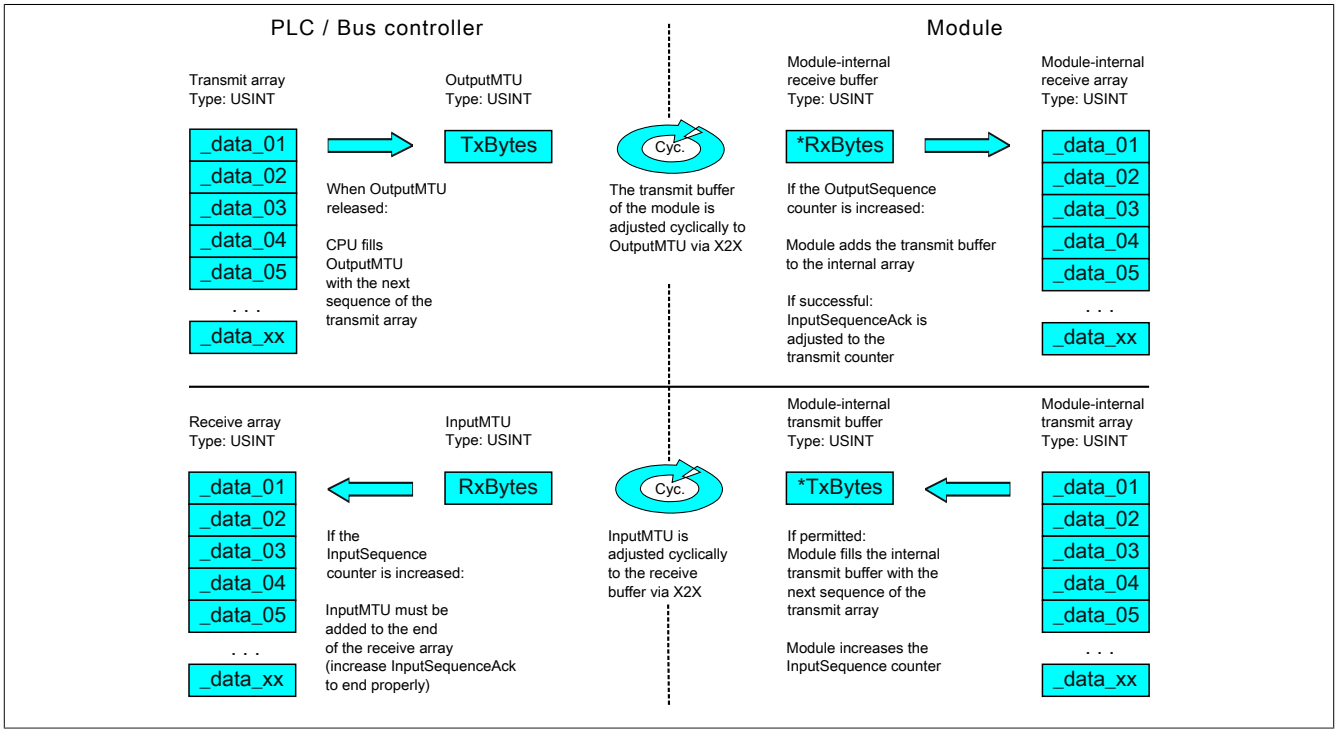

Figure 313: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.18.6.9.10.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Format of input and output bytes

Name:

"Format of Flat stream" in Automation Studio

This function sets how the Flatstream input and output bytes (Tx or Rx bytes) are transferred.

- **packed variable:** Transfers data as an array
- **byte variables:**Transfers data as individual bytes

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

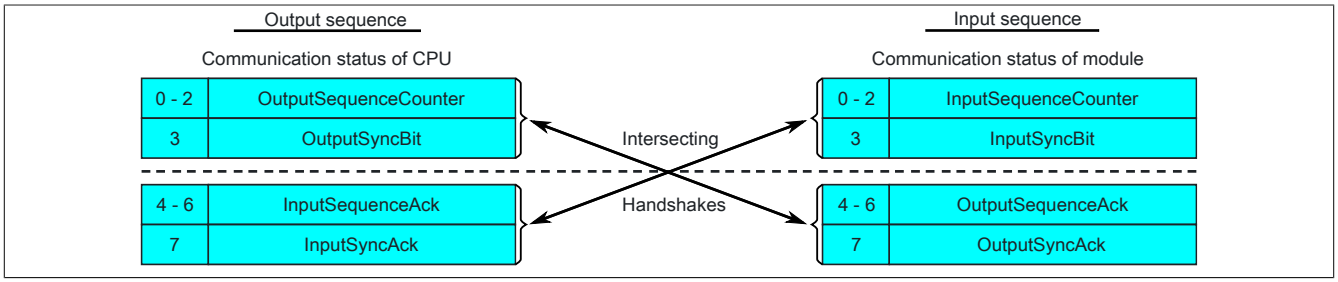

Figure 314: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

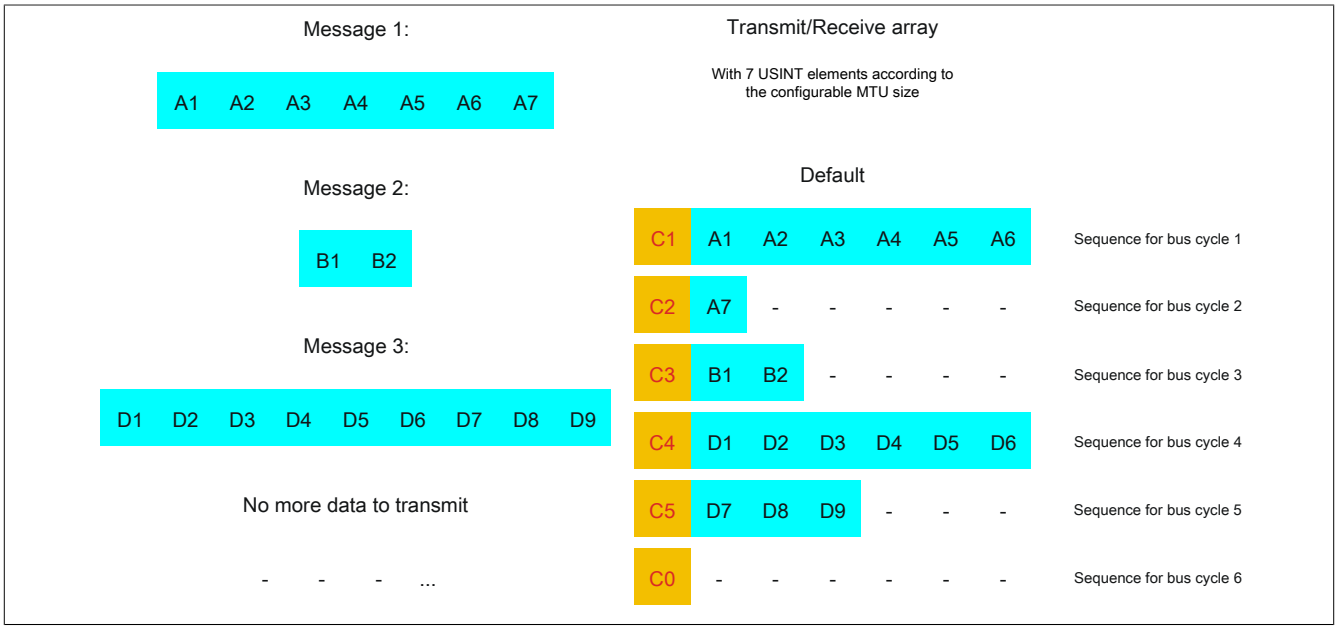

Figure 315: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 407: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 408: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

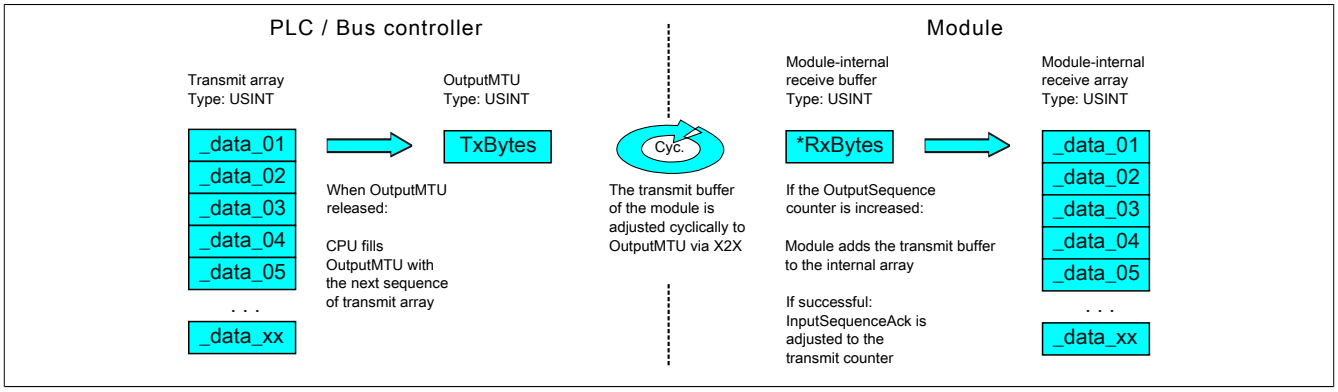

Figure 316: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

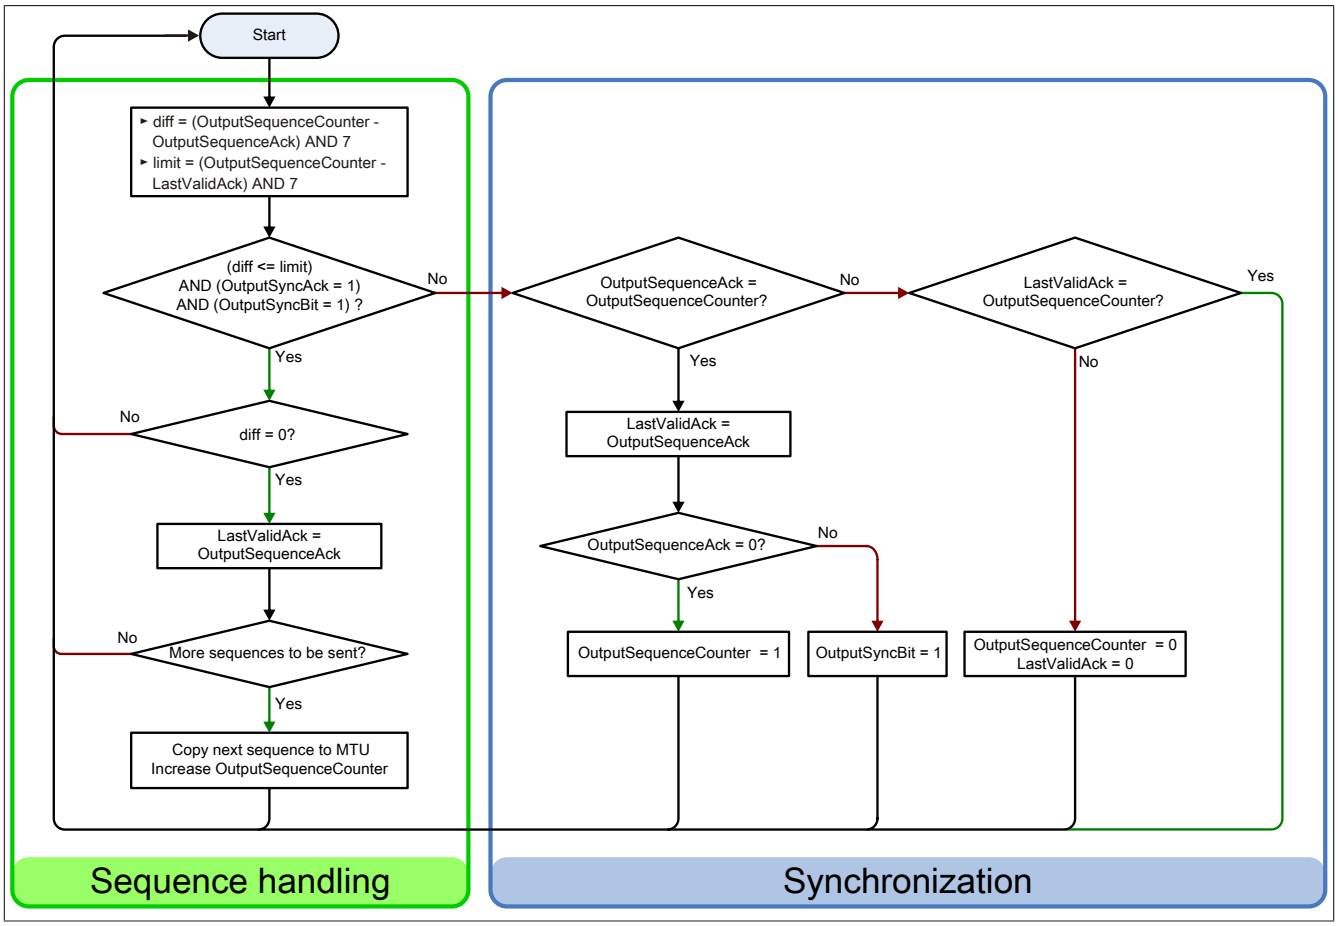

Figure 317: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

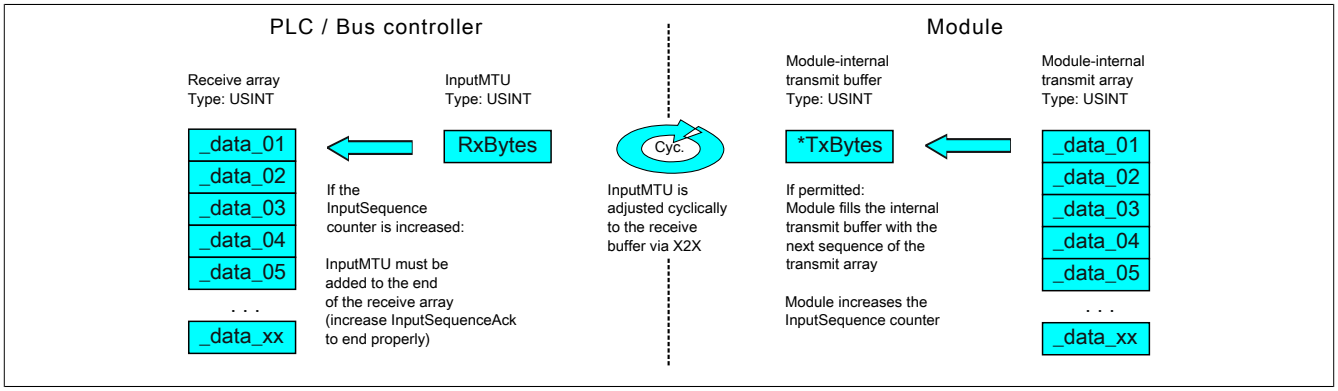

Figure 318: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

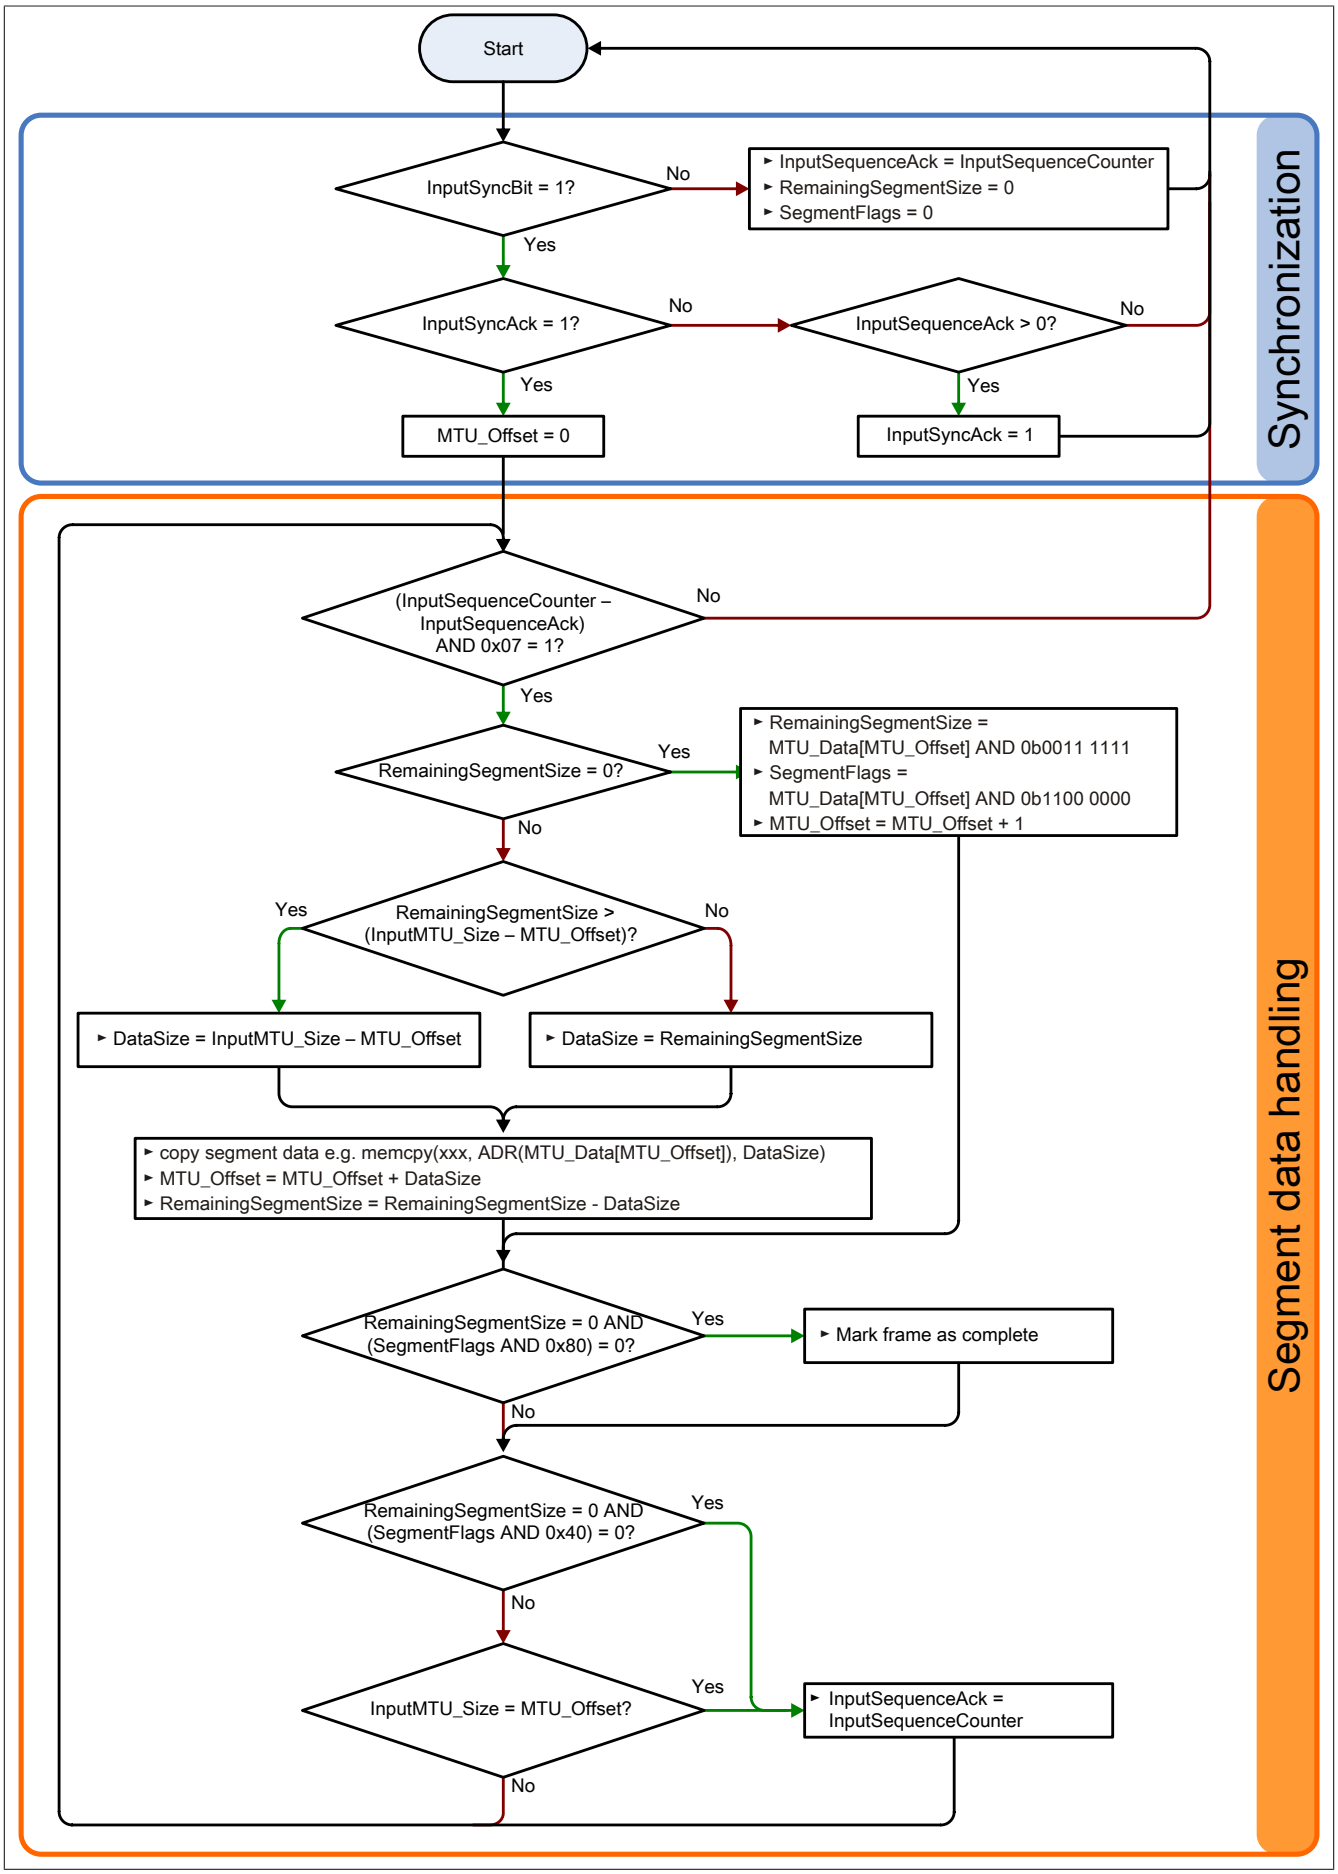

Figure 319: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

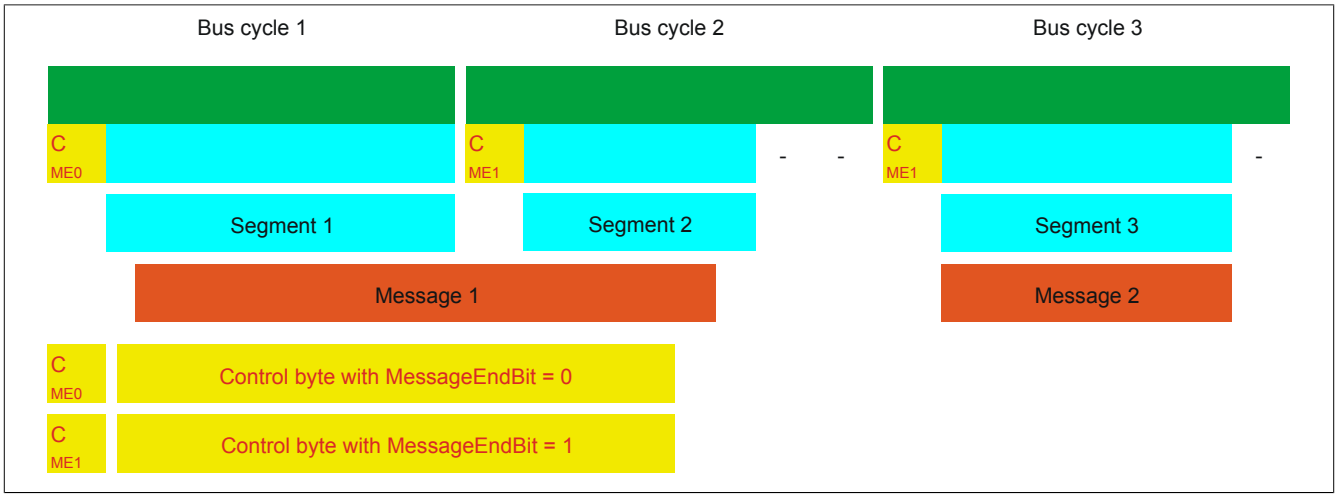

Figure 320: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

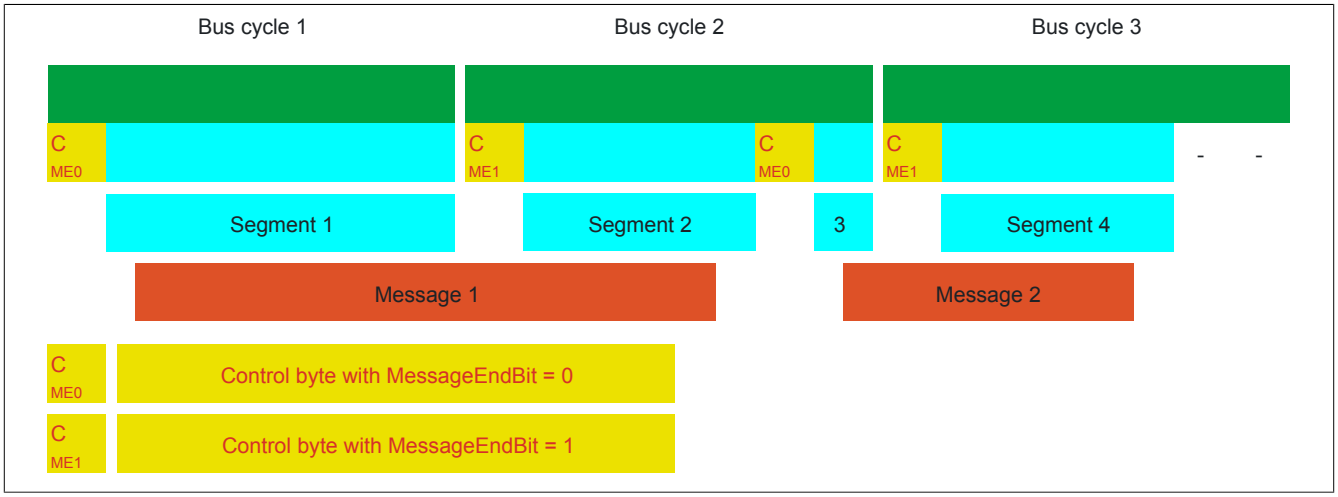

Figure 321: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

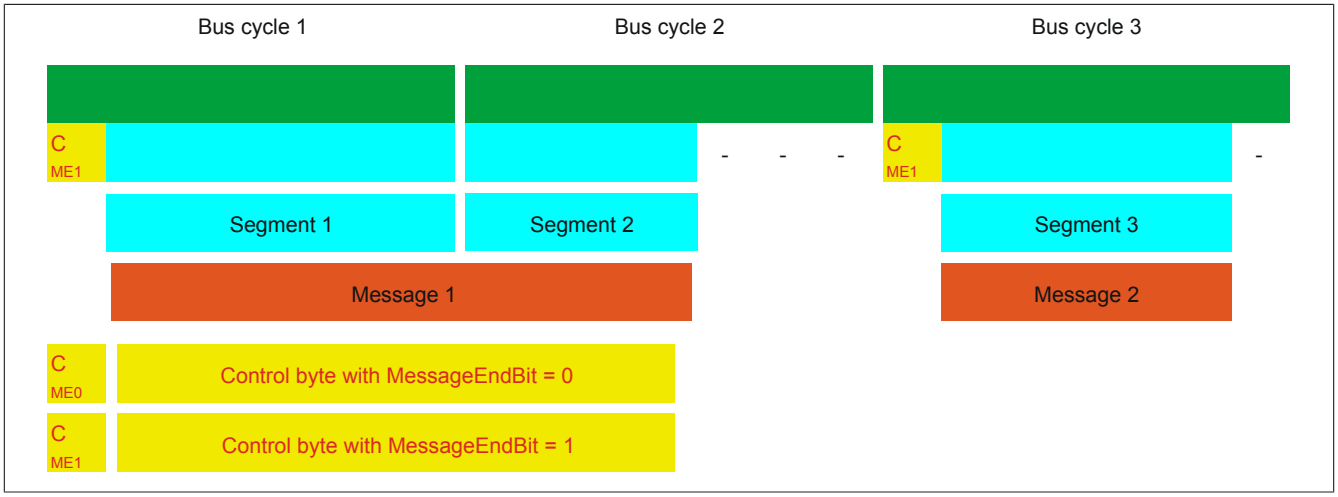

Figure 322: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

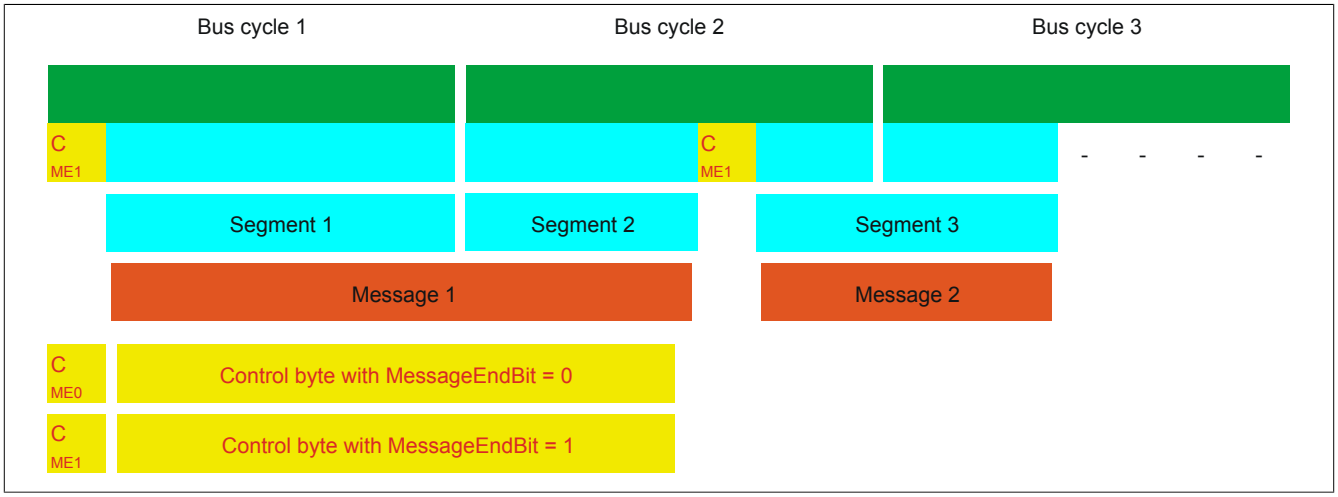

Figure 323: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

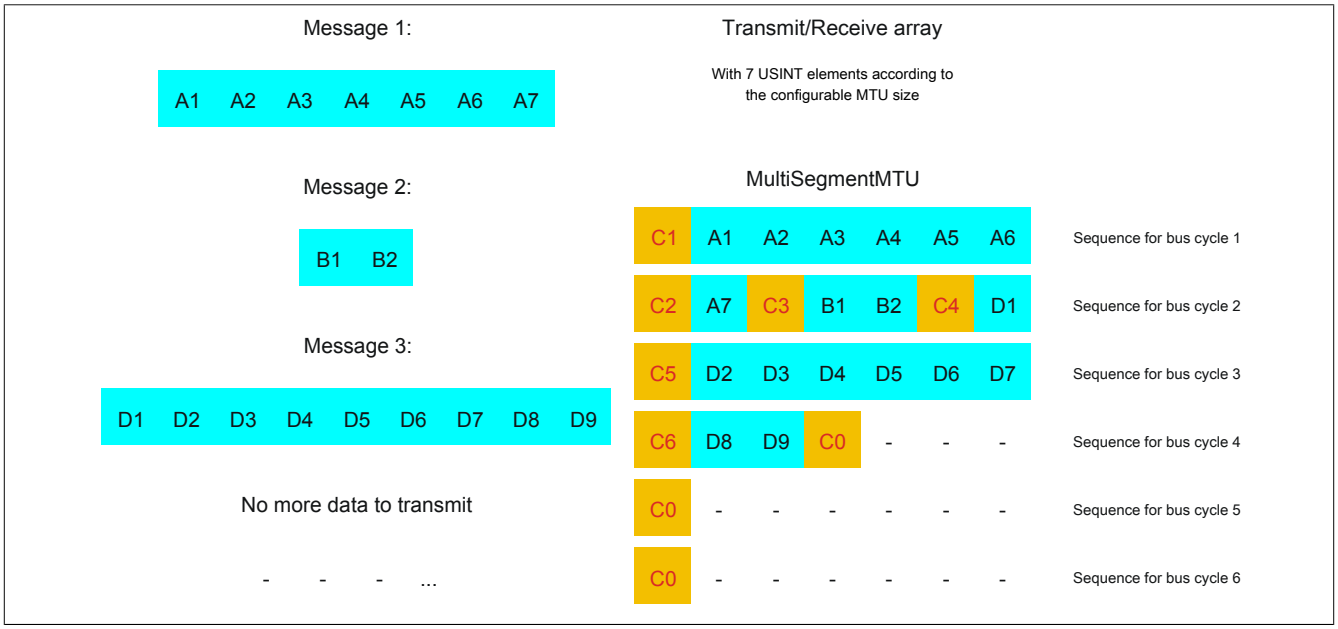

Figure 324: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 409: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 410: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

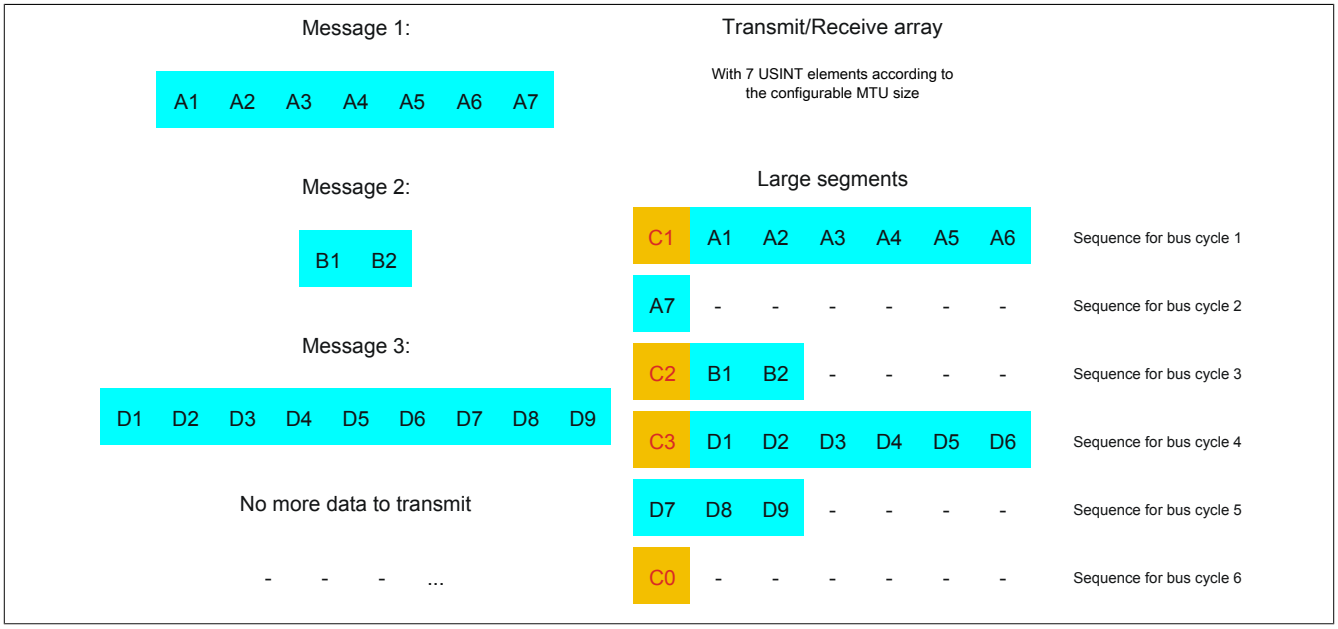

Figure 325: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 411: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

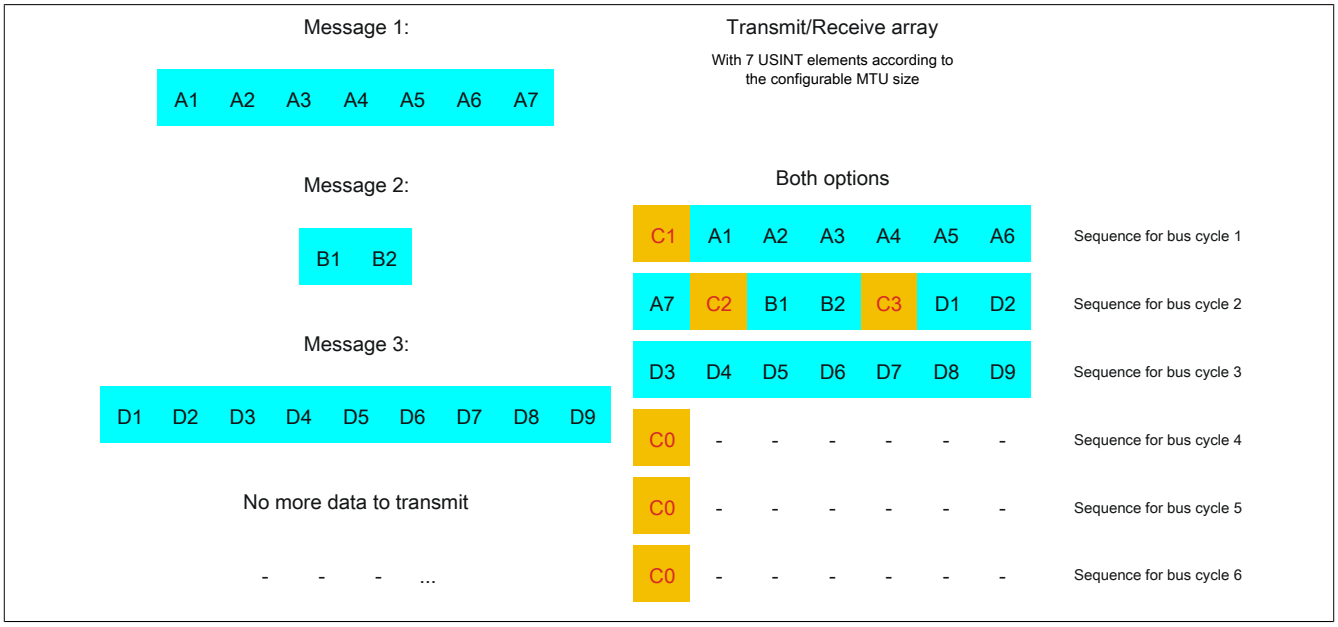

Figure 326: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 412: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.18.6.9.10.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

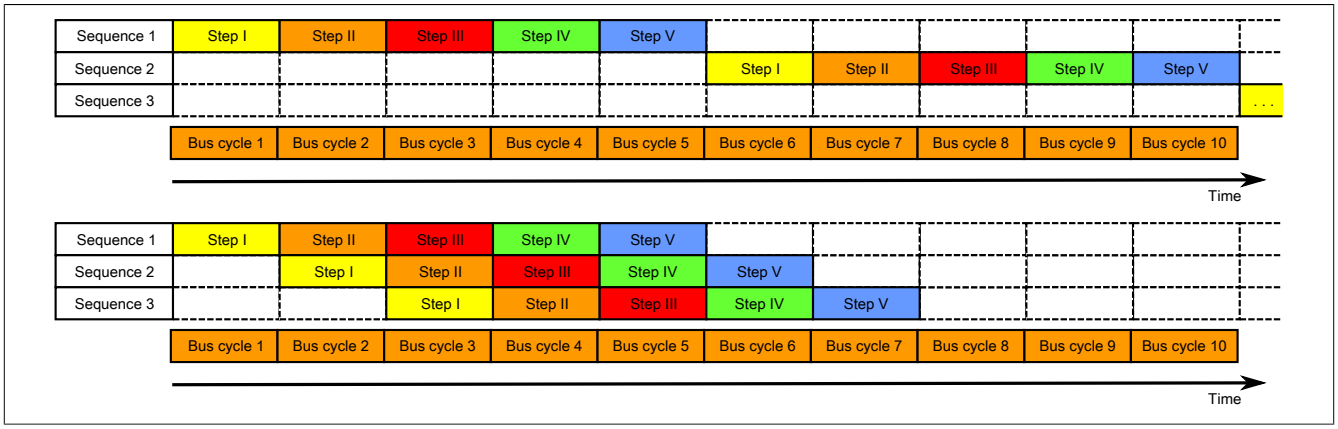

Figure 327: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

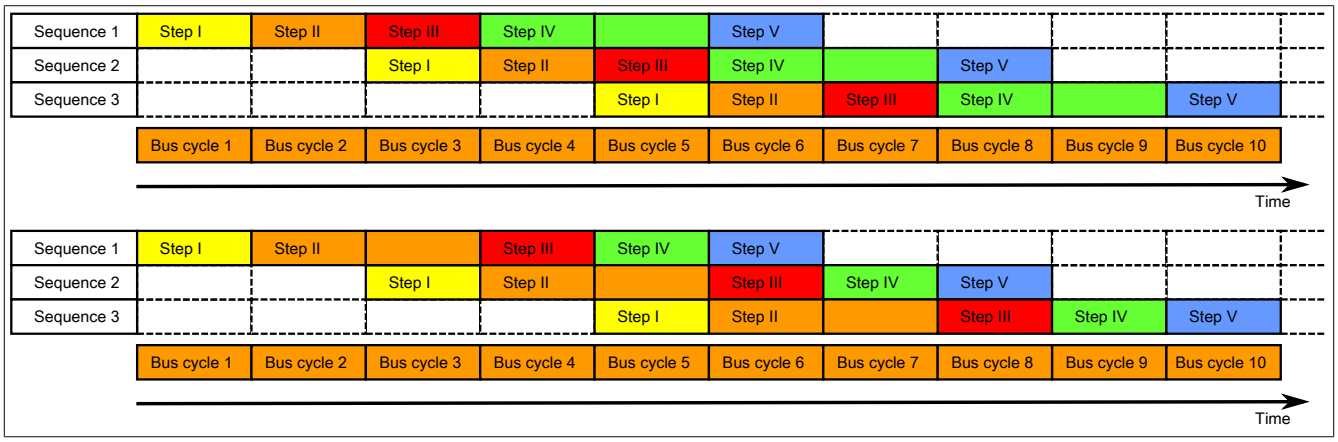

Figure 328: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

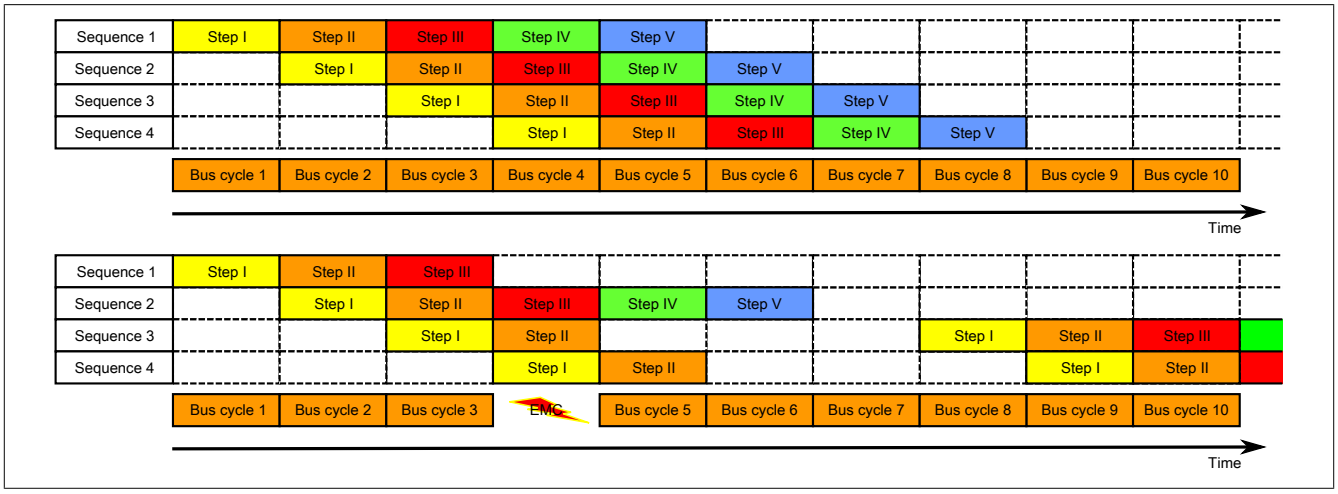

Figure 329: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.18.6.9.11 Serial with FlatStream

When using FlatStream communication, the module acts as a bridge between the X2X Link master and an intelligent field device connected to the module. FlatStream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

In a serial network, the module is always the master (DTE). Various adjustments can be made to ensure that signals are transmitted without errors.
The user can, for example, define a handshake algorithm or set the baud rate in order to adapt the transmission quality to the requirements of the application.

Operation

When using FlatStream, the general structure of the FlatStream frame must be maintained.

Input/Output sequence	Tx/Rx bytes	
(unchanged)	Control byte (unchanged)	Serial frame (without hand-shake or similar measures)

4.18.6.9.12 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.18.6.9.13 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.6.9.14 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.18.7 X20CS1070

4.18.7.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20CS communication modules are designed precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- CAN bus interface for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistor

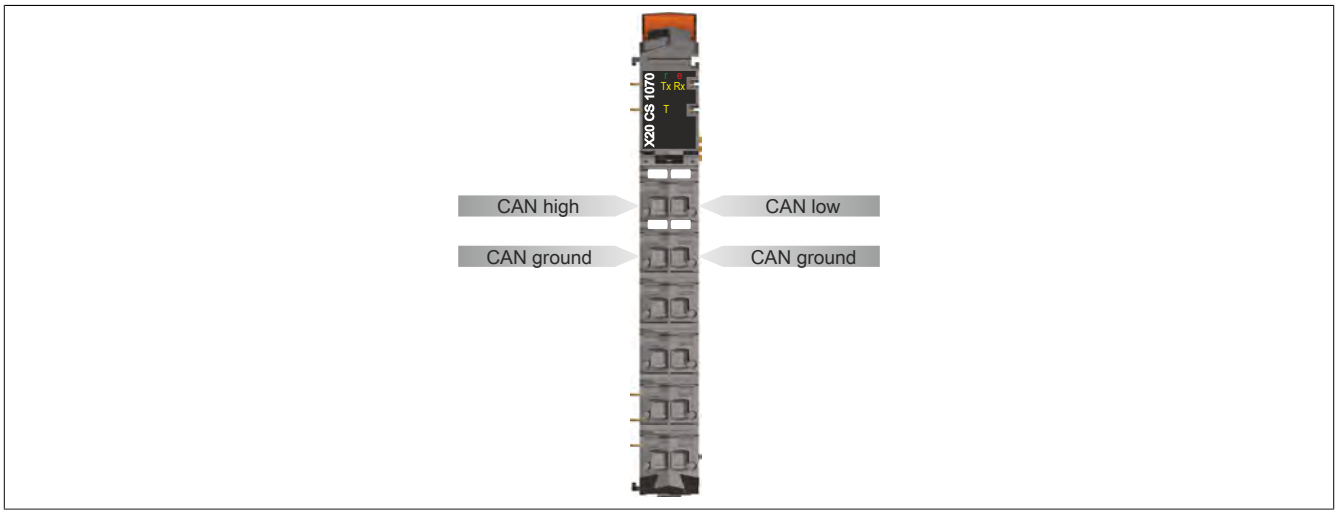
4.18.7.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

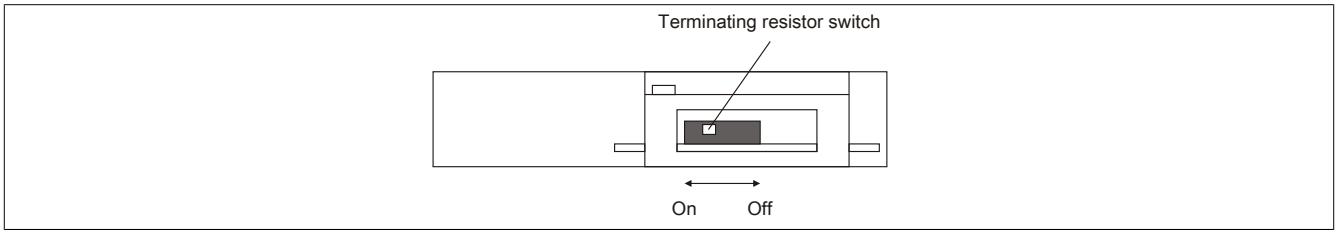
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	I/O error occurred • CAN bus: Warning, passive or off • Buffer overflow
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	Tx	Yellow	On	The module is sending data via the CAN bus interface
	Rx	Yellow	On	The module is receiving data via the CAN bus interface
	T	Yellow	On	Terminating resistor integrated in the module switched on

1) Depending on the configuration, a firmware update can take up to several minutes.

4.18.7.5 Pinout



4.18.7.6 Terminating resistor

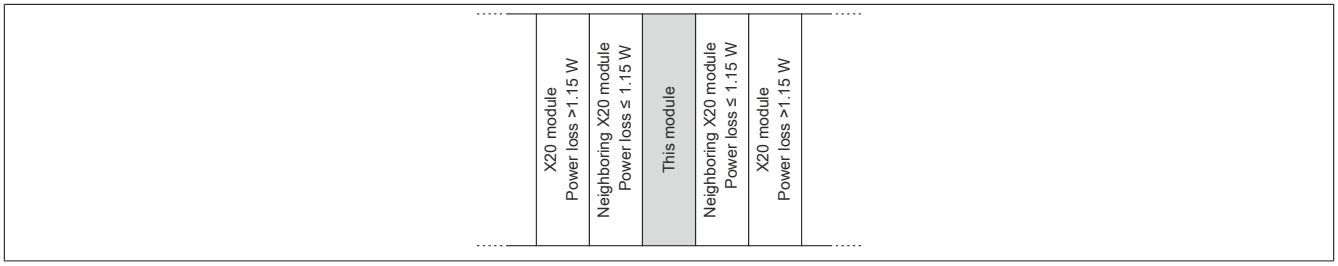


A terminating resistor is integrated in the communication module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T" LED.

4.18.7.7 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.18.7.8 Register description

4.18.7.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.7.8.2 Function model 0 - Flat

In the "Flat" function model, CAN information is transferred via cyclic input and output registers. All data for a CAN object (8 CAN data bytes, identifier, status, etc.) is accessible as individual data points (see also 4.18.7.8.7 "CAN object" on page 2042).

To transmit a CAN object, the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be transmitted must be written to the cyclic I/O data points. Then, "TXCount" is increased to send the transmission. The data is held in the module's internal buffer (max. 18 objects) and transmitted over the CAN network at the next available opportunity.

Receiving information from the CAN network uses the same algorithm. The module saves the CAN messages in its internal buffer along with the respective identifiers. Then the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be processed are written to the cyclic I/O data points. "RXCount" tells the application how much new data must be taken from these input data points.

Information:

- **The "CAN_Lib" library can't be used.**

Register	Name	Data type	Read		Write

4.18.7.8.3 Function model 2 - Stream and Function model 254 - Cyclic stream

The "Stream" and "Cyclic stream" function models use a module-specific driver for the CPU's operating system. The interface can be controlled using the "CAN_Lib" library and be reconfigured at runtime.

Function model - Stream

In the "Stream" function model, the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

The "Cyclic stream" function model was implemented later. From the application's point of view, there is no difference between the "Stream" and "Cyclic stream" function models. Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- **In order to use the "Stream" and "Cyclic stream" function models, you must be using B&R controllers of the type "SG4".**

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Module - Configuration						
-	AsynSize	-

6209	CAN error acknowledgment	USINT			•	
	QuitCANwarning	Bit 0				
	QuitCANpassive	Bit 1				
	QuitCANbussoff	Bit 2				
	QuitCANRXoverrun	Bit 3				

4.18.7.8.4 Function model 254 - FlatStream

The "FlatStream" function model provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the CAN module. CAN information (identifier, status, etc.) is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see 4.3.7.10.8 "FlatStream communication" on page 223).

When using the Flatstream function model, the user can choose whether to use the "AsFltGen" library in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

Information:

- **The "CAN_Lib" library can't be used.**
- **Higher data rates can be achieved between X2X master and module compared to the "Flat" function model.**

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic

4.18.7.8.5 Function model 254 - Bus controller

The "Bus controller" function model is a reduced form of the "FlatStream" function model. Instead of up to 27 Tx / Rx bytes, a maximum of 7 Tx / Rx bytes can be used.

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Interface - Configuration							
257	-	ConfigBaudrate	USINT				•
259	-	ConfigSJW	USINT				•
261	-	ConfigSPO	USINT				•
266	-	ConfigTXtrigger	UINT				•

		QuitCANbussoff	Bit 2				
		QuitCANRXoverrun	Bit 3				
FlatStream - Configuration							
193	-	outputMTU	USINT				•
195	-	inputMTU	USINT				•
197	-	mode	USINT				•
199	-	forward	USINT				•
206	-	forwardDelay	UINT				•
FlatStream - Communication							
0	0	InputSequence	USINT	•			
Index * 1 + 0	Index * 1 + 0	RxByte1 to RxByte7	USINT	•			
32	0	OutputSequence	USINT			•	
Index * 1 + 32	Index * 1 + 0	TxByte1 to TxByte7	USINT			•	

1) The offset specifies the position of the register within the CAN object.

4.18.7.8.5.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.18.7.8.6 Using this module with SGC target systems

> **Note:**
>
> **This module can only be used with SGC target systems if the function model is set to "Flatstream" or "Flat".**

4.18.7.8.7 CAN object

A CAN object is always made up of a 4-byte identifier and a maximum of 8 subsequent data bytes. This also results in the relationship between CAN object length and the amount of CAN payload data. This is important because the number of CAN payload data bytes for communication via "FlatStream" always has to be determined using the frame length.

Composition of a CAN object / CAN frame

Bytes	Function	Information
1	Code	ID bit 0 to 7
2		ID bit 8 to 15
3		ID bit 16 to 23
4		ID bit 24 to 31
5 - 12	CAN payload data	0 to 8 CAN payload data bytes

Code

The 32 bits (4 bytes) of the CAN identifier are used as follows:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.7.8.7.1 CAN module data stream

In function model 254, the data packets to be transferred in a data stream are referred to as frames.

Information:

For the CAN module, that means:

- **A frame always contains one CAN object and therefore cannot be longer than 12 bytes.**
- **The CAN object is only transferred to the transmit buffer after the frame has been completed.**
- **The CAN payload data length has a fixed relationship with the frame length and the actual size of the CAN object. The following rules apply:**
  - **CAN payload data length = Frame length - 4**
  - **Frame length = CAN payload data length + 4**

4.18.7.8.8 Interface - Configuration

4.18.7.8.8.1 Transfer rate

Name:
ConfigBaudrate

"Baud rate" in the AS I/O configuration.

Configuration of the CAN transfer rate for the interface.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Transfer rate	1	10 kbit/s
		2	20 kbit/s
		3	50 kbit/s
		4	100 kbit/s
		5	125 kbit/s
		6	250 kbit/s
		7	500 kbit/s (default)
		8	800 kbit/s
		9	1000 kbit/s
4 - 7	Reserved	-	

4.18.7.8.8.2 Synchronization Jump Width

Name:
ConfigSJW

"Synchronization jump width" in the AS I/O configuration.

The synchronization jump width (SJW) is used to resynchronize the sample point within a CAN telegram.

A detailed description of the SJW can be found in the CAN specification.

Data type	Value	Meaning
USINT	0 to 4	Synchronization jump width (default = 3)

4.18.7.8.8.3 Offset for the sampling instant

Name:
ConfigSPO

"Sample point offset" in the AS I/O configuration.

Offset for the sample point of the individual bits on the CAN bus.

A detailed description of the SPO can be found in the CAN specification.

Data type	Value	Meaning
USINT	0 to 1	Sample point offset (default = 0)

4.18.7.8.8.4 Start of transmission

Name:
ConfigTXtrigger

"TX objects / TX triggers" in the AS I/O configuration.

Defines the number of CAN objects that must be copied to the transmit buffer before the transmission is started.

Data type	Value	Meaning
UINT	0 to 8	Number of CAN objects in the transmit buffer before transmission is started (default = 1)

4.18.7.8.8.5 Configuration of error messages

Name:
CfO_ErrorID0007

This register must be used first to configure the error messages that have to be transferred. If the corresponding enable bit is not set, no error status will be sent to the higher-level system when the error occurs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CANwarning	0	Disabled
		1	Enabled
1	CANpassive	0	Disabled
		1	Enabled
2	CANbussoff	0	Disabled
		1	Enabled
3	CANRXoverrun	0	Disabled
		1	Enabled
4 - 7	Reserved	-	

4.18.7.8.8.6 Size of the transmit buffer

Name:
Cfo_FIFOTXlimit

"TX FIFO size" in the AS I/O configuration.

Determines the size of the transmit buffer for the respective interface.

Data type	Value	Meaning
USINT	0 to 18	Size of the transmit buffer (default = 1)

4.18.7.8.8.7 Display of unprocessed elements remaining in transmit/receive buffer

Name:
Cfo_TXRXinfoFlags

This register can be used to specify that the number of unprocessed elements in the transmit and receive buffers is indicated in the upper 4 bits of the "TxCountReadback" and "RxCount" registers for the interface.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TxFifoInfo "Mode of channel TXCountReadBack" in the AS I/O configuration	0	The "TXCountReadBack" on page 2046 and "TXCountLatchReadBack" on page 2046 registers are used to read back "TXCount".
		1	The lower 4 bits of the "TXCountReadBack" on page 2046 and "TXCountLatchReadBack" on page 2046 registers are used to read back "TXCount". The upper 4 bits are used to return the number of frames in the transmit buffer that have not been transmitted.
1	RxFifoInfo "Mode of channel RXCount" in the AS I/O configuration	0	The "RXCount" on page 2046 and "RXCountLatch" on page 2047 registers are used to indicate the number of telegrams that have been received.
		1	The lower 4 bits of the "RXCount" on page 2046 and "RXCountLatch" on page 2047 registers are used to indicate the number of telegrams received. The upper 4 bits are used to indicate the number of received but not acknowledged telegrams in the receive buffer.
2 - 7	Reserved	-	

4.18.7.8.9 Interface - Communication

4.18.7.8.9.1 CAN error status

Name:
CAN error status

The bits in this register indicate the error states defined in the CAN protocol. If an error occurs, the corresponding bit is set. For an error bit to be reset, the corresponding bit must be acknowledged (see 4.18.7.8.9.2 "CAN error acknowledgment" on page 2045).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CANwarning	0	No error
		1	CANwarning error on IF1
1	CANpassive	0	No error
		1	CANpassive error on IF1
2	CANbusoff	0	No error
		1	CANbusoff error on IF1
3	CANRXoverrun	0	No error
		1	CANRXoverrun error on IF1
4 - 7	Reserved	-	

4.18.7.8.9.2 CAN error acknowledgment

Name:
CAN error acknowledgment

Setting the bits in this register acknowledges the error assigned to the bit and clears the corresponding bit in the "CAN error status" register. The application thus informs the module that it has recognized the error state.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	QuitCANwarning	0	No acknowledgment
		1	Acknowledge CANwarning error on IF1
1	QuitCANpassive	0	No acknowledgment
		1	Acknowledge CANpassive error on IF1
2	QuitCANbussoff	0	No acknowledgment
		1	Acknowledge CANbusoff error on IF1
3	QuitCANRXoverrun	0	No acknowledgment
		1	Acknowledge CANRXoverrun error on IF1
4 - 7	Reserved	-	

4.18.7.8.9.3 New CAN telegram for transmit buffer

Name:
TXCount

By increasing this value, the application notifies the module that a new CAN telegram should be transferred into the transmit buffer.

Data type	Value
USINT	0 to 255

4.18.7.8.9.4 Read "TXCount"

Name:
TXCountReadBack

The value of "TXCount" is copied from the module into this register. This makes it possible for the application task to verify that the CAN telegram data was transfered from the module correctly.

The meaning of the value depends on the "TxFifoInfo" bit. This is located in the Cfo_TXRXinfoFlags register

Data type	Value	"TxFifoInfo" bit	Meaning
USINT	0 to 255	0	Read back "TX-Count"
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	Read back "TX-Count"	0 to 15	Only the lower 4 bits
4 - 7	Number of frames in the transmit buffer that have not been transmitted	0 to 15	If this number exceeds the 15 (a maximum of 18 possible), the value 15 is returned.

4.18.7.8.9.5 Read "TXCount" from the previous cycle

Name:
TXCountLatchReadBack

This register is used to copy the "TxCount" value from the previous cycle from the module. In the event of an X2X Link or POWERLINK transfer error, this makes it possible to determined if the error occurred on the way from the CPU to the module or on the way from the module to the CPU (see 4.18.7.8.10.4 "Taking possible errors into consideration when transmitting" on page 2048).

The meaning of the value depends on the "TxFifoInfo" on page 2044 bit in the "Cfo_TXRXinfoFlags" register.

Data type	Value	"TxFifoInfo" bit	Meaning
USINT	0 to 255	0	TX-Count read back from the previous cycle
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	TX-Count read back from the previous cycle	0 to 15	Only the lower 4 bits
4 - 7	Number of frames in the transmit buffer that have not been transmitted	0 to 15	From the previous cycle

4.18.7.8.9.6 Counter for received CAN telegrams

Name:
RXCount

This counter is increased by 1 with each CAN telegram. The application task can thus detect when new data is received and get it from the corresponding "RXData" registers.

The meaning of the value depends on the "RxFifoInfo" on page 2044 bit in the "Cfo_TXRXinfoFlags" register.

Data type	Value	"RxFifoInfo" bit	Meaning
USINT	0 to 255	0	Counter for received telegrams
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	Counter for received telegrams	0 to 15	Only the lower 4 bits
4 - 7	Number of unacknowledged telegrams in the receive buffer	0 to 15	

4.18.7.8.9.7 Read "RXCount" from the previous cycle

Name:
RXCountLatch

This register always contains the "RXCount" value from the previous cycle. It can be used to detect transfer errors from the module to the CPU (see 4.18.7.8.10.4 "Taking possible errors into consideration when transmitting" on page 2048).

The meaning of the value depends on the "RxFifoInfo" on page 2044 bit in the "Cfo_TXRXinfoFlags" register.

Data type	Value	"RxFifoInfo" bit	Meaning
USINT	0 to 255	0	Counter for received telegrams from the previous cycle
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	Counter for received telegrams from the previous cycle	0 to 15	Only the lower 4 bits
4 - 7	Number of telegrams in the receive buffer from the previous cycle	0 to 15	

4.18.7.8.10 Send buffer

4.18.7.8.10.1 Number of CAN payload data bytes

Name:
TXDataSize

Number of CAN payload data bytes to be transmitted If a value less than 0 is specified here, this CAN telegram is marked as being invalid and is not transferred into the transmit buffer. This is useful in connection with transmit error detection between the module and the CPU (see 4.18.7.8.10.4 "Taking possible errors into consideration when transmitting" on page 2048).

Data type	Value	Meaning
USINT	-128 to 8	Amount of CAN payload data to be transmitted (Default = 0).

4.18.7.8.10.2 Identifier of the CAN telegram to be transmitted.

Name:
TXIdent

Identifier of the CAN telegram to be transmitted. The frame format and the identifier format are also defined in this register.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.7.8.10.3 Configuration of the CAN payload data being sent

Name:
TXDataByte0 to TXDataByte7
TXDataWord0 to TXDataWord3
TXDataLong0 to TXDataLong1

CAN payload data in the transmit direction. The 8 payload data bytes for a telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

Data type	Value	Description
USINT	0 to 255	CAN payload data transmitted as bytes
UINT	0 to 65,535	CAN payload data transmitted as words
UDINT	0 to 4.294.967.295	CAN payload data transmitted as longs

4.18.7.8.10.4 Taking possible errors into consideration when transmitting

Data on the POWERLINK network or X2X Link can be lost due to transmission errors. One-time failures of cyclic data are tolerated by the I/O systems. This is possible since all I/O data is re-transferred in the subsequent cycle. A transfer error cannot be detected from the I/O variables; they remain frozen on the value from the last cycle.

These tolerated one-time I/O failures can lead to data loss or the delayed CAN telegram transmission. The counter feedback is derived on the module and used to detect these cases.

Register for counter feedback:

- "TXCountReadBack" on page 2046
- "TXCountLatchReadBack" on page 2046

4.18.7.8.11 Receive buffers 0 and 1

4.18.7.8.11.1 Number of valid CAN payload data bytes

Name:
RXDataSize0
RXDataSize1

Number of valid CAN payload data bytes.

This register also uses the value -1 (0xFF) to indicate a general error or gap in the input data stream. Details regarding the error that has occurred can be seen in the "" on page register.

Data type	Value	Meaning
USINT	1 to 8	Number CAN payload data
	-1	Error

4.18.7.8.11.2 Identifier of the received data

Name:
RXIdent0
RXIdent1

Identifiers assigned to the received data. The frame format and the identifier format can also be read from this register.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.7.8.11.3 Configuration of the CAN payload data to be received

Name:
RXData0Byte0 to RXData0Byte7
RXData0Word0 to RXData0Word3
RXData0Long0 to RXData0Long1

RXData1Byte0 to RXData1Byte7
RXData1Word0 to RXData1Word3
RXData1Long0 to RXData1Long1

These registers hold the payload data of the CAN object to be transferred from the receive buffer to the CPU in the current cycle. If new data is received or if the receive buffer contains additional CAN objects, these registers are overwritten with the new data in the next cycle.

To avoid losing CAN objects, the application must respond immediately to a change in the "RXCount" and copies the data from these registers.

The maximum 8 bytes for a CAN telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

Data type	Value	Description
USINT	0 to 255	Received CAN payload data as bytes
UINT	0 to 65,535	Received CAN payload data as words
UDINT	0 to 4.294.967.295	Received CAN payload data as longs

4.18.7.8.12 FlatStream communication

4.18.7.8.12.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

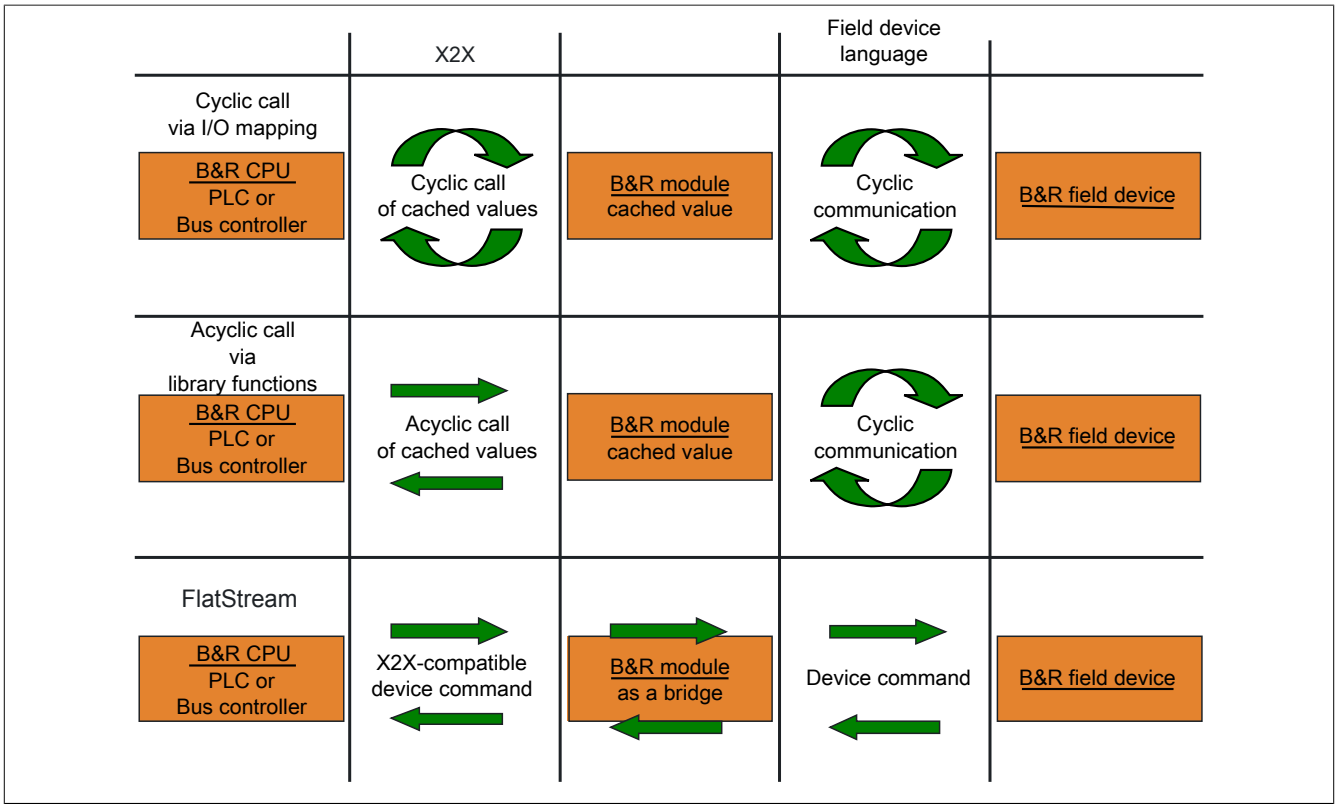

Figure 330: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.18.7.8.12.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.18.7.8.12.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

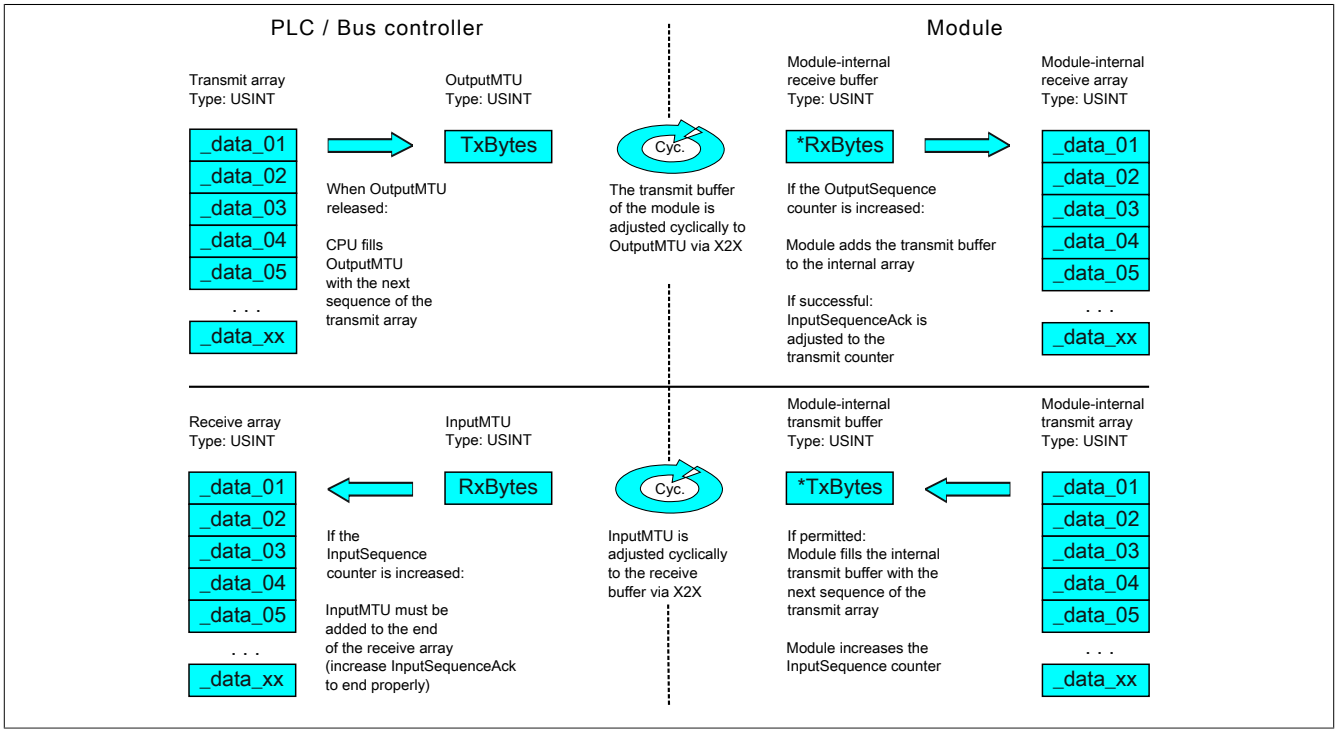

Figure 331: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.18.7.8.12.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Format of input and output bytes

Name:

"Format of Flat stream" in Automation Studio

This function sets how the Flatstream input and output bytes (Tx or Rx bytes) are transferred.

- **packed variable:** Transfers data as an array
- **byte variables:**Transfers data as individual bytes

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

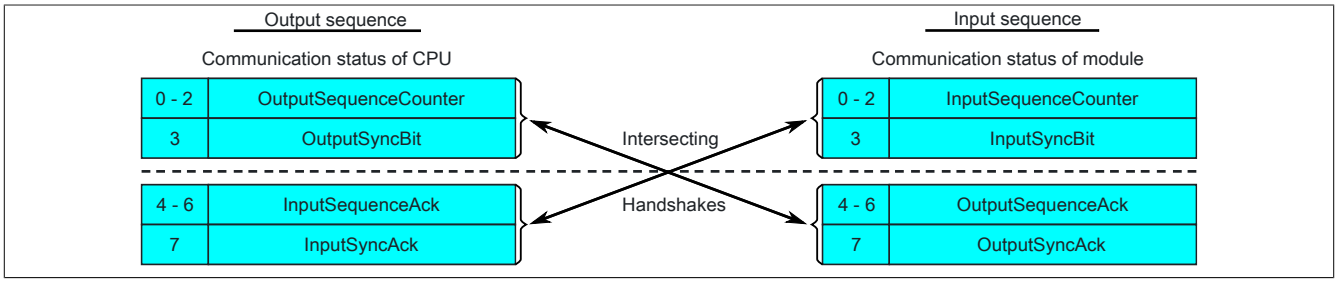

Figure 332: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

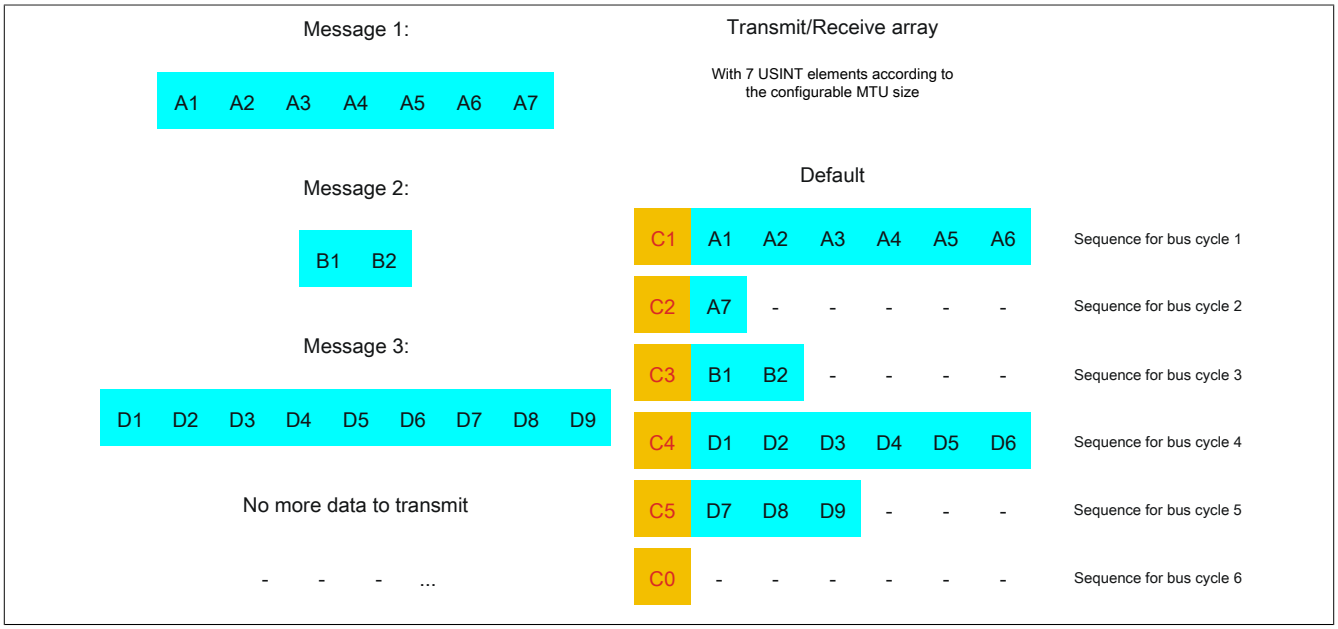

Figure 333: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 415: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 416: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

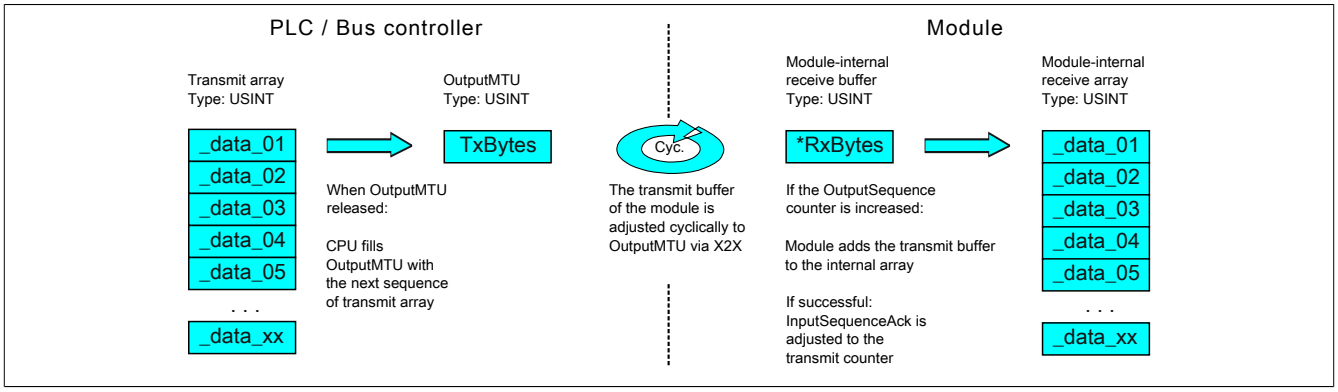

Figure 334: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

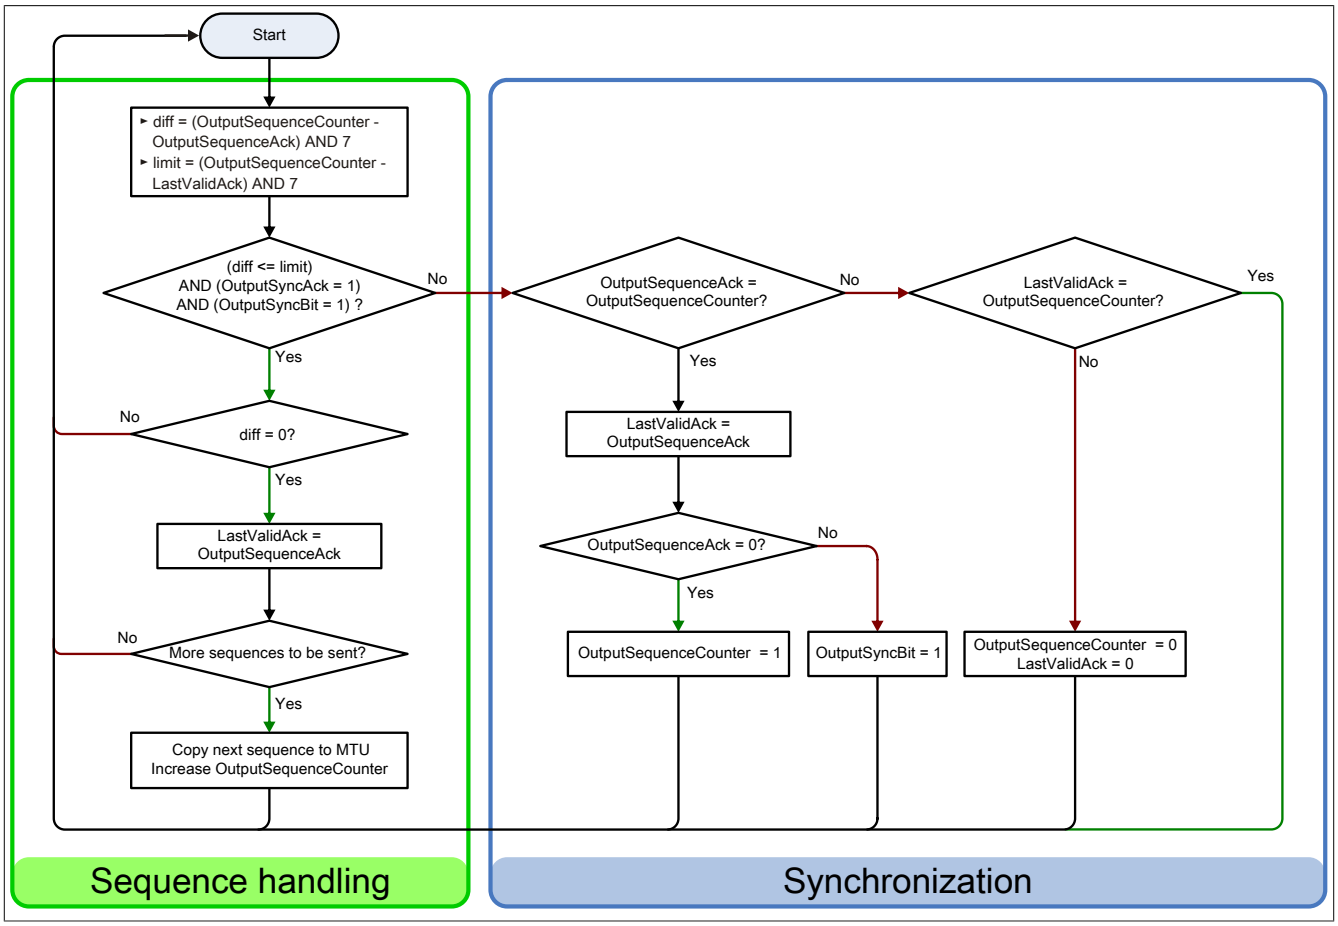

Figure 335: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

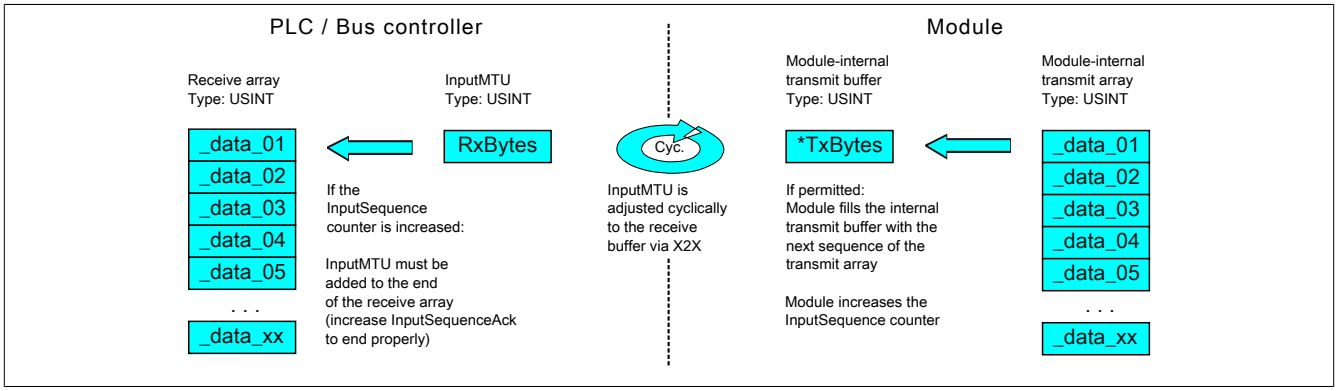

Figure 336: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

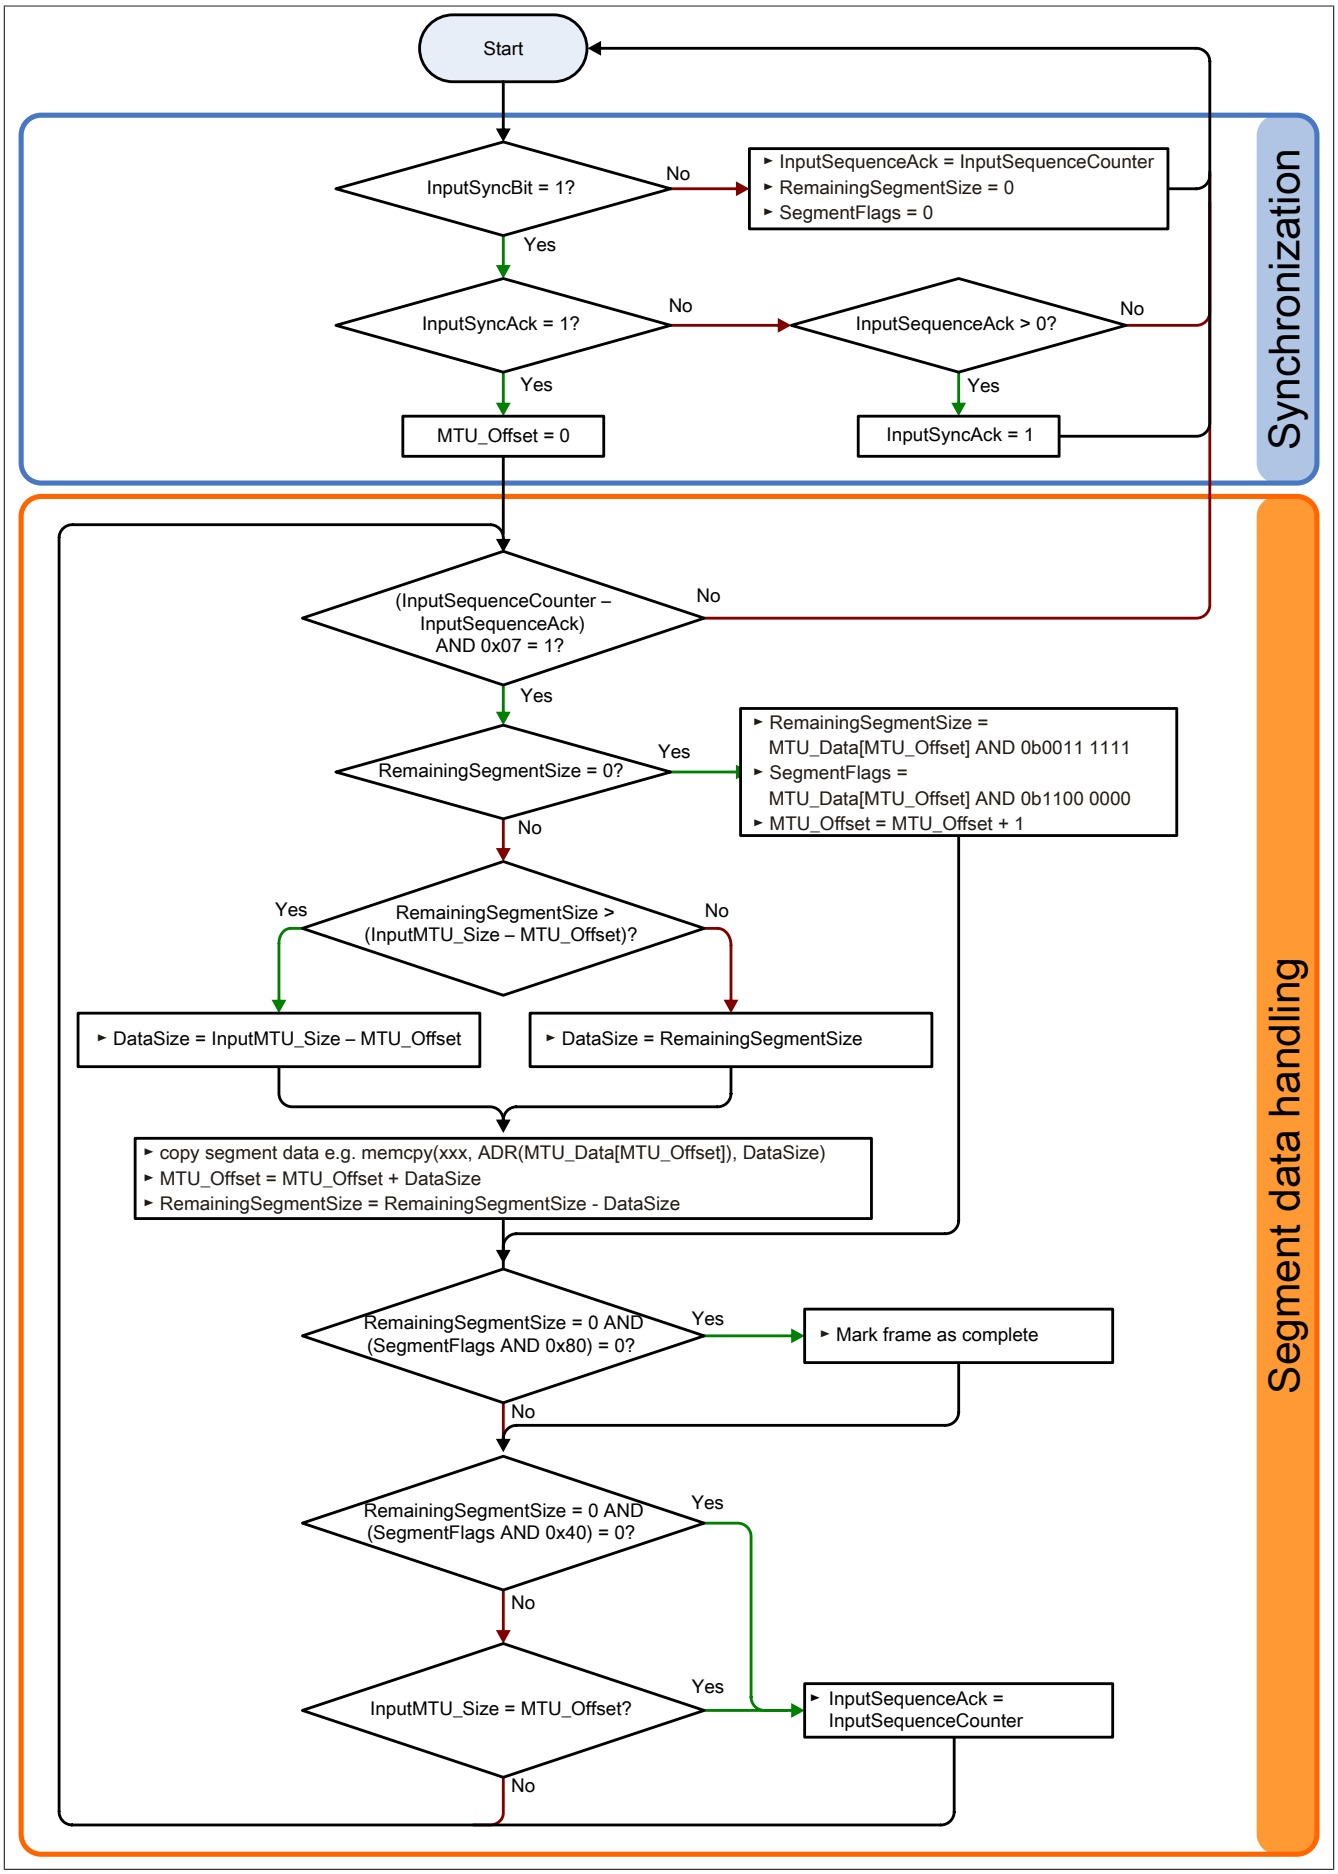

Figure 337: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

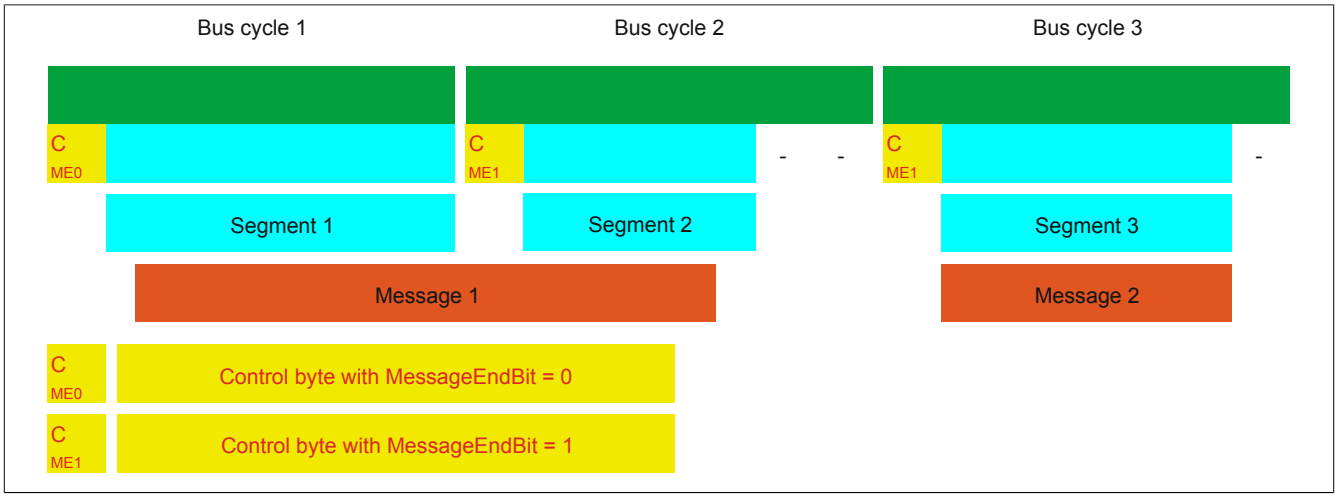

Figure 338: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

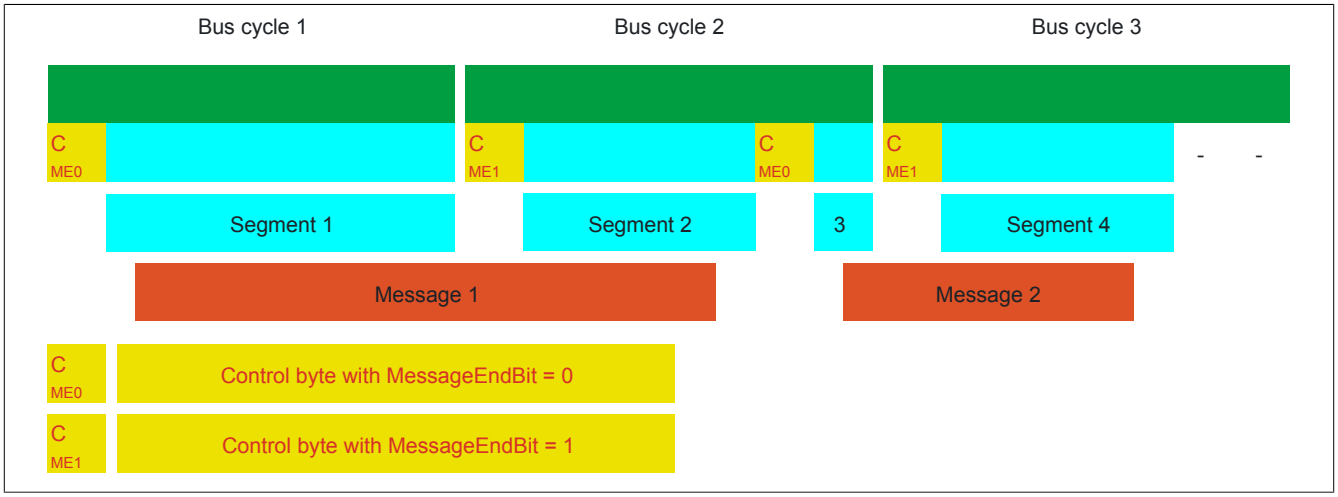

Figure 339: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

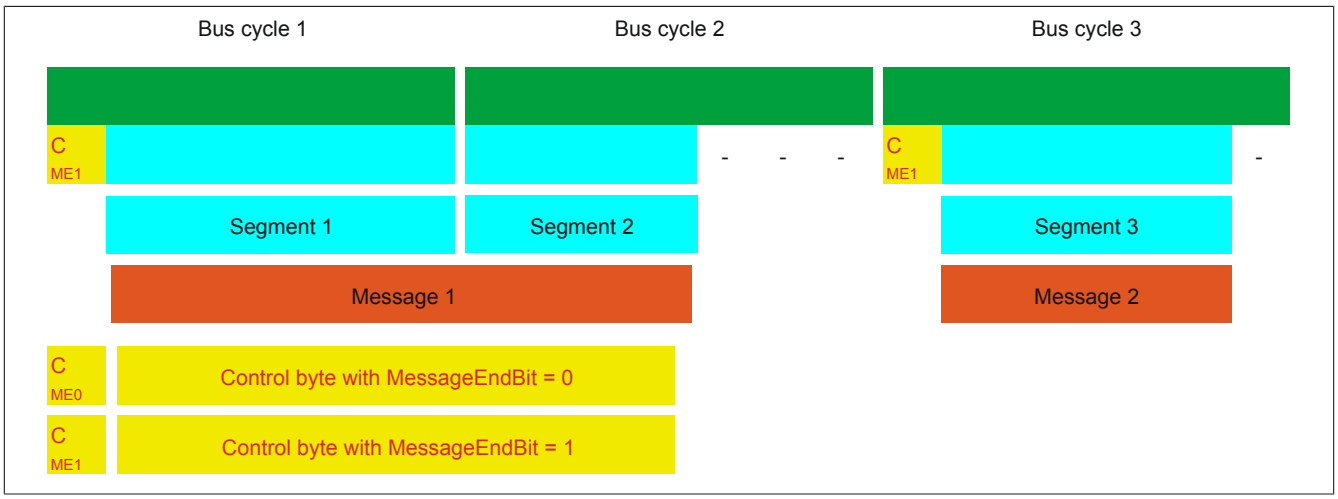

Figure 340: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

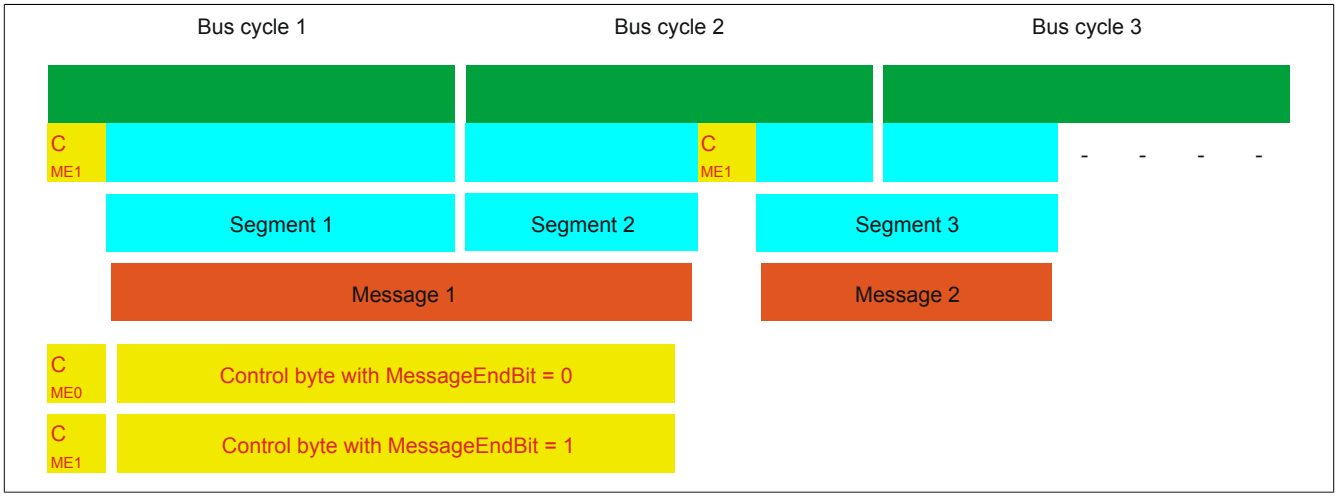

Figure 341: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

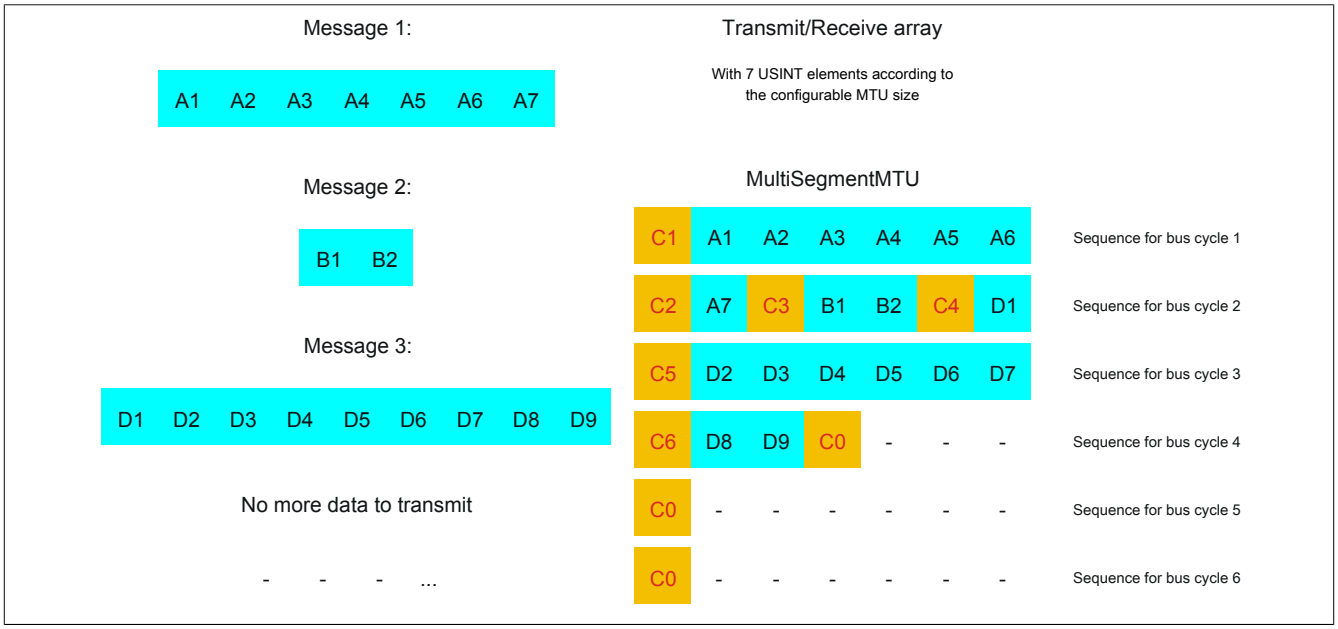

Figure 342: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 417: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 418: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

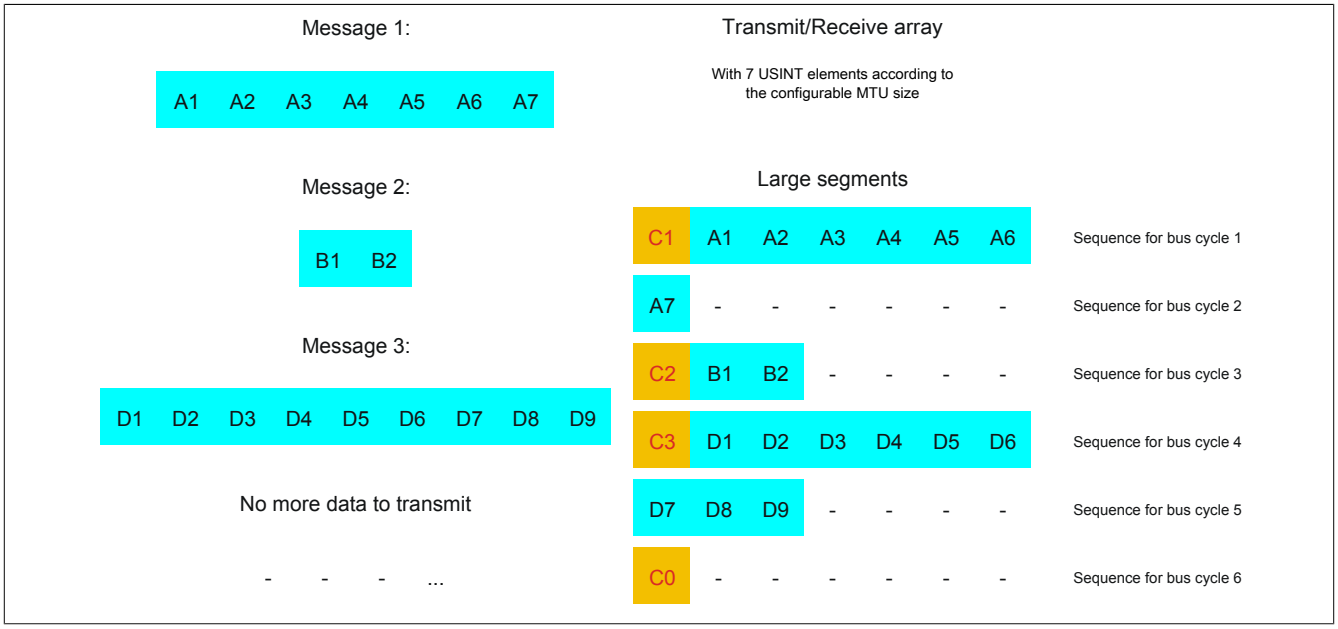

Figure 343: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 419: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

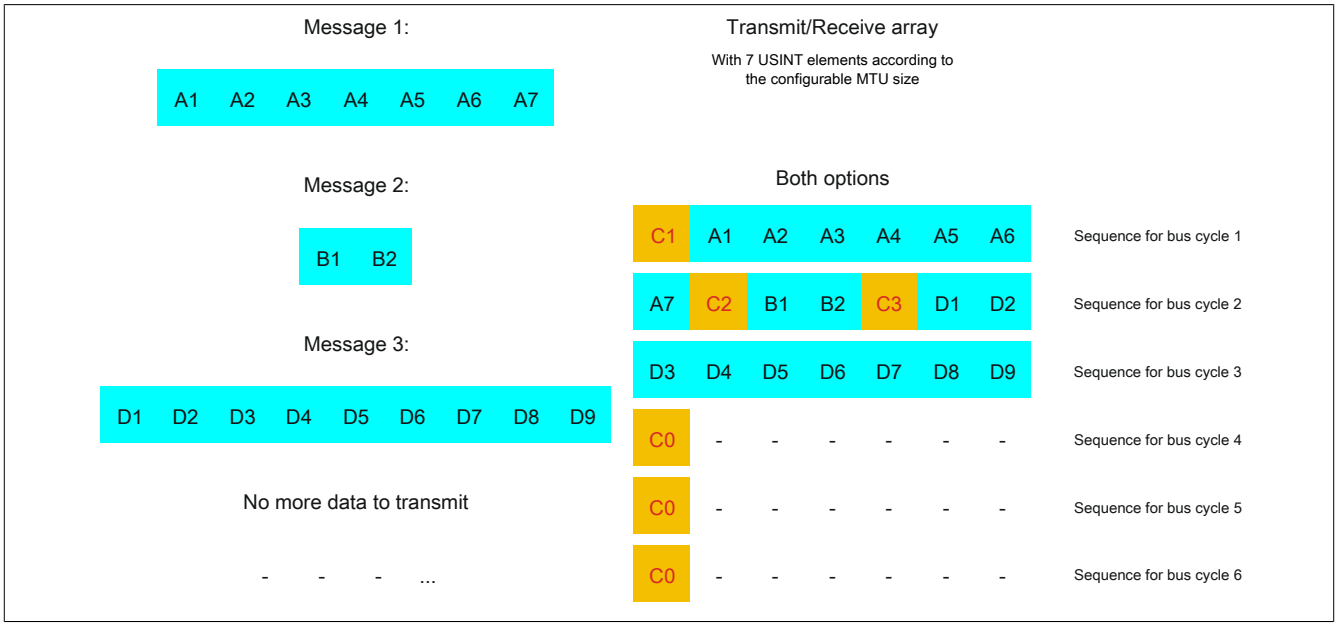

Figure 344: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 420: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.18.7.8.12.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

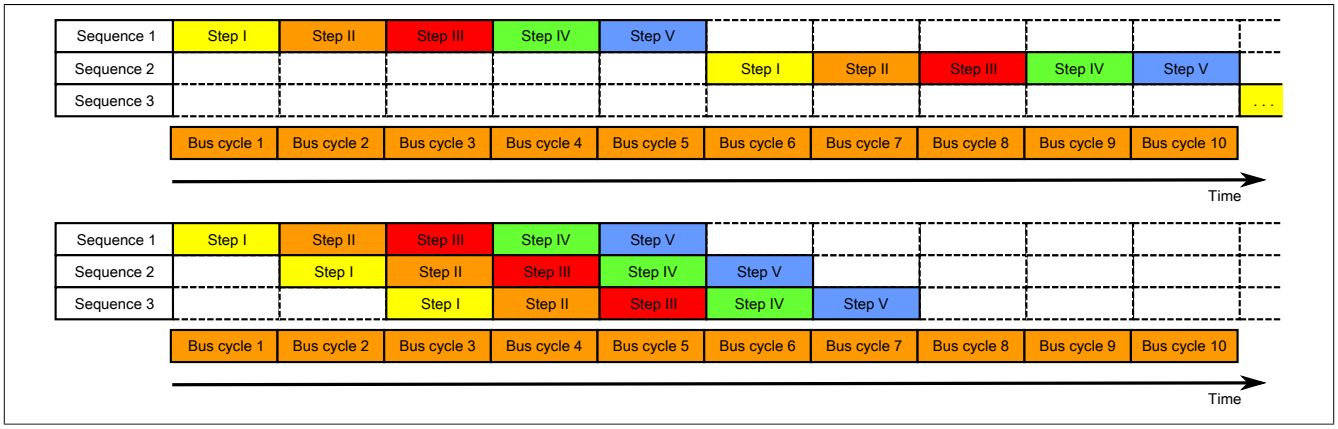

Figure 345: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

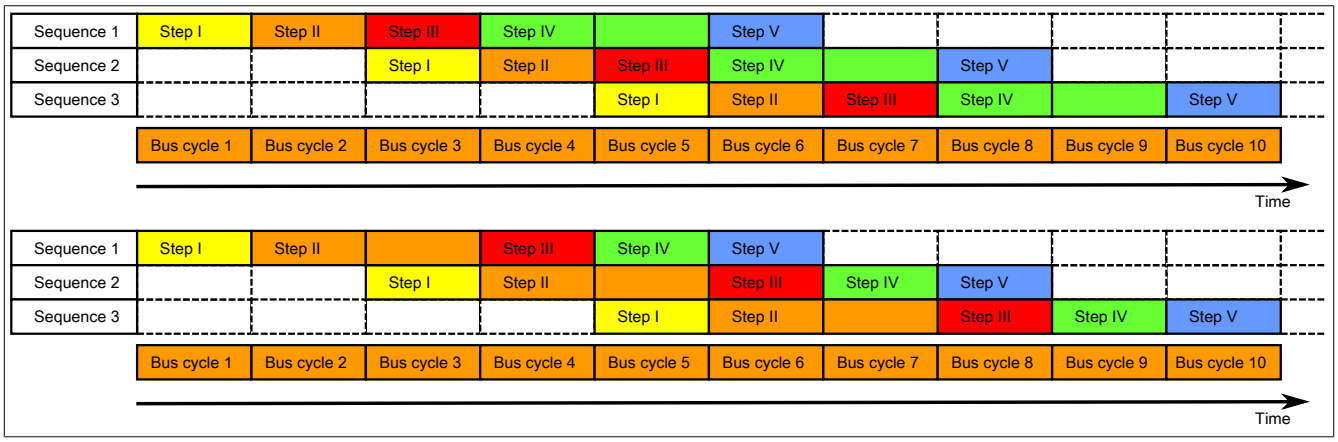

Figure 346: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

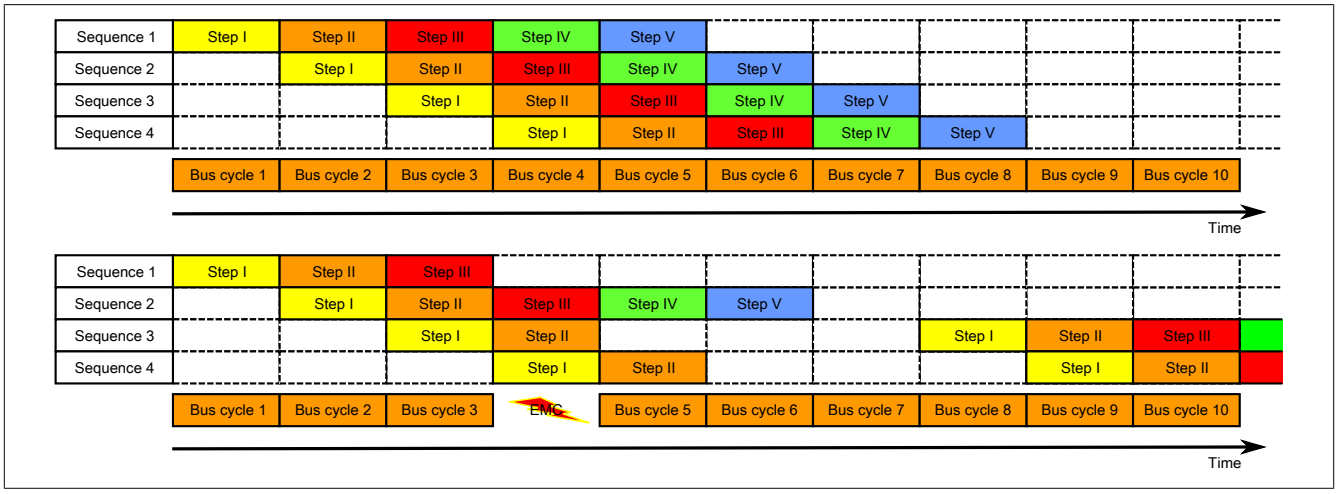

Figure 347: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.18.7.8.13 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.18.7.8.14 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.7.8.15 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.18.8 X20CS2770

4.18.8.1 General information

In addition to the standard I/O, complex devices often need to be connected. The X20 CS communication modules are intended precisely for cases like this. As normal X20 electronics modules, they can be placed anywhere on the remote backplane.

- 2 CAN bus interfaces for serial, remote connection of complex devices to the X20 system
- Integrated terminating resistors

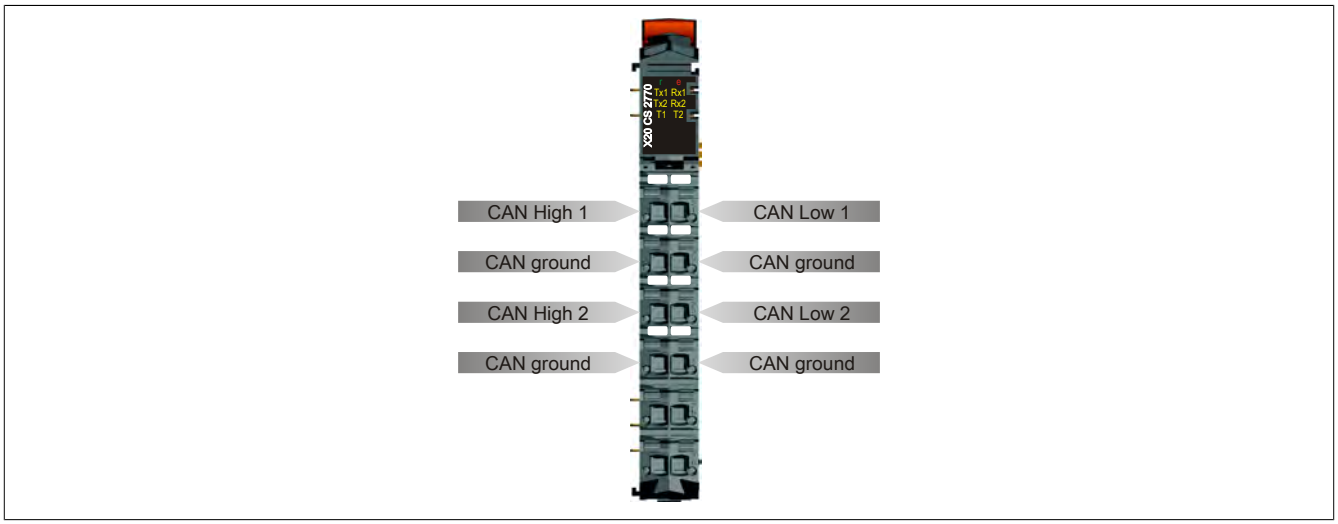
4.18.8.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

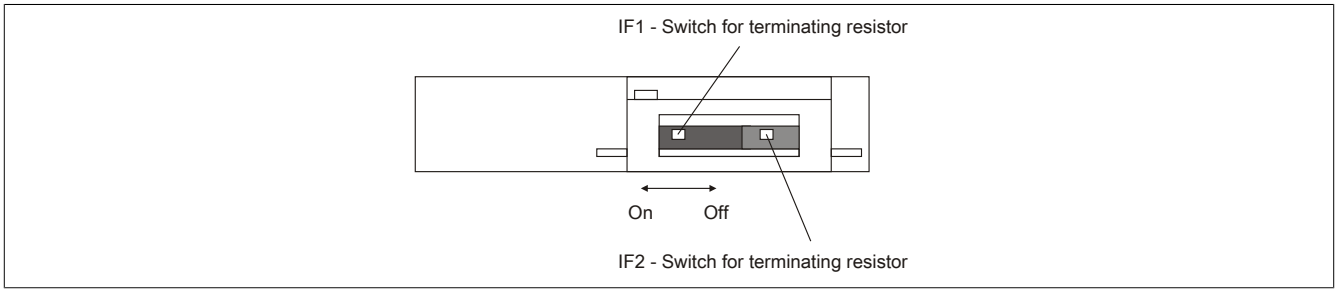
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	I/O error occurred • CAN bus: Warning, passive or off • Buffer overflow
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	Tx1/2	Yellow	On	The module is sending data via the CAN bus interface IF1/IF2
	Rx1/2	Yellow	On	The module is receiving data via the CAN bus interface IF1/IF2
	T1/2	Yellow	On	The integrated terminating resistor for the CAN bus interface IF1/IF2 is turned on

1) Depending on the configuration, a firmware update can take up to several minutes.

4.18.8.5 Pinout



4.18.8.6 Terminating resistors

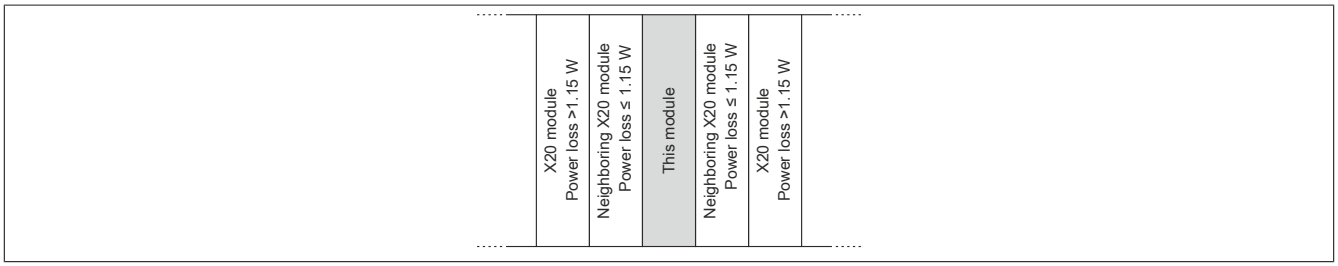


Two terminating resistors are integrated in the communication module. The respective resistor can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "T1" or "T2" LED.

4.18.8.7 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.18.8.8 Register description

4.18.8.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.18.8.8.2 Function model 0 - Flat

In the "Flat" function model, CAN information is transferred via cyclic input and output registers. All data for a CAN object (8 CAN data bytes, identifier, status, etc.) is accessible as individual data points (see also 4.18.7.8.7 "CAN object" on page 2042).

To transmit a CAN object, the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be transmitted must be written to the cyclic I/O data points. Then, "TX0[x]Count" is increased to send the transmission. The data is held in the module's internal buffer (max. 18 objects) and transmitted over the CAN network at the next available opportunity.

Receiving information from the CAN network uses the same algorithm. The module saves the CAN messages in its internal buffer along with the respective identifiers. Then the CAN identifier, the CAN data (max. 8 bytes) and the number of bytes to be processed are written to the cyclic I/O data points. RX0[x]Count tells the application how much new data must be taken from these input data points.

Information:

- **The "CAN_Lib" library can't be used.**

4.18.8.8.3 Function model 2 - Stream and Function model 254 - Cyclic stream

The "Stream" and "Cyclic stream" function models use a module-specific driver for the CPU's operating system. The interface can be controlled using the "CAN_Lib" library and be reconfigured at runtime.

Function model - Stream

In the "Stream" function model, the CPU communicates with the module acyclically. The interface is relatively convenient, but the timing is very imprecise.

Function model - Cyclic stream

The "Cyclic stream" function model was implemented later. From the application's point of view, there is no difference between the "Stream" and "Cyclic stream" function models. Internally, however, the cyclic I/O registers are used to ensure that communication follows deterministic timing.

Information:

- **In order to use the "Stream" and "Cyclic stream" function models, you must be using B&R controllers of the type "SG4".**

4.18.8.8.4 Function model 254 - FlatStream

The "FlatStream" function model provides independent communication between an X2X Link master and the module. This interface was implemented as a separate function model for the CAN module. CAN information (identifier, status, etc.) is transferred via cyclic input and output registers. The sequence and control bytes are used to control this data stream (see 4.3.7.10.8 "FlatStream communication" on page 223).

When using the Flatstream function model, the user can choose whether to use the "AsFltGen" library in AS for implementation or to adapt Flatstream handling directly to the individual requirements of the application.

Information:

- **The "CAN_Lib" library can't be used.**
- **Higher data rates can be achieved between X2X master and module compared to the "Flat" function model.**

FlatStream - Communication							
0	0	Input01Sequence	USINT	•			
64	8	Input02Sequence	USINT	•			
Index * 1 + 0	Index * 1 + 0	Rx01Byte1 to Rx01Byte7	USINT	•			
Index * 1 + 64	Index * 1 + 8	Rx02Byte1 to Rx02Byte7	USINT	•			
32	0	Output01Sequence	USINT			•	
96	8	Output02Sequence	USINT			•	
Index * 1 + 32	Index * 1 + 0	Tx01Byte1 to Tx01Byte7	USINT			•	
Index * 1 + 96	Index * 1 + 8	Tx02Byte1 to Tx02Byte7	USINT			•	

1) The offset specifies the position of the register within the CAN object.

4.18.8.8.5.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.18.8.8.6 Using this module with SGC target systems

Note:

This module can only be used with SGC target systems if the function model is set to "Flatstream" or "Flat".

4.18.8.8.7 CAN object

A CAN object is always made up of a 4-byte identifier and a maximum of 8 subsequent data bytes. This also results in the relationship between CAN object length and the amount of CAN payload data. This is important because the number of CAN payload data bytes for communication via "FlatStream" always has to be determined using the frame length.

Composition of a CAN object / CAN frame

Bytes	Function	Information
1	Code	ID bit 0 to 7
2		ID bit 8 to 15
3		ID bit 16 to 23
4		ID bit 24 to 31
5 - 12	CAN payload data	0 to 8 CAN payload data bytes

Code

The 32 bits (4 bytes) of the CAN identifier are used as follows:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.8.8.7.1 CAN module data stream

In function model 254, the data packets to be transferred in a data stream are referred to as frames.

Information:

For the CAN module, that means:

- **A frame always contains one CAN object and therefore cannot be longer than 12 bytes.**
- **The CAN object is only transferred to the transmit buffer after the frame has been completed.**
- **The CAN payload data length has a fixed relationship with the frame length and the actual size of the CAN object. The following rules apply:**
  - **CAN payload data length = Frame length - 4**
  - **Frame length = CAN payload data length + 4**

4.18.8.8.8 Interface - Configuration

4.18.8.8.8.1 Transfer rate

Name:
Config01Baudrate
Config02Baudrate

"Baud rate" in the AS I/O configuration.

Configuration of the CAN transfer rate for the respective interface.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Transfer rate	1	10 kbit/s
		2	20 kbit/s
		3	50 kbit/s
		4	100 kbit/s
		5	125 kbit/s
		6	250 kbit/s
		7	500 kbit/s (default)
		8	800 kbit/s
		9	1000 kbit/s
4 - 7	Reserved	-	

4.18.8.8.8.2 Synchronization Jump Width

Name:
Config01SJW
Config02SJW

"Synchronization jump width" in the AS I/O configuration.

The synchronization jump width (SJW) is used to resynchronize the sample point within a CAN telegram.

A detailed description of the SJW can be found in the CAN specification.

Data type	Value	Meaning
USINT	0 to 4	Synchronization jump width (default = 3)

4.18.8.8.8.3 Offset for the sampling instant

Name:
Config01SPO
Config02SPO

"Sample point offset" in the AS I/O configuration.

Offset for the sample point of the individual bits on the CAN bus.

A detailed description of the SPO can be found in the CAN specification.

Data type	Value	Meaning
USINT	0 to 1	Sample point offset (default = 0)

4.18.8.8.8.4 Start of transmission

Name:
Config01TXtrigger
Config02TXtrigger

"TX objects / TX triggers" in the AS I/O configuration.

Defines the number of CAN objects that must be copied to the transmit buffer before the transmission is started.

Data type	Value	Meaning
UINT	0 to 8	Number of CAN objects in the transmit buffer before transmission is started (default = 1)

4.18.8.8.8.5 Configuration of error messages

Name:
CfO_ErrorID0007

This register must be used first to configure the error messages that have to be transferred. If the corresponding enable bit is not set, no error status will be sent to the higher-level system when the error occurs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CANIF1warning	0	Disabled
		1	Enabled
1	CANIF1passive	0	Disabled
		1	Enabled
2	CANIF1bussoff	0	Disabled
		1	Enabled
3	CANIF1RXoverrun	0	Disabled
		1	Enabled
4	CANIF2warning	0	Disabled
		1	Enabled
5	CANIF2passive	0	Disabled
		1	Enabled
6	CANIF2bussoff	0	Disabled
		1	Enabled
7	CANIF2RXoverrun	0	Disabled
		1	Enabled

4.18.8.8.8.6 Size of the transmit buffer

Name:
Cfo_FIFOTXlimit01
Cfo_FIFOTXlimit02

"TX FIFO size" in the AS I/O configuration.

Determines the size of the transmit buffer for the respective interface.

Data type	Value	Meaning
USINT	0 to 18	Size of the transmit buffer (default = 1)

4.18.8.8.8.7 Display of unprocessed elements remaining in transmit/receive buffer

Name:
Cfo_TXRXinfoFlags01
Cfo_TXRXinfoFlags02

This register can be used to specify that the number of unprocessed elements in the transmit and receive buffers is indicated in the upper 4 bits of the "TX0[x]CountReadBack" and "RX0[x]Count" registers for the respective interface.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TxFifoInfo "Mode of channel TX0[x]CountReadBack" in the AS I/O configuration	0	The "TX0[x]Count" is read in the "TX0[x]CountReadBack" on page 2091 register.
		1	The "TX0[x]Count" is read in the "TX0[x]CountReadBack" on page 2091 register. The upper 4 bits are used to return the number of frames in the transmit buffer that have not been transmitted.
1	RxFifoInfo "Mode of channel RX0[x]Count" in the AS I/O configuration	0	The number of received telegrams is shown in the "RX0[x]Count" on page 2091 register.
		1	The number of received telegrams is shown in the lower 4 bits of the "RX0[x]Count" on page 2091 register. The upper 4 bits are used to indicate the number of received but not acknowledged telegrams in the receive buffer.
2 - 7	Reserved	-	

4.18.8.8.9 Interface - Communication

4.18.8.8.9.1 CAN error status

Name:
CAN error status

The bits in this register indicate the error states defined in the CAN protocol. If an error occurs, the corresponding bit is set. For an error bit to be reset, the corresponding bit must be acknowledged (see 4.18.8.8.9.2 "CAN error acknowledgment" on page 2090).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CANIF1warning	0	No error
		1	CANwarning error on IF1
1	CANIF1passive	0	No error
		1	CANpassive error on IF1
2	CANIF1busoff	0	No error
		1	CANbusoff error on IF1
3	CANIF1RXoverrun	0	No error
		1	CANRXoverrun error on IF1
4	CANIF2warning	0	No error
		1	CANwarning error on IF2
5	CANIF2passive	0	No error
		1	CANpassive error on IF2
6	CANIF2busoff	0	No error
		1	CANbusoff error on IF2
7	CANIF2RXoverrun	0	No error
		1	CANRXoverrun error on IF2

4.18.8.8.9.2 CAN error acknowledgment

Name:
CAN error acknowledgment

Setting the bits in this register acknowledges the error assigned to the bit and clears the corresponding bit in the "CAN error status" register. The application thus informs the module that it has recognized the error state.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	QuitCANIF1warning	0	No acknowledgment
		1	Acknowledge CANwarning error on IF1
1	QuitCANIF1passive	0	No acknowledgment
		1	Acknowledge CANpassive error on IF1
2	QuitCANIF1bussoff	0	No acknowledgment
		1	Acknowledge CANbusoff error on IF1
3	QuitCANIF1RXoverrun	0	No acknowledgment
		1	Acknowledge CANRXoverrun error on IF1
4	QuitCANIF2warning	0	No acknowledgment
		1	Acknowledge CANwarning error on IF2
5	QuitCANIF2passive	0	No acknowledgment
		1	Acknowledge CANpassive error on IF2
6	QuitCANIF2bussoff	0	No acknowledgment
		1	Acknowledge CANbusoff error on IF2
7	QuitCANIF2RXoverrun	0	No acknowledgment
		1	Acknowledge CANRXoverrun error on IF2

4.18.8.8.9.3 New CAN telegram for transmit buffer

Name:
TX01Count
TX02Count

By increasing this value, the application notifies the module that a new CAN telegram should be transferred into the transmit buffer.

Data type	Value
USINT	0 to 255

4.18.8.8.9.4 Read "TX0[x]Count"

Name:
TX01CountReadBack
TX02CountReadBack

The value of "TX0[x]Count" is copied from the module into this register. This makes it possible for the application task to verify that the CAN telegram data was transfered from the module correctly.

The meaning of the value depends on the "TxFifoInfo" bit. This is located in the Cfo_TXRXinfoFlags0[x] register.

Data type	Value	"TxFifoInfo" bit	Meaning
USINT	0 to 255	0	Read "TX0[x]Count"
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	Read "TX0[x]Count"	0 to 15	Only the lower 4 bits
4 - 7	Number of frames in the transmit buffer that have not been transmitted	0 to 15	If this number exceeds the 15 (a maximum of 18 possible), the value 15 is returned.

4.18.8.8.9.5 Counter for received CAN telegrams

Name:
RX01Count
RX02Count

This counter is increased by 1 with each CAN telegram. The application task can thus detect when new data is received and get it from the corresponding "RX0[x]Data" registers.

The meaning of the value depends on the "Cfo_TXRXinfoFlags0[x]" on page 2089 bit in the "Cfo_TXRXinfoFlags" register.

Data type	Value	"RxFifoInfo" bit	Meaning
USINT	0 to 255	0	Counter for received telegrams
		1	See bit structure.

Bit structure:

Bit	Function	Value	Information
0 - 3	Counter for received telegrams	0 to 15	Only the lower 4 bits
4 - 7	Number of unacknowledged telegrams in the receive buffer	0 to 15	

4.18.8.8.10 Transmit buffer for IF1 and IF2

4.18.8.8.10.1 Number of CAN payload data bytes

Name:
TX01DataSize
TX02DataSize

Number of CAN payload data bytes to be transmitted If a value less than 0 is specified here, this CAN telegram is marked as being invalid and is not transferred into the transmit buffer. This is useful in connection with transmit error detection between the module and the CPU (see 4.18.8.8.10.4 "Taking possible errors into consideration when transmitting" on page 2092).

Data type	Value	Meaning
USINT	-128 to 8	Amount of CAN payload data to be transmitted (Default = 0).

4.18.8.8.10.2 Identifier of the CAN telegram to be transmitted.

Name:
TX01Ident
TX02Ident

Identifier of the CAN telegram to be transmitted. The frame format and the identifier format are also defined in this register.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.8.8.10.3 Configuration of the CAN payload data being sent

Name:
TX0[x]DataByte0 to TX0[x]DataByte7
TX0[x]DataWord0 to TX0[x]DataWord3
TX0[x]DataLong0 to TX0[x]DataLong1

CAN payload data in the transmit direction. The 8 payload data bytes for a telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

Data type	Value	Description
USINT	0 to 255	CAN payload data transmitted as bytes
UINT	0 to 65,535	CAN payload data transmitted as words
UDINT	0 to 4.294.967.295	CAN payload data transmitted as longs

4.18.8.8.10.4 Taking possible errors into consideration when transmitting

Data on the POWERLINK network or X2X Link can be lost due to transmission errors. One-time failures of cyclic data are tolerated by the I/O systems. This is possible since all I/O data is re-transferred in the subsequent cycle. A transfer error cannot be detected from the I/O variables; they remain frozen on the value from the last cycle.

These tolerated one-time I/O failures can lead to data loss or the delayed CAN telegram transmission. The counter feedback is derived on the module and used to detect these cases.

Register for counter feedback: "TX0[x]CountReadBack" on page 2091

4.18.8.8.11 Receive buffer for IF1 and IF2

4.18.8.8.11.1 Number of valid CAN payload data bytes

Name:
RX01DataSize
RX02DataSize

Number of valid CAN payload data bytes.

This register also uses the value -1 (0xFF) to indicate a general error or gap in the input data stream. Details regarding the error that has occurred can be seen in the "" on page register.

Data type	Value	Meaning
USINT	1 to 8	Number CAN payload data
	-1	Error

4.18.8.8.11.2 Identifier of the received data

Name:
RX01Ident
RX02Ident

Identifiers assigned to the received data. The frame format and the identifier format can also be read from this register.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Frame format	0	Standard frame format (SFF) with an 11-bit identifier
		1	Extended frame format (EFF) with an 29-bit identifier
1	Frame type	0	Data frame
		1	Remote frame (RTR)
2	Reserved	-	
3 - 31	CAN identifier for telegram to be transmitted	x	Extended frame format (EFF) with 29 bits Standard frame format (SFF) with 11 bits[1)]

1) Only bits 21 to 31 used; bits 3 to 20 = 0

4.18.8.8.11.3 Configuration of the CAN payload data to be received

Name:
RX0[x]DataByte0 to RX0[x]DataByte7
RX0[x]DataWord0 to RX0[x]DataWord3
RX0[x]DataLong0 to RX0[x]DataLong1

These registers hold the payload data of the CAN object to be transferred from the receive buffer to the CPU in the current cycle. If new data is received or if the receive buffer contains additional CAN objects, these registers are overwritten with the new data in the next cycle.

To avoid losing CAN objects, the application must respond immediately to a change in the "RX0[x]Count" and copies the data from these registers.

The maximum 8 bytes for a CAN telegram can be used as data points with 8 individual bytes, 4 words or 2 longs as needed.

Data type	Value	Description
USINT	0 to 255	Received CAN payload data as bytes
UINT	0 to 65,535	Received CAN payload data as words
UDINT	0 to 4.294.967.295	Received CAN payload data as longs

4.18.8.8.12 FlatStream communication

4.18.8.8.12.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

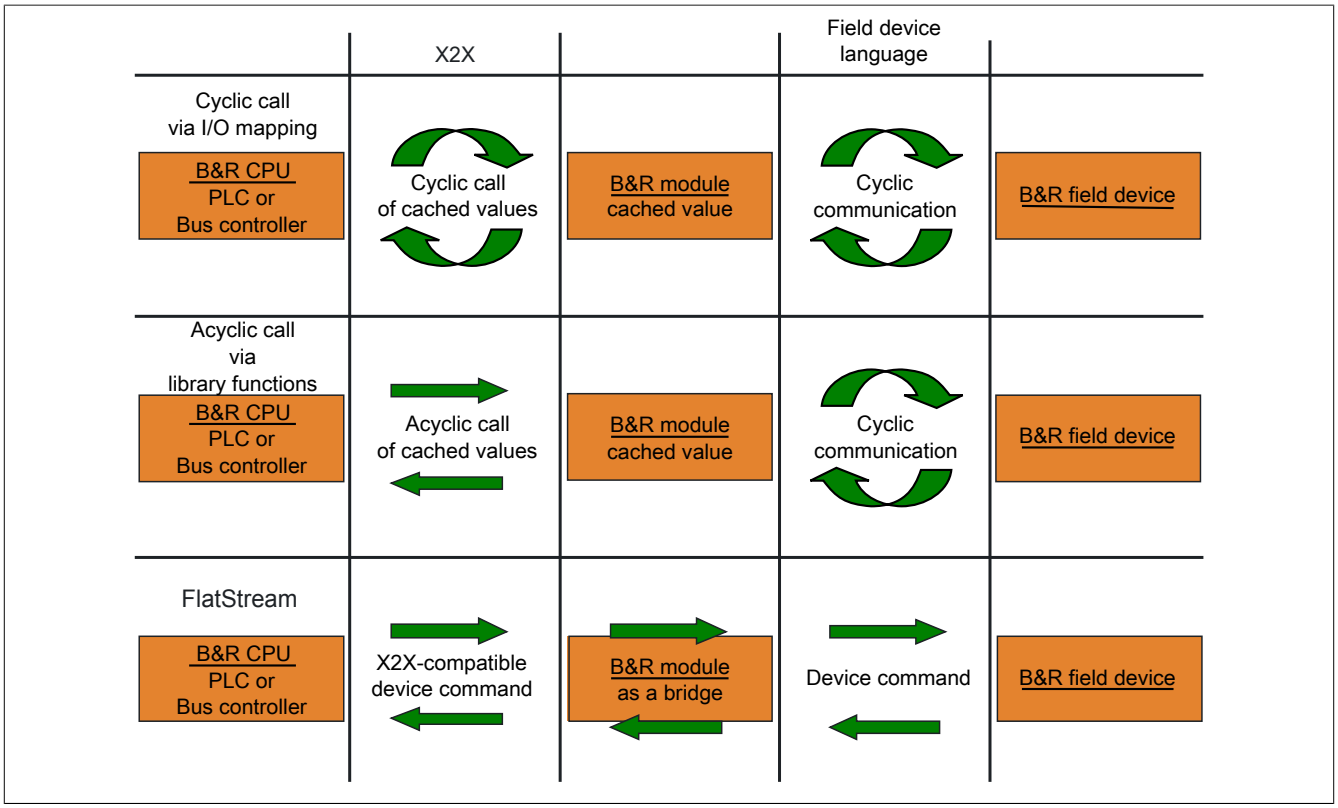

Figure 348: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.18.8.8.12.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.18.8.8.12.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

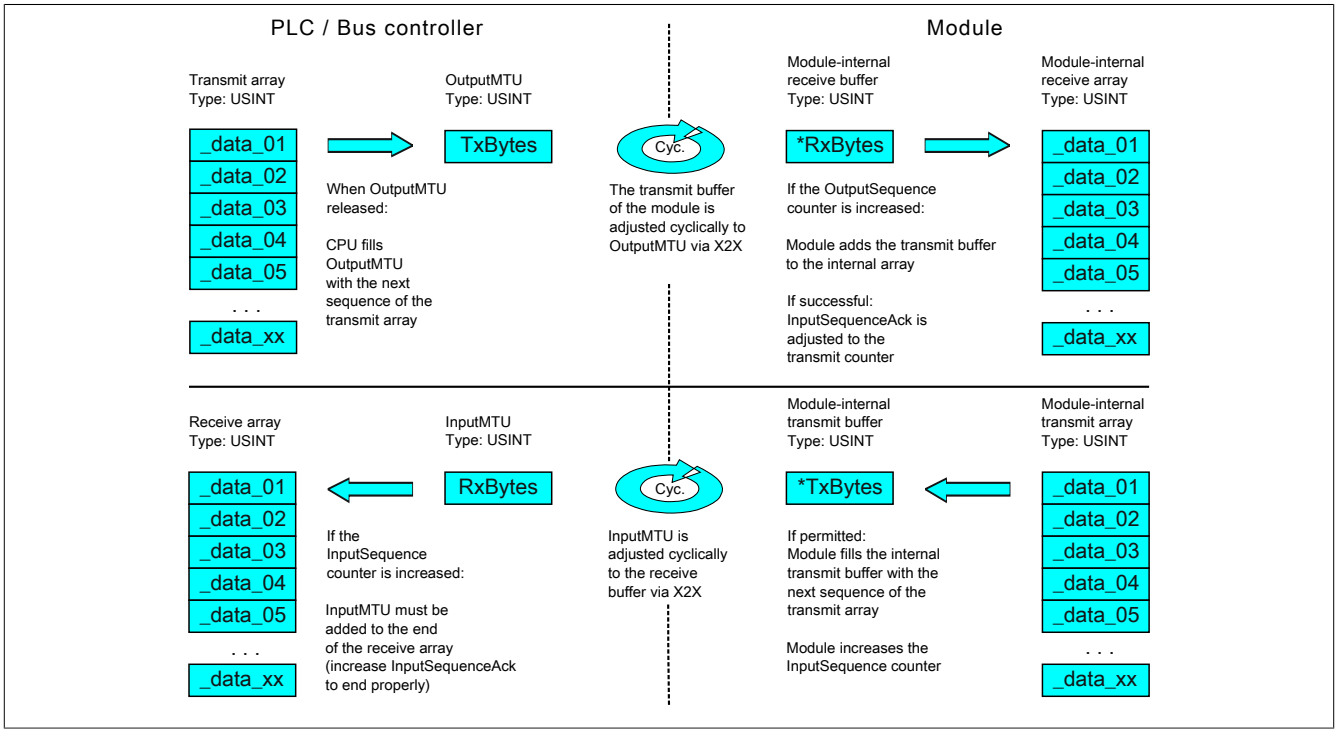

Figure 349: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.18.8.8.12.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Format of input and output bytes

Name:

"Format of Flat stream" in Automation Studio

This function sets how the Flatstream input and output bytes (Tx or Rx bytes) are transferred.

- **packed variable:** Transfers data as an array
- **byte variables:**Transfers data as individual bytes

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

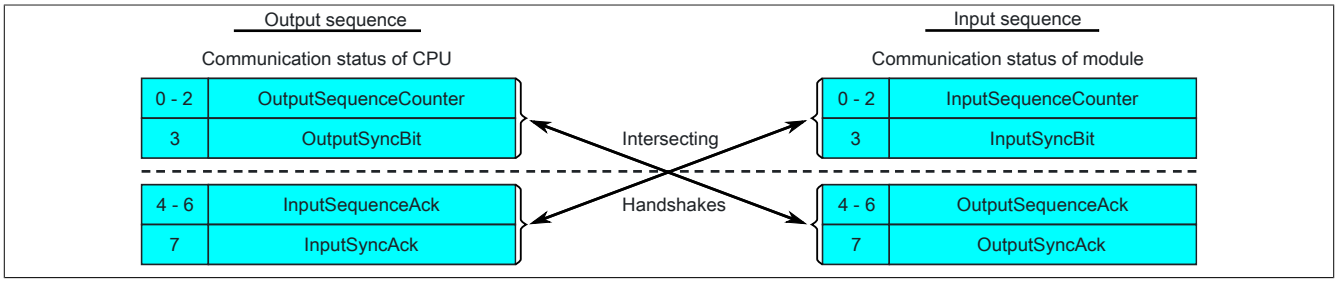

Figure 350: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

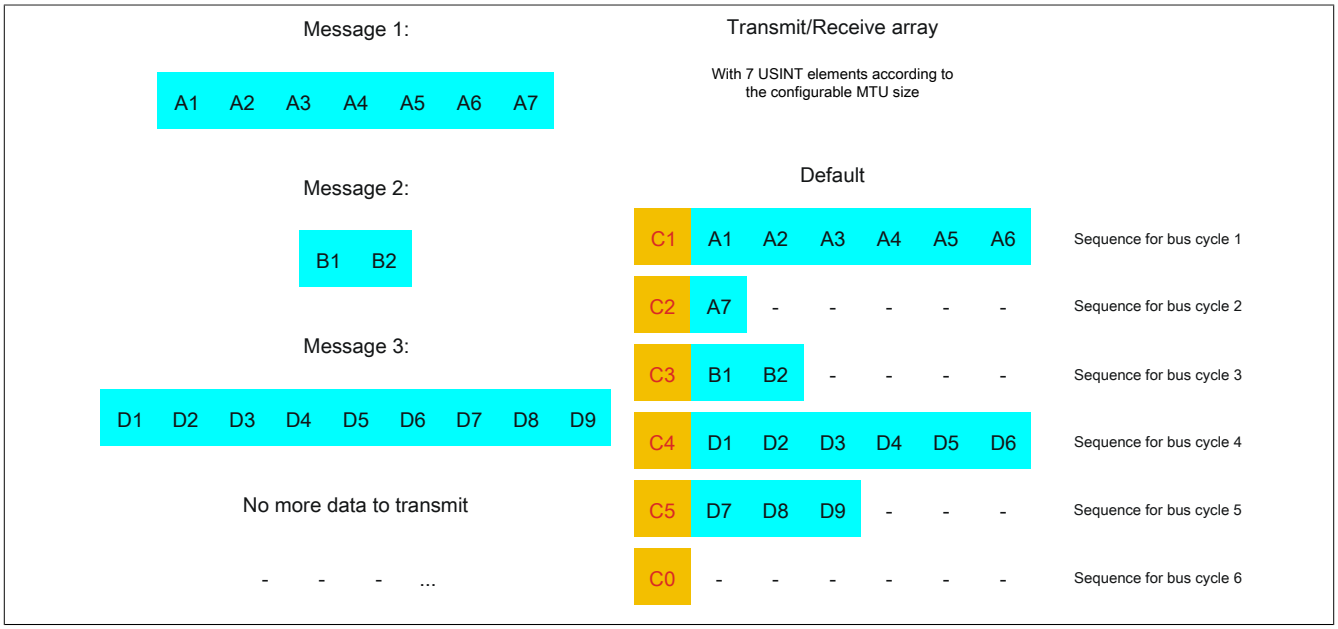

Figure 351: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 423: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 424: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

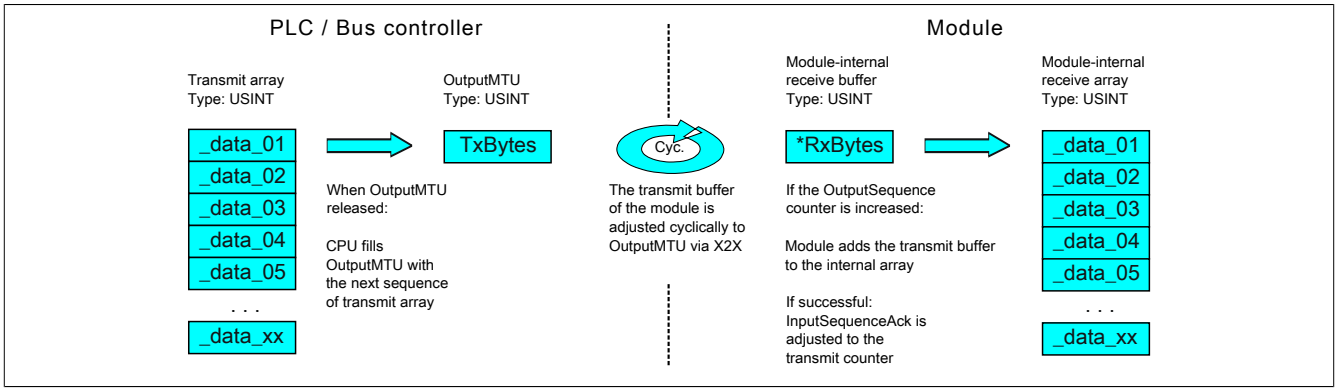

Figure 352: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

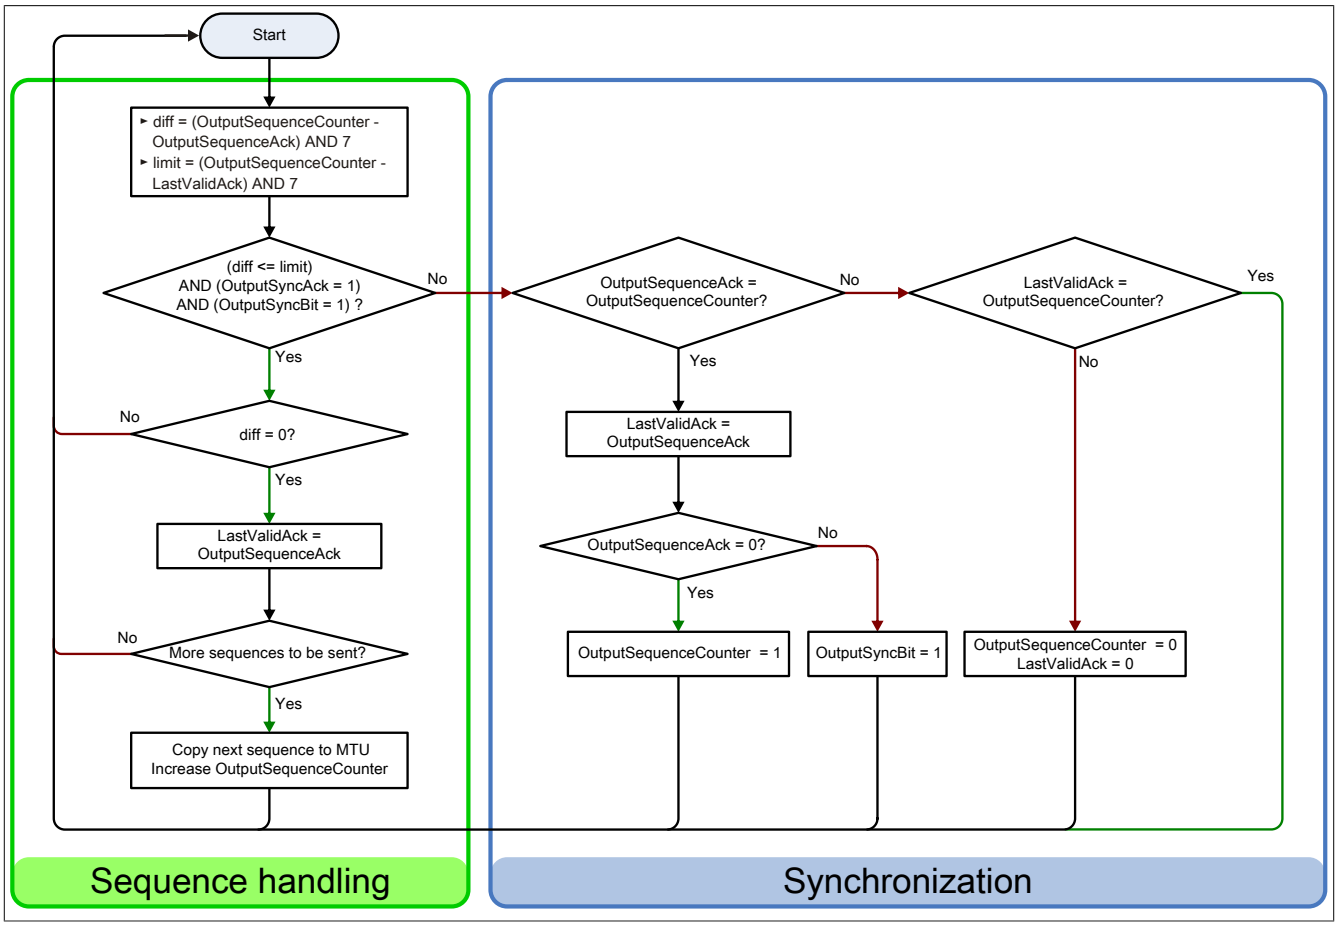

Figure 353: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

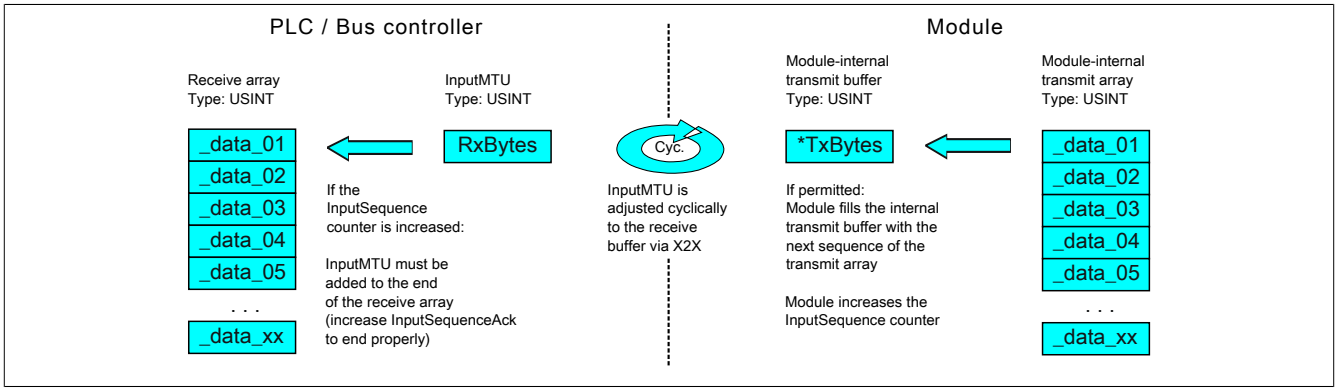

Figure 354: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

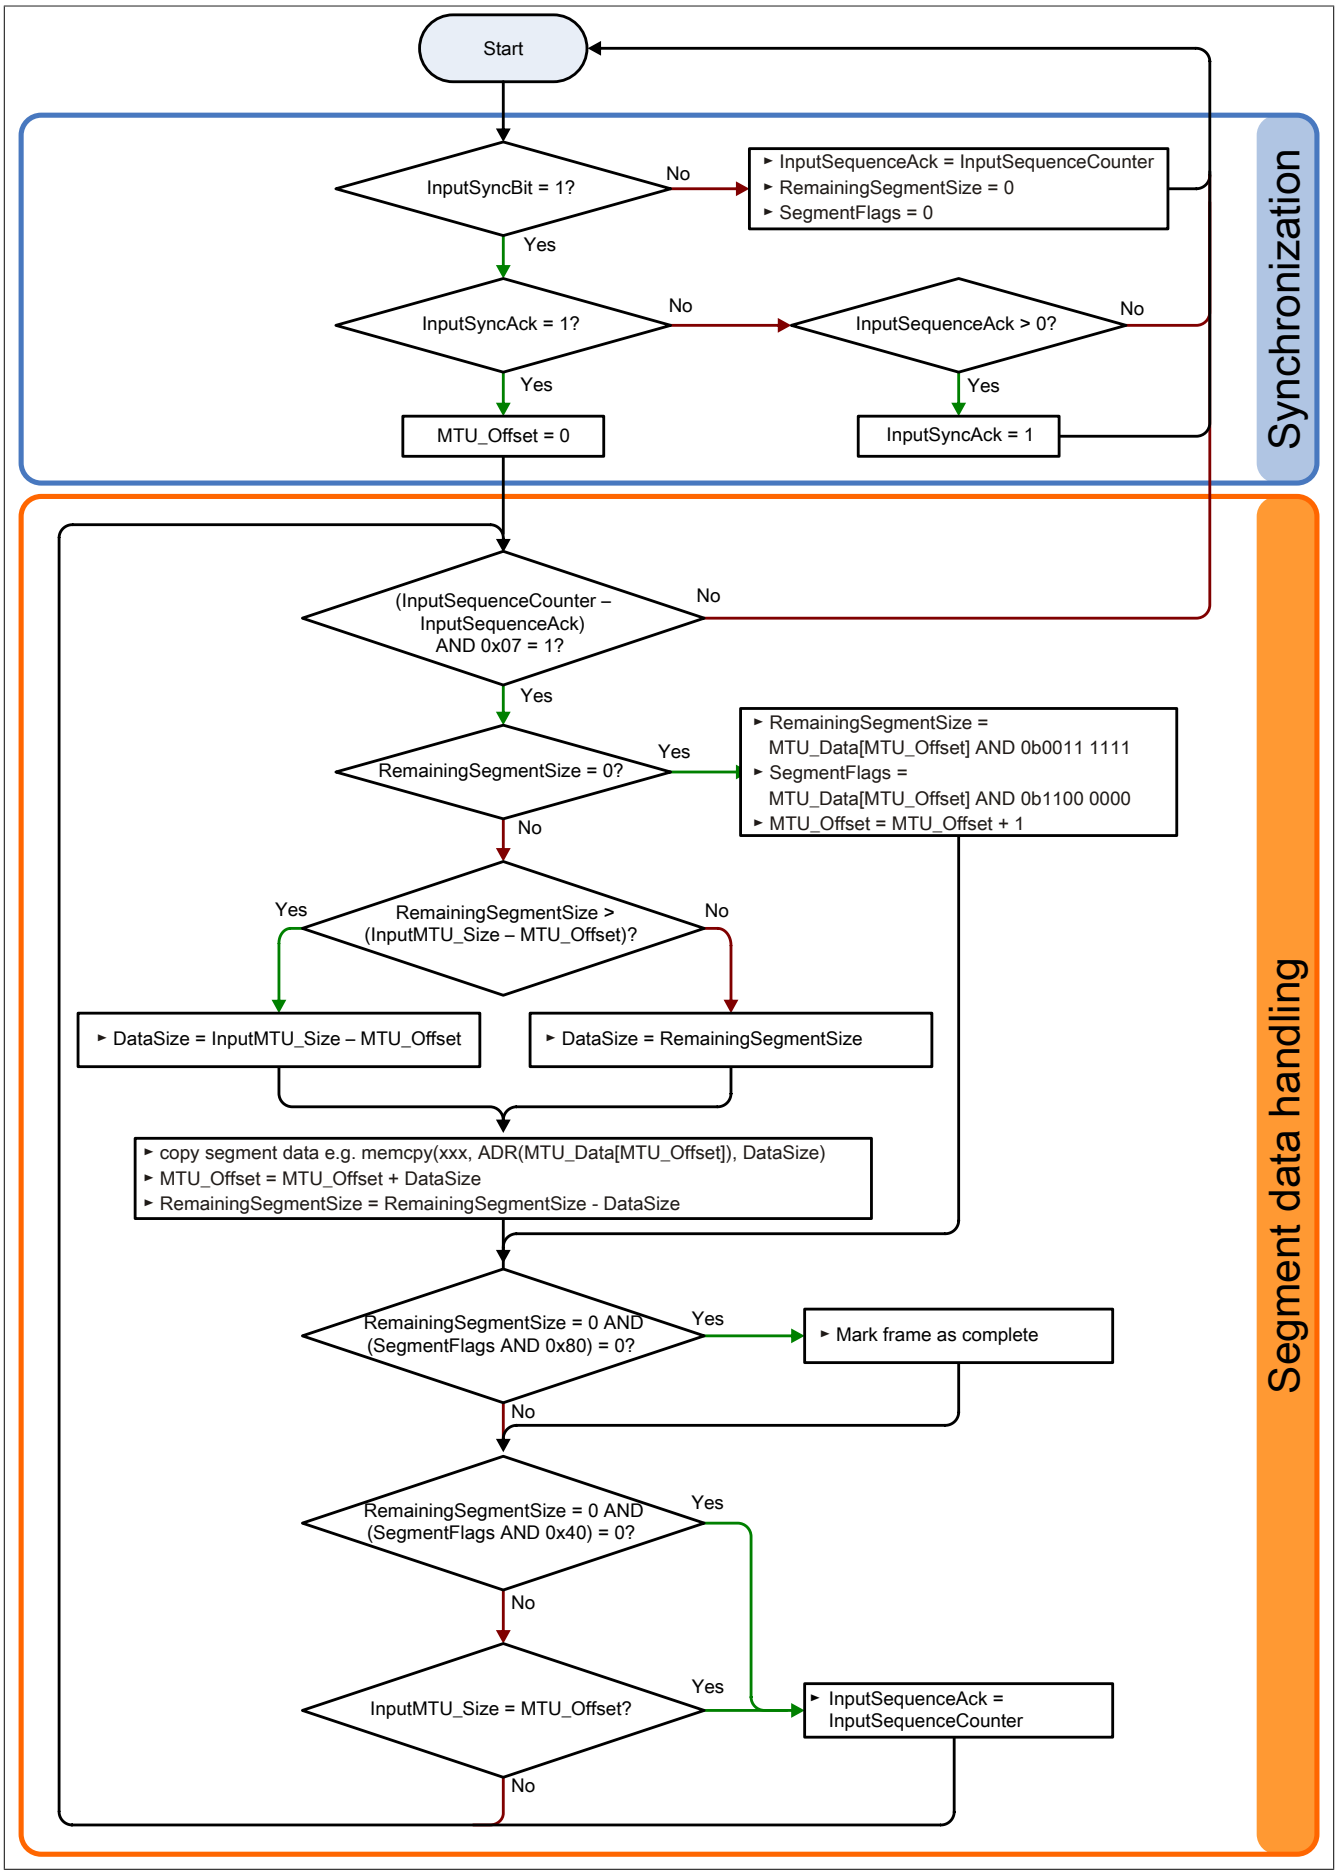

Figure 355: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

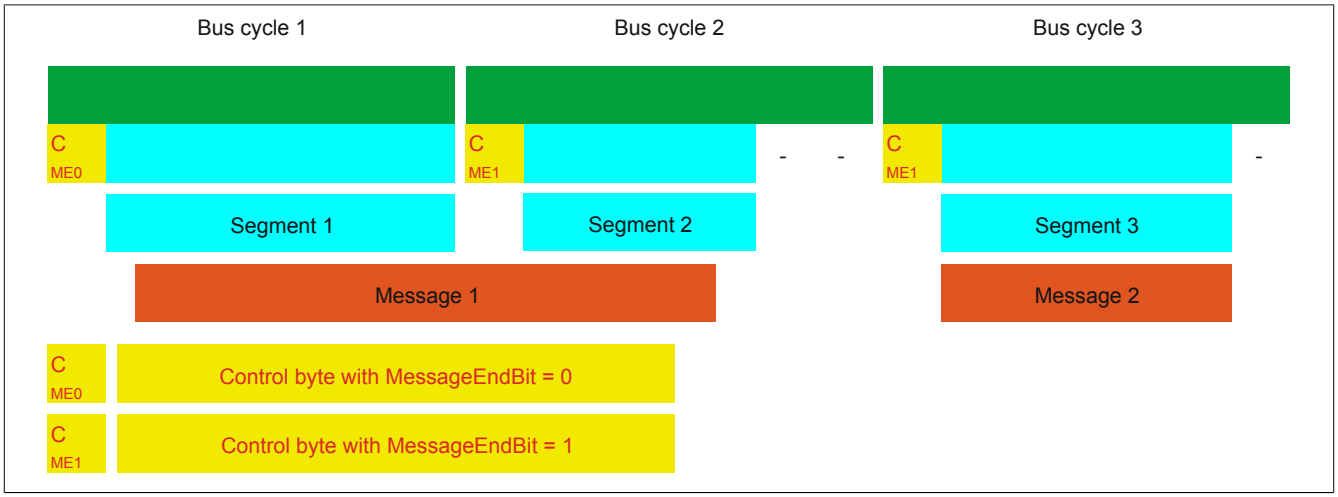

Figure 356: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

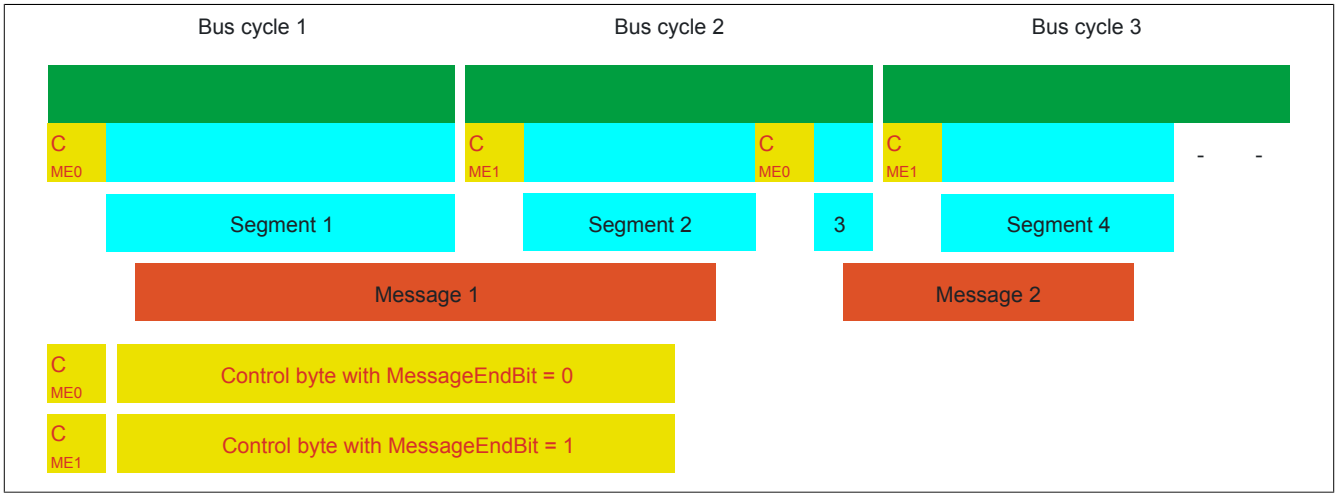

Figure 357: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

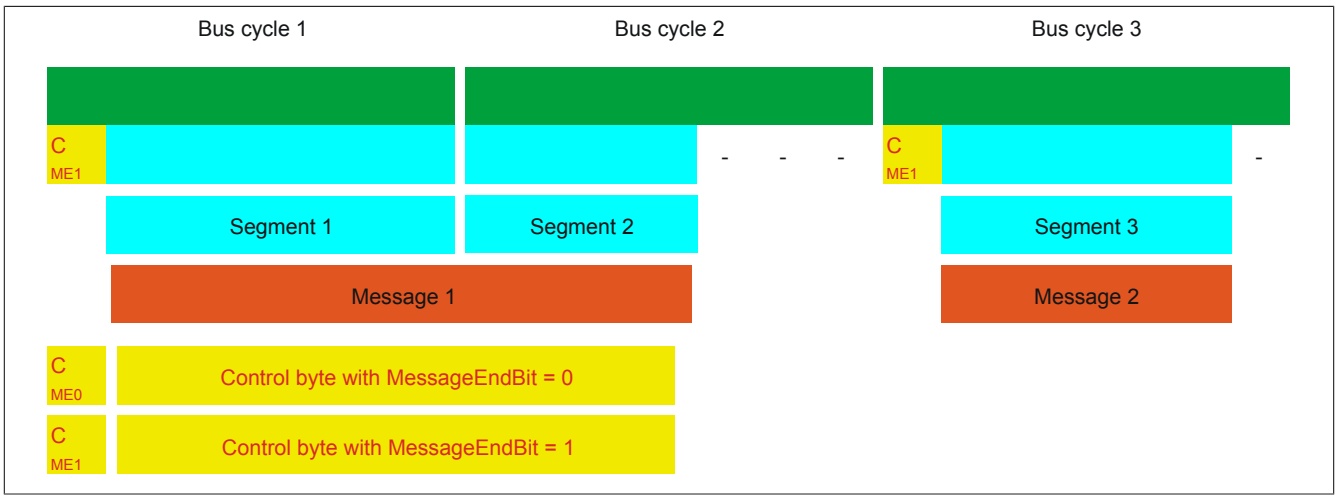

Figure 358: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

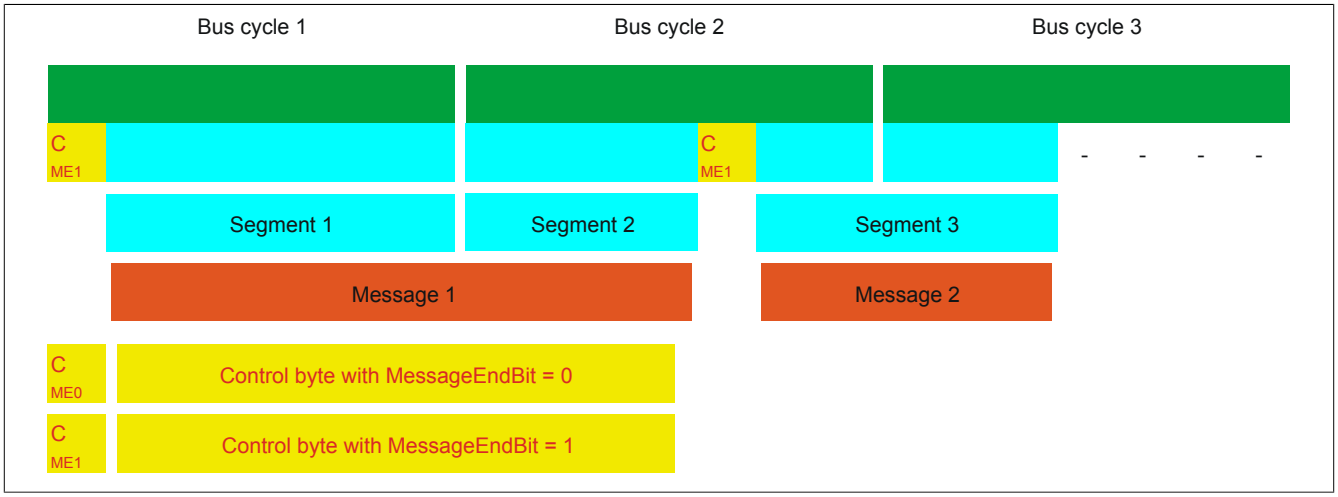

Figure 359: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

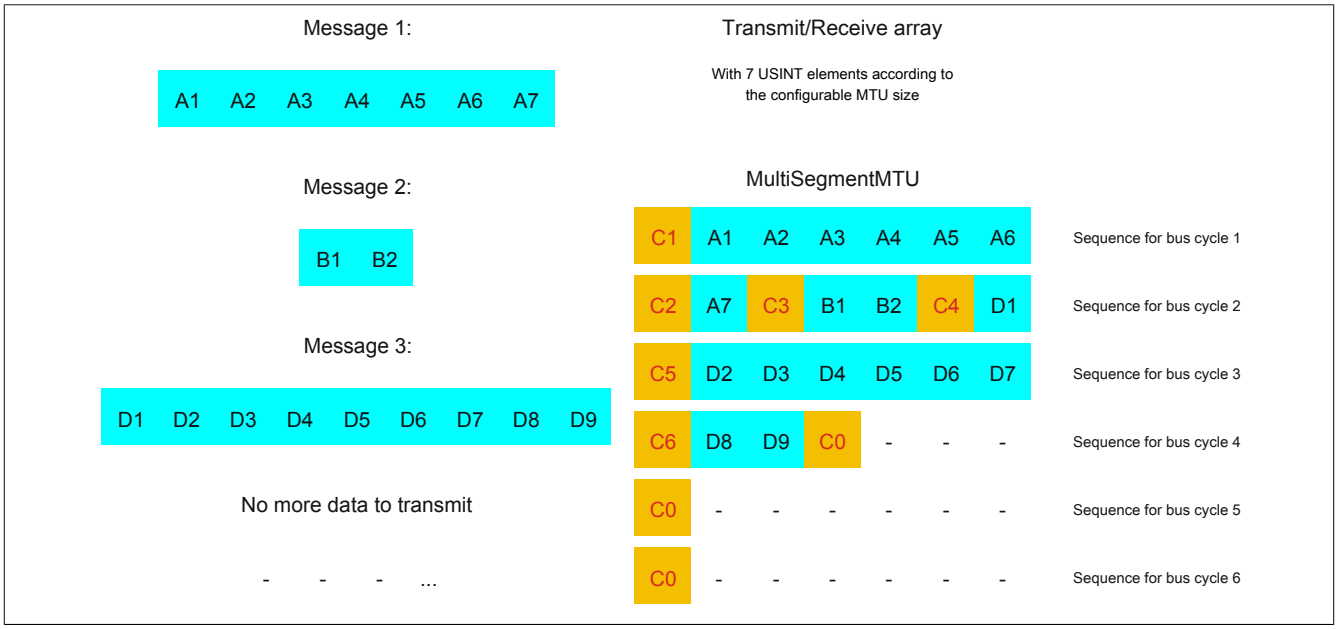

Figure 360: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 425: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 426: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

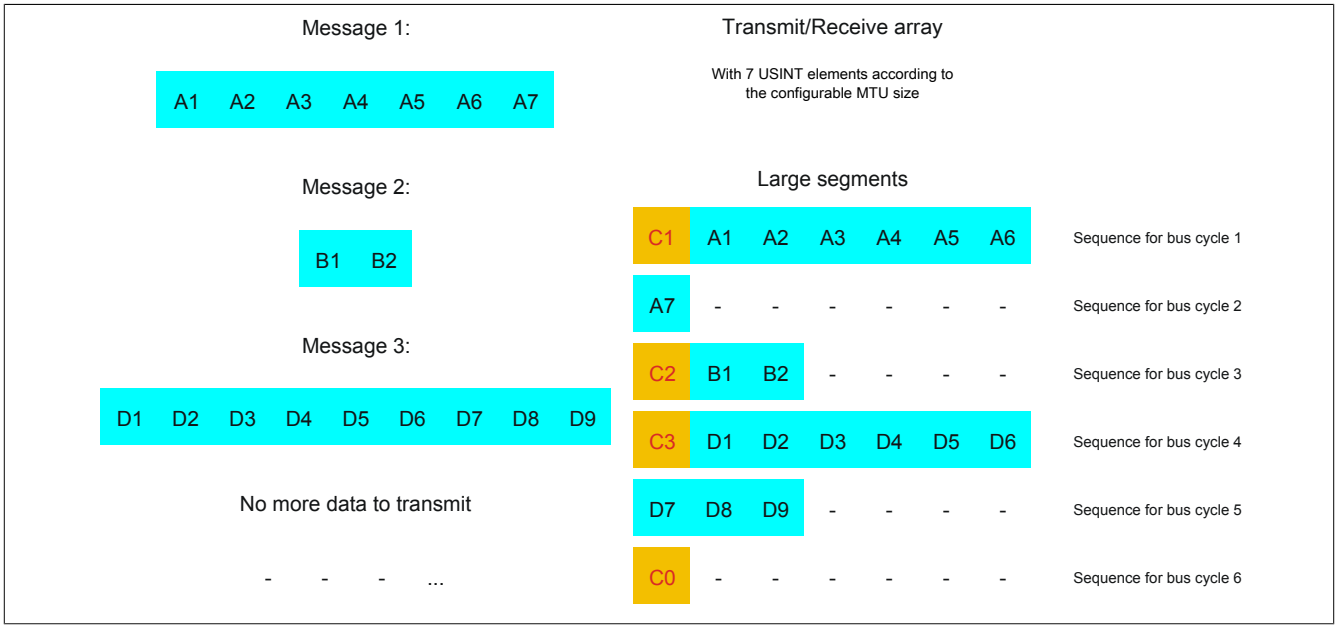

Figure 361: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 427: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

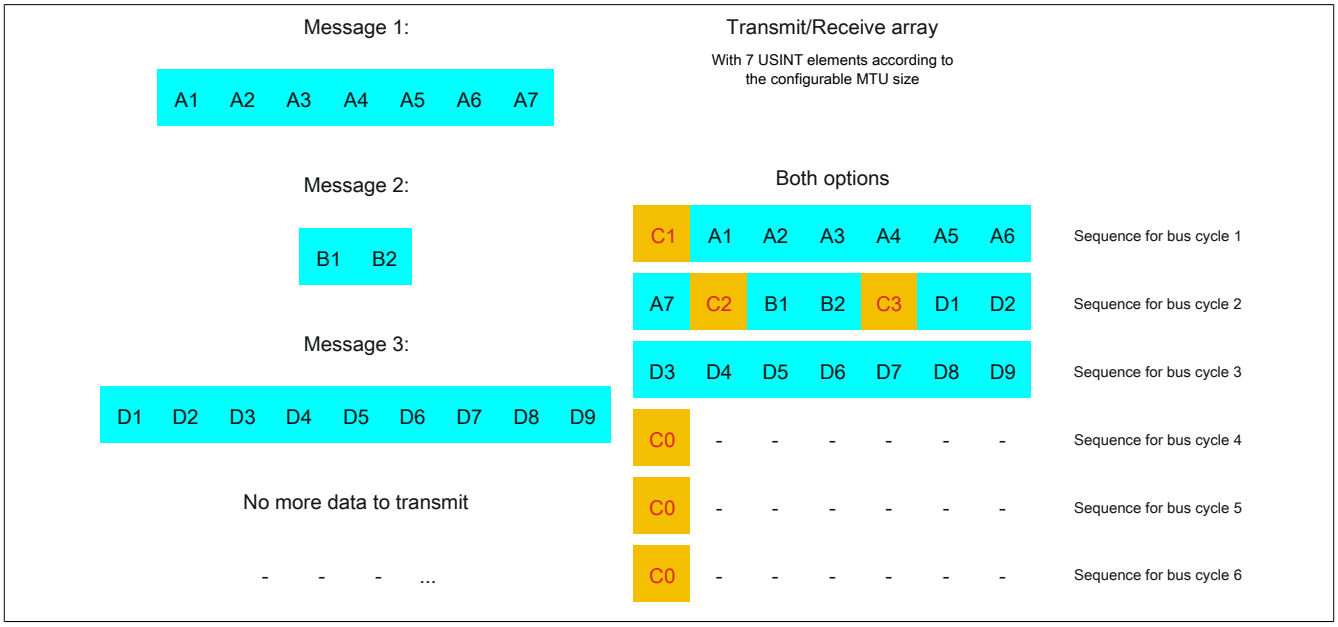

Figure 362: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 428: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.18.8.8.12.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

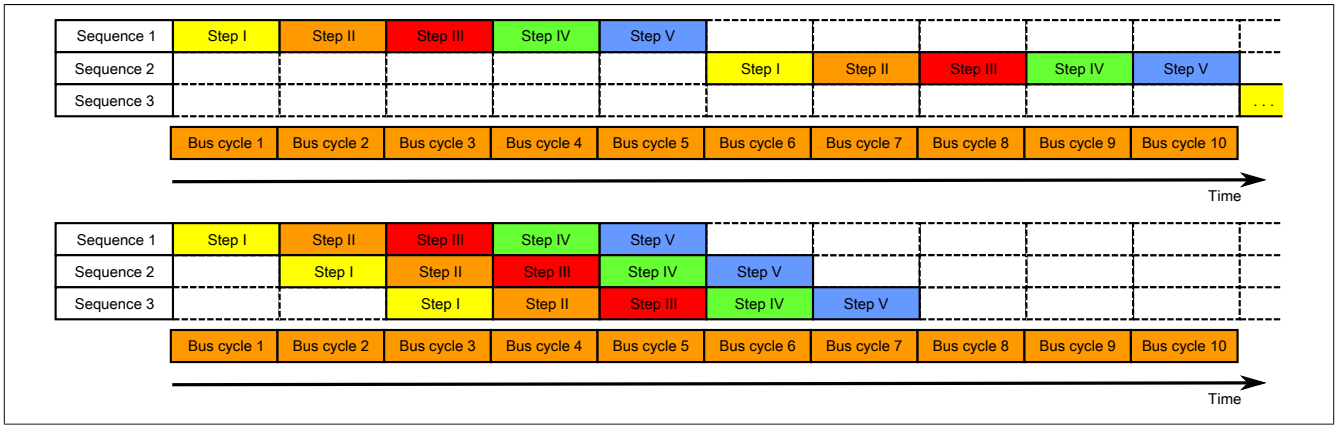

Figure 363: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

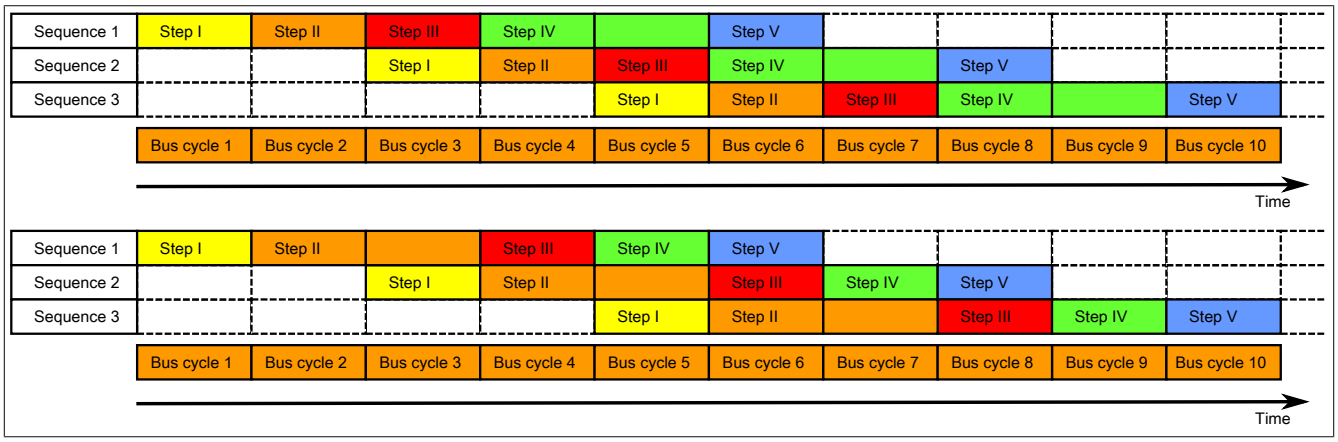

Figure 364: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

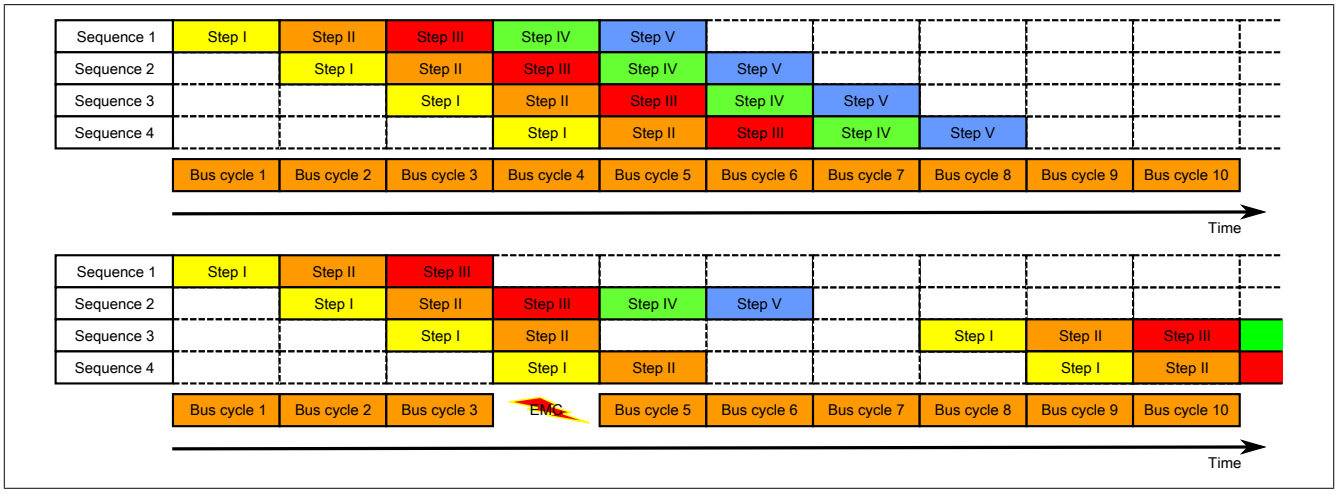

Figure 365: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.18.8.8.13 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.18.8.8.14 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.18.8.8.15 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.19 Expandable bus controllers

The expandable bus controller is based on the POWERLINK bus controller X20BCx083. The bus modules expanded to the left allow connection of up to two interface or hub expansion modules, depending on the bus controller.

Despite the sleek profile of only 62.5mm and 87.5, the bus controller contains the supply feed for the bus controller, the X2X Link bus supply, and the I/O module feed. No additional power modules are necessary.

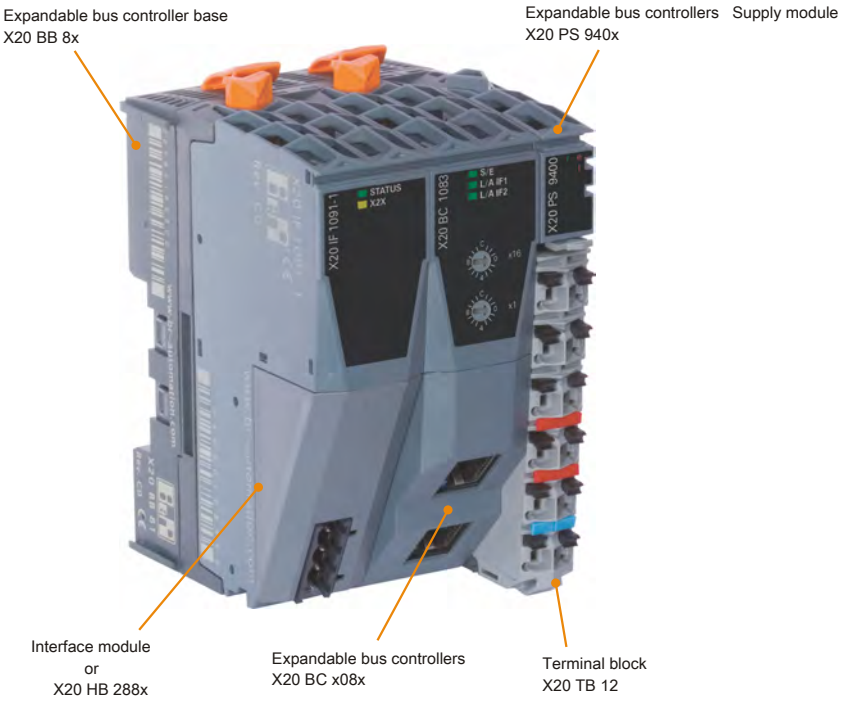

Figure 366: Modular structure of the expandable bus controller

4.19.1 Brief information

Product ID	Short description	on page
X20BC1083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2125
X20BC8083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2132
X20BC8084	X20 bus controller, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2138
X20BC80G3	X20 bus controller, 1 EtherNet/IP interface, supports expansion with X20 EtherCAT junction modules, 2x RJ45, order bus base, power supply module and terminal block separately.	2145
X20cBC1083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2125
X20cBC8083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2132
X20cBC8084	X20 bus controller, coated, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately	2138

4.19.2 X20(c)BC1083

4.19.2.1 General information

The X20BC1083 bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK V1 and V2. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) ensures that the standard remains open and is continually developed: www.ethernet-powerlink.org

The bus modules expanded to the left allow connection of up to two interface modules in addition to the bus controller.

- POWERLINK
- I/O configuration and FW update via the fieldbus
- Integrated hub for efficient cabling
- Up to two slots for interface modules

4.19.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.19.2.3 Order data

Model number	Short description	Figure
	Expandable bus controllers

Spacing [3]		
X20BB81	62.5$^{+0.2}$ mm	
X20BB82	87.5$^{+0.2}$ mm	

Table 430: X20BC1083, X20cBC1083 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB81 or X20BB82 bus base. Up to two interfaces modules and one X20PS9400 or X20PS9402 supply module are also always required for the bus controller.

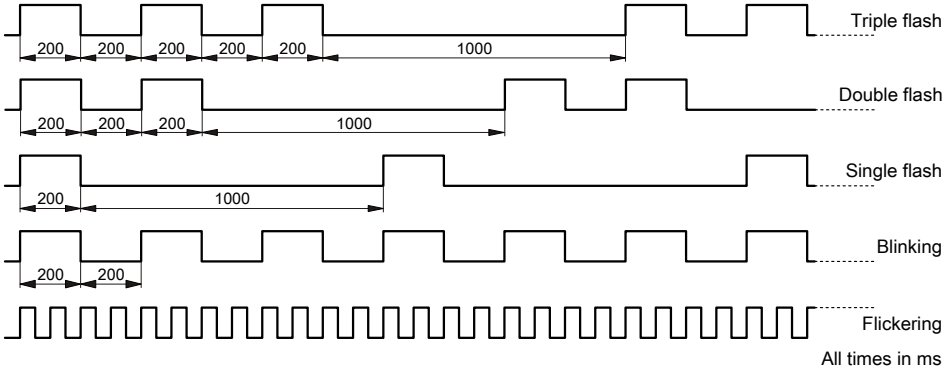
4.19.2.5 LED status indicators

Figure	LED	Color	Status	Description
	S/E[1]	Green	Off	No power supply or mode is NOT_ACTIVE. The controlled node (CN) is either not getting power, or it is in the NOT_ACTIVE state. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the module. If no POWERLINK communication is detected during these 5 seconds, the CN goes into the BASIC_ETHERNET state (flickering). If POWERLINK communication is detected before this time passes, however, the CN goes directly into the PRE_OPERATIONAL_1 state.
			Flickering	BASIC_ETHERNET mode. The CN has not detected any POWERLINK communication. It is possible to communicate directly with the CN in this state (e.g. with UDP, IP, etc.). If POWERLINK communication is detected while in this state, the CN goes into the PRE_OPERATIONAL_1 state.
			Single flash	PRE_OPERATIONAL_1 mode. When operated on a POWERLINK V1 manager, the CN goes directly into the PRE_OPERATIONAL_2 state. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then goes into the PRE_OPERATIONAL_2 state.
			Double flash	PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. Issuing a command (POWERLINK V2) or setting the data valid flag in the output data (POWERLINK V1) then switches to the READY_TO_OPERATE state.
			Triple flash	READY_TO_OPERATE mode. In a POWERLINK V1 network, the CN automatically switches to the OPERATIONAL state as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command.
			On	OPERATIONAL mode. PDO mapping is active and cyclic data is being evaluated.

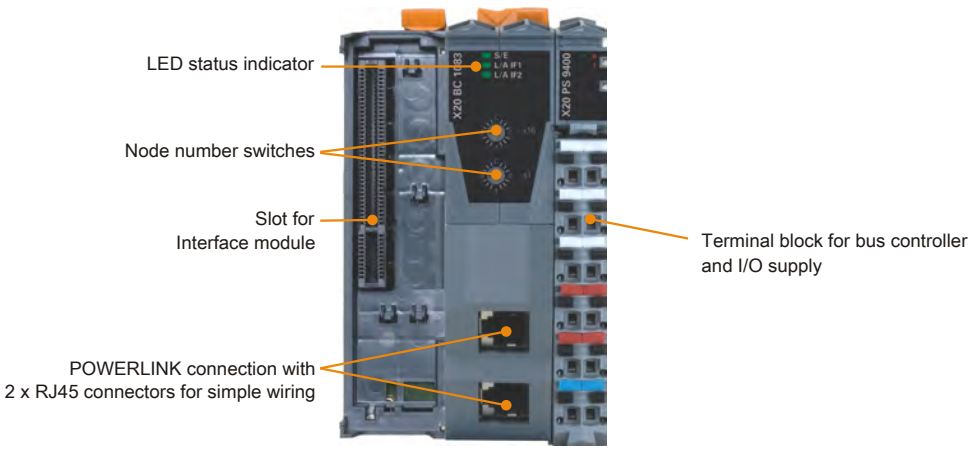
Figure	LED	Color	Status	Description
			Blinking	STOPPED mode. No output data is produced or input data supplied. It is only possible to enter or leave this state after the manager has given the appropriate command.
		Red	On	The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: • The LED blinks red several times immediately after startup. This is not an error. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via Dynamic Node Allocation (DNA).
	L/A IFx	Green	On	Link established to the remote station
			Blinking	A link to the remote station has been established and there is activity on bus.

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LEDs - Blinking patterns



4.19.2.6 Operating and connection elements



4.19.2.7 POWERLINK node number

The node number for the POWERLINK node is set using the two number switches. Node numbers between 0x01 and 0xEF are permitted.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node Operation as a controlled node.
0xF0 - 0xFF	Reserved, switch position not permitted

4.19.2.8 Dynamic Node Allocation (DNA)

The node numbers of all POWERLINK bus controllers can be assigned dynamically. This has the following advantages:

- No need to set the node number switch
- Easier installation
- Reduced error sources

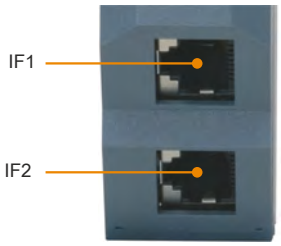
For information about configuration as well as an example, see the AS help system (Communication → POWERLINK → General information → Dynamic Node Allocation (DNA)).

Information:

The IF1 interface must always be used as the input from the preceding node.

4.19.2.9 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.19.2.10 Slot for interface modules

Depending on the bus base, up to two interface modules can be installed on the left side of the expandable bus controller:

Bus base	Slots for interface modules
X20BB81	1
X20BB82	2

Table 431: Slots for interface modules for various bus bases

4.19.2.11 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.19.2.12 SG3

This module is not supported on SG3 targets.

4.19.2.13 SG4

This module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. If the two versions are different, the Automation Runtime firmware is loaded to the module.

The latest firmware is made available automatically when updating Automation Runtime.

4.19.3 X20(c)BC8083

4.19.3.1 General information

The X20BC8083 bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) ensures that the standard remains open and is continually developed: www.ethernet-powerlink.org

The bus modules expanded to the left allow connection of up to two hub expansion modules in addition to the bus controller. Each expansion module is equipped with two RJ45 connections. This means that a basic device provides up to six hub ports.

- POWERLINK
- I/O configuration and FW update via the fieldbus
- Integrated hub for efficient cabling
- Up to two slots for hub expansion modules
- 2x/4x/6x Fast Ethernet hub

4.19.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

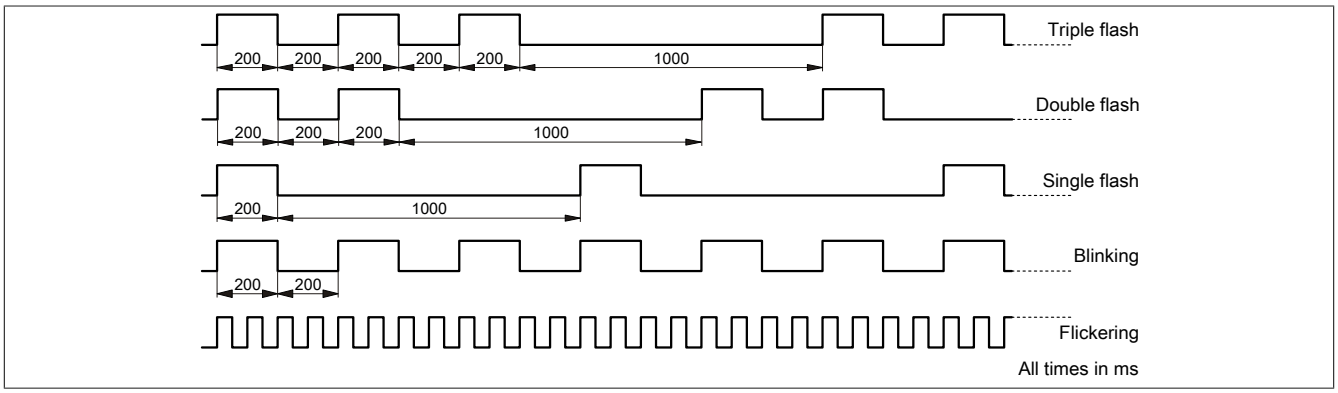
4.19.3.5 LED status indicators

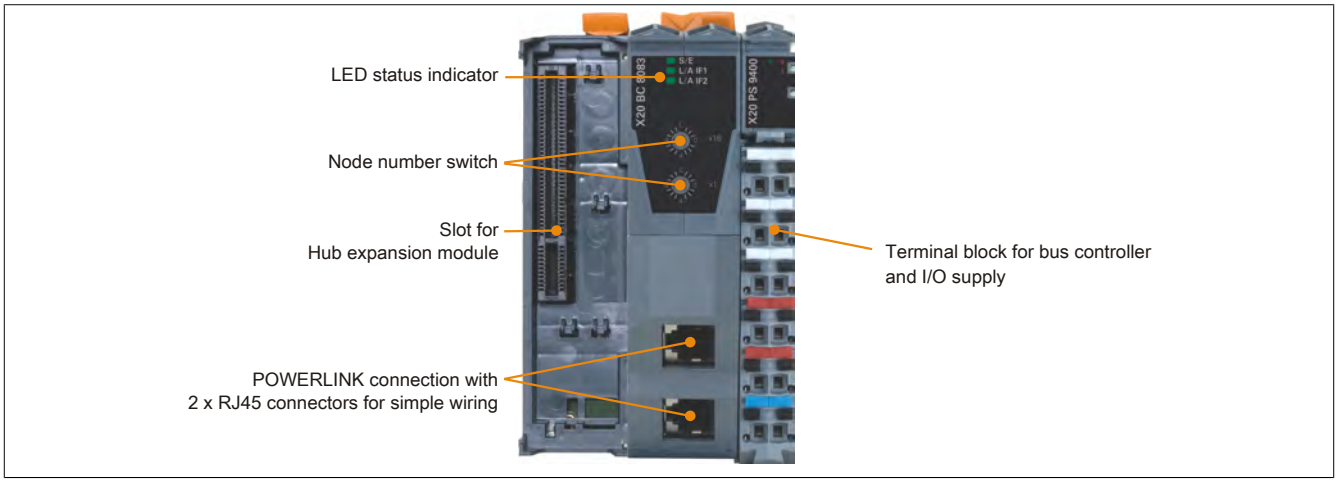
Figure	LED	Color	Status	Description
	S/E[1]	Green	Off	No power supply or mode is NOT_ACTIVE. The controlled node (CN) is either not getting power, or it is in the NOT_ACTIVE state. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the module. If no POWERLINK communication is detected during these 5 seconds, the CN goes into the BASIC_ETHERNET state (flickering). If POWERLINK communication is detected before this time passes, however, the CN goes directly into the PRE_OPERATIONAL_1 state.
			Flickering	BASIC_ETHERNET mode. The CN has not detected any POWERLINK communication. It is possible to communicate directly with the CN in this state (e.g. with UDP, IP, etc.). If POWERLINK communication is detected while in this state, the CN goes into the PRE_OPERATIONAL_1 state.
			Single flash	PRE_OPERATIONAL_1 mode. When operated on a POWERLINK V1 manager, the CN goes directly into the PRE_OPERATIONAL_2 state. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then goes into the PRE_OPERATIONAL_2 state.
			Double flash	PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. Issuing a command (POWERLINK V2) or setting the data valid flag in the output data (POWERLINK V1) then switches to the READY_TO_OPERATE state.
			Triple flash	READY_TO_OPERATE mode. In a POWERLINK V1 network, the CN automatically switches to the OPERATIONAL state as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command.
			On	OPERATIONAL mode. PDO mapping is active and cyclic data is being evaluated.
			Blinking	STOPPED mode. No output data is produced or input data supplied. It is only possible to enter or leave this state after the manager has given the appropriate command.
		Red	On	The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: • The LED blinks red several times immediately after startup. This is not an error. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via Dynamic Node Allocation (DNA).
	L/A IFx	Green	On	Link established to the remote station
			Blinking	A link to the remote station has been established and there is activity on bus.

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LEDs - Blinking patterns



4.19.3.6 Operating and connection elements



4.19.3.7 POWERLINK node number

The node number for the POWERLINK node is set using the two number switches. Node numbers between 0x01 and 0xEF are permitted.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node Operation as a controlled node.
0xF0 - 0xFF	Reserved, switch position not permitted

4.19.3.8 Dynamic Node Allocation (DNA)

The node numbers of all POWERLINK bus controllers can be assigned dynamically. This has the following advantages:

- No need to set the node number switch
- Easier installation
- Reduced error sources

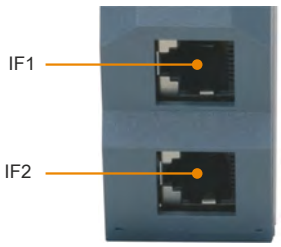
For information about configuration as well as an example, see the AS help system (Communication → POWERLINK → General information → Dynamic Node Allocation (DNA)).

Information:

The IF1 interface must always be used as the input from the preceding node.

4.19.3.9 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



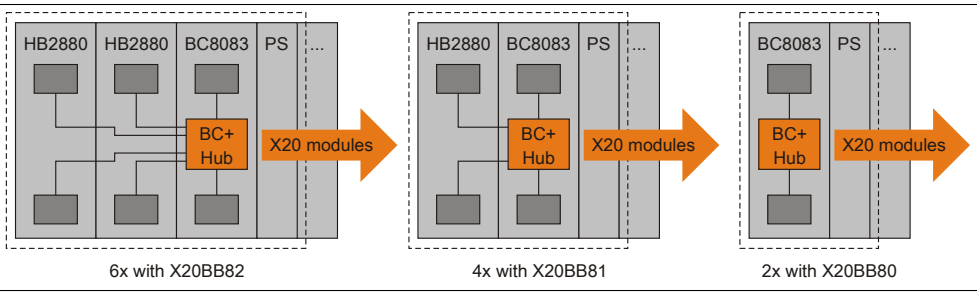
Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.19.3.10 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the bus controller:

Bus base	Slot for hub expansion modules
X20BB81	1
X20BB82	2

The X20HB2880 hub expansion module for the bus controller is equipped with 2 RJ45 connections, which means that up to 6 hub ports are available.



4.19.3.11 SG3

This module is not supported on SG3 targets.

4.19.3.12 SG4

This module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. If the two versions are different, the Automation Runtime firmware is loaded to the module.

The latest firmware is made available automatically when updating Automation Runtime.

4.19.4 X20(c)BC8084

4.19.4.1 General information

The X20BC8084 bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) ensures that the standard remains open and is continually developed: www.ethernet-powerlink.org

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the bus controller X20BC8084.

- POWERLINK
- I/O configuration and FW update via the fieldbus
- Integrated compact link selector function
- Two active hub expansion modules can be connected to the bus controller
- Redundant supply possible

4.19.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Spacing 3) X20BB80 X20BB82	 37.5 +0.2 mm 87.5+0.2 mm	

Table 435: X20BC8084, X20cBC8084 - Technical data

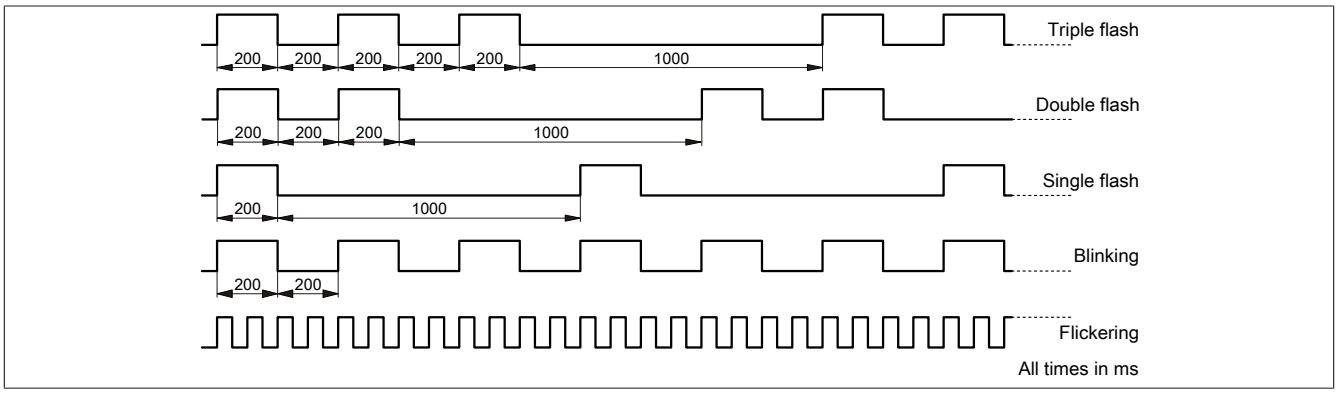
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB81 or X20BB82 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller. To save cabling for external hubs, the X20BC8084 can be expanded with two active hub modules, the X20HB2885 or the X20HB2886.

4.19.4.5 LED status indicators

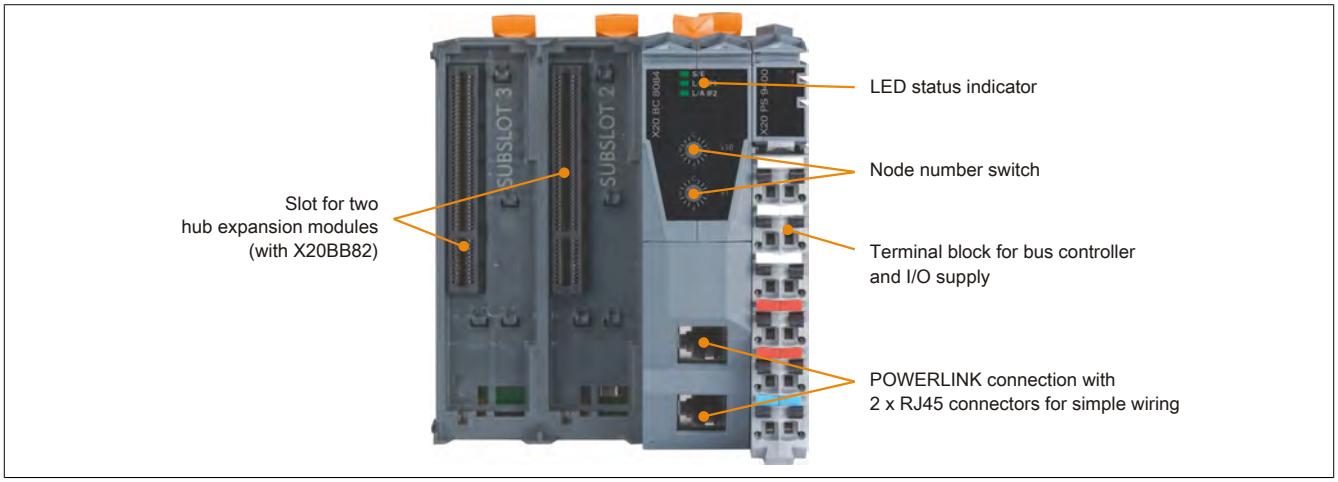
Figure	LED	Color	Status	Description
	S/E1)	Green	Off	No power supply or mode is NOT_ACTIVE. The controlled node (CN) is either not getting power, or it is in the NOT_ACTIVE state. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the module. If no POWERLINK communication is detected during these 5 seconds, the CN goes into the BASIC_ETHERNET state (flickering). If POWERLINK communication is detected before this time passes, however, the CN goes directly into the PRE_OPERATIONAL_1 state.
			Flickering	BASIC_ETHERNET mode. The CN has not detected any POWERLINK communication. It is possible to communicate directly with the CN in this state (e.g. with UDP, IP, etc.). If POWERLINK communication is detected while in this state, the CN goes into the PRE_OPERATIONAL_1 state.
			Single flash	PRE_OPERATIONAL_1 mode. When operated on a POWERLINK V1 manager, the CN goes directly into the PRE_OPERATIONAL_2 state. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then goes into the PRE_OPERATIONAL_2 state.
			Double flash	PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. Issuing a command (POWERLINK V2) or setting the data valid flag in the output data (POWERLINK V1) then switches to the READY_TO_OPERATE state.
			Triple flash	READY_TO_OPERATE mode. In a POWERLINK V1 network, the CN automatically switches to the OPERATIONAL state as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command.
			On	OPERATIONAL mode. PDO mapping is active and cyclic data is being evaluated.
			Blinking	STOPPED mode. No output data is produced or input data supplied. It is only possible to enter or leave this state after the manager has given the appropriate command.
		Red	On	The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: • The LED blinks red several times immediately after startup. This is not an error. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via Dynamic Node Allocation (DNA).
	L/A IFx	Green	On	Link established to the remote station
			Blinking	A link to the remote station has been established and there is activity on bus.

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LEDs - Blinking patterns



4.19.4.6 Operating and connection elements



4.19.4.7 POWERLINK node number

The node number for the POWERLINK node is set using the two number switches. Node numbers between 0x01 and 0xEF are permitted.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node Operation as a controlled node.
0xF0 - 0xFF	Reserved, switch position not permitted

4.19.4.8 Dynamic Node Allocation (DNA)

The node numbers of all POWERLINK bus controllers can be assigned dynamically. This has the following advantages:

- No need to set the node number switch
- Easier installation
- Reduced error sources

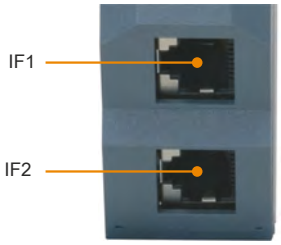
For information about configuration as well as an example, see the AS help system (Communication → POWERLINK → General information → Dynamic Node Allocation (DNA)).

Information:

The IF1 interface must always be used as the input from the preceding node.

4.19.4.9 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
Shielded RJ45	8	Termination	

4.19.4.10 SG3

This module is not supported on SG3 targets.

4.19.4.11 SG4

This module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. If the two versions are different, the Automation Runtime firmware is loaded to the module.

The latest firmware is made available automatically when updating Automation Runtime.

4.19.4.12 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

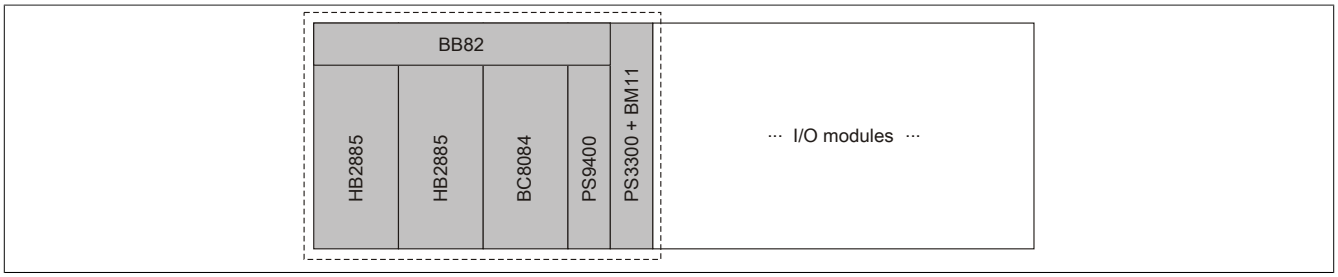
The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

4.19.4.13 Redundant supply voltage

When operating the bus controller with two X20HB2885 hub modules, a redundant supply voltage for the system can be easily implemented using two X20 supply modules.

Hardware configuration for redundant supply voltage



Connection example for supply modules

X20PS9400

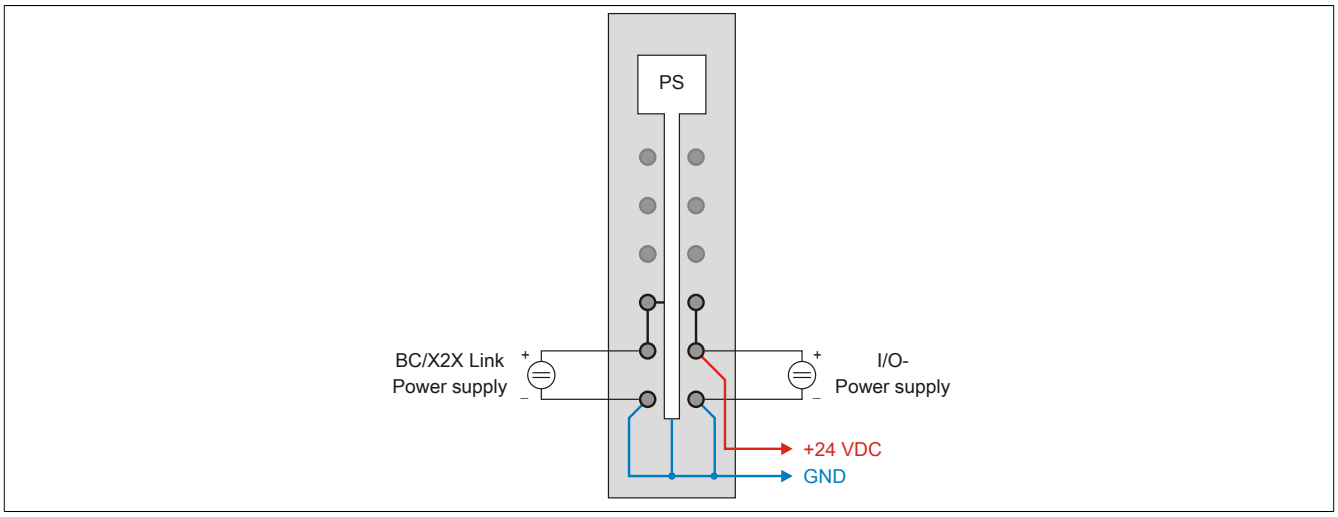


Figure 367: The X20PS9400 is connected as usual

X20PS3300

The supply module X20PS3300 is operated with a X20BM11 bus module. Only the BC/X2X Link supply is connected. A redundant I/O supply is not possible. By using the X20BM11 bus module, the I/O supply of the X20PS9400 supply module is connected to the I/O modules.

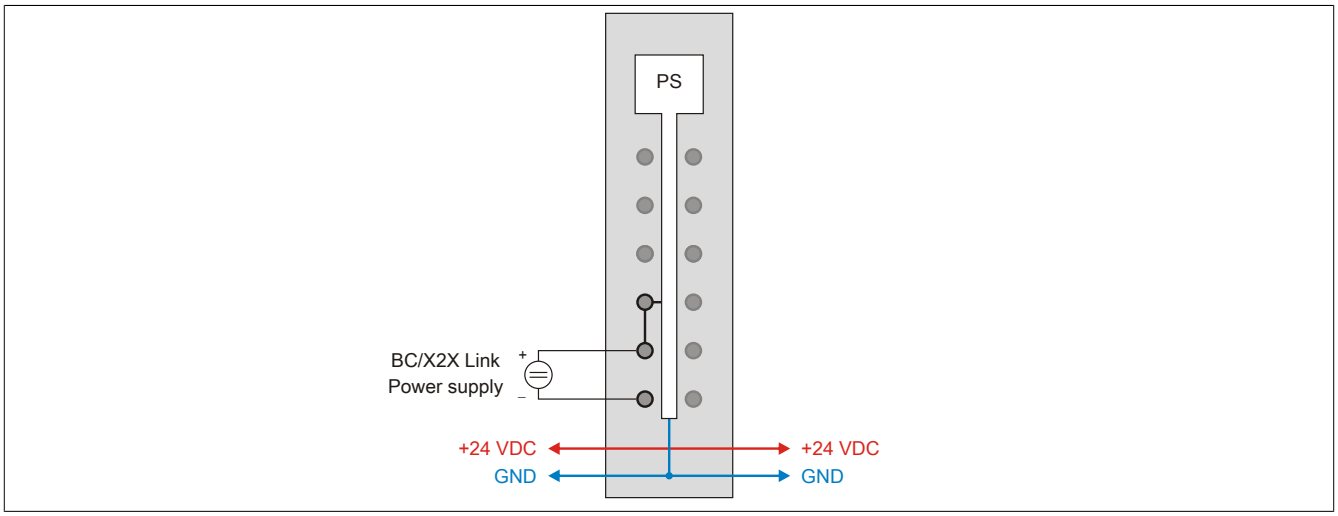

Figure 368: Only the BC/X2X Link supply is connected for the X20PS3300

4.19.5 X20BC80G3

4.19.5.1 General information

EtherCAT is an Ethernet-based fieldbus developed by Beckhoff. The protocol is suitable for hard and soft real-time requirements in automation technology. In addition to a ring structure, which becomes logically necessary because of the summation frame telegram used, the EtherCAT technology also physically supports topologies such as line, tree, star (limited) and combinations of these topologies. B&R's X20BC80G3 (expandable bus controller module) and X20HB88G0 (stand alone junction base module) are available for implementing these topologies.

EtherCAT slave devices take the data designated for them from a telegram as it is passing through the device. Input data is also inserted in the telegram as it is passing through. The X20BC80G3 bus controller allows X2X Link I/O modules to be coupled to EtherCAT and can be operated on any EtherCAT master system. A transition between IP20 and IP67 protection outside of the control cabinet is possible by aligning X20, X67 or XV modules one after the other as needed at distances up to 100 m.

Master systems without FoE (File Access over EtherCAT) support require an appropriate configuration tool to transfer the configuration (optional).

By expanding the bus module to the left, the X20BC80G3 bus controller has an additional slot available for an X20HB28G0 EtherCAT junction module. The junction module is equipped with two RJ45 connections. This means that a basic device provides four hub ports.

- Fieldbus: EtherCAT
- Auto-configuration of I/O modules
- I/O configuration and firmware update via the fieldbus (FoE)
- Full support of the modular slice concept via CoE (CANopen over EtherCAT)
- Configurable I/O cycle (0.2 to 4 ms)
- Synchronization between the fieldbus and X2X Link
- One slot for X20HB28G0 EtherCAT junction module

Information:

Only the default function model is supported (see respective module description) when the bus controller automatically configures multi-function modules.

All other function models are supported when configured accordingly (see EtherCAT user's manual). The easy-to-use B&R FieldbusDESIGNER can help in this regard and is available for free download from www.br-automation.com/designer.

4.19.5.2 Order data

Model number	Short description	Figure
	Expandable bus controllers

Table 437: X20BC80G3 - Technical data

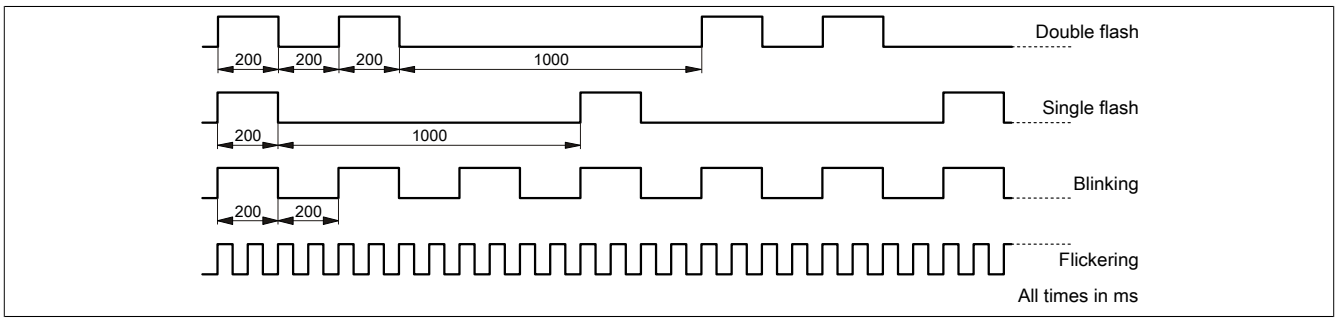
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) For the interfaces on the X20HB28G0 EtherCAT junction module, the hub runtime is 1.1 µs instead of 750 ns.
3) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
4) Spacing is based on the width of the X20BB81 bus base. One X20HB28G0 hub expansion module and one X20PS9400 or X20PS9402 supply module are also always required for the bus controller.

4.19.5.4 LED status indicators

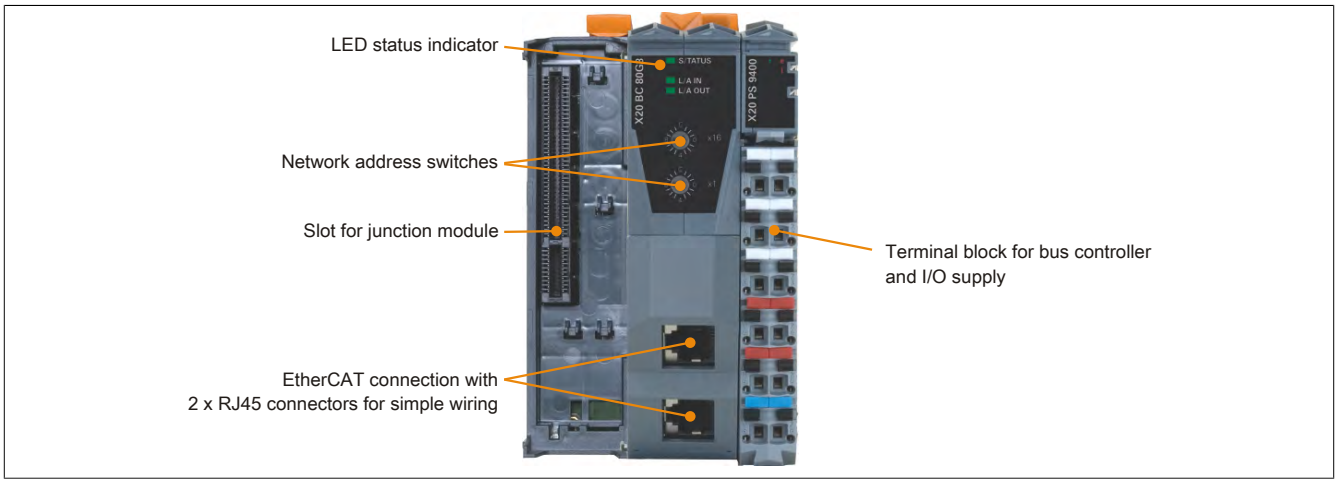
Figure	LED	Color	Status	Description
	STATUS1)	Green	On	The bus controller is OPERATIONAL.
			Blinking	PREOPERATIONAL status
			Single flash	SAFE-OPERATIONAL status
			Flickering	The bus controller has started and is not yet in INIT status or it is in BOOTSTRAP status (e.g.while downloading firmware).
			Off	INIT status
		Red	On	A critical communication or application error has occurred.
			Blinking	Invalid configuration data
			Single flash	The bus controller has an internal error and changed the EtherCAT status on its own
			Double flash	Watchdog timeout (process data watchdog or EtherCAT watchdog)
			Flickering	Error in the start procedure (INIT status has been achieved, but the error indicator bit in the AL status register is set)
			Off	No error
	L/A IN L/A OUT	Green	Blinking	The respective LED blinks when Ethernet activity is present (PORT OPEN) on the corresponding RJ45 port (IN, OUT).
			On	Connection (link) established, however no communication (PORT OPEN).
			Off	No physical Ethernet connection exists (PORT CLOSED).

1) The "STATUS" LED is a green/red dual LED and is used to indicate EtherCAT states ERROR and RUN.

Status LEDs - Blinking patterns

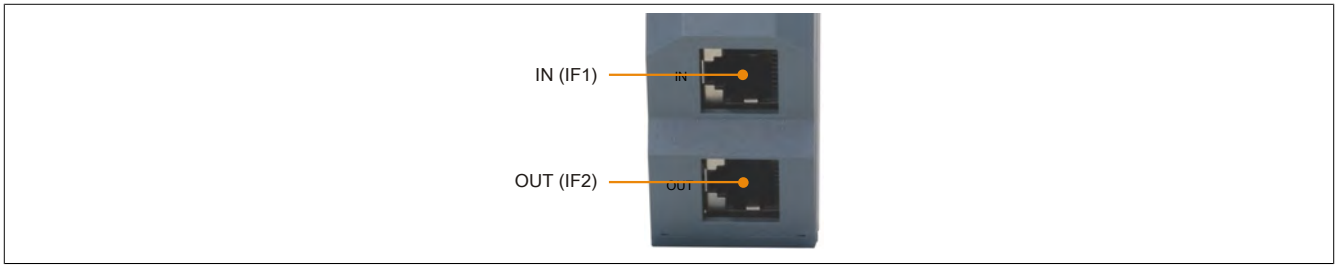


4.19.5.5 Operating and connection elements



4.19.5.6 RJ45 ports

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.19.5.7 EtherCAT network address switch

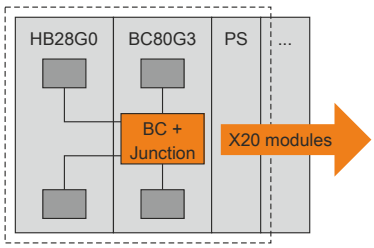
A slave alias address can be set using the two network address switches on the bus controller. During the initialization phase (during start-up), the bus controller writes the value of the address switch to the ESC register 0x12 or 0x13. However, the value is only accepted in the register if the value of the switch value is between 0x00 and 0xFA (decimal 250).

Switch position	Description
0x00 to 0xFA	Writes the address switch value to the "Station Alias" register.
0xFB to 0xFE	Address switch value not used. ESC Alias registers not changed.
0xFF	Address switch value not used. ESC Alias registers not changed. The bus controller boots with the default values if the address switch is set to the value "0xFF" before a restart. All set parameters remain unchanged in flash memory.

The master determines whether the alias address is used for the slave addressing by setting the corresponding bit in the ESC DL control register (bit 24).

4.19.5.8 Slot

The bus controller is equipped with an additional slot. The X20HB28G0 EtherCAT junction module is operated in this slot. The junction module is equipped with 2 RJ45 connections, which means that 4 ports are available.



4x with X20BB81

4.20 Expandable bus controllers system modules

The expandable X20 bus controllers are made up of a bus controller fieldbus interface, a bus controller system module and an X20TB12 terminal block.

Expandable bus controller system modules include the base module and the supply module for providing power to the entire system.

4.20.1 Brief information

Product ID	Short description	on page
X20BB81	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	2150
X20BB82	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	2152
X20IF1091-1	X20 interface module, for expandable bus controller, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately	2154
X20cBB81	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	2150
X20cBB82	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	2152

4.20.2 X20(c)BB81

4.20.2.1 General information

The bus module has an expansion slot. The following modules are used on this module:

- Base module (BC, HB, etc.)
- Add-on module (IF, HB, etc.)
- Supply module

The left and right end plates are included in the delivery.

- Bus base with one expansion slot

Information:

The bus controller must be placed in the rightmost slot.

4.20.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.20.4.4 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.20.4.5 LED status indicators

Figure	LED	Color	Status	Description
	STATUS	Green	On	Interface module active
		Red	On	Bus controller booting
	X2X	Yellow	On	The module sends data via the X2X Link interface

	2	X2X⊥	
	3	X2X\	
	4	SHLD	Shield
4-pin male multipoint connector			

4.20.4.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.21 Fieldbus CPUs

Fieldbus CPUs are a variation of Compact CPUs. Their modular structure makes it easy to meet the unique requirements of each application.

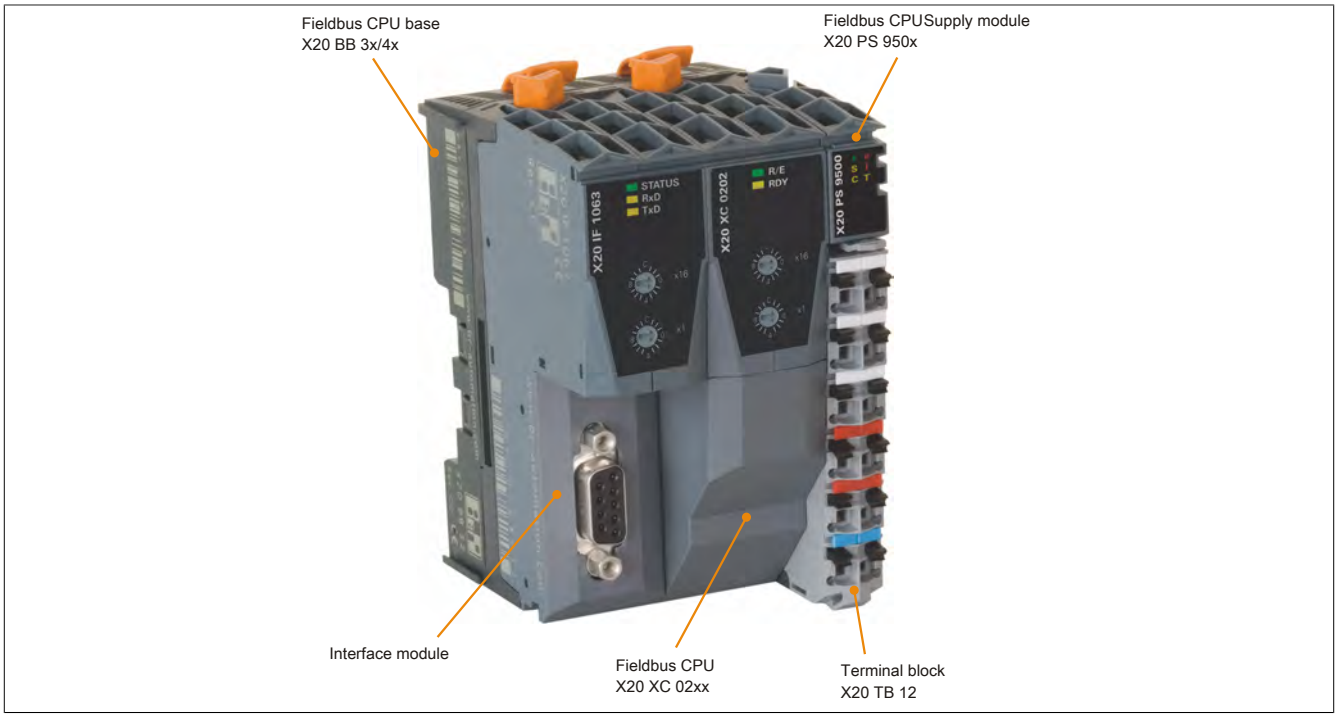

Figure 369: Modular structure of the Fieldbus CPU

Adaptable to individual requirements

- Embedded µP 25 with or without Ethernet on-board
- Embedded µP 16

- PROFIBUS DP master
- PROFIBUS DP slave
- CAN bus
- RS232
- RS485/RS422

- Bus module with RS232 connection
- Bus module with RS232 and CAN bus connections
- Both versions with one or two slots for interface modules

- Supply module for Fieldbus CPU, X2X Link bus supply and I/O
- RS232 interface connection
- CAN bus connection
- Without or without electrical isolation of the CPU/X2X Link supply

- 12-pin terminal block

The battery-free CPU

To meet the high demands of the market, the Fieldbus CPU was designed to run without a battery. This makes it completely maintenance-free. The following features make operation without a buffer battery possible.

The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor.

This FRAM stores its contents ferroelectrically. Unlike normal SRAM, this does not require a battery.

Compact design

Despite the sleek profile of only 62,5 mm, the CPU supply, the X2X Link bus supply, and the I/O module supply are integrated in the CPU. No additional power modules are necessary.

4.21.1 Brief information

Product ID	Short description	on page
X20XC0201	X20 fieldbus CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately	2160

4.21.2 X20XC0201, X20XC0202, X20XC0292

4.21.2.1 General information

Fieldbus CPUs are variations of Compact CPUs. In addition to these features, there is also the option of connecting fieldbus modules to the left side. These CPUs make applications possible in which data preprocessing has to take place remotely within the I/O bus connection.

- Embedded µP 16 / µP 25 with additional I/O processor
- 100/750 kB User SRAM
- 1 MB / 3 MB User FlashPROM
- X20XC0292: Onboard Ethernet
- Up to two slots for fieldbus modules
- Only 62.5 mm wide
- No battery

X20BB4x	87.5+0.2 mm		

Table 445: X20XC0201, X20XC0202, X20XC0292 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor. The gold foil capacitor is completely charged after 18 continuous hours of operation.
3) This FRAM stores its contents ferroelectrically. Therefore, no backup battery is needed.
4) Not buffered.
5) For technical data, see the data sheet for the X20PS9500 power supply module.
6) For technical data, see the data sheet for the X20PS9502 power supply module.
7) Spacing is based on the width of the X20BB3x/4x fieldbus CPU base. The CPU always requires up to two fieldbus modules and one supply module X20PS9500 or X20PS9502.

4.21.2.4 LED status indicators

X20XC020x

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
		Red	On	SERVICE mode
			Off	1)
	RDY	Yellow	On	SERVICE mode
			Off	1)

1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

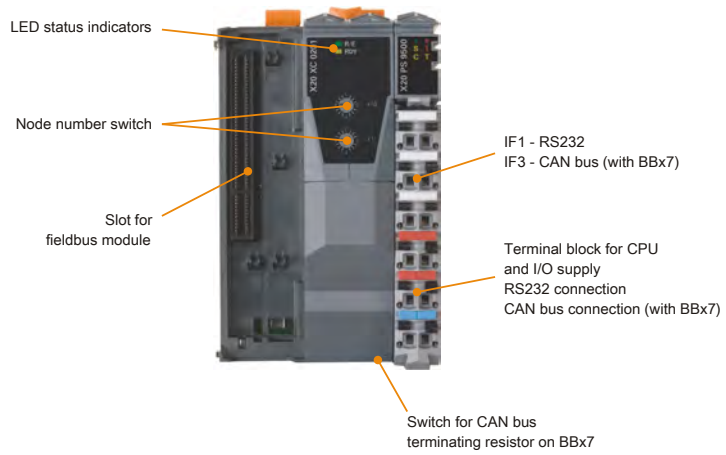
X20XC0292

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
		Red	On	SERVICE mode
		Off		1)
	RDY	Yellow	On	SERVICE mode
			Off	1)
	L/A	Green	On	A link to the peer station has been established.
			Blinking	A link to the peer station has been established. Indicates Ethernet activity is taking place on the bus.

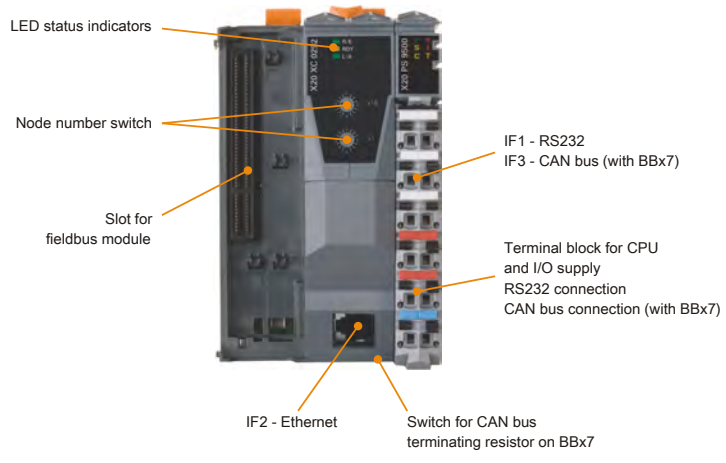
1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

4.21.2.5 Operating and connection elements

X20XC0201 and X20XC0202



X20XC0292



4.21.2.6 Node number switches

The node number is set using the two hex switches. The switch setting can be evaluated by the application program at any time. The operating system only evaluates the switch position when the device is switched on.

Switch position	Operating mode	Description
0x00	BOOT	In this switch position, the operating system can be installed via the RS232 interface configured as the online interface. User Flash is deleted only after the update begins.
0x01 - 0xFE	RUN	RUN mode, the application is running.
0xFF	Diagnostics	Boots the CPU in Diagnostics mode. Program sections in User RAM and User FlashPROM are not initialized. Following diagnostics mode, the CPU always boots with a **cold restart**.

X20XP0201 and X20XP0202

When used with the X20BB37 or X20BB47 bus module, the CPUs have access to a CAN bus interface. The INA2000 station number for CAN is set using the node number switches.

X20XP0292

This CPU is equipped with an onboard Ethernet interface. When used with the X20BB37 or X20BB47 bus module, it also has access to a CAN bus interface.

The number set using the two hex switches defines the INA2000 station number of both the CAN and the Ethernet interface.

4.21.2.7 Ethernet interface (IF2)

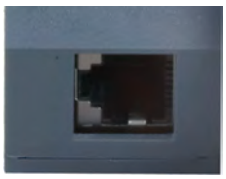


Figure 370: X20 compact CPUs - Ethernet interface for X20CP0291 and X20CP0292

The X20XC0292 is equipped with an Ethernet interface. The connection is made using a 100 BASE-T twisted pair RJ45 socket.

Pinout

Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).

Information:

The Ethernet interface (IF2) is not suited for POWERLINK.

Starting with operating system version 1.07, CPUs have a default IP address.

IP address: 192.168.0.1
Subnet mask: 255.255.0.0

4.21.2.8 Slot for fieldbus modules

Up to two fieldbus modules can be connected to the left side of the Fieldbus CPUs depending on the CPU base:

CPU base	Slots for fieldbus modules
X20BB32, X20BB37	1
X20BB42, X20BB47	2

Table 446: X20 Fieldbus CPUs - Slots for fieldbus modules depending on CPU base

The X20 system can be connected to various bus and network systems by selecting the appropriate fieldbus modules. The following fieldbus modules can be operated with the CPUs:

Module	Description
X20IF1020	X20 interface module, 1 RS232, max. 115.2 kbit/s, electrically isolated
X20IF1030	X20 interface module, 1 RS485/RS422, max. 115.2 kbit/s, electrically isolated
X20IF1041-1	X20 interface module for DTM configuration, 1 CANopen master interface, electrically isolated
X20IF1043-1	X20 interface module for DTM configuration, 1 CANopen slave interface, electrically isolated
X20IF1051-1	X20 interface module for DTM configuration, 1 DeviceNet scanner interface, electrically isolated
X20IF1053-1	X20 interface module for DTM configuration, 1 DeviceNet slave (adapter) interface, electrically isolated
X20IF1061	X20 interface module, 1 Profibus DP master interface, max.12 Mbit/s, max. 3.5 KB input data and max. 3.5 KB output data, electrically isolated
X20IF1061-1	X20 interface module for DTM configuration, 1 PROFIBUS DP V1 master interface, electrically isolated
X20IF1063	X20 interface module, 1 Profibus DP slave interface, max.12 Mbit/s, electrically isolated
X20IF1063-1	X20 interface module for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20IF1074	X20 interface module for SGC, 1 CAN interface, max. 1 Mbit/s, electrically isolated,...
X20IF10A1-1	X20 interface module for DTM configuration, 1 ASi master interface, electrically isolated
X20IF10D1-1	X20 interface module for DTM configuration, 1 EtherNet/IP scanner interface, electrically isolated
X20IF10D3-1	X20 interface module for DTM configuration, 1 EtherNet/IP slave interface, electrically isolated
X20IF10E1-1	X20 interface module for DTM configuration, 1 PROFINET RT controller (master), electrically isolated
X20IF10E3-1	X20 interface module for DTM configuration, 1 PROFINET RT device (slave), electrically isolated
X20IF10G3-1	X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated
X20IF10H3-1	X20 interface module for DTM configuration, 1 Sercos III slave interface, electrically isolated

Table 447: X20 fieldbus CPUs - Possible fieldbus modules

4.21.2.9 Programming the system flash memory

General information

CPUs are delivered with a runtime system. When delivered, the node number switch is set to switch position 0x00 (bootstrap loader mode).

A suitable switch position must be set (0x01 to 0xFE) in order to boot the PLC in RUN mode. Updating the runtime system is only possible in RUN mode.

Runtime system update

The runtime system can be updated via the programming environment. When updating the runtime system via an online connection, the following procedure must be carried out:

1. An online runtime system update is only possible if the processor is in RUN mode. For this to be true, the node number must be set to a value in the range 0x01 to 0xFE.
2. Switch on the power.
3. The runtime system update is performed via the existing online connection. The online connection can be established via the onboard serial RS232 interface, for example. If a CPU has an Ethernet interface, then it too can be used to perform the update.
4. Start B&R Automation Studio.
5. Start the update procedure by selecting **Online** from the **Project** menu. Select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions given by B&R Automation Studio.
6. A window opens up for setting the runtime system version. The runtime system version is already pre-selected by the project settings made by the user. The drop-down menu can be used to select one of the runtime system versions stored in the project. Clicking on the **Browse** button allows a runtime system version to be loaded from the hard drive or CD.

   Clicking on **Next** opens a pop-up window that allows the user to select whether modules with target memory SYSTEM ROM should be transferred during the subsequent runtime system update. If not, these modules can also be transferred later during an application download.

   Clicking on **Next** opens a dialog box where the user can set the CAN transfer rate, CAN ID and CAN node number (the CAN node number set here is only relevant if an interface module does not have a CAN node number switch). The CAN node number must be between decimal 01 and 99. Assigning a unique node number is especially important with online communication over a CAN network (INA2000 protocol).
7. The update procedure is started by clicking on **Next**. Update progress is shown in a message box.

   > **Information:**
   >
   > **User flash memory is deleted.**
8. When the update procedure is complete, the online connection is reestablished automatically.
9. The PLC is now ready for use.

Updating the runtime system is possible not only via an online connection, but also via a CAN network, serial network (INA2000 protocol) or Ethernet network, depending on the system configuration.

4.22 Fieldbus CPUs system modules

The X20 system Fieldbus CPUs consist of the Fieldbus CPU, Fieldbus CPU system modules and the X20TB12 terminal block.

Fieldbus CPU system modules include the base module and the supply modules for providing power to the entire system.

4.22.1 Brief information

Product ID	Short description	on page
X20BB32	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, Slot for X20 interface module, X20 connection, X20 locking plates (left and right) X20AC0SL1/ X20AC0SR1 included	2168
X20BB37	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, Slot for X20 interface module, X20 connection, X20 locking plates X20AC0SL1/ X20AC0SR1 (left and right) included	2170
X20BB42	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/ X20AC0SR1 included	2172
X20BB47	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	2174
X20IF1074	X20 interface module, for SGC, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately	2176

4.22.2 X20BB32

4.22.2.1 General information

The bus module is the base for all X20 Fieldbus CPUs.

The left and right end plates are included in the delivery.

- Base for all X20 Fieldbus CPUs
- RS232 connection

Information:

The bus controller must be placed in the rightmost slot.

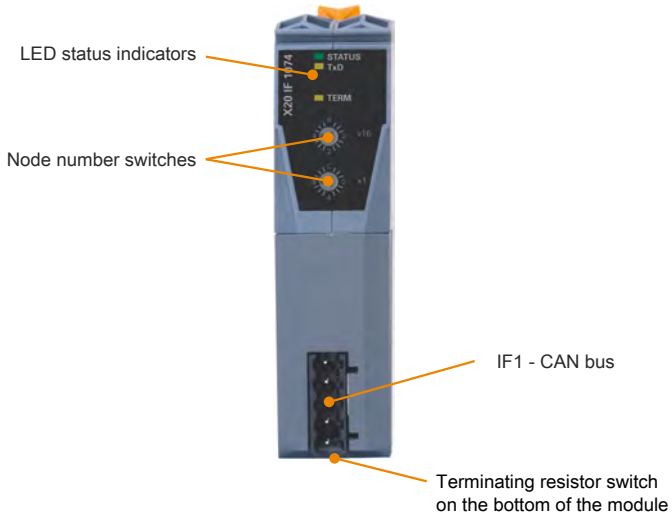
4.22.6.4 LED status indicators

Figure	LED	Color	Status	Description
	STATUS	Green	On	Interface module active
		Red	On	CPU starting up
	TxD	Yellow	On	The module is sending data via the CAN bus interface
	TERM	Yellow	On	Terminating resistor integrated in the module switched on.

4.22.6.5 Operating and connection elements



4.22.6.6 Node number switch

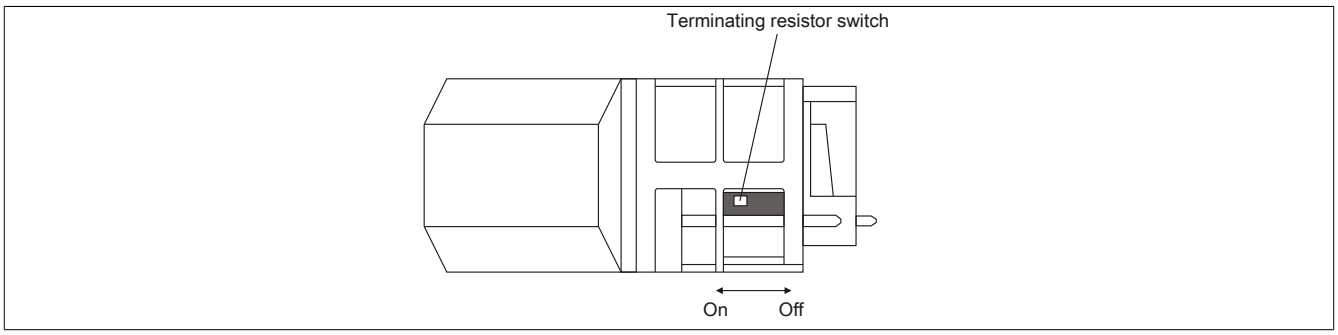
The node number for the interface is set with the two hex switches.

4.22.6.7 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	**Terminal**	**Function**	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.22.6.8 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.22.6.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23 X20 interface module communication

The interface modules are added to the X20 CPU as an application-specific interface expansion.

4.23.1 Brief information

Product ID	Short description	on page
X20IF1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s, electrically isolated	2181

4.23.2.7 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.3 X20(c)IF1030

4.23.3.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an RS485/RS422 interface.

- RS485/RS422 connection

4.23.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.23.3.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.4 X20(c)IF1041-1

4.23.4.1 General information

The interface module is equipped with a CANopen master interface. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

- CANopen master
- Integrated terminating resistor

4.23.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

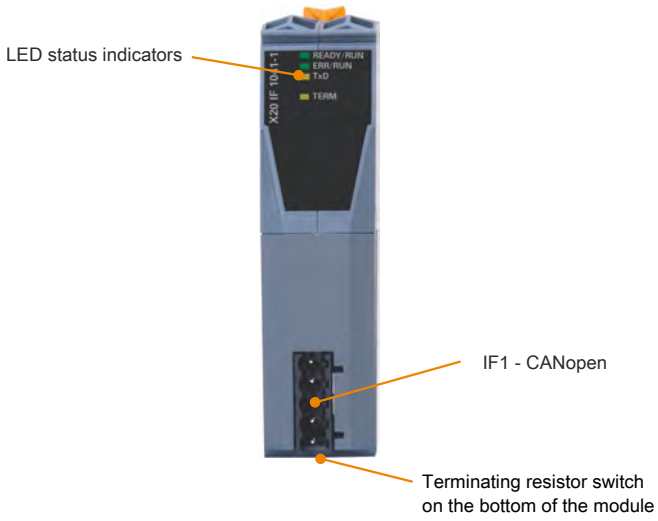
4.23.4.5 LED status indicators

Figure	LED	Color	Status	Description
	READY/RUN	Green/red	Off	No power to module
		Green	On	PCI bus communication in progress
		Red	Blinking	Error when booting
			On	Communication on the PCI bus has not yet been started
	ERR/RUN	Green/red	Off	Module executes a reset
			Green on Red blinking with double pulse	CANopen communication disrupted. This may be due to one of the following reasons: • The CAN bus cable is broken or the CAN bus controller is in "Bus off" mode • The module is in PREOPERATIONAL mode • At least one configured CANopen slave is not functioning
			Green on Red blinking	Communication was stopped (the module is in STOPPED mode)
		Green	Blinking	Communication is being started (module is being initialized)
			On	Communication is ready
	TxD	Yellow	Flickering or on	Module sending data via the CANopen interface
	TERM	Yellow	On	Terminating resistor integrated in the module switched on

4.23.4.6 Operating and connection elements

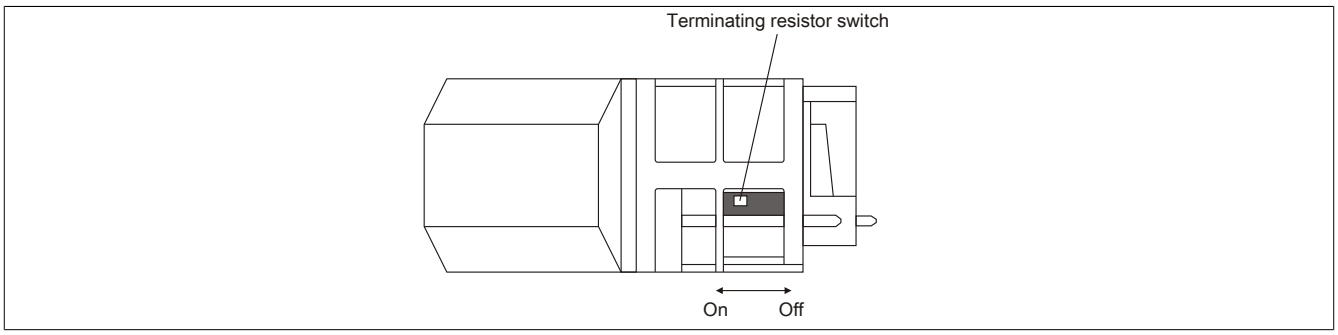


4.23.4.7 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	Terminal	Function	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.23.4.8 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.4.9 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.4.9.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.4.10 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.5 X20IF1043-1

4.23.5.1 General information

The interface module is equipped with a CANopen slave interface. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

- CANopen slave
- Integrated terminating resistor

4.23.5.2 Order data

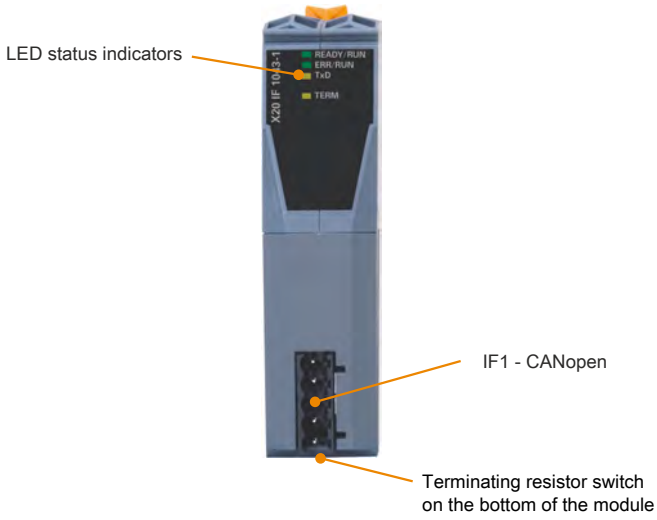
		Green	Blinking	Communication is being started (module is being initialized)
			On	Communication is ready
	TxD	Yellow	Flickering or on	Module sending data via the CANopen interface
	TERM	Yellow	On	Terminating resistor integrated in the module switched on

4.23.5.5 Operating and connection elements

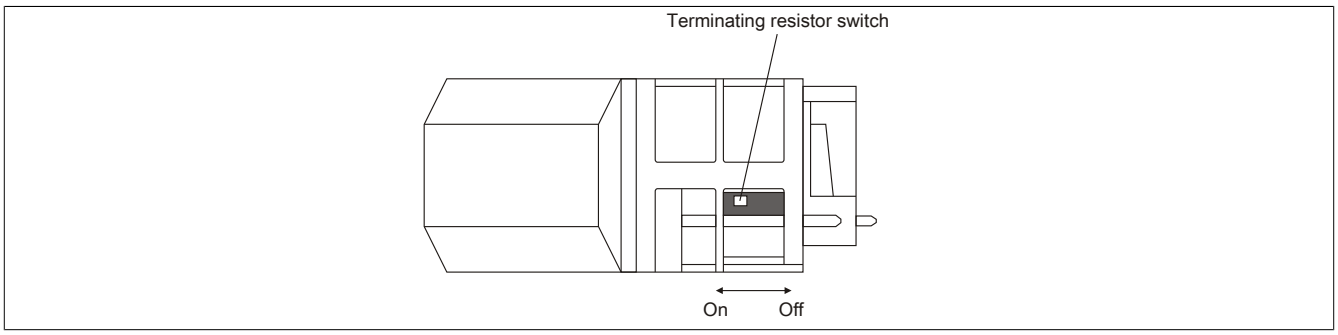


4.23.5.6 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	Terminal	Function	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.23.5.7 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.5.8 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.5.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.5.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.6 X20IF1051-1

4.23.6.1 General information

The interface module is equipped with a DeviceNet scanner interface. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

- DeviceNet Scanner
- Integrated terminating resistor

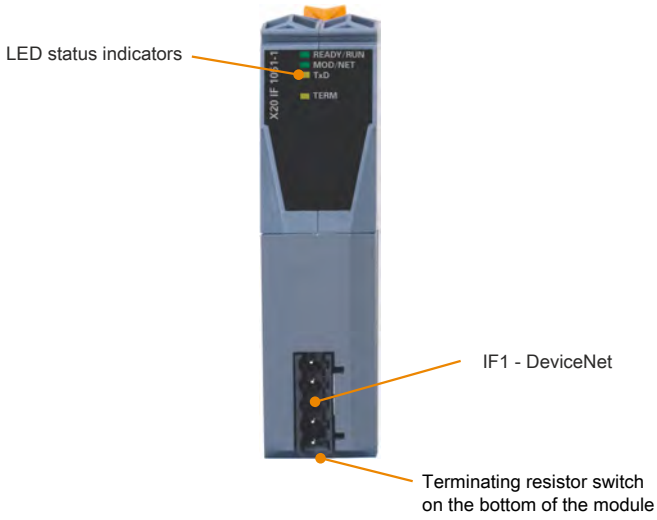
4.23.6.4 LED status indicators

Figure	LED	Color	Status	Description
	READY/RUN	Green/red	Off	No power to module
		Green	On	PCI bus communication in progress
		Red	On	Communication on the PCI bus has not yet been started
	MOD/NET	Green/red	Off	Module supply not connected or module is not online
		Green	Blinking	Module is online but the I/O connection is not active
			On	Module is online and the I/O connection is active ("operating")
		Red	Blinking	The red LED blinks if at least one of the following errors has occurred: • Minor fault (recoverable fault) • Connection error • No DeviceNet supply voltage
			On	Critical fault or critical connection error (double MAC ID, bus failure or module defect)
	TxD	Yellow	Flickering or on	Module sending data via the DeviceNet interface
	TERM	Yellow	On	Terminating resistor integrated in the module switched on

4.23.6.5 Operating and connection elements



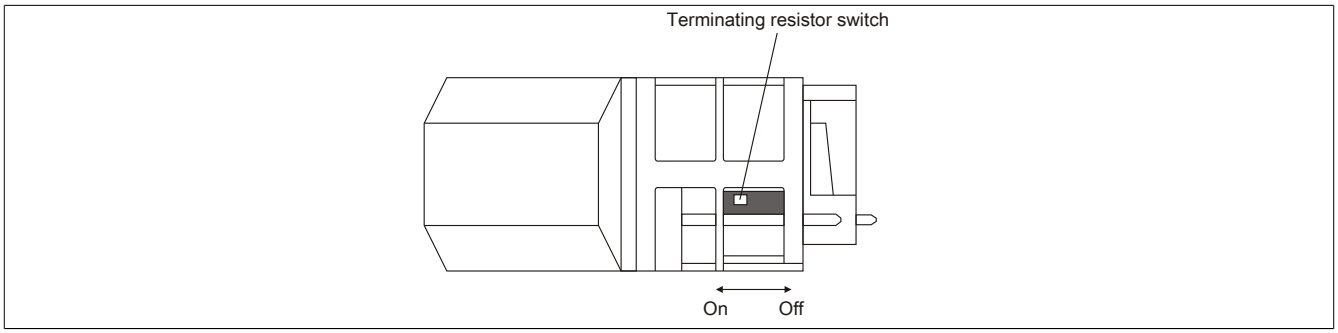
4.23.6.6 DeviceNet interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	Terminal	DeviceNet	
	1	CAN⊥ (V-)	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	V+	Supply voltage[1)]

1) The 24 VDC in the DeviceNet network must be fed in externally in order to guarantee correct operation and data exchange. 24 VDC is not made available by the device.

4.23.6.7 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.6.8 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.6.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.6.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.7 X20IF1053-1

4.23.7.1 General information

The interface module is equipped with a DeviceNet slave (adapter) interface. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

- DeviceNet slave (adapter)
- Integrated terminating resistor

4.23.7.2 Order data

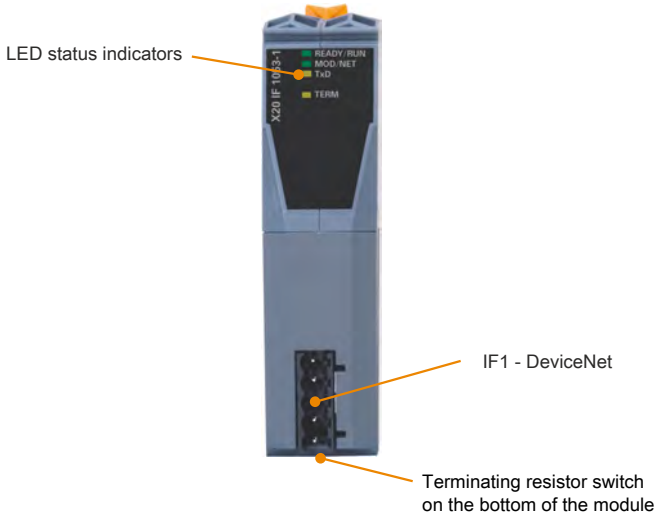
4.23.7.5 Operating and connection elements



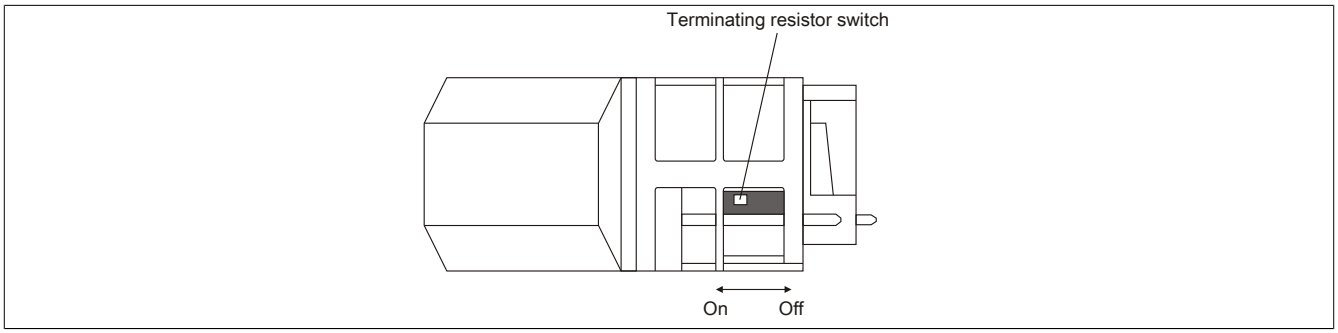
4.23.7.6 DeviceNet interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	Terminal	DeviceNet	
	1	CAN⊥ (V-)	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	V+	Supply voltage[1)]

1) The 24 VDC in the DeviceNet network must be fed in externally in order to guarantee correct operation and data exchange. 24 VDC is not made available by the device.

4.23.7.7 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.7.8 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.7.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.7.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.8 X20IF1061

4.23.8.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with a PROFIBUS DP V1 master interface.

- PROFIBUS DP V1 master

4.23.8.7 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.9 X20(c)IF1061-1

4.23.9.1 General information

The interface module functions as a DP V1 master. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

- PROFIBUS DP V1 master

4.23.9.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.23.9.8 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.9.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.9.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.9.10 Minimum DTM version for coated modules

Information:

The minimum DTM version required by coated modules is 1.0370.140220.12186. This version is included beginning with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

4.23.10 X20IF1063

4.23.10.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with a PROFIBUS DP V0 slave interface.

- PROFIBUS DP V0 slave connection

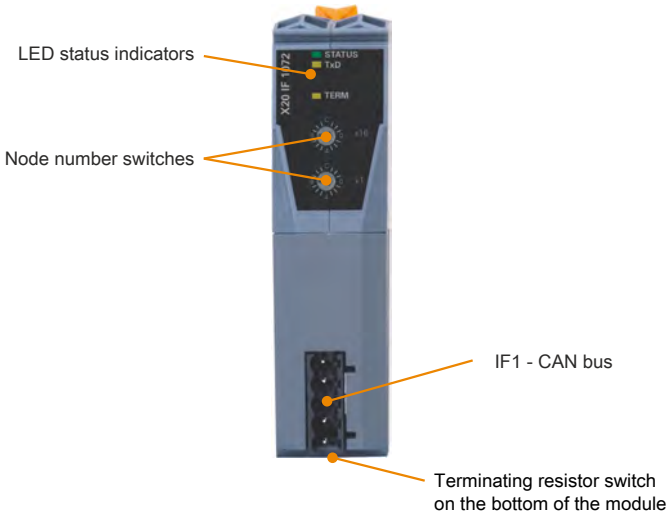
2) This CAN bus interface can be configured as a CANopen master in Automation Studio 3.0 and higher.

4.23.13.5 LED status indicators

Figure	LED	Color	Status	Description
	STATUS	Green	On	Interface module active
		Red	On	CPU starting up
	TxD	Yellow	On	The module is sending data via the CAN bus interface
	TERM	Yellow	On	Terminating resistor integrated in the module switched on

4.23.13.6 Operating and connection elements



4.23.13.7 Node number switch

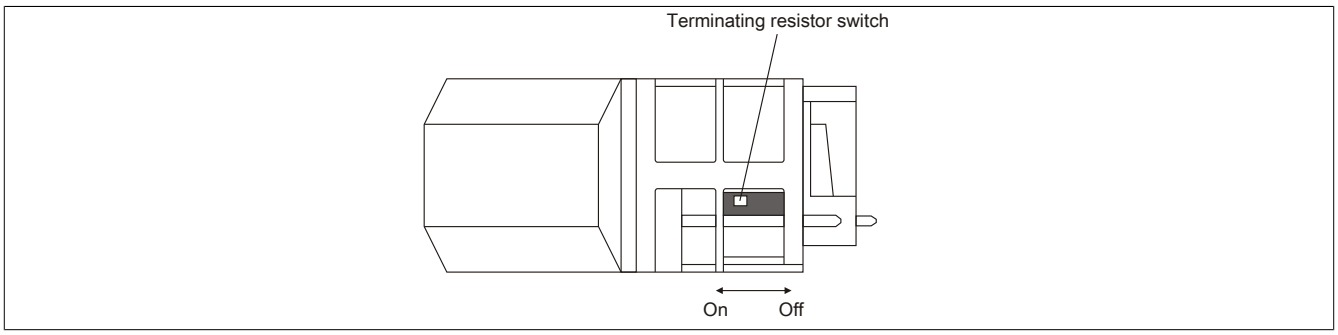
The node number for the interface is set with the two hex switches.

4.23.13.8 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	**Terminal**	**Function**	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.23.13.9 Terminating resistor



A terminating resistor is integrated in the interface module. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.13.10 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.14 X20IF1082

4.23.14.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

The interface has two RJ45 sockets. Both connections lead to an integrated hub. This makes it easy to create daisy-chain connections using POWERLINK.

- POWERLINK V1/V2 for real-time Ethernet communication
- Integrated hub for efficient cabling
- Configurable ring redundancy

4.23.14.4 LED status indicators

Figure	LED	Color	Status	Description
	S/E	Green/Red		Status/Error LED. The LED indicators are described in section 4.12.3.4.1 ""S/E" LED".
	L/A IFx	Green	On	A link to the remote station has been established.
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus

4.23.14.4.1 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.23.14.4.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 484: Status/Error LED - Ethernet operating mode

4.23.14.4.1.2 POWERLINK V1

Status LED		Status of the POWERLINK node
Green	Red	
On	Off	The POWERLINK node is running with no errors.
Off	On	A system error has occurred. The error type can be read using the PLC logbook. An irreparable problem has occurred. The system cannot properly carry out its tasks. This state can only be changed by resetting the module.
Blinking alternately		The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the configured node number lies within the range 0x01 - 0xFD.
Off	Blinking	System failure. The red blinking LED signals an error code (see section 4.12.2.4.2 "System failure error codes").
Off	Off	Module is: • Off • Starting up • Not configured correctly in Automation Studio • Defective

Table 485: Status/Error LED - POWERLINK V1 operating mode

4.23.14.4.1.3 POWERLINK

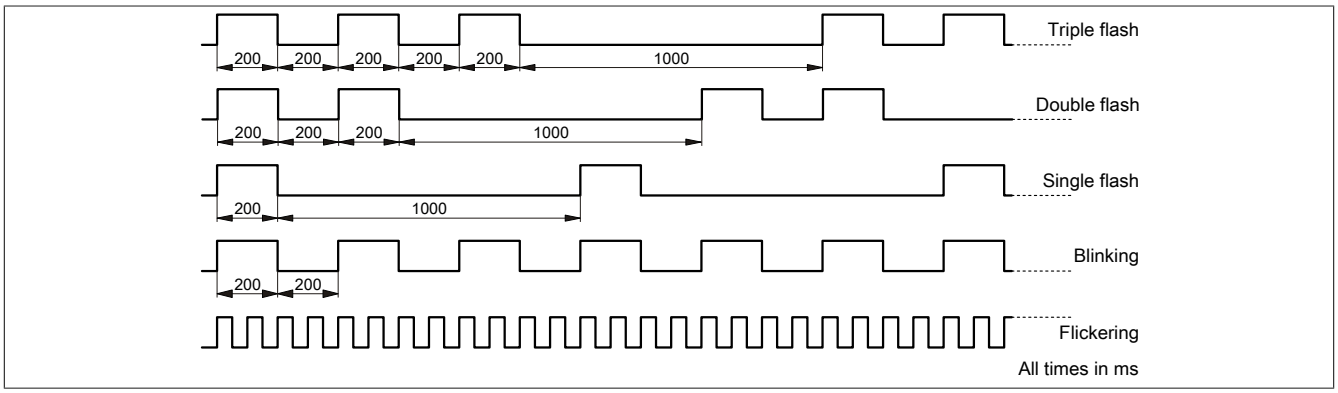
Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 486: Status/Error LED as Error LED - POWERLINK operating mode

Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 487: Status/Error LED as Status LED - POWERLINK operating mode

Status LEDs - Blinking patterns



4.23.14.4.1.4 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	•	•	•	-	Pause	•	•	•	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	•	•	-	Pause	-	•	•	-	Pause

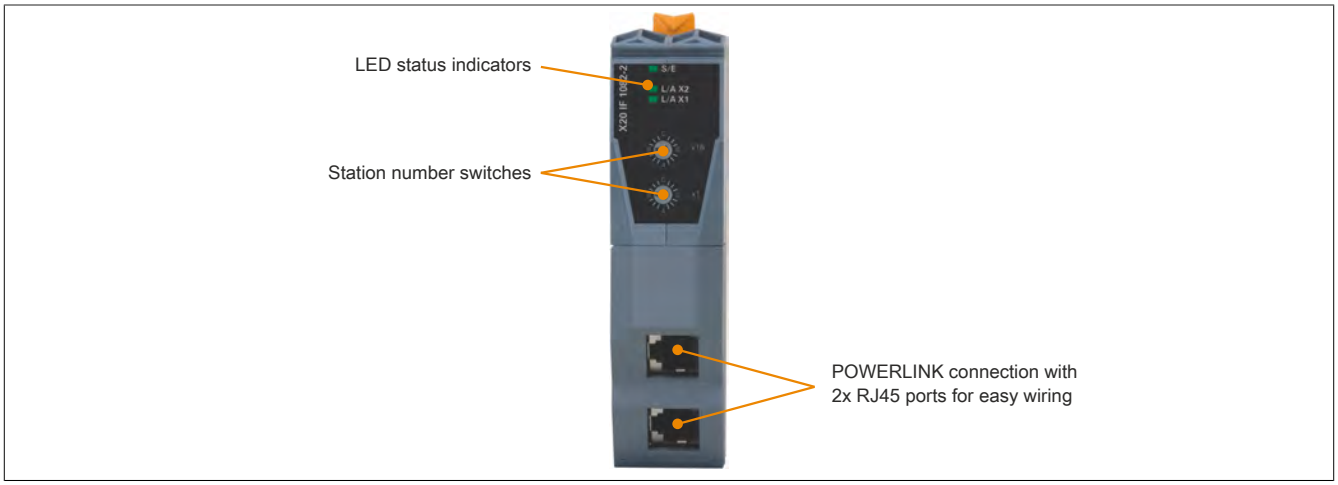
- - ... 600 ms
- Pause ... 2 second delay

4.23.14.5 Operating and connection elements



4.23.14.6 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

4.23.14.6.1 POWERLINK V1

Switch position	Description
0x00	Operation as managing node.
0x01 - 0xFD	Node number of the POWERLINK node. Operation as controlled node.
0xFE - 0xFF	Reserved, switch position not permitted

Table 489: POWERLINK V1 - Node numbers

4.23.14.6.2 POWERLINK

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as a controlled node.
0xF0	Operation as a managing node.
0xF1 - 0xFF	Reserved, switch position not permitted

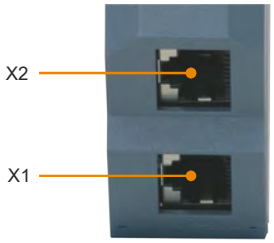
Table 490: POWERLINK node number

4.23.14.6.3 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number can be set using the B&R Automation Studio software.

4.23.14.7 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.23.14.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.15 X20(c)IF1082-2

4.23.15.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

The interface has two RJ45 sockets. Both connections lead to an integrated hub. This makes it easy to create daisy-chain connections using POWERLINK.

- POWERLINK for real-time Ethernet communication
- Integrated hub for efficient cabling
- Configurable ring redundancy
- Poll response chaining
- Dynamic Node Allocation (DNA)

4.23.15.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Figure	LED	Color	Status	Description
	S/E	Green/Red		Status/Error LED. The LED indicators are described in section 4.12.3.4.1 ""S/E" LED".
	L/A X1	Green	On	A link to the remote station has been established.
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus

4.23.16.5 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.23.16.5.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 502: Status/Error LED - Ethernet operating mode

4.23.16.5.2 POWERLINK V1

Status LED		Status of the POWERLINK node
Green	Red	
On	Off	The POWERLINK node is running with no errors.
Off	On	A system error has occurred. The error type can be read using the PLC logbook. An irreparable problem has occurred. The system cannot properly carry out its tasks. This state can only be changed by resetting the module.
Blinking alternately		The POWERLINK managing node has failed. This error code can only occur when operated as a controlled node. This means that the configured node number lies within the range 0x01 - 0xFD.
Off	Blinking	System failure. The red blinking LED signals an error code (see section 4.12.2.4.2 "System failure error codes").
Off	Off	Module is: • Off • Starting up • Not configured correctly in Automation Studio • Defective

Table 503: Status/Error LED - POWERLINK V1 operating mode

4.23.16.5.3 POWERLINK

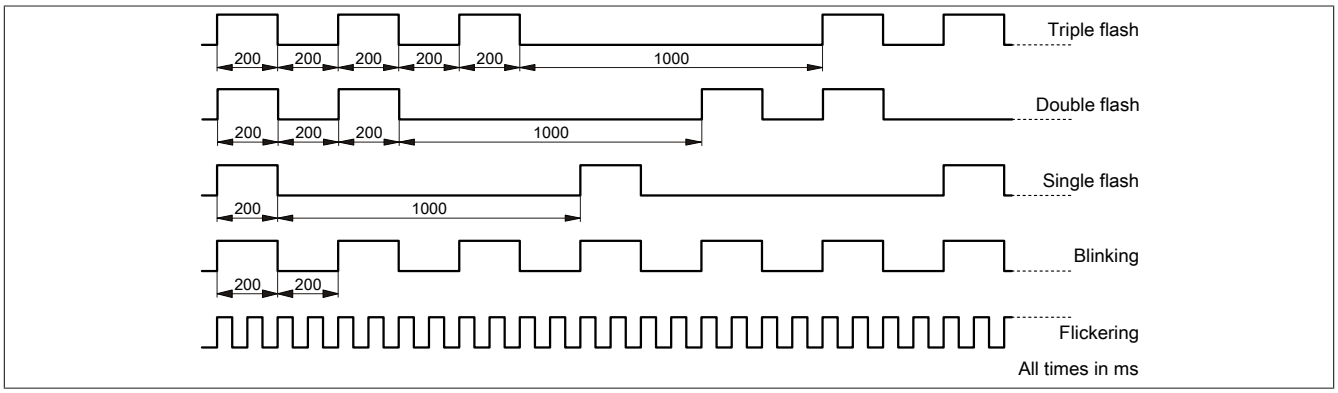
Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 504: Status/Error LED as Error LED - POWERLINK operating mode

Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 505: Status/Error LED as Status LED - POWERLINK operating mode

Status LEDs - Blinking patterns



4.23.16.5.4 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

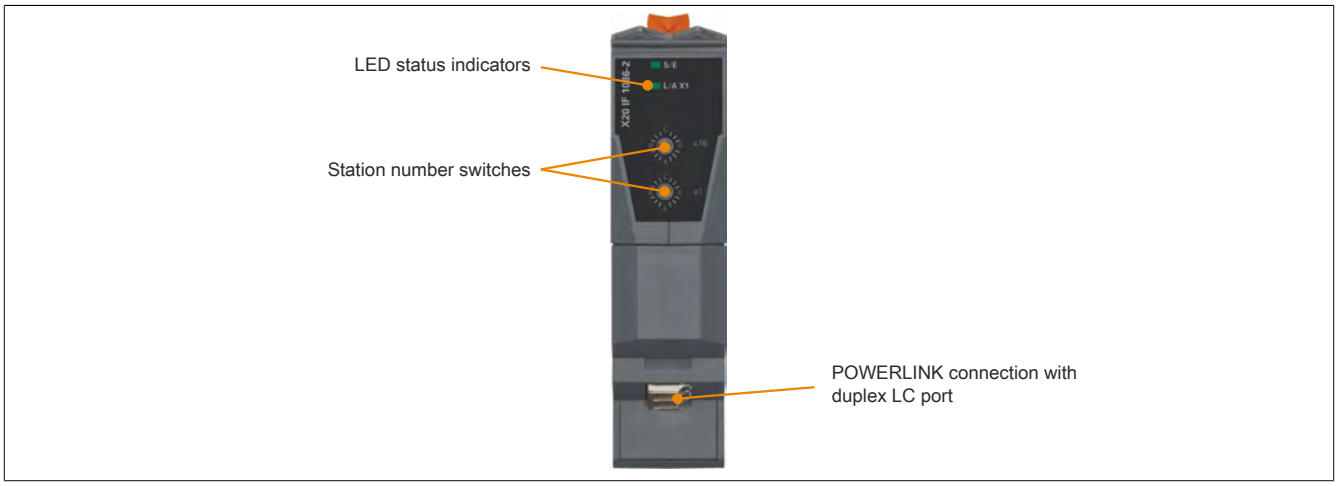
The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	•	•	•	-	Pause	•	•	•	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	•	•	-	Pause	-	•	•	-	Pause

Table 506: Status/Error ("S/E") LED - System failure error codes

Key:
- • ... 150 ms
- - ... 600 ms
- Pause ... 2 second delay

4.23.16.6 Operating and connection elements



4.23.16.7 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

4.23.16.7.1 POWERLINK V1

Switch position	Description
0x00	Operation as managing node.
0x01 - 0xFD	Node number of the POWERLINK node. Operation as controlled node.
0xFE - 0xFF	Reserved, switch position not permitted

Table 507: POWERLINK V1 - Node numbers

4.23.16.7.2 POWERLINK

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as a controlled node.
0xF0	Operation as a managing node.
0xF1 - 0xFF	Reserved, switch position not permitted

Table 508: POWERLINK node number

4.23.16.7.3 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number can be set using the B&R Automation Studio software.

4.23.16.8 Duplex LC port

Figure	Description
	100 Base FX port, Duplex LC socket

4.23.16.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.16.10 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 µm or 50/125 µm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

4.23.17 X20IF1091

4.23.17.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with an X2X Link master interface.

- X2X Link connection

4.23.17.7 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.18 X20IF10A1-1

4.23.18.1 General information

The interface module is equipped with an AS master interface. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

AS-i stands for actuator-sensor interface and is a bus system for the lowest field level of automation technology. Using AS-i bus systems provides an easy and affordable way to connect, operate and service sensors and actuators.

This eliminates the need for parallel wiring, where each individual sensor or actuator was connected to the input or output module via a separate wire. A dual-core wire is used instead, which transfers both power and information at the same time.

- AS interface master
- Electrically isolated
- 4-pin bus connector

4.23.18.7 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.18.7.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.18.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.19 X20IF10D1-1

4.23.19.1 General information

The interface module functions as an EtherNet/IP scanner (master). It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

The interface has two RJ45 sockets. Both connections lead to an integrated switch. This makes it easy to create daisy-chain connections using EtherNet/IP.

- EtherNet/IP Scanner
- Integrated switch for efficient cabling

4.23.19.7 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.19.7.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.19.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.20 X20(c)IF10D3-1

4.23.20.1 General information

The interface module functions as an EtherNet/IP adapter (slave). It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

The interface has two RJ45 sockets. Both connections lead to an integrated switch. This makes it easy to create daisy-chain connections using EtherNet/IP.

- EtherNet/IP adapter (slave)
- Integrated switch for efficient cabling

4.23.20.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.20.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.20.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.20.10 Minimum DTM version for coated modules

Information:

The minimum DTM version required by coated modules is 1.0370.140220.12186. This version is included beginning with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

4.23.21 X20IF10E1-1

4.23.21.1 General information

The interface module functions as a PROFINET RT controller (master). It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

The interface has two RJ45 sockets. Both connections lead to an integrated switch. This makes it easy to create daisy-chain connections using PROFINET RT.

- PROFINET RT controller
- Integrated switch for efficient cabling

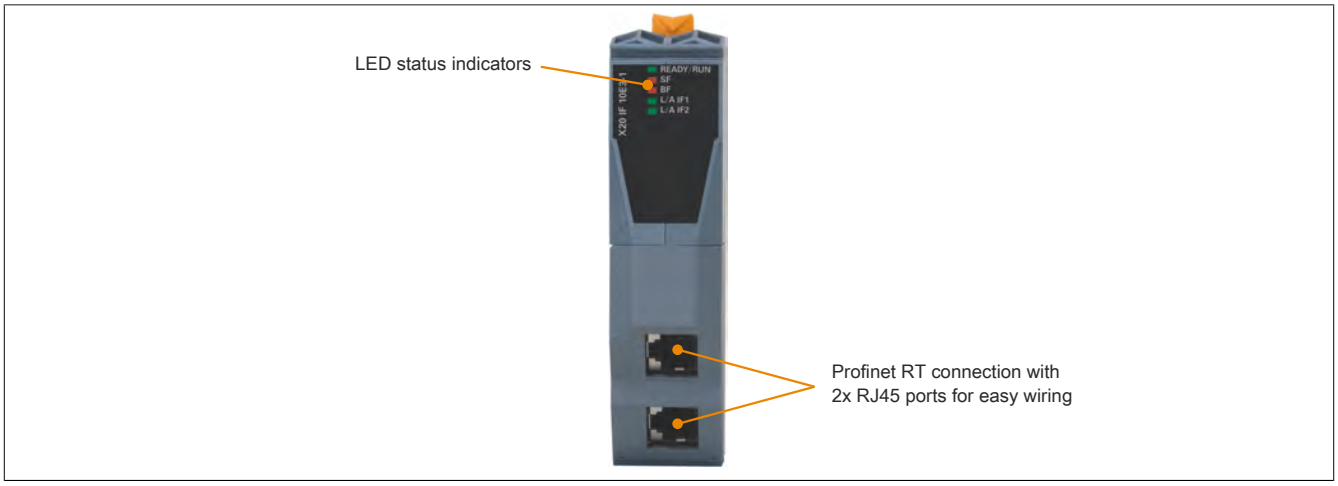
4.23.21.4 LED status indicators

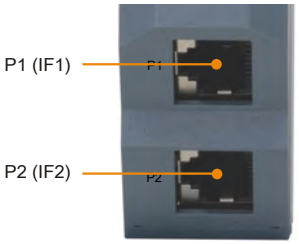
Figure	LED	Color	Status	Description
	READY/RUN	Green/red	Off	No power to module
		Red	Blinking	Boot error
			On	Communication on the PCI bus has not yet been started
		Green	On	PCI bus communication in progress
	SF	Red	Off	No error
			Blinking	Invalid configuration
			On	System errors
	BF	Red	Off	No error
			Blinking	Configuration error: Not all configured I/O modules are connected
			On	No link to remote station
	L/A IF1/IF2	Green	Off	No link to remote station
			Flickering	A link to the remote station has been established. The LED blinks when Ethernet activity is taking place on the bus.
			On	A link to the remote station has been established.

4.23.21.5 Operating and connection elements



4.23.21.6 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.23.21.7 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.21.7.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.21.8 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.22 X20(c)IF10E3-1

4.23.22.1 General information

The interface module functions as a PROFINET RT device (slave). It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

The interface has two RJ45 sockets. Both connections lead to an integrated switch. This makes it easy to create daisy-chain connections using PROFINET RT.

- PROFINET RT device
- Integrated switch for efficient cabling

4.23.22.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

	8	Termination	

4.23.22.8 Use with POWERLINK bus controllers

When this module is connected to the expandable POWERLINK bus controller, the amount of cyclic data is limited by the POWERLINK frame to 1488 bytes in each direction (input and output).
When using multiple IF10xx-1 interfaces or other X2X modules with a POWERLINK bus controller, the 1488 bytes are divided between all connected modules.

4.23.22.8.1 Operating netX modules with the X20BC1083 bus controller

The following must be taken into account to operate netX modules with the bus controller without problems:

- A minimum revision ≥E0 is required for the bus controller.
- NetX modules can only be operated with POWERLINK V2. V1 is not permitted.

4.23.22.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.22.10 Recognizing an invalid connection

All cyclic data is set to zero in the event of an invalid connection between the master and slave.
An invalid connection may be caused by the following:

- No connection between the master and the slave
- Interface card initialization is not yet complete.
- The master is in error mode.
- Data is marked as invalid (IOPS = Bad).

It cannot be determined whether the data is valid or invalid based on the transmitted data. In order to be able to reliably recognize an invalid connection, it is necessary to evaluate the master's IOPS data additionally in the application.

Forwarding IOPS data to the application can be enabled via the interface card's DTM ("I/O state information" in AS).

4.23.22.11 Minimum DTM version for coated modules

Information:

The minimum DTM version required by coated modules is 1.0370.140220.12186. This version is included beginning with Automation Studio upgrade packs V4.0.18.x and V3.0.90.29.

4.23.23 X20IF10G3-1

4.23.23.1 General information

The interface module functions as an EtherCAT slave. It can be operated in X20 CPUs or in the expandable X20BC1083 POWERLINK bus controller.

The interface has two RJ45 sockets. Both connections lead to an integrated switch. This simplifies daisy-chain connections with EtherCAT.

- EtherCAT slave
- Integrated switch for efficient cabling

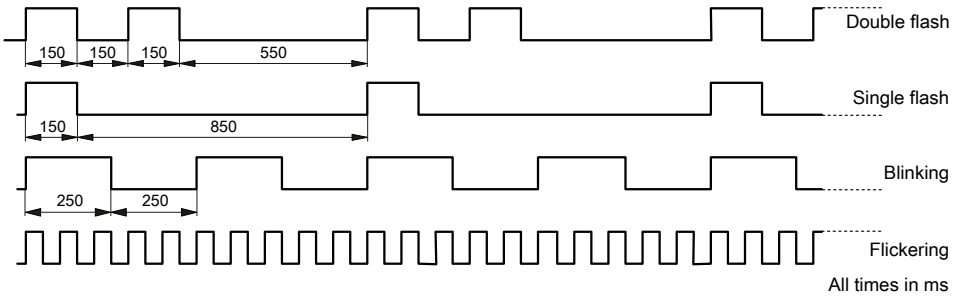
4.23.24.5 LED status indicators

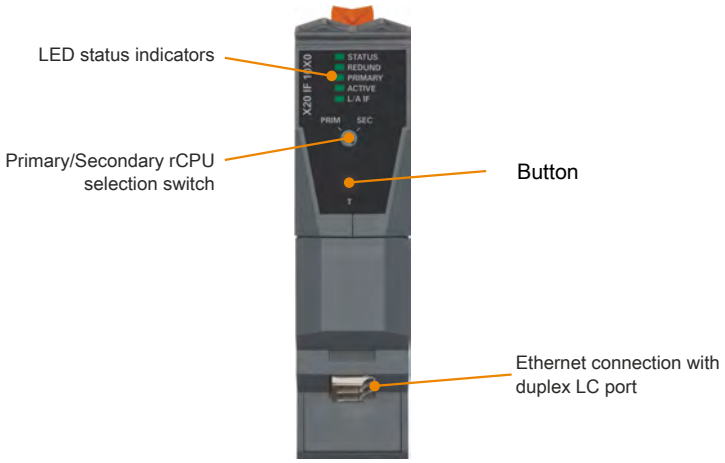
Figure	LED	Color	Status	Description
	STATUS[1)]	Green	On	Interface module active
		Red	Blinking	CPU starting up
	REDUND[1)]	Green	On	Possible to failover CPU with hot redundancy
			Blinking	Possible to failover CPU with warm redundancy
			Double flash	Possible to failover CPU with cold redundancy
			Flickering	Application synchronization in progress
		Red	On	Not possible to failover CPU. No distinction is made here between whether failover is temporarily or permanently not supported.
	PRIMARY[1)]	Green	On	rCPU = Primary CPU
			Off	rCPU = Secondary CPU
		Red	On	Invalid use of the selection switch. One rCPU must be configured as primary, the other as secondary. It is not permitted to change the switch position during operation.
	ACTIVE	Green	On	rCPU actively executing the application
			Off	rCPU inactive
	LA/IF[1)]	Green	On	Connection established to the redundancy partner
			Blinking	Redundancy link active. Data is being transferred for synchronization purposes.
		Red	On	No connection to the redundancy partner

1) This is a green/red dual LED.

LEDs - Blinking patterns



4.23.24.6 Operating and connection elements



4.23.24.7 Switch positions

The CPU can be set to primary or secondary using the "PRIM/SEC" selection switch.

During configuration, make sure that one rCPU is set as primary and the other rCPU as secondary.

Information:

It is not permitted to change the switch position during operation.

The "T" button is used for redundancy switchovers and manually synchronizing the application.

4.23.24.8 Derating

The temperatures listed in the technical data are valid when the unit is operated in the left IF slot of the X20CP358x CPUs.
When operated in the IF slot of the X20CP158x CPUs, the maximum temperature values are reduced by 5°C

4.23.24.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.25 X20(c)IF2181-2

4.23.25.1 General information

The interface module is used to expand the X20 CPU for specific applications. It is equipped with an POWERLINK interface.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) (see www.ethernet-powerlink.org).

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the X20IF2181-2 module.

- POWERLINK V2 for real-time Ethernet communication
- Integrated link selector function (preconfigured)
- Redundant Managing Node for CPU redundancy
- Integrated hub for efficient cabling (configurable)
- Configurable ring redundancy
- Poll response chaining
- Dynamic Node Allocation (DNA)

4.23.25.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.23.25.5 LED status indicators

Figure	LED	Color	Status	Description
	S/E	Green/Red		Status/Error LED. The LED indicators are described in section 4.12.3.4.1 ""S/E" LED".
	RS	Green	On	Both cable connections are OK.
		Red	On	At least one cable connection is faulty.
	L/A X1/X2	Green	On	A link to the POWERLINK remote station has been established.
			Blinking	A link to the POWERLINK remote station has been established. Indicates Ethernet activity is taking place on the bus

4.23.25.5.1 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.23.25.5.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 527: Status/Error LED - Ethernet operating mode

4.23.25.5.1.2 POWERLINK

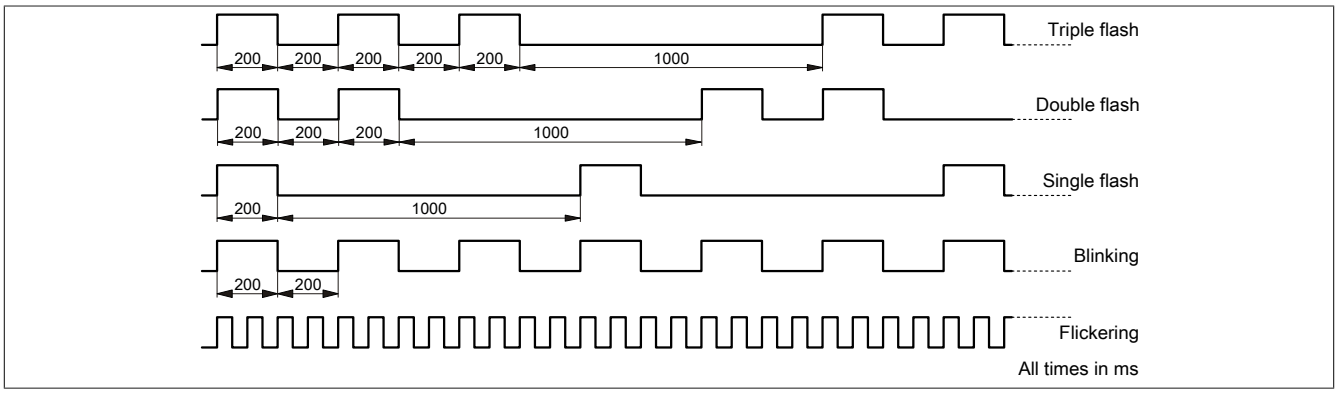
Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 528: Status/Error LED as Error LED - POWERLINK operating mode

Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 529: Status/Error LED as Status LED - POWERLINK operating mode

Status LEDs - Blinking patterns



4.23.25.5.2 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

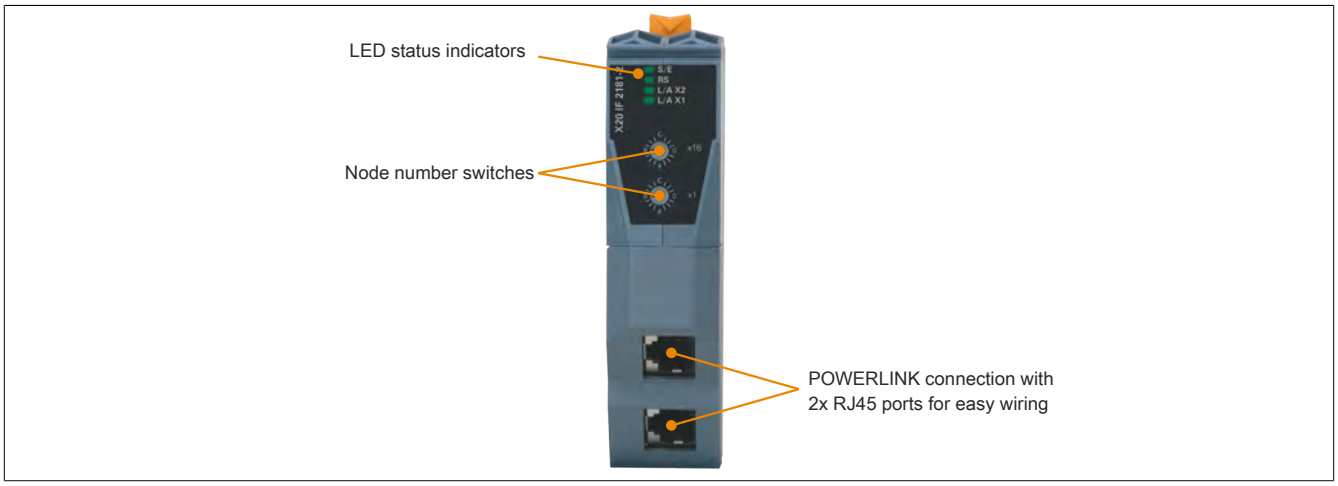
The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	•	•	•	-	Pause	•	•	•	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	•	•	-	Pause	-	•	•	-	Pause

Table 530: Status/Error ("S/E") LED - System failure error codes

Key:
- • ... 150 ms
- - ... 600 ms
- Pause ... 2 second delay

4.23.25.6 Operating and connection elements



4.23.25.7 POWERLINK node number

The node number for the POWERLINK station is set using the two number switches. The node number can also be directly configured using Automation Studio.

4.23.25.7.1 POWERLINK V2

Switch position	Description
0x00	Reserved, switch position not permitted.
0x01 - 0xEF	Node number of POWERLINK station. Operation as controlled node.
0xF0	Operation as managing node.
0xF1 - 0xF7	Reserved, switch position not permitted.
0xF8	CPU redundancy: Function as primary CPU
0xF9	CPU redundancy: Function as secondary CPU
0xFA - 0xFF	Reserved, switch position not permitted.

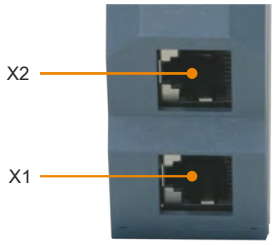
Table 531: POWERLINK V2 - Node numbers

4.23.25.7.2 Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number can be set using the B&R Automation Studio software.

4.23.25.8 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.23.25.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.25.10 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

4.23.26 X20IF2772

4.23.26.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with 2 CAN bus interfaces.

- Dual CAN bus connection
- Integrated terminating resistors

4.23.26.2 Order data

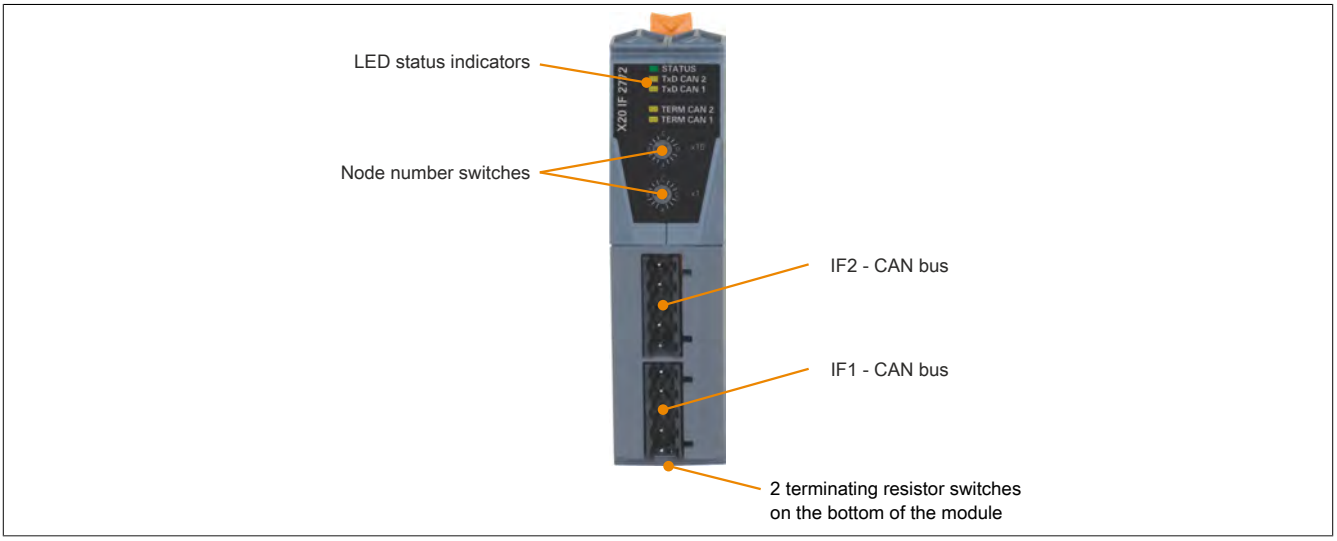
	TERM CAN 2	Yellow	On	The integrated terminating resistor for the CAN bus interface (IF2) is turned on

4.23.26.5 Operating and connection elements



4.23.26.6 CAN bus node number

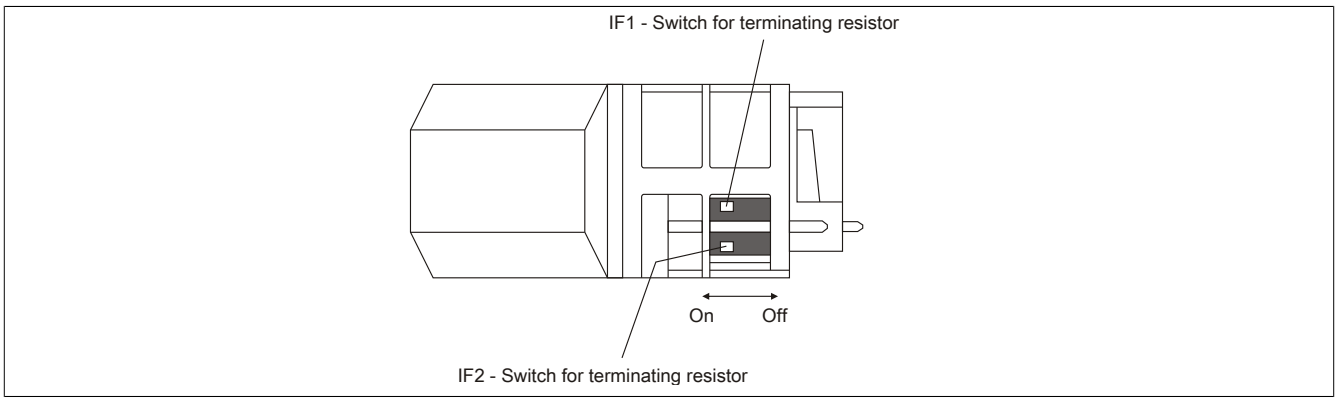
The node number for the CAN bus interfaces is set with the two hex switches.

4.23.26.7 Interfaces CAN bus 1 and CAN bus 2 (IF1 and IF2)

Both interfaces feature a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	**Terminal**	**Function**	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.23.26.8 Terminating resistor



Two terminating resistors are integrated in the interface module. The respective resistor can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM CAN 1" or "TERM CAN 2".

4.23.26.9 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.23.27 X20IF2792

4.23.27.1 General information

The interface module can be used to expand the X20 CPU for specific applications. It is equipped with both an X2X Link interface and a CAN bus interface.

- X2X Link connection
- CAN bus connection
- Integrated terminating resistor

	2	X2X⊥	
	3	X2X\	
	4	SHLD	Shield
4-pin male multipoint connector			

4.23.27.7 CAN bus node number

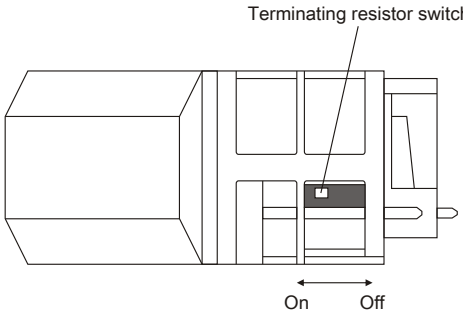
The node number for the CAN bus interface (IF2) is set with the two hex switches.

4.23.27.8 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
	Terminal	Function	
 5-pin male multipoint connector	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.23.27.9 Terminating resistor



The interface module has an integrated terminating resistor for the CAN bus interface. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.23.27.10 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

4.24 Hub system

The X20HB8880 hub is a device that can be used universally in standard Ethernet networks or POWERLINK networks. It is suitable for 100 Mbit/s (Fast Ethernet) networks. Due to its modular structure, the hub can be configured as 2/4/6x Fast Ethernet hub as needed.

The X20BC8083 bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the bus controller. This means that a 2/4/6x Fast Ethernet hub is also available on the bus controller depending on the degree of expansion.

4.24.1 Brief information

Product ID	Short description	on page
X20ET8819	X20 Ethernet analysis tool, can be expanded with active hub modules, 2x RJ45	2289
X20HB8815	X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45	2301
X20HB8880	X20 base hub module, integrated 2-port hub, 2x RJ45	2309
X20HB88G0	X20 EtherCAT junction base module integr. 2x EtherCAT junction, 2x RJ45 connection	2313
X20cHB8815	X20 POWERLINK - TCP/IP gateway, coated, can be expanded with active hub modules, 2x RJ45	2301
X20cHB8880	X20 base hub module, coated, integrated 2-port hub, 2x RJ45	2309

4.24.2 X20ET8819

4.24.2.1 General information

Analyzing POWERLINK

POWERLINK has proven itself in the field for years and rarely has problems during commissioning and production. Nonetheless, it is still possible for communication disturbances to occur due to damaged or poor quality cables. If an error occurs, localizing and correcting it is usually very easy thanks to the heterogeneous structure of this flat network type (all data is always visible throughout the network). What's problematic are errors that occur sporadically. This is where tools such as Omnipeek™ or Wireshark come in.

These tools (or more likely the standard PC technology being used) reach their limits, however, when dealing with machines that have short network cycles. Either not all frames can be recorded, or some telegrams are lost altogether. In these cases, what's needed is a special hardware tool that can work very quickly, record and save every bit of traffic and then pass it on to a laptop.

Ethernet analysis tool X20ET8819

This module provides different operating modes. For example, it can work passively on the network, in which case the real-time behavior remains unchanged. The device listens in and selectively takes in data when certain defined trigger conditions are met. It can read all of the data, mark it with a timestamp, store it temporarily and ultimately pass it on to a PC. The data is then analyzed in the familiar PC environment.

- NetTime time stamp has a resolution of 20 ns
- Recording and analysis of CRC and frame errors
- Triggers can also be activated using external digital signals
- Analysis of both half-duplex and full-duplex networks
- Able to record two networks simultaneously
