		Accessories added New: Appendix B "B&R ID codes"
2.00	July 2007	Book updated New module groups added • CPU modules • Compact CPUs • Compact CPU system modules • Fieldbus CPUs • Fieldbus CPU system modules • Communication in the X20 IF module • X20 electronics module communication • Digital mixed modules • Other modules Existing module groups updated • Bus modules • Terminal blocks • Bus controller • Power supply modules • Digital input modules • Digital output modules • Analog input modules • Counter modules Accessories added
1.20	June 2006	First edition

1.2 Safety notices

1.2.1 Introduction

Programmable logic controllers, operating and monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels etc.) as well as the uninterruptible power supplies have all been designed, developed, and produced by B&R for conventional use in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 or comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

1.2.2 Intended use

Electronic devices are never completely failsafe. If the programmable control system, operating/monitoring device or uninterruptible power supply fails, the user is responsible for ensuring that other connected devices, e.g. motors, are brought to a secure state.

Modules from B&R are designed as "open equipment" (EN 61131-2) and "open type equipment" (UL). They are therefore designated for installation in an enclosed control cabinet. All applicable national and international standards and guidelines, such as machinery directive 2006/42/EC, must be observed and complied with.

1.2.3 Protection against electrostatic discharge

Electrical components that can be damaged by electrostatic discharge (ESD) must be handled accordingly.

1.2.3.1 Packaging

- Electrical components with a housing
  … do not require special ESD packaging, but must be handled properly.
  (see section "Electrical components with a housing").
- Electrical components without a housing
  … are protected by ESD-suitable packaging.

1.2.3.2 Guidelines for proper ESD handling

Electrical components with a housing

- Do not touch the connector contacts on the device (bus data contacts).
- Do not touch the connector contacts on connected cables.
- Do not touch the contact tips on circuit boards.

Electrical components without a housing

The following applies in addition to the points listed under "Electrical components with a housing":

- Any persons handling electrical components or devices with installed electrical components must be grounded.
- Components are only permitted to be touched on their narrow sides or front plate.
- Components should always be stored in a suitable medium (ESD packaging, conductive foam, etc.).
  Information: Metallic surfaces are not suitable storage surfaces!
- Components should not be subjected to electrostatic discharge (e.g. through the use of charged plastics).
- Ensure a minimum distance of 10 cm from monitors and TV sets.
- Measuring instruments and equipment must be grounded.
- Probes on potential-free measuring instruments must be discharged on sufficiently grounded surfaces before taking measurements.

Individual components

- ESD protective measures for individual components are thoroughly integrated at B&R (conductive floors, footwear, arm bands, etc.).
- These increased ESD protective measures for individual components are not necessary for customers handling B&R products.

1.2.4 Transport and storage

During transport and storage, devices must be protected against undue stress (mechanical loads, temperature, moisture, corrosive atmospheres, etc.).

Devices contain components sensitive to electrostatic charges that can be damaged by inappropriate handling. It is therefore necessary to provide the required protective measures against electrostatic discharge when installing or removing these devices (see also section 1.2.3 "Protection against electrostatic discharge").

1.2.5 Installation

- Installation must be performed according to this documentation using suitable equipment and tools.
- Devices are only permitted to be installed by qualified personnel without voltage applied.
- General safety guidelines and national accident prevention regulations must be observed.
- Electrical installation must be carried out in accordance with applicable guidelines (e.g. line cross sections, fuses, protective ground connections).
- Take the necessary steps to protect against electrostatic discharges (see section 1.2.3 "Protection against electrostatic discharge").

1.2.5.1 Inserting and removing I/O modules while the controller is running

I/O modules may be connected and disconnected while the controller is running under the following conditions:

- Connectors are not allowed to carry voltages and must be removed.
- Replacing a module during operation must be supported by the software; otherwise, disconnecting a module will cause an emergency stop of the controller.

1.2.5.2 Connecting/Disconnecting IF modules while the controller is running

Unlike I/O modules, IF module CANNOT be connected or disconnected while the controller is running.

Warning!

IF modules that are connected or disconnected while the controller is running are not recognized by the CPU or bus controller and will cause the application to behave incorrectly.

1.2.6 Operation

1.2.6.1 Protection against touching electrical parts

To operate programmable logic controllers, operating and monitoring devices, and uninterruptible power supplies, certain components must carry dangerous voltage levels. Touching one of these parts can result in a life-threatening electric shock. This could lead to death, severe injury or damage to equipment.

Before turning on the programmable logic controller, operating/monitoring devices or uninterruptible power supply, the housing must be properly grounded (PE rail). Ground connections must be established even when testing or operating operating/monitoring devices or the uninterruptible power supply for a short time!

Before turning the device on, all parts that carry voltage must be securely covered. During operation, all covers must remain closed.

1.2.7 Environmentally friendly disposal

All B&R control components are designed to inflict as little harm on the environment as possible.

1.2.7.1 Separation of materials

It is necessary to separate different materials so the device can undergo an environmentally friendly recycling process.

Component	Disposal
X20 modules Cables	Electronic recycling
Cardboard/paper packaging	Paper/Cardboard recycling

Table 1: Environmentally friendly separation of materials

Disposal must comply with applicable legal regulations.

1.2.8 Organization of safety notices

Safety notices in this manual are organized as follows:

Safety notice	Description
Danger!	Disregarding these safety guidelines and notices can be life-threatening.
Warning!	Disregarding these safety guidelines and notices can result in severe injury or substantial damage to equipment.
Caution!	Disregarding these safety guidelines and notices can result in injury or damage to equipment.
Information:	This information is important for preventing errors.

Table 2: Description of the safety notices used in this documentation

1.3 Terminology

Term	Explanation
SG3	System Generation 3 (SG3) - CPUs with Motorola processors The following CPUs belong to this series: • IF161, IP161 • XP152 • CP100, CP104, CP152, CP153, CP200, CP210, CP260, CP430, CP470, CP474, CP476, CP770, CP774 • PP15, PP21, PP35, PP41
SG4	System Generation 4 (SG4) - CPUs with Intel processors The following CPUs belong to this series: • CP1583, CP1584, CP1585, CP1586, CP3583, CP3584, CP3585, CP3586 • CP1483, CP1483-1 • CP340, CP360, CP380, CP382, CP570 • PP45, PP65 • PP100/200, PP300/400 • MP100/200 • EC20, EC21 • AC140, AC141 • ARsim, ARwin, ARemb • APC620, APC700, APC810
SGC	System Generation Compact CPUs (SGC) - CPUs with Motorola processors (embedded µP) The following CPUs belong to this series: • CP0201, CP0291, CP0292 • XC0201, XC0202, XC0292

Table 3: Terminology

2 System features

2.1 Setting the standards in automation

There are many different I/O slice systems. With the X20 system, B&R continues to set standards according to its motto "Perfection in Automation". Born from experience gained from applications all over the world, numerous conversations with customers and with the aim for easier, more economical and secure usage, the X20 system is a universal solution for any automated task in machine and system manufacturing.

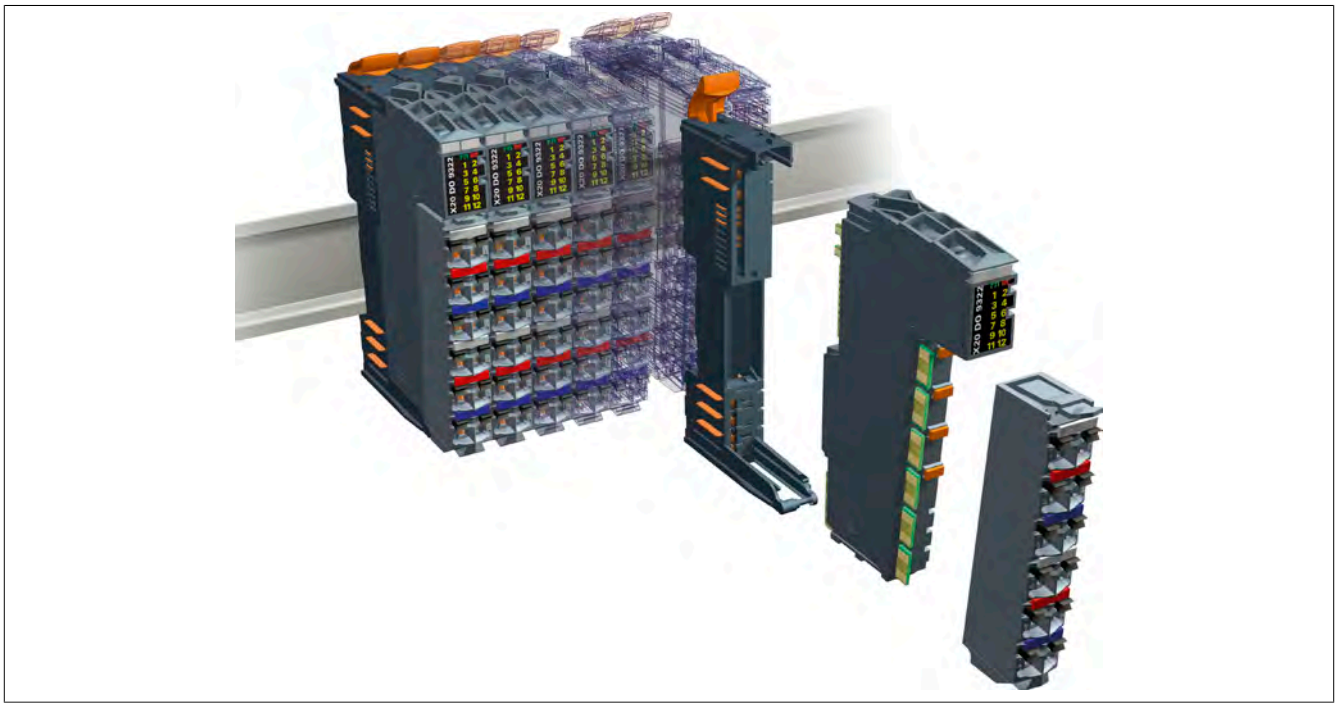

Figure 1: Each module consists of three basic elements: Terminal block – Electronics module – Bus module

2.1.1 More than just I/O

With its well thought-out details and a sophisticated ergonomic design, the X20 system is more than a remote I/O system – it's a complete control solution. The X20 system family makes it possible to combine the exact components needed to meet any application requirements.

- The X20 system is the ideal addition to a standard fieldbus and expands the possibilities of conventional control systems. Simply connect it, configure it and you're done.
- Teamed up with other B&R components, the X20 system achieves its full potential and allows the implementation of applications with unimagined performance and flexibility. This type of seamless integration is a major advantage.

2.1.2 3 x 1 = 1

Three basic elements make up one module: Terminal block – Electronic module – Bus module

This modularity results in a system that combines the advantages of both rack and I/O slice systems:

- Prewiring without the module
- Hot pluggable electronics
- Extra bus slots for added options

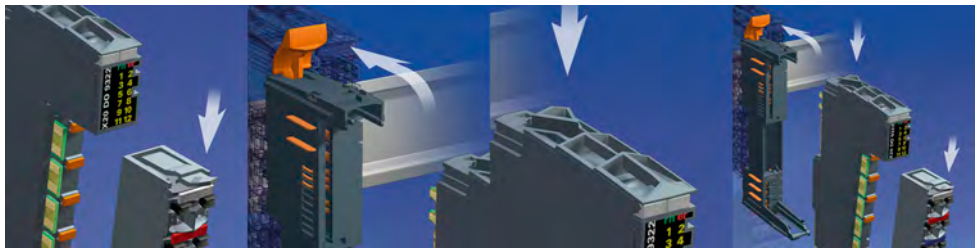

Figure 2: X20 modules are divided into three parts to guarantee the simplest usability

The X20 system delivers 50% more component density, perfected connection technology and optimal granularity.

- **Added value**
  12 channels with a width of 12.5 mm allow a component density never before achieved with optimal terminal ergonomics. As a result, the X20 system offers 50% more channels than conventional slice systems. And this without sacrificing terminal connections.
- **Uniformity**
  Consistent implementation of 1-, 2- or 3-wire connections – no additional jumper terminals needed.
- **Granularity**
  1-channel and 2-channel modules: Maximum flexibility so you only have to pay for what you really need.

2.2 Optimized design

X20 modules consist of three submodules to provide maximum ease of use throughout their entire life cycle. This division into bus module, electronics module and terminal block has several advantages.

- **Preconfigured for different machine types**
  The X20 system bus modules are the basic platform for many machine variations. The design of the machine determines which electronics modules are used. The software recognizes this design automatically and makes sure that the right functions are provided where they are needed. Handling a range of different machine variants couldn't be easier.
- **Industrial control cabinet construction**
  X20 system terminal blocks are separate from the electronics module and make it possible to pre-wire the entire control cabinet. This is especially ideal for series-produced machines.
- **Easy maintenance**
  X20 modules can be easily exchanged to simplify troubleshooting. The electronic modules can be exchanged without interrupting operation. The wiring remains exactly the same thanks to the separate terminal blocks. Being able to quickly replace automation components guarantees reduced down-time.

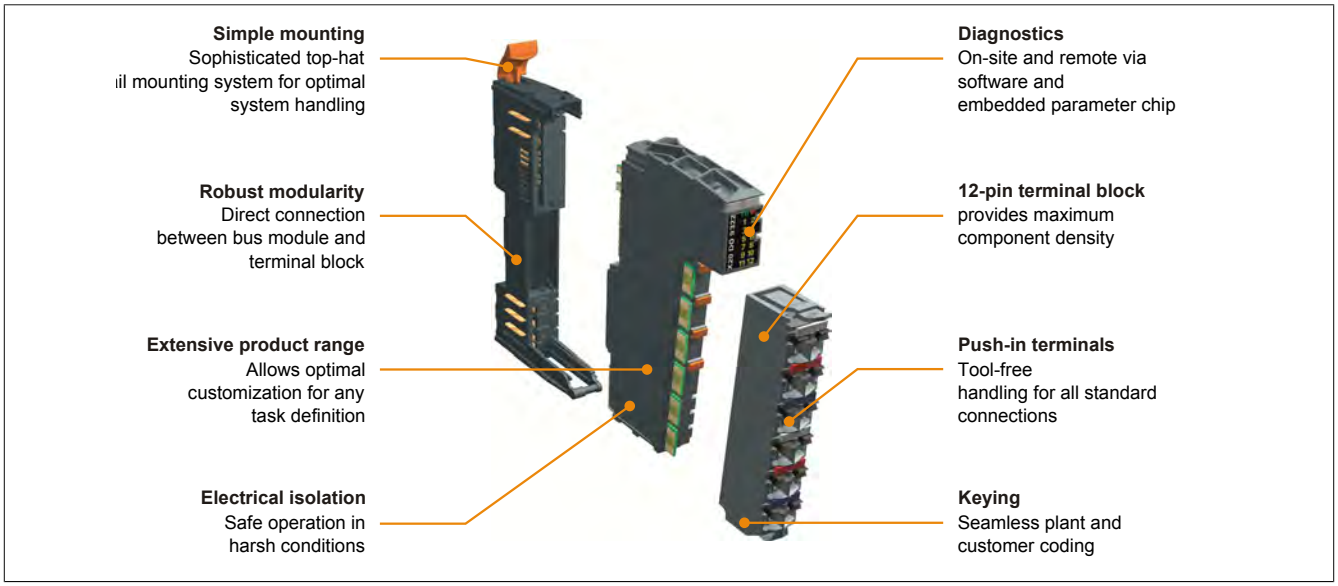

Figure 3: Features of the X20 system

2.3 Remote backplane

The main idea: Remote backplane for a rack system – in other words, the cable is the backplane. All modules are connected to the uniform backplane (X2X Link). Directly connected X20, X67 or XV modules can each be placed at a distance of up to 100 m outside the confines of the control cabinet. X2X Link guarantees the highest possible level of resistance to disturbances based on twisted copper cables.

This not only provides a universal remote backplane which handles the communication between bus modules and via the X2X Link cable, but makes it possible without converters or any loss in performance. A unique feature of the X20 is the possibility to later integrate machine options on bus modules that are not yet being used without having to change the software addressing.

Note:

A 100 m X2X Link cable is available from B&R for custom assembly (model number: X67CA0X99.1000).

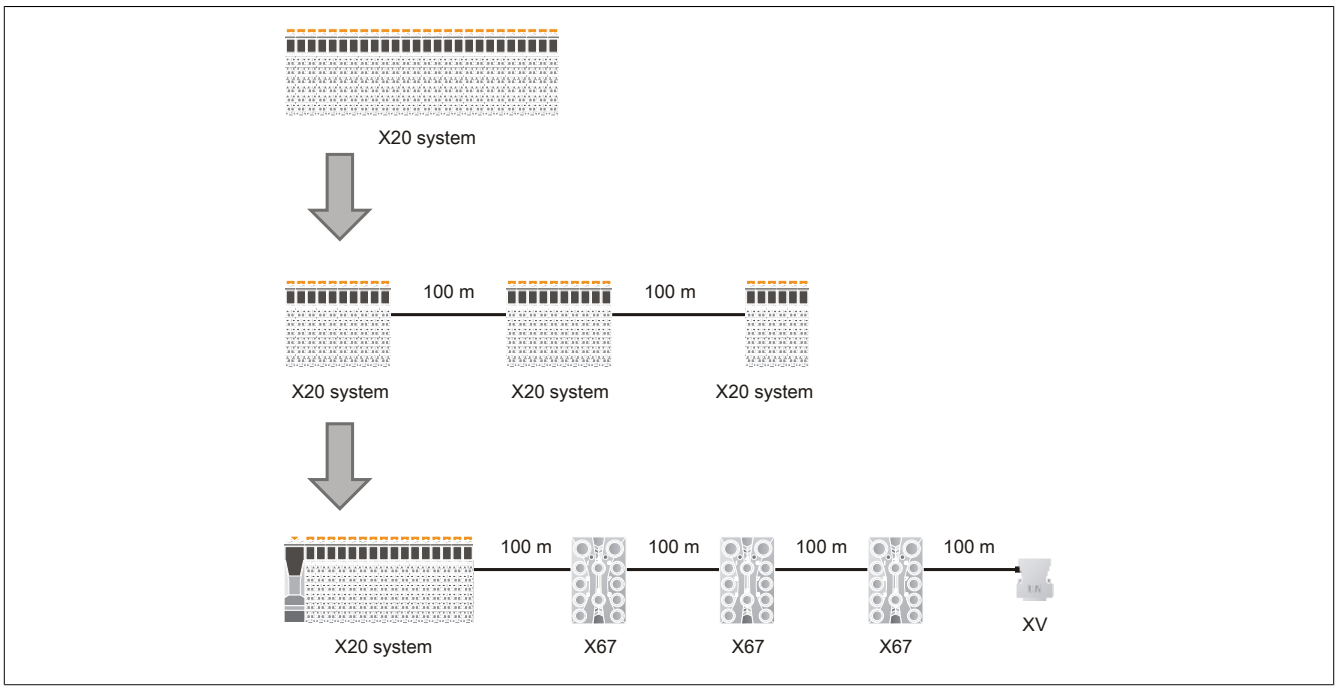

Figure 4: X2X Link - universal backplane based on twisted copper cables

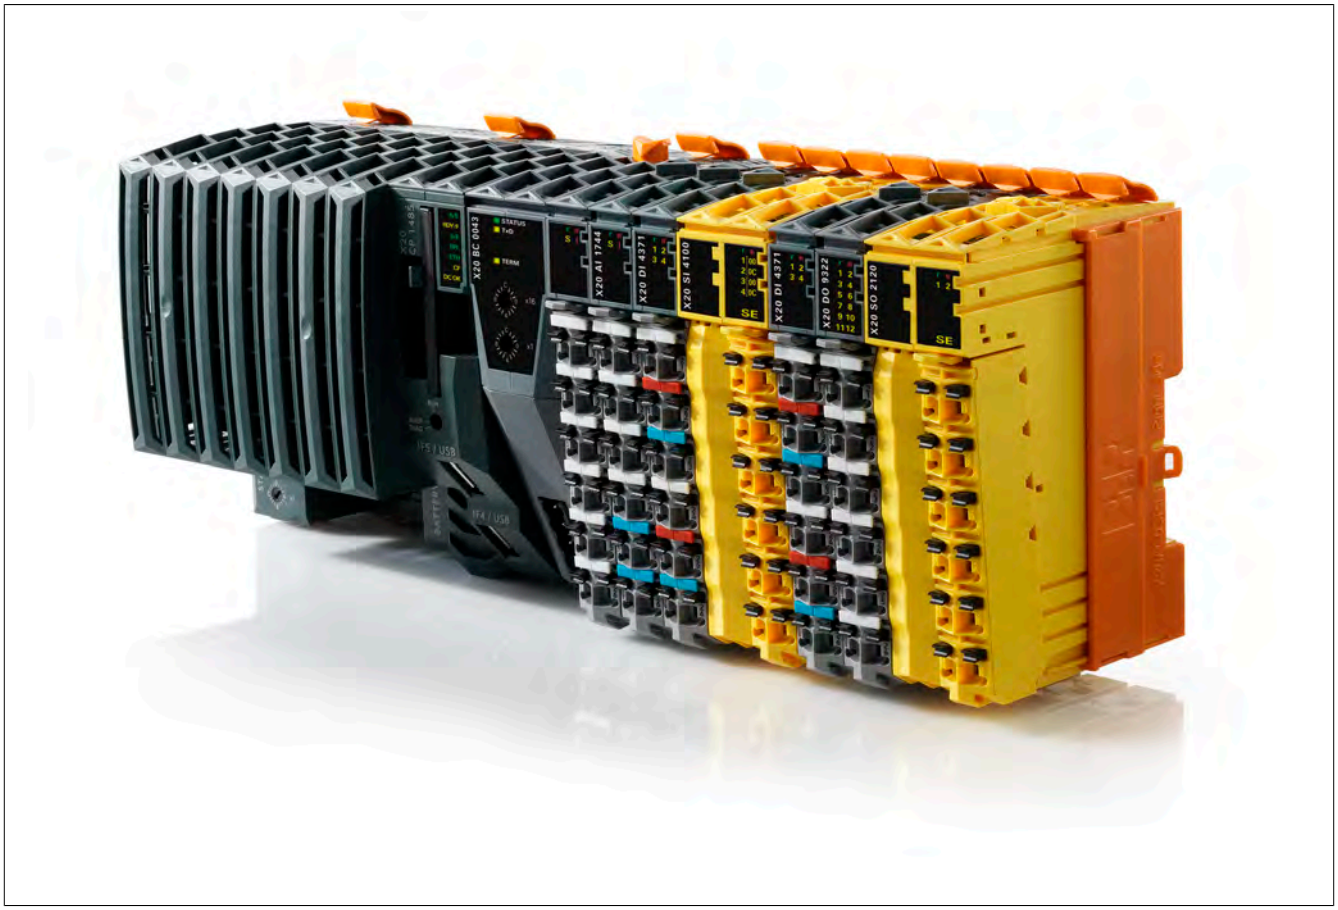
2.4 X20 CPUs

2.4.1 General information

The optimally scaled X20 system CPU line satisfies a wide range of needs. It can be implemented anywhere, from standard applications to the most demanding applications with the highest performance requirements. It can even master cycle times of 100 µs.

At B&R, RS232, Ethernet and USB are already standard equipment. Network capability and connecting USB devices are therefore possible at no additional cost. In addition, every CPU has a POWERLINK interface for real-time communication. The possibility to directly connect axes is already integrated. Although the standard features of the CPUs can handle the majority of applications, there are also up to three multipurpose slots for additional interface modules.

Because the X20 CPU was designed for top-hat rail installation in a control cabinet, up to 250 X20 I/O modules – 3000 channels – can be connected directly. This provides the highest performance as well as the advantages of the remote backplane.



2.4.2 Remote backplane

A power supply integrated in the CPU with I/O supply terminals provides power for the backplane and I/O sensors and actuators, eliminating the need for additional system components. With a direct I/O connection to an X20 CPU, you get all the advantages of the remote backplane, i.e. the ability to repeatedly place I/O line sections anywhere within 100 m using a cable or to add modules with IP67 protection.

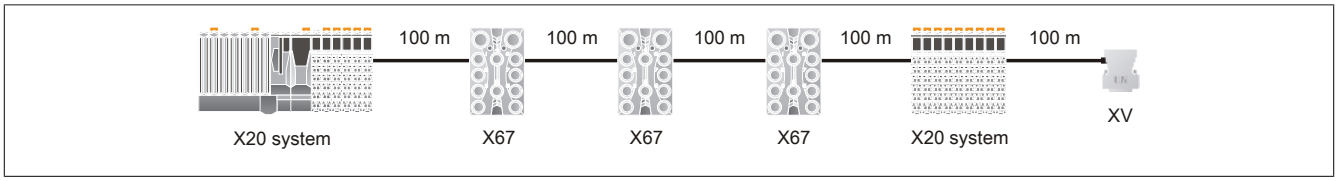


Figure 5: X20 CPUs - Direct I/O connection to X20 CPU and advantages of remote backplanes

2.4.3 B&R Automation Studio

B&R Automation Studio is the only programming tool needed for all platforms. It can be used to create application software in all relevant IEC 61131-3 languages as well as C. Integrated visualization, NC and soft CNC functions and web server technologies complete the range of powerful features.

2.4.4 PC-based technology

Based on the latest Intel ATOM™ processor technology, X20 CPUs can effectively utilize cycle times down to 100 µs.

An extensive amount of RAM provides the user with unlimited freedom when it comes to application development. This is complemented by battery-backed nonvolatile SRAM for task-specific data and remanent variables. In the case of a power failure, variables that have been declared as being remanent are automatically copied from the fast RAM to the secure SRAM. Data contents are therefore retained after the controller is restarted so that the process can simply be resumed. A slot for a CompactFlash card is also integrated into the system to hold program memory or application data such as recipes.

2.4.5 Suitable for industrial use

Providing the highest performance, with many standard interfaces and interface modules for expansions, yet the dimensions are unbelievably compact. The dimensions of the CPU match those of the X20 modules, which prevents unnecessary waste of space in the control cabinet.

Fanless operation - a demand the X20 CPUs can satisfy. None of the processors require a fan, which makes them virtually maintenance-free.

2.5 X20 Compact CPUs

2.5.1 General information

With a width of 37.5 mm the X20 Compact CPUs are extremely compact, yet surprisingly powerful. Less powerful than the PC-based CPUs, there are several models of Compact CPUs available in 2 performance classes.

Compact CPUs are ideal for situations where cycle times in the millisecond range are sufficient and a cost-benefit analysis plays a decisive role. A range of models with CAN bus and Ethernet can be perfectly adapted to all requirements, resulting in extremely sleek automation solutions.

The Compact CPU's design and dimensions correspond to the X20 system. The X20 I/O modules are connected directly to the CPU. These are attached seamlessly to the CPU, making the entire system an extreme space saver in the control cabinet. Despite the sleek profile, the CPU supply, the X2X Link supply, and the I/O module supply are integrated in the system. No additional power modules are necessary.

All CPUs have at least two things in common: multitasking capability and programming with B&R Automation Studio using all relevant IEC61131-3 languages and C.

2.5.2 Product range

The many different variants start with the most space-saving solution, the X20 compact CPU. This module is equipped with an RS232 online interface and an integrated X20 module connection. Selecting another bus module also provides an additional onboard CAN bus interface. The upper end of the product range is characterized by CPUs with a Fast Ethernet interface. The variant with Ethernet is also available with approx. 60% more processing power.

Figure 6: X20 compact CPUs

2.6 X20 Fieldbus CPUs

2.6.1 General information

Remote design of I/O systems is one of the standard topologies used in automation solutions for machines and equipment. In addition, fieldbuses with bus controllers are normally used. Larger topologies or standard fieldbuses like CANopen, PROFIBUS DP, or DeviceNet can cause relatively long response times.

An input must travel via the bus controller to the CPU before it is processed. The output data must then return on the same path. This is sufficient for most I/O functions. However, this response time is too long for some functions. The best solution is for the bus controller to process the data. This type of data preprocessing is usually associated with limited CPU functionality in the programmable bus controller.

Fieldbus CPUs with integrated fieldbus connections overcome these limitations. Fieldbus CPUs are variations of Compact CPUs. In addition to these features, there is also the option of connecting fieldbus modules to the left side. The full CPU functionality of the Compact CPUs plus a plug-in fieldbus module create many more possibilities than simply data preprocessing. There are enough reserves for relatively complex application processing. Intelligent substations are another area of use. That means a part of the machine part must continue to function, even when separated from the main controller.

Based on the Compact CPU platform with up to two plug-in interface modules for the respective fieldbus connection, this results in a very compact (62.5 mm and 87.5 mm), powerful and intelligent fieldbus controller.

Figure 7: Fieldbus CPU with connected interface module

2.6.2 Product range

As with the Compact CPUs, the new CPUs with fieldbus connection are available in two performance classes. Depending on the bus module being used, the CPU has an RS232 interface or an RS232 interface plus a CAN bus interface. The CPU with higher processing power is available with or without an onboard Ethernet interface. Various fieldbus modules are available.

2.6.3 Programming

All CPUs have several features in common, including integrated connection of X20 modules and system multitasking capability. With B&R Automation Studio, programming can be done in all IEC 61131-3 languages and in C.

2.7 For all fieldbuses, integration through standardization

The X20 system is ideally suited for expanding existing control systems using standard fieldbus technology.

For example, a bus controller allows the X20 system to be used as a powerful I/O expansion unit. Standardized EDS or GSD description files allow X20 system components to be integrated, configured, and programmed in the programming environment of a non-B&R system.

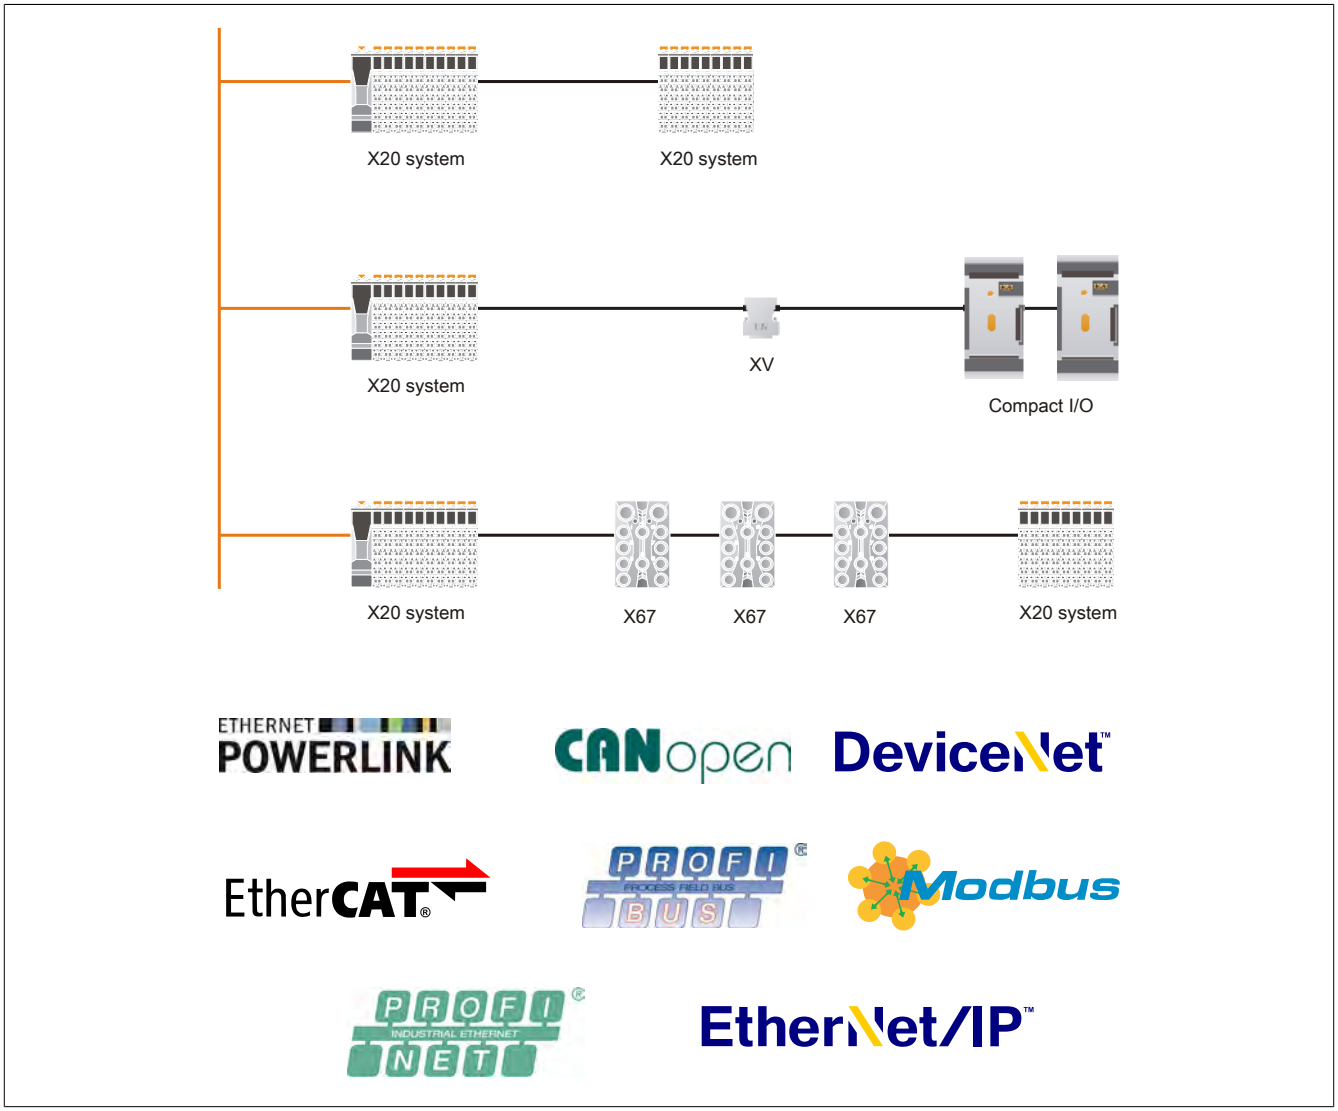

Figure 8: Expansion of existing control systems using standard fieldbuses and the X20 system

2.8 Complete system

2.8.1 IP67 - then X67

The X67 is the robust version of the X20 for use outside the control cabinet. The same basic technology, with an extremely robust housing and 4 to 32 channel modules, guarantees economical solutions in the roughest conditions.

2.8.2 Integrated valve terminal control

The development of the XV system allows for the first time direct and manufacturer-independent control of valve terminals. A complete digital output module in a size and form comparable with a normal DSUB connector. XV allows any valve terminal manufacturer to be selected because it is connected directly to the standardized multiple pin connector on the valve terminal.

Fully integrated in the remote backplane, it rounds off the X20 and X67 for complete automation solutions. One system, several variations - advantages that pay off. You select your automation components and distribute them as needed inside and outside the control cabinet.

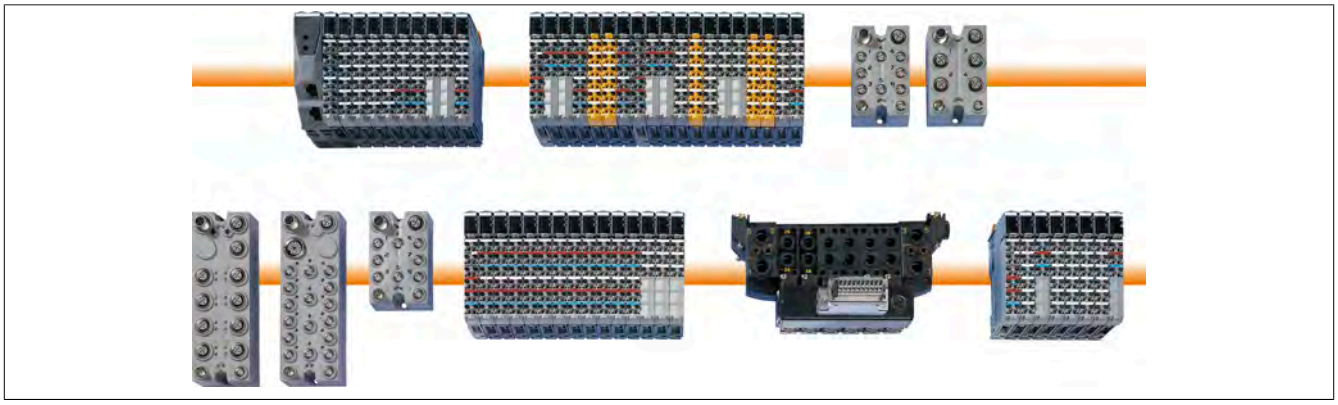

Figure 9: X20, X67, XV - variations of a single system

2.9 Easy wiring

Industrial control cabinet construction streamlines production cycles. Prefabricated cable trees enable faster and easier assembly directly on the machine or system. The X20 system supports efficient prewiring of the entire control cabinet using separate terminal blocks. The complete X20 system configuration is mounted in the control cabinet and connected to the prewired cable trees.

The supply of the X20 modules and the supply of the sensors and actuators do not add any requirements for energy distribution. The X20 system reduces manual wiring to a minimum.

2.9.1 Install the wires, plug it in, and it's ready to go

Simple, tool-free wiring for fast installation. The X20 system terminal blocks use a fully integrated and proven push-in connector system. Each terminal can also handle double wire sleeves up to a diameter of 2x 0.75 mm². The user saves time wiring the system multiple times and distributing the signals.

The wire connections can be removed with a screwdriver. Each terminal also has an access point for a measurement probe. A great deal of thought was given to designing every aspect of the X20 system. Right down to the wire connectors.

Information:

To avoid damaging the terminals, the X20AC0SD1 B&R screwdriver should be used.

	**Detached** The terminals can be prewired apart from the actual I/O module. This provides many advantages for control cabinet construction. Separate manufacturing, just-in-time logistics and the installation of preassembled systems during start-up become reality.		**Tool-free** Simple, tool-free wiring for fast installation. The X20 system terminals use a fully integrated and proven push-in connector system. Available with 6-pin and extremely compact 12-pin terminals.
	**Coded in the system** Factory coding prevents dangerous mix-ups. Coding guarantees that only parts which are permitted to be combined can be combined. Intuitively and without additional work.		**Ergonomic** Component density does not have to negatively affect ergonomics. With terminal spacing of more than 5 mm, this was handled optimally on the X20 system. Experience gained in the field - used in the field.
	**Coded in the application** Incorrectly inserting terminals does not necessarily damage the electronics, but always causes faulty functioning of the system. Application coding prevents this problem.		**Unmistakable** Distinct forms intuitively define various functions, such as clearly assigned latching and unlatching functions for terminals. This prevents errors from the very beginning.
	**Labeling** Each terminal is clearly labeled, directly in the plastic. Additional label tags are available as system accessories including a printer with ECAD connection.		**Easy servicing** A system's strengths can be seen in its details: In addition to the terminal connector and unlocking mechanism, each terminal has an access point for a test probe. You can easily measure the terminal potential without disconnecting the wire.

2.10 Sophisticated mechanics

The name B&R stands for many years of experience in developing and manufacturing industrial electronics. But it's also the mechanics of the X20 system that have been thought through to the last detail. Its robust design, long guides and strengthened housing guarantee the stability it needs in industrial environments. These features allow the X20 system to be mounted on a top-hat rail with the same ease as a rack system. They also make it just as simple to remove it from the rail.

The sophisticated mechanics of the X20 are needed not just to provide this type of handling, but also to be able to quickly and easily remove I/O slices from the entire system.

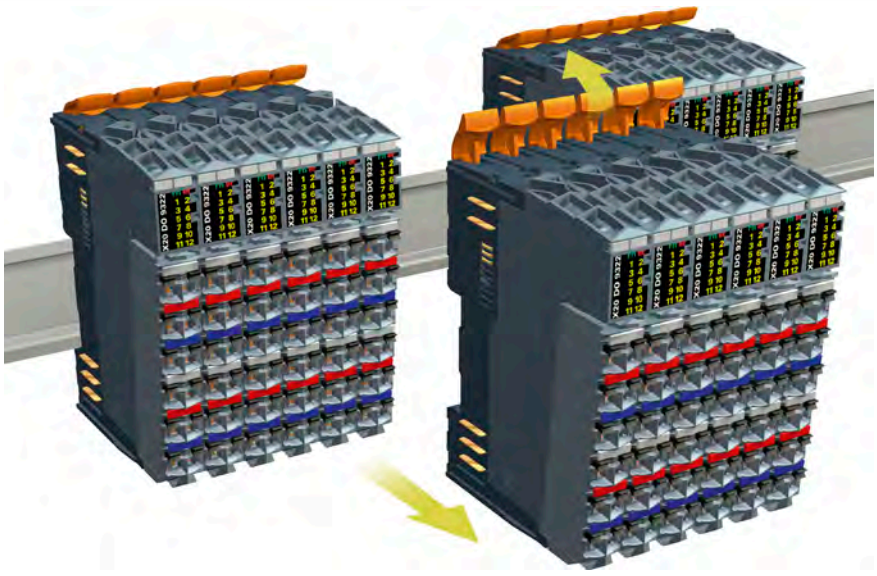

Figure 10: Easy mounting on and removal from the top-hat rail

	**Unlocking mechanism with two positions** Closed for secure fit on the top-hat rail.		**Defined open position makes the difference** Open to remove a module or the entire system.
	**Removing a single module from the system** Remove or reconnect vertically.		**Mount the entire system as a whole** Or just as easily removing the entire system.

2.11 Diagnostics

Outstanding diagnostic options are needed for errors to be found quickly. The X20 system offers several levels of diagnostics:

- Direct on the module using visual LED displays. Bus status, I/O status and channel states are displayed in direct relationship to the channels or the function. The different states are displayed in different ways, e.g. green for OK, red for error.
- Via software in the cyclic data image. With the X20 system, status data does not result in an additional communication load, which would result in considerable differences between theoretically possible bus speeds and real requirements during operation. All necessary status data is always transferred cyclically, with no exceptions.
- Expanded diagnostic data in acyclic data traffic without loss in performance. If a problem occurs, detailed diagnostic data can be requested from the application by the respective module using an asynchronous channel. This does not result in additional communication load and cycle times remain unchanged.

Figure 11: Visual diagnostics directly on the module using LED indicators

2.11.1 re LEDs

Most X20 I/O modules have LEDs for diagnostics at the top.

The operating state of the module firmware is indicated by the two topmost LEDs "r" (green) and "e" (red). The operating state can also be indicated with the help of special LED status indicators (e.g. on the X20ATC402 module).

Additional LEDs depend on the module and generally indicate the status of I/O channels. Green LEDs are usually used for inputs, while orange is used for outputs. These I/O LED status indicators are only operational in RUN mode on some modules.

Operating states and error states

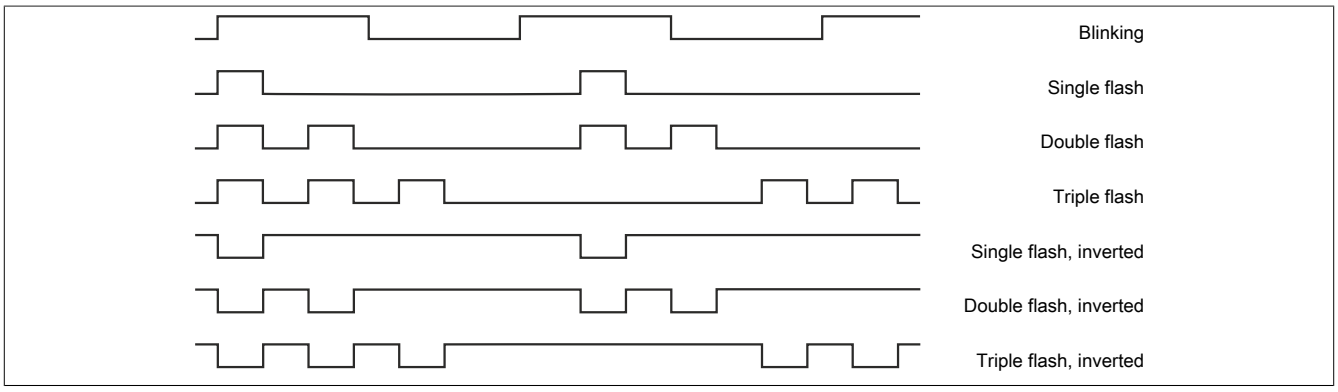
The following table provides a complete description of all operating states and error states for X20 I/O modules. The operating state and error state actually indicated by the I/O module depends on the type of module as well as how it is being used.

	LED	Description	Note
	"r" and "e" off	No power to module	Module does not have power.
	Module status LED "r"		
	Single flash ("e" = Off)	RESET mode	No connection to the X2X Link master, or the X2X Link master is not yet running. Some modules remain in single flash mode during a firmware update.
	Single flash ("e" = On)	Firmware is not valid	Invalid firmware: Occurs when a firmware update has been interrupted. The firmware is reloaded as soon as the X2X Link master is active again. It is only loaded if the module is also entered in the configuration, however.
	Double flash	BOOT mode (RESET mode with communication)	Firmware update. A firmware update usually only takes place once after the module has been replaced or if new firmware has been loaded to the master CPU during a project update. **Depending on the configuration, a firmware update can take several minutes.**
	Blinking	PREOPERATIONAL mode	Modules whose slot is configured for a different module (or none at all) remain in PREOPERATIONAL mode. Possible error: • Incorrect module connector or slot not configured • Incorrect slot number for bus modules with node number switches
	On	RUN mode	No error
	Error status LED "e", if "r" = On		
	Off		Everything OK
	On	Fatal error	It is not possible for the module to continue functioning correctly. Possible error: • Power supply outside warning range • Operating temperature outside permitted range **Monitoring for fatal errors is not integrated into all modules.**
	Single flash or blinking	I/O channel error	An error or warning is present on one or more I/O channels. Which channel error on the module is being indicated depends on the module and can be determined with the respective module description.
	Double flash	System errors	A system error occurred in the module. The cause of error depends on the module and can be determined with the respective module description.
	Triple flash	I/O error and system error	An I/O error and system error occurred at the same time.
	Single flash inverted[1)]	Fatal error and I/O error	A fatal error and I/O error occurred at the same time.
	Double flash inverted[1)]	Fatal error and system error	A fatal error and system error occurred at the same time.
	Triple flash inverted[1)]	Fatal error, I/O error and system error	A fatal error, I/O error and system error occurred at the same time.

1) Only on modules that monitor for fatal errors.

LED status indicators - Flashing sequences

The flashing sequences shown in this image specify only the principle ratio between the switch-on and switching-off times for the LED. The actual ratio of blink times to each other can vary depending on the module.



2.12 Embedded parameter chip

Information such as module type, serial number, functionality and version number is contained in the embedded parameter chip of the X20 module. This information is automatically evaluated by the programming environment (Automation Studio) and by the application program. This prevents errors during both commissioning and service. In addition, the system configuration is automated and flexible variations are made possible.

Serial numbers of modules that are defined worldwide are gaining increasing significance in validated systems as demanded, for example, by the FDA.

2.13 Space for options

The X20 system family makes it possible to combine the exact components necessary depending on the user's demands and individual application requirements. This allows machine options to be implemented easily and flexibly. Bus modules provide the base, and are more or less a rack replacement. Depending on the option, the necessary electronics modules are then inserted in the predefined slots.

Addresses are assigned implicitly via the slot. Software that has been developed once is valid for all versions and does not need to be changed. This is even possible for later machine expansion. The I/O modules are simply inserted in the defined bus modules, and assigned to the corresponding potential groups and E-stop groups.

To prevent unwanted expansion, each module can be identified and then enabled using the application software.

2.14 Flexibility for options

The implementation of different machine variations using free bus modules is only one of the many features that the X20 system offers. With the support of B&R Automation Studio, there is an optimized solution using I/O mapping. What does this mean?

Each I/O configuration is created optimally according to the actual requirements. However, the application software is designed to handle all potential options. Only the I/O channels that are actually available are configured in the application program. If an expansion is required, then the additional hardware needed can be easily connected and the I/O mapping changed. This is done without having to compile the application software.

It doesn't matter where the I/O mapping list is created:

- Manually in B&R Automation Studio
- With tools, e.g. with a database or a table calculation program
- Directly from an ERP system, just like the parts list for the machine
- Automatically in the application software, depending on the hardware used

	**Machine variation A** The possibilities of the X20 system can be best explained using examples. This is a machine constellation with two variations, A and B. All of the necessary electronics modules for machine variation A are shown in the picture to the left. The bus modules needed for variation B are also present, but without electronic modules.
	**Machine variation B** Variation B shows the necessary electronic modules but the modules necessary for variation A are missing. The distribution of the free bus modules for the variations is also clear: The variable I/O modules can be very easily connected to the required electrically isolated groups and don't need to be attached in the back. The extensive process of taking apart the configuration to expand existing electrically isolated groups is also eliminated. Simply insert the electronic module and attach the terminal block.
	**Machine variation A - optimized** The features included in Automation Studio can also be used to achieve completely optimized hardware configurations without losing the advantage of comprehensive application software for all variations. As described earlier, simply mapping physical I/O points to the application program makes it extremely easy to optimize the hardware variations without even requiring compilation.

2.15 Configurable X2X Link address

The remote X2X Link backplane, which connects the individual I/O modules with each other, is set up to be self-addressing. Because of this, it is not necessary to set the node numbers. The module address is assigned according to its position in the X2X Link line.

In certain cases, e.g. when configurations of modular machines change, it is necessary to define specific module groups at a fixed address, regardless of the preceding modules in the line.

For this purpose, there are modules in both the X20 system and the X67 system with node number switches that allow you to set the X2X Link address. All subsequent modules refer to this offset and use it automatically for addressing purposes.

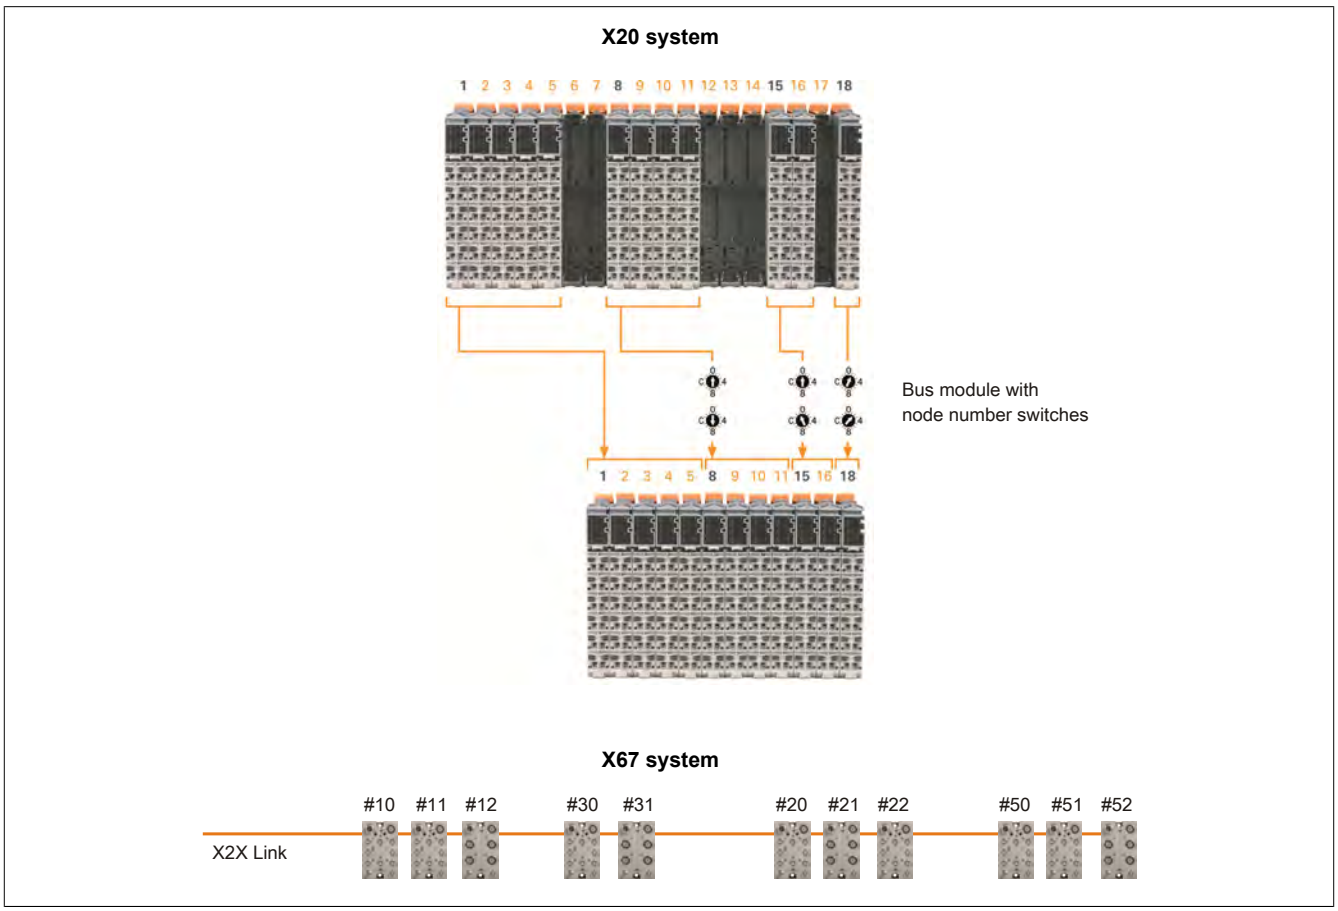


Figure 12: Setting the X2X Link address

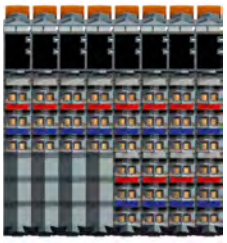
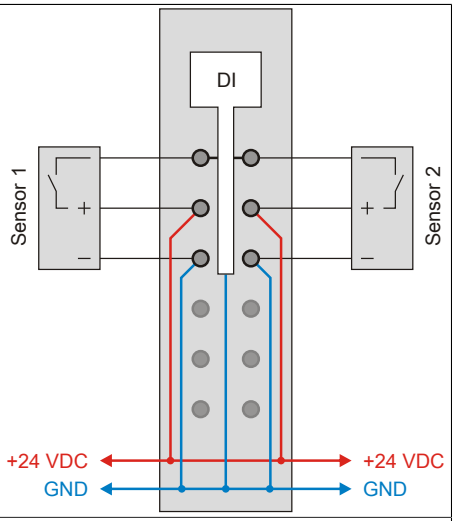
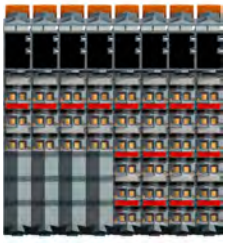
2.16 Universal 1, 2, 3-wire connections

Consistent connection types for all requirements – no additional jumper terminals are needed. All connection types can also be mixed and matched.

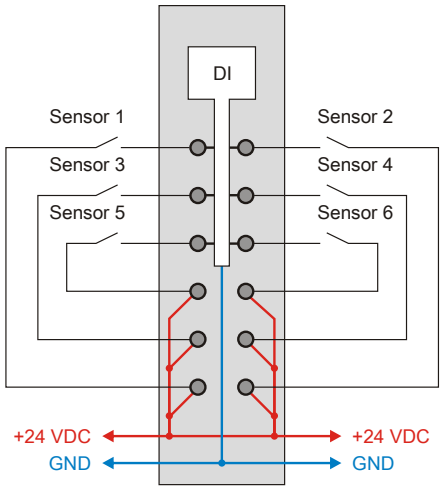


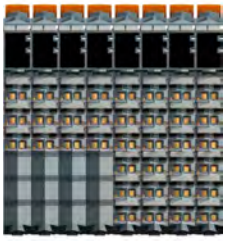
Universal 3-wire connections
Integrated supply and ground for sensors and actuators.



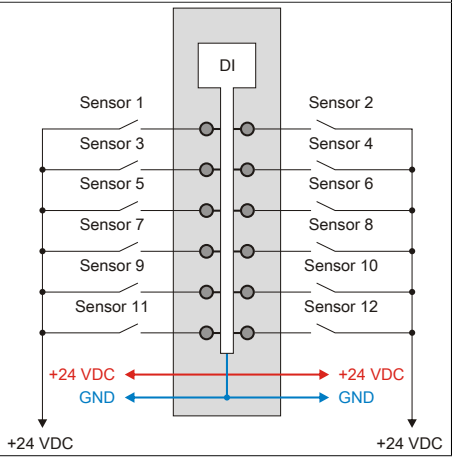


Universal 2-wire connections
No extra terminals needed.





Universal 1-wire connections
12 channels - unequaled component density



2.17 Coated X20 system

The X20 system includes modules with a protective coating for the electronics. These modules are suitable for use in adverse atmospheric conditions and are protected against condensation and corrosive gases.

Data sheets can be found under 5 "Coated modules".

2.18 Redundancy

The X20 system provides the following forms of redundancy:

- Controller
- Network
- Power supply modules for X20 standalone devices and expandable POWERLINK bus controllers
- X2X Link supply

The first three areas are covered in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

For a description of the redundant X2X Link supply, see section 3.20 "X2X Link supply".

2.19 reACTION technology

The X20 Compact CPUs and a number of I/O modules are available featuring ultrafast reACTION technology. This allows the I/O channels integrated in the reACTION module to be controlled with response times down to 1 µs. This new approach allows extremely time-critical subprocesses to be managed using standard hardware – which lowers hardware costs by reducing the load on the controller and allowing it to be scaled down.

All of the commands that can be used for reACTION programs are provided as function blocks in special libraries (e.g. AsIORTI). Programming using the standard Function Block Diagram (FBD) editor in Automation Studio is compliant with IEC 61131-2.

Documentation for reACTION technology is included in the Automation Studio help system.

2.20 X20 system configuration

The X20 system is designed so that can be connected to standard fieldbuses (with a bus controller) or the remote X2X Link backplane (with a bus receiver). The connection to the next station is made with a bus transmitter. Supply modules and I/O modules are placed between the bus receiver or bus controller and the bus transmitter as needed.

The power supply system used in the X20 systems is described in the section 3.8 "The supply concept".

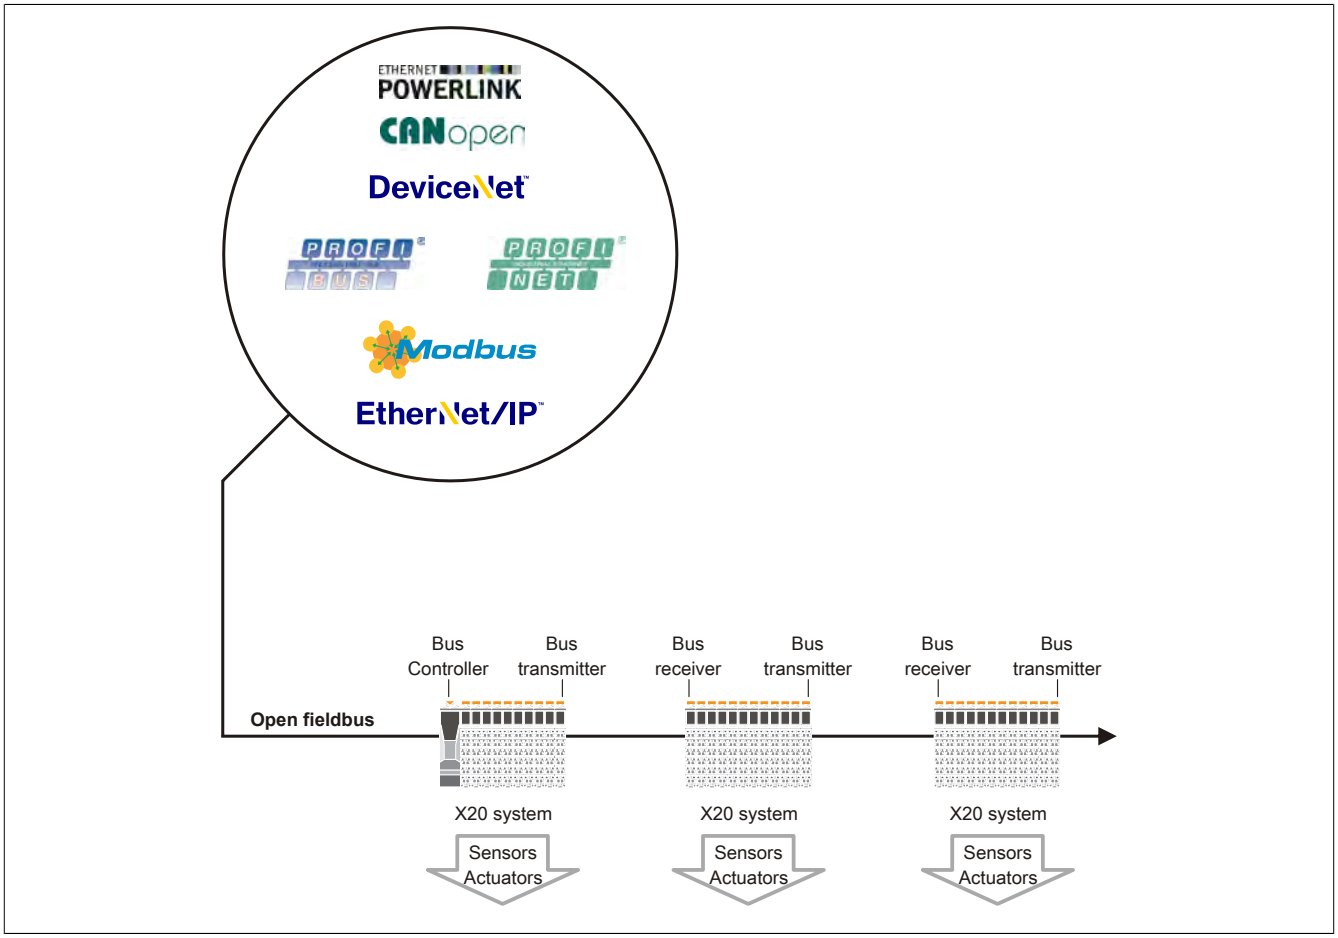


Figure 13: X20 system configuration

2.20.1 Fieldbus connection

Several bus controllers for standard fieldbus technologies like POWERLINK, DeviceNet, PROFIBUS, CANopen, ModbusTCP or EtherNet/IP are available to connect X20 modules to existing control systems. Fieldbus configurators transparently integrate the X20 system into the 3rd-party development environment.

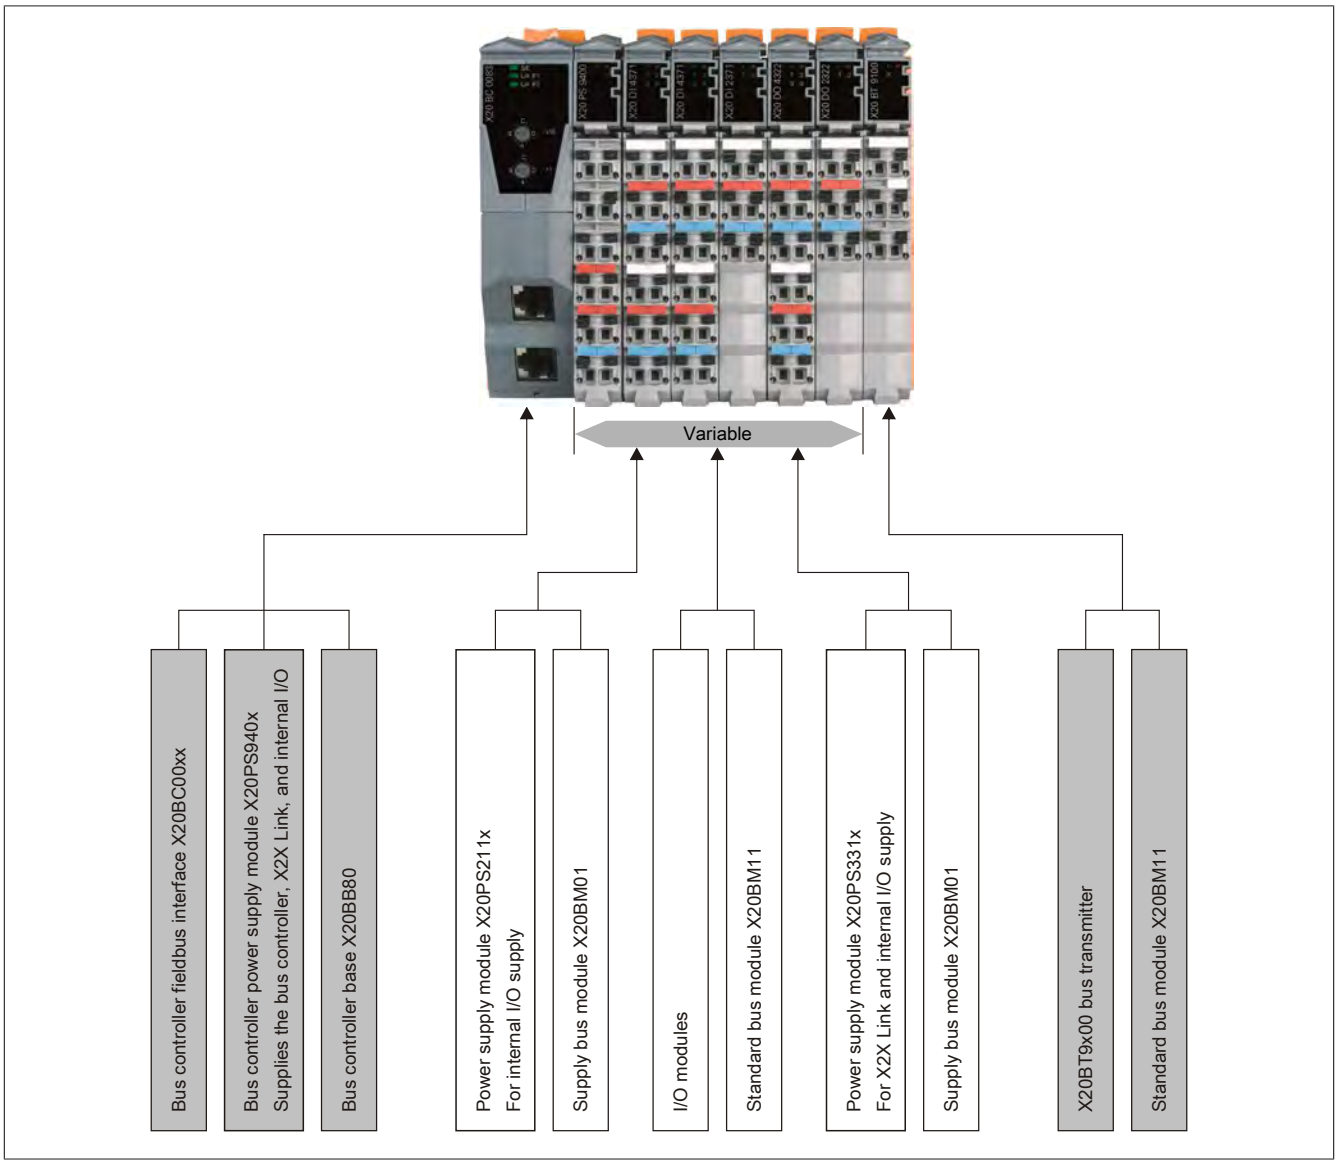

Figure 14: X20 system configurator for fieldbus connection

2.20.2 Connection to X2X Link backplane

The bus receiver X20BR9300 is used to connect the X20 system directly to the remote X2X Link backplane.

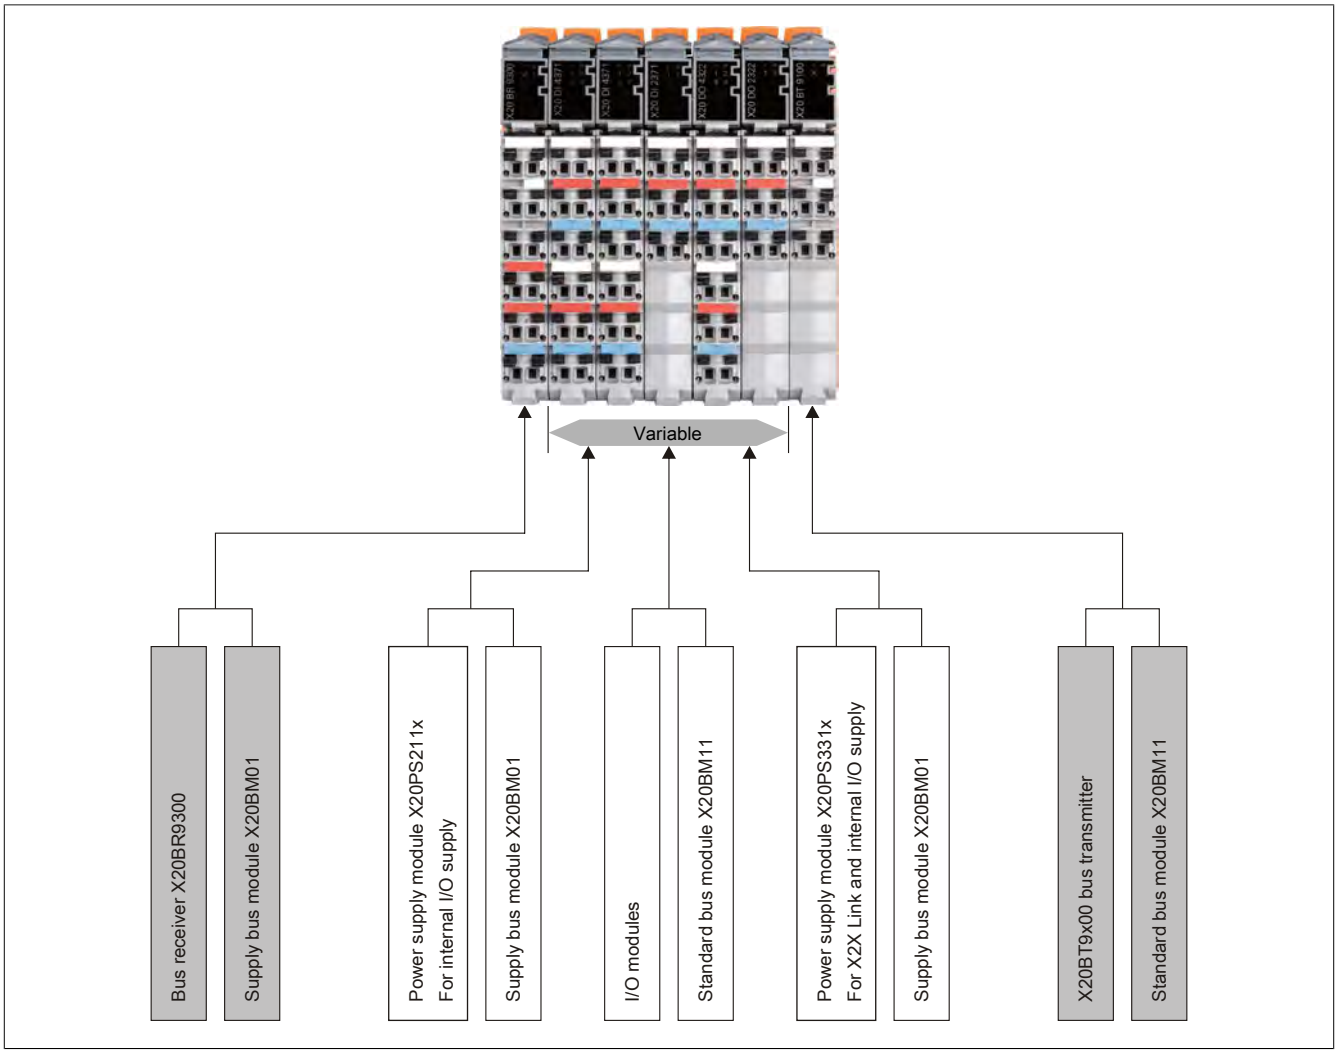

Figure 15: X20 system configurator for connection to X2X Link backplane

3.1.4.2 With two additional slots

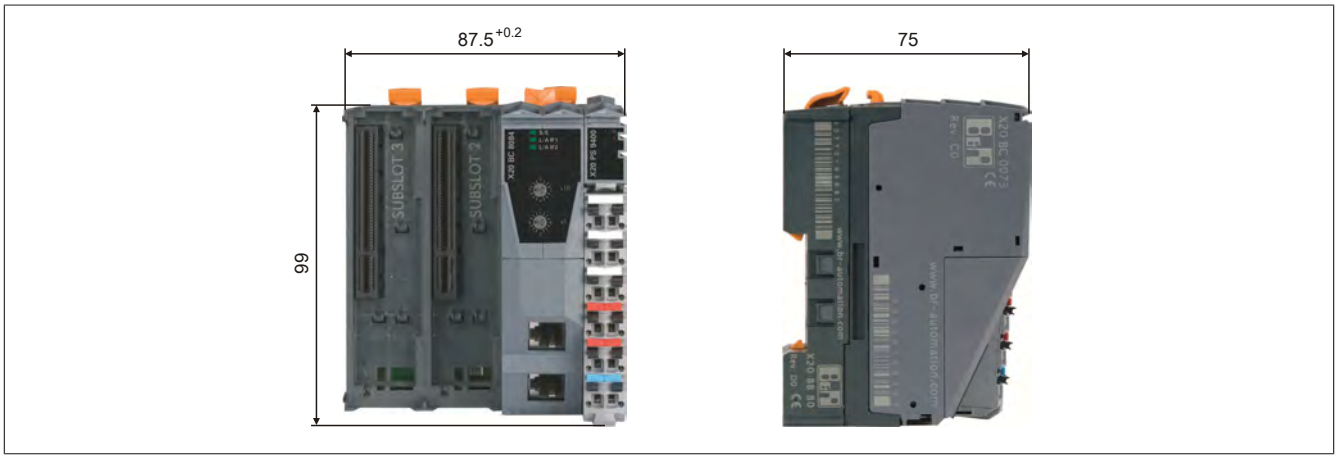

Figure 20: Dimensions of the fieldbus CPUs and expandable bus controller with two additional slots

3.1.5 I/O modules

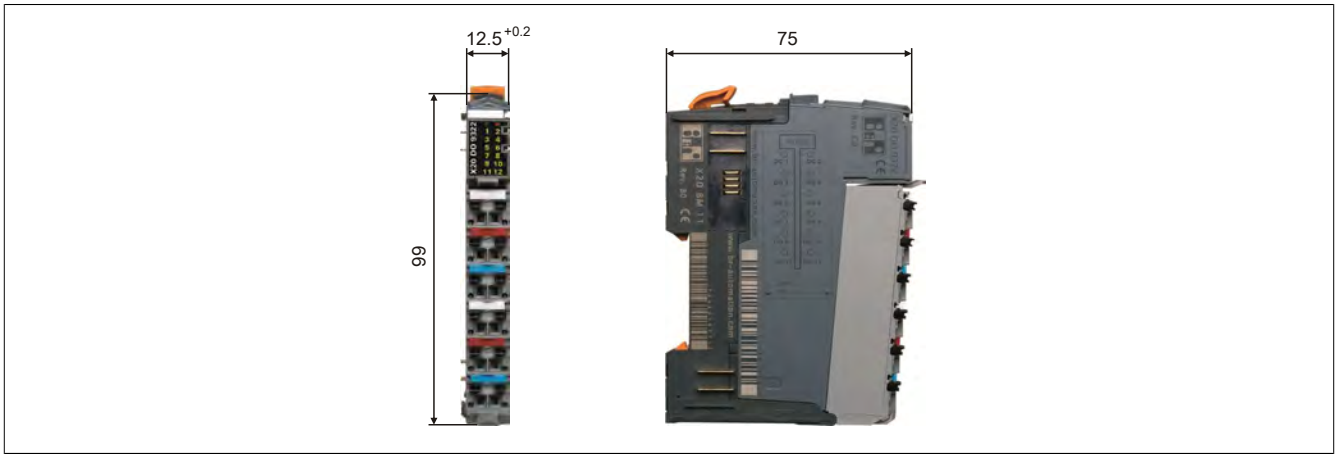

Figure 21: Dimensions of the I/O modules

3.1.6 CAD support

To ensure CAD support, the dimensions are included in the ECAD macros in 2D. STEP data is available to allow 3D viewing.

The STEP data can be found in the Downloads section of the B&R website at www.br-automation.com under the respective module.

3.2 Design support

3.2.1 Macros for ECAD systems

The electronics in a machine must be designed in a way that optimizes use of available space and materials. Graphic ECAD systems have proven themselves as the right tool for this job.

Every module in the X20 system is delivered with pre-designed electronic descriptions of the mechanical dimensions, electrical signals and module functions. These macros can be loaded directly to proven ECAD systems. The wiring plans are automatically applied by the configuration and programming system, Automation Studio. Design and changes are immediately reflected at all levels of development. This saves time for the more important tasks and prevents errors right from the start. The accelerated development, programming, maintenance and documentation involved with the X20 system mean lower costs, enhanced quality and increased sales by earlier entry into the market.

3.2.2 Printing support

System printers and standard identification labels are supported by the appropriate printer software. Printing can be done manually from table calculations or directly from ECAD software (all methods are supported). The software and printer systems correspond with the Weidmüller standard.

3.3 Installation

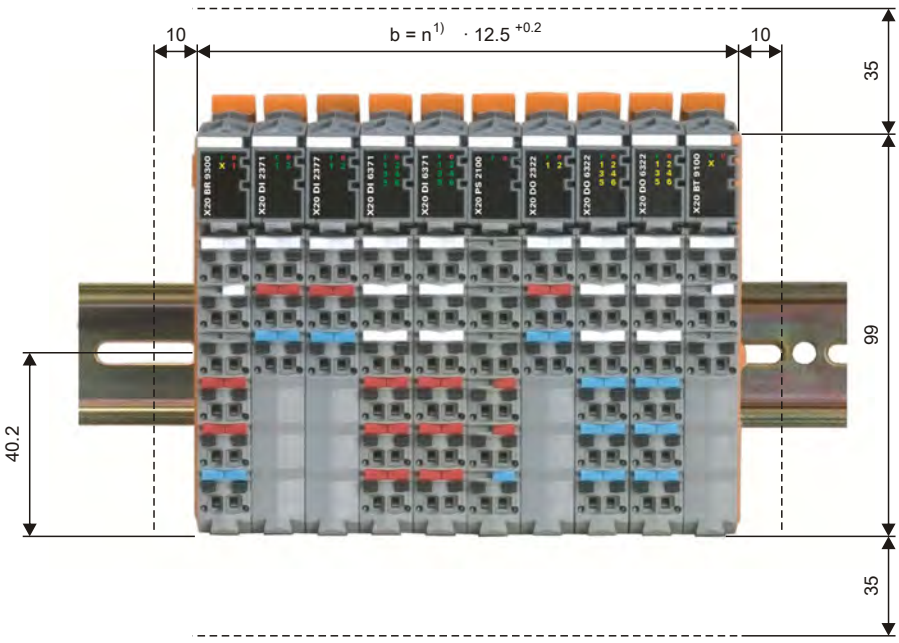
A top-hat rail conforming to the EN 60715 standard (TH35-7.5) is required to mount the PLC. The conductive top-hat rail is fastened to the back wall of the control cabinet.

The complete system including all individual modules is hung in the desired location on the top-hat rail with the unlocking mechanisms open and locked in place by closing the unlocking mechanisms. Finally, the modules are equipped with the prewired terminal blocks.

Information:

Only horizontal or vertical mounting orientation is permitted.

3.3.1 Horizontal installation

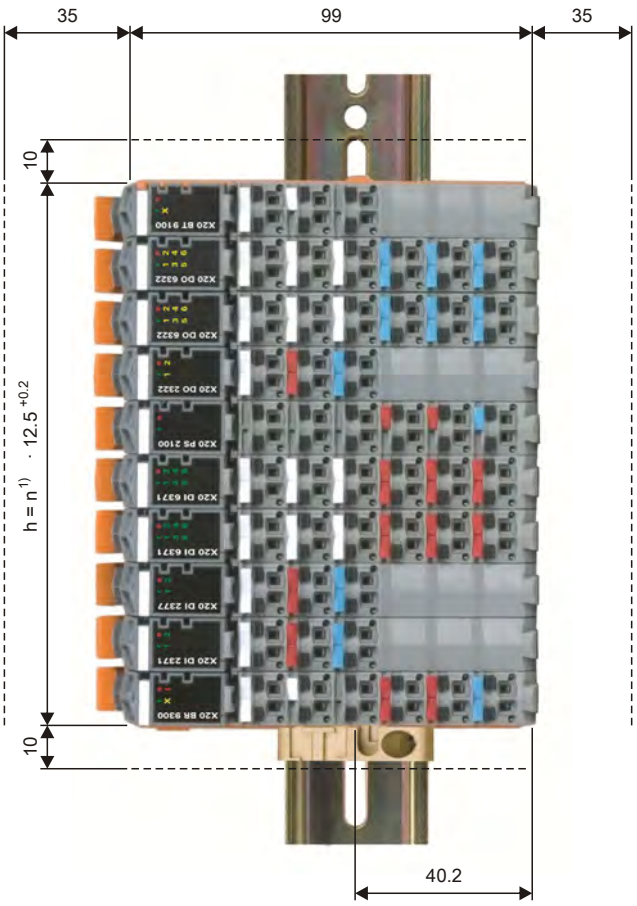


1) n ... Number of modules

Figure 22: X20 system - Horizontal installation

For optimal cooling and air circulation, there must be at least 35 mm free space above the modules. To the left and right of the X20 system, there must be at least 10 mm of free space. Underneath the modules, 35 mm space must be left free for I/O and power supply cabling.

3.3.2 Vertical installation



1) n ... Number of modules

Figure 23: X20 system - Vertical installation

For optimal cooling and air circulation, there must be at least 35 mm free space to the left of the modules. Above and below the X20 system, there must be at least 10 mm of free space. To the right of the modules, 35 mm space must be left free for I/O and power supply cabling.

The modules must be arranged so that the controller is on the lower end of the system. The temperature range is limited to -25 to 50°C when modules are mounted vertically.

Information:

The controller must be secured against slipping. An end bracket or ground terminal can be used for securing.

3.4 Wiring

In order to achieve a secure connection in the terminal blocks, wires must be stripped accordingly.

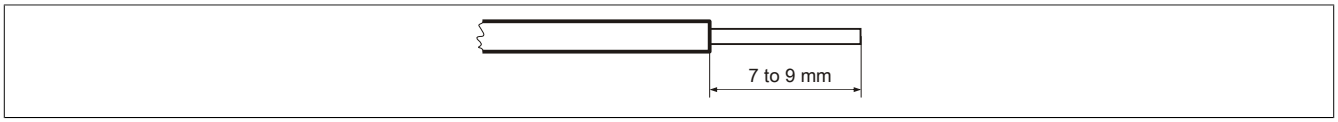


Figure 24: Wire stripping for a secure connection

Information:

The wire stripping length must not be more or less than 7 to 9 mm.

3.5 Stress relief using cable ties

Figure 25: Stress relief using cable ties

The X20 system terminal blocks have slots for the cable ties. If needed, a cable tie can be fed through these slots to reduce the stress on the cable.

Cable tie dimensions:	Width ≤ 4.0 mm Thickness ≤ 1.2 mm

Figure 26: Slots through which the cable ties are fed

3.6 Shielding

In principle, the shield must be grounded in all shielded cables:

- Analog signals (inputs and outputs)
- Interface modules
- Counter modules
- X2X Link cables
- Fieldbus connections (PROFIBUS DP, CAN bus, etc.)

In general, the following guidelines apply for shielding:

- The X20 top-hat rail must always be mounted to a conductive backplane.
- Shielded cables must be grounded on both sides.

3.6.1 Direct shielding connection

The shield is twisted and connected to the bus module's ground connection using a cable lug (2.8 x 0.5 mm). The cable is additionally secured to the terminal block using a cable tie (stress relief).

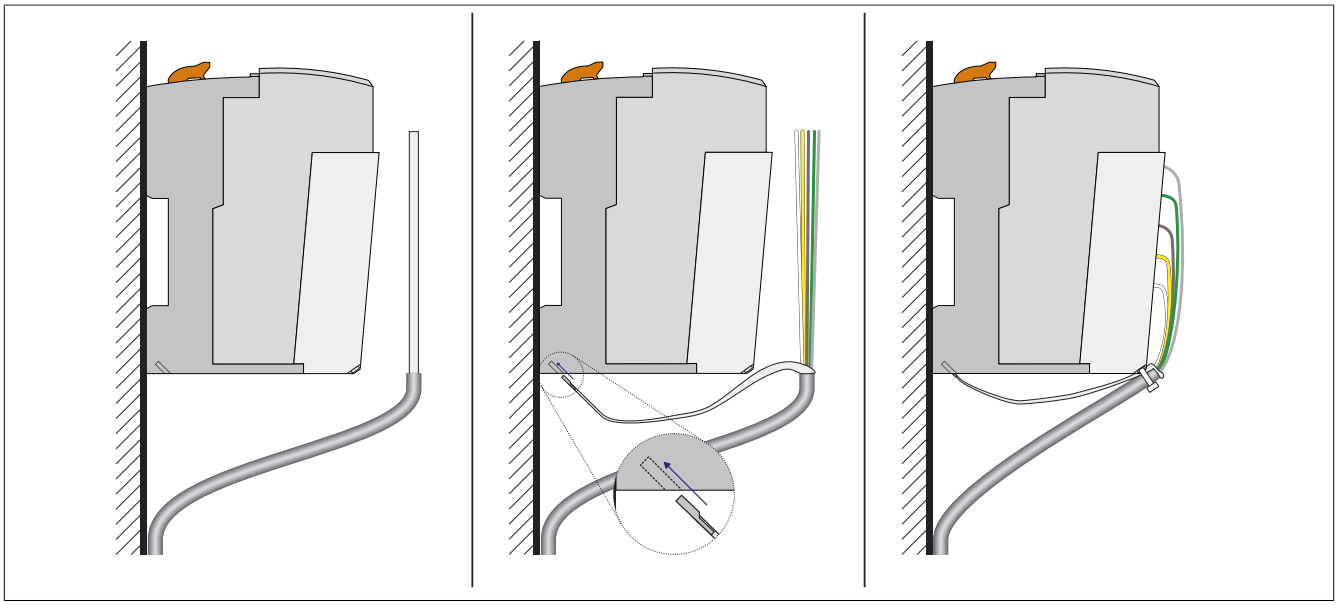

Figure 27: Direct shielding connection

Information:

The ground connection should be made as short and with as little resistance as possible.

3.6.2 X20 cable shield clamp

The X20 cable shield clamp (model number X20AC0SG1) is latched to the terminal block and connected to the bus module's ground connection using a cable lug. Cable ties are used to press the shield against the grounding plate.

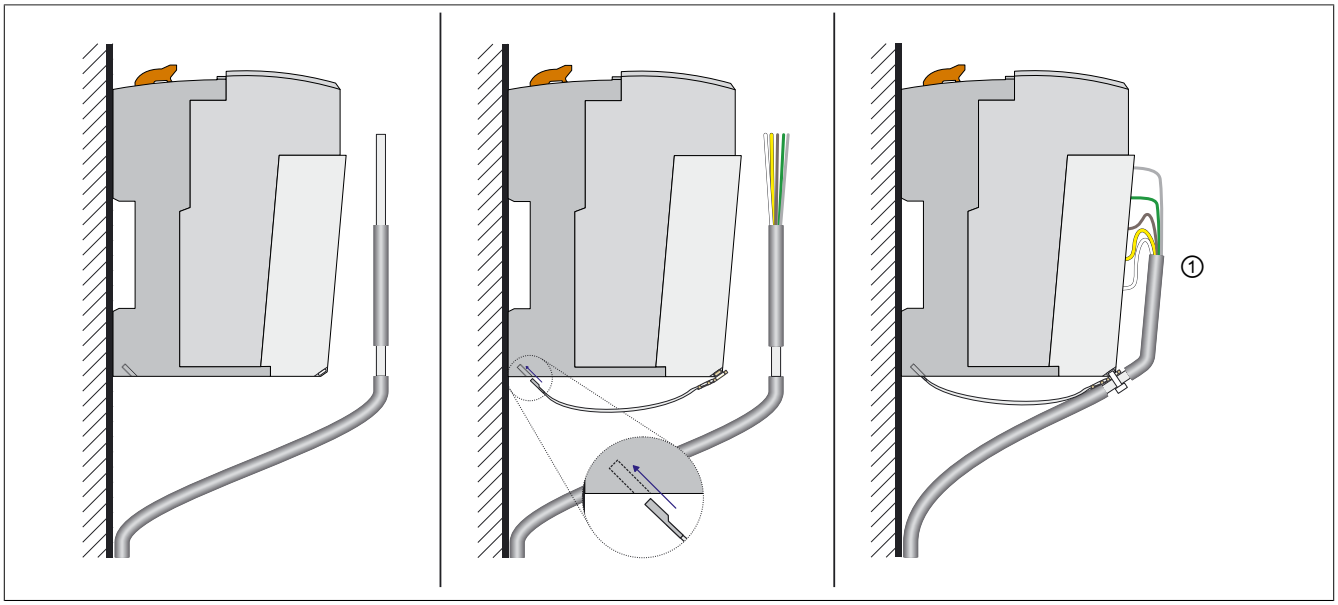

Figure 28: Shielding via X20 cable shield clamp

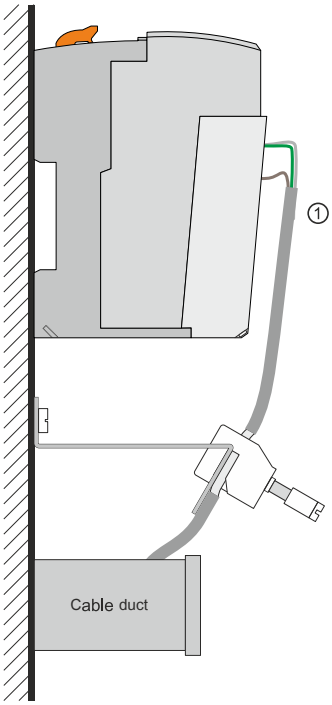
To reduce the EMC emissions most effectively, the cable shield must be as long as possible after the cable tie (see ① in the diagram above).

3.6.3 X20 shielding bracket

The X20 shielding bracket (model number X20AC0SF7.0010) is installed below the X20 system. The shield is pressed against the shielding bracket using ground terminals from another manufacturer (e.g. PHOENIX or WAGO) or a cable tie.

Attaching the shield with a ground terminal	Attaching the shield with a cable tie
	


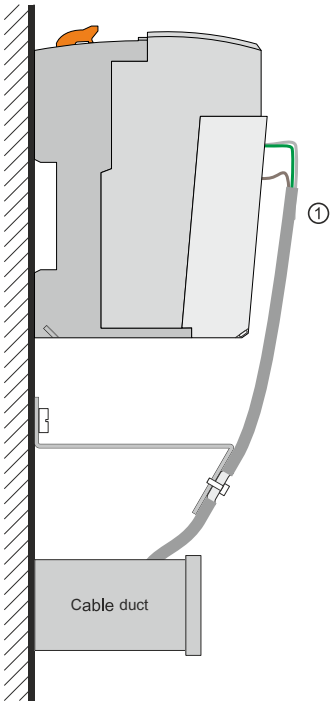


Table 4: Cable shielding via X20 shielding bracket

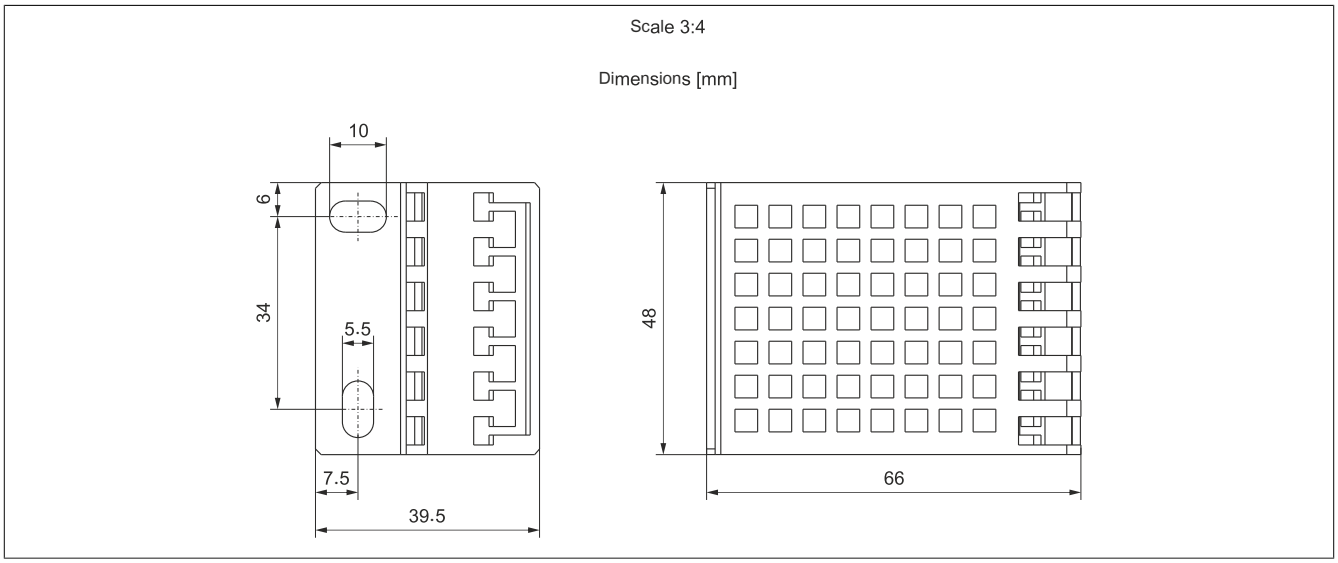
To reduce the EMC emissions most effectively, the cable shield must reach as high as possible after the cable tie (see ① in the diagram above).

Dimensions



Content of delivery

- 10 X20 shielding brackets
- Installation template

3.6.4 Shielding via top-hat rail or bus bar

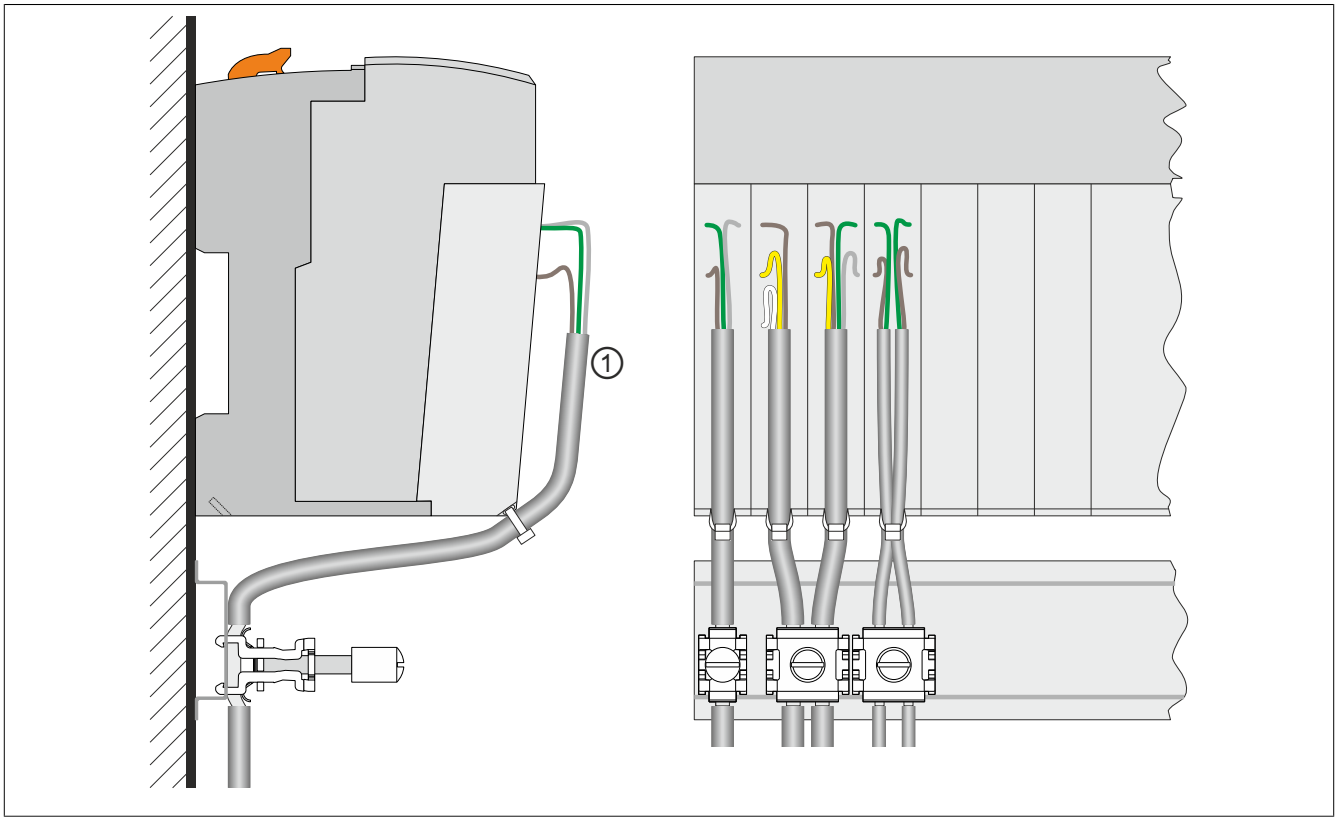


Figure 29: Shielding via top-hat rail or bus bar

Grounding terminals from other manufacturers (such as GOGATEC) can be used to achieve shielding right on the top-hat rail or on special bus bars directly below the controller.

- B&R recommends always using a grounding terminal via the top-hat rail to connect the X2X Link cable shield directly with the conductive and grounded backplane. This will generally exceed the specified EMC minimal requirements.
- The shielded cables from other modules can be grouped and clamped together. This may also be necessary due to space limitations. A different number of cables can be grounded together with a single terminal depending on the grounding terminals being used.

To reduce the EMC emissions most effectively, the cable shield must be as long as possible after the cable tie (see ① in the diagram above).

3.7 Wiring guidelines for X20 modules with an Ethernet cable

A number of X20 modules are based on Ethernet technology. POWERLINK cables offered by B&R can be used for the necessary wiring.

Model number	Connection type
X20CA0E61.xxxx	Connection cable - RJ45 to RJ45
X67CA0E41.xxxx	Attachment cable - RJ45 to M12

Table 5: POWERLINK cable with RJ45 connector

The following wiring guidelines must be observed:

- Use CAT5 SFTP cables.
- Observe minimum cable flex radius (see data sheet for the cable)
- Secure the cable underneath the bus controller. The cable must be secured vertically under the female RJ45 connector on the bus controller.

Information:

Using POWERLINK cables offered by B&R (X20CA0E61.xxxx and X67CA0E41.xxxx) satisfies the EN 61131-2 product standard.

For any further requirements, the customer must take additional measures.

Wiring diagram

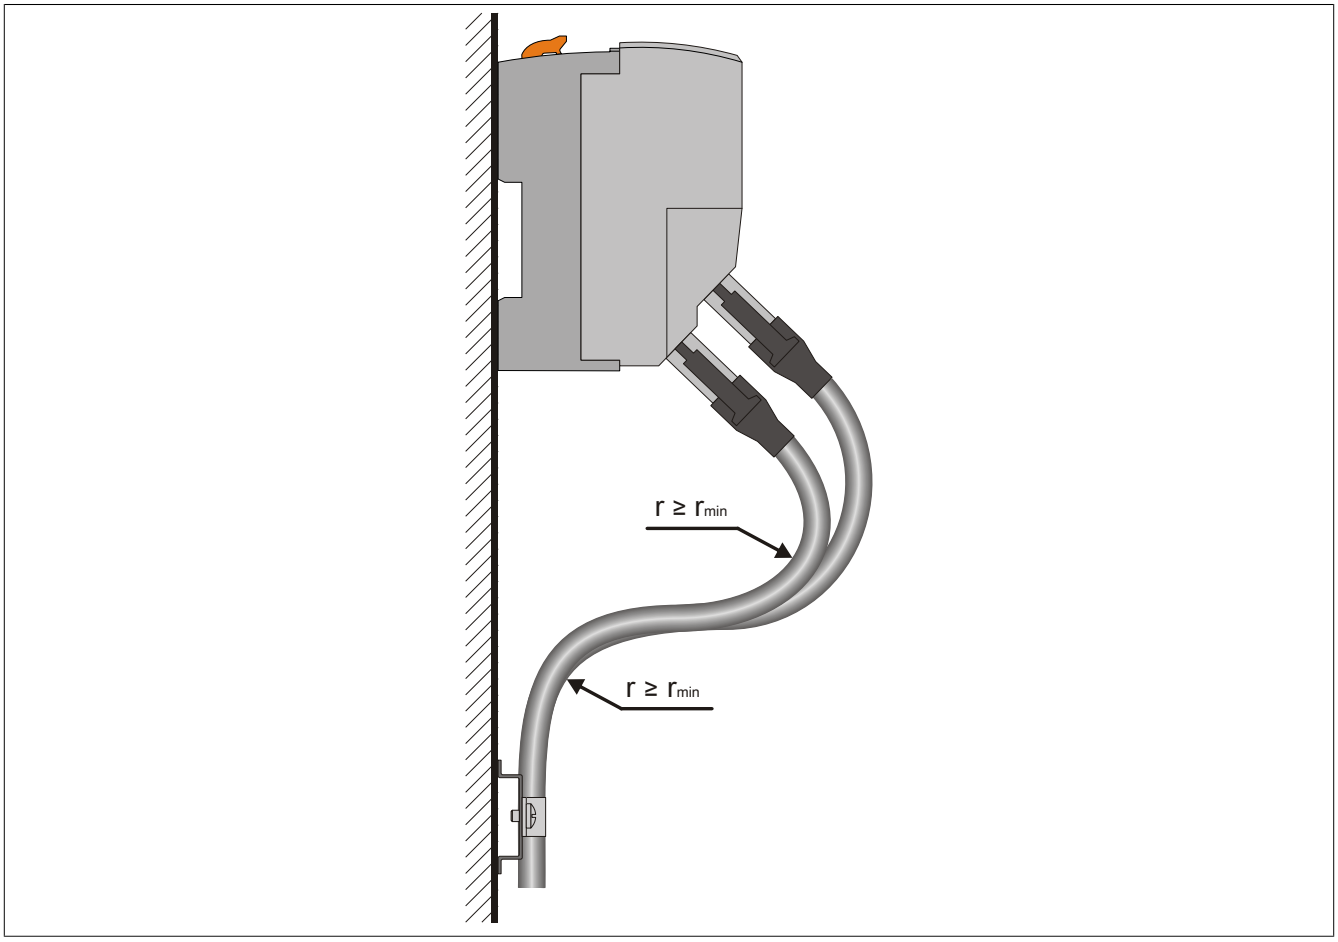

Figure 30: Wiring diagram for X20 modules with an Ethernet cable

3.8 The supply concept

Danger!

In order to guarantee a specific supply voltage, a SELV power supply that conforms to IEC 60204 must be used to supply the bus and I/O.

3.8.1 Bus module rack replacement

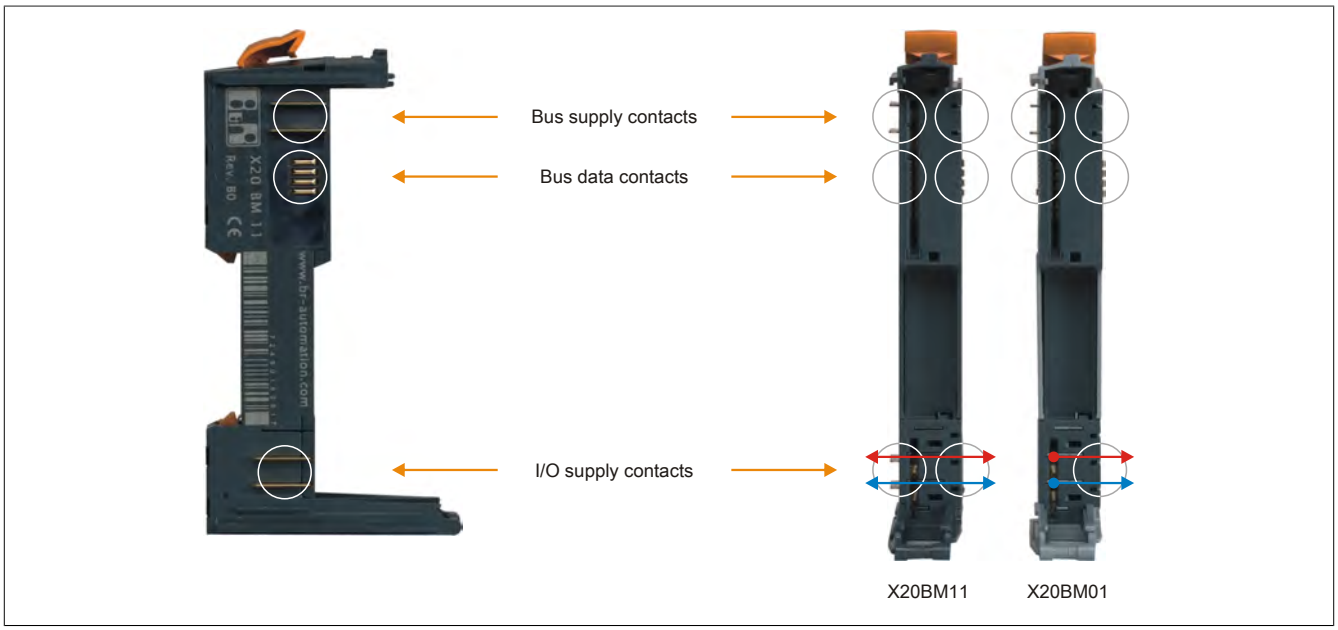

Figure 31: The bus module replaces the rack in the X20 system

The bus module is the backbone of the X20 system regarding the bus supply and bus data as well as the I/O supply for the electronics modules. Each bus module is an active bus station, even without an electronics module. There are two variations of the bus module:

- Interconnected I/O supply
- I/O supply isolated to the left (for power supply modules)

3.9 X20 system infrastructure

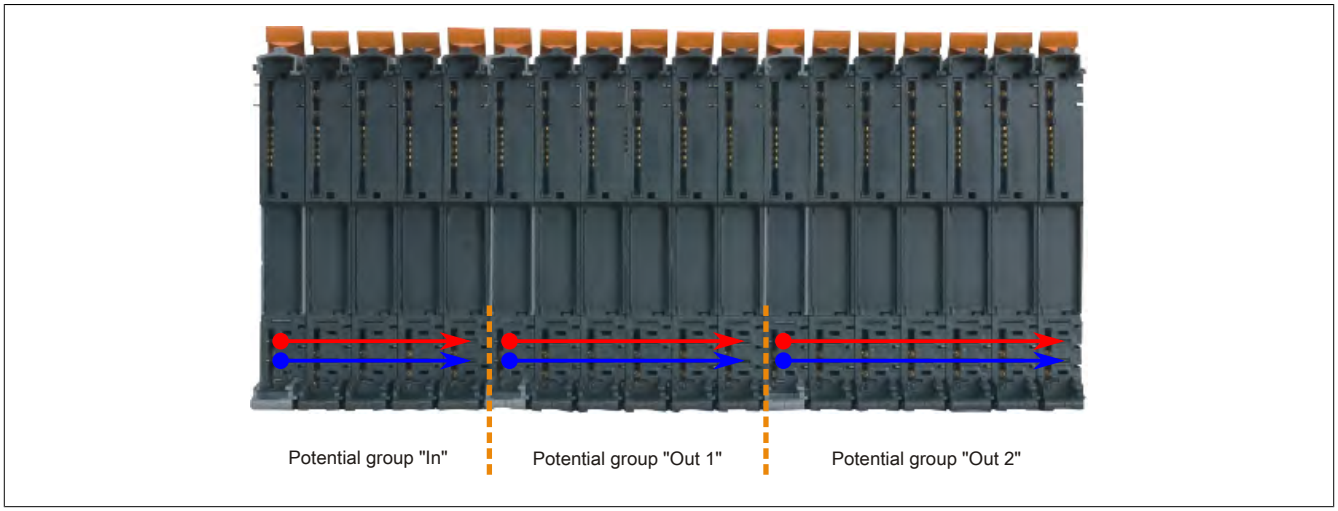

Figure 32: Simple implementation of different potential groups

Different potential groups can be implemented with the appropriate arrangement of supply bus modules, (e.g. for input groups or different E-stop circuits on the outputs). The I/O supply is fed by power supply modules.

3.10 Bus supply

Because the remote X2X Link backplane and I/O electronics are completely electrically isolated, the X2X Link supply needs to be fed in at certain intervals. This is initially handled by the bus receiver. A supply module for X2X Link must be added to refresh the supply after approximately 30 modules (for an example calculation, see 3.23 "Calculating the power requirements"). On the same module, a separate feed for the I/O supply can also be connected.

3.11 Potential groups

The I/O supply is connected via the bus modules, and the supply is fed in using corresponding power supply modules. This makes it possible to implement simple potential groups (e.g. for input groups or different output groups). For isolation, the corresponding bus module is also necessary, which provides isolation of the internal I/O supply.

3.12 Output modules with supply

Generally, a power supply module is also necessary for current output modules with many channels, such as the 8 channel output module with 2 amp outputs. This is not the case with the X20 system. With this module, the supply is provided directly on the module, thereby saving power supply modules and construction width.

3.13 Bus receiver with supply

The X20BR9300 bus receiver for the X20 system is equipped with a supply for X2X Link as well as for the internal I/O supply. This eliminates the need for an additional power supply module.

3.14 Supply module for internal I/O supply

The first I/O modules in an X20 system are supplied by the bus receiver. The internal I/O supply is refreshed via the X20PS2100 power supply module.

3.15 Power supply module for internal I/O supply and bus supply

The X2X Link is fed by the X20BR9300 bus receiver. After approx. 30 modules (see section 3.23 "Calculating the power requirements" for a calculation example), the supply must be "refreshed". The X20PS3300 power supply module is used for this. This module is equipped with a feed for X2X Link as well as for the internal I/O supply.

3.16 Bus transmitter with supply

The X20BT9100 bus transmitter has an integrated I/O supply feed. This saves a power supply module for the last potential group.

3.17 Internal I/O supply failure (ModuleOk)

The ModuleOk status for monitoring the X20 modules is made up of different module parameters. A loss of voltage in modules that are supplied via the internal I/O supply causes the ModuleOk data point to return the value 0 (false). This affects all modules that require 0.01 W on X2X Link.

3.18 X20 system power supply

The X20 system is powered by a B&R 24 VDC power supply. B&R power supplies ensure that control systems are reliably supplied even when operated at the minimum mains input voltage or when maximum power is output even if there are temporary power failures (≤10 ms).

3.19 X20 system protection

The protection for the X20 system depends on the supply concept.

3.19.1 Potential groups

Using the X20BM01 bus module and organizing the power supply bus modules accordingly allows various potential groups to be implemented (e.g. for input groups or various power circuits for the outputs).

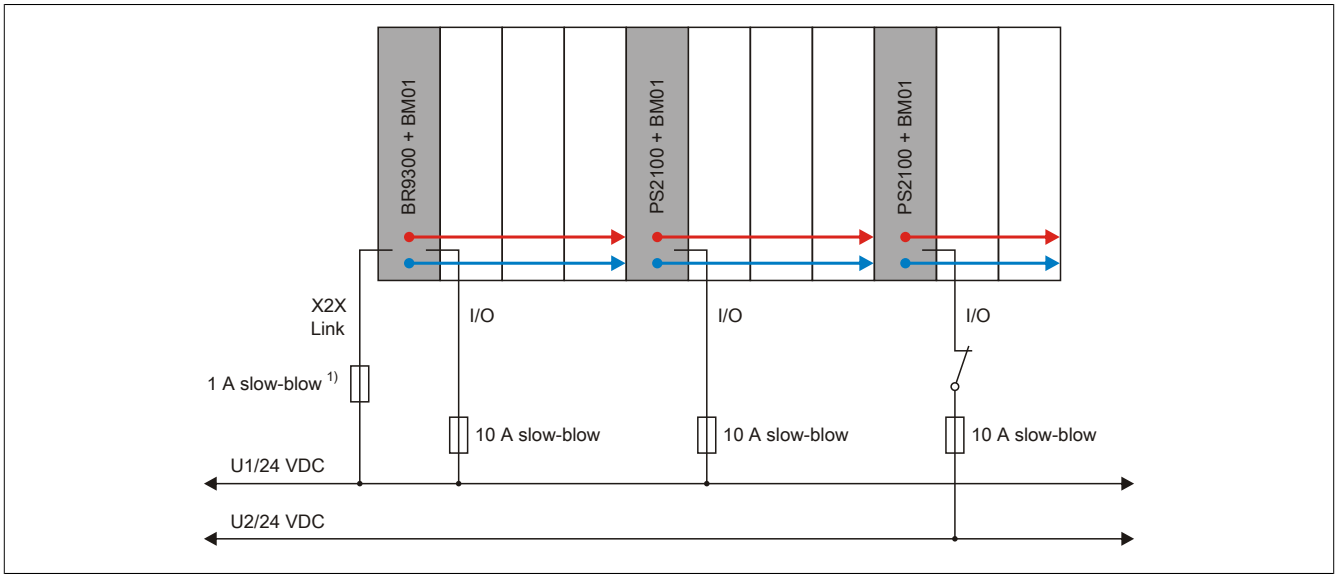

Figure 33: Protecting various potential groups

1) Recommended for line protection.

3.19.2 Supply via bus transmitter

The bus transmitter has an integrated internal I/O supply feed. This saves a power supply module for the last potential group.

Keep in mind: this potential group is separated from the rest of the potential groups by an I/O module with the bus module.

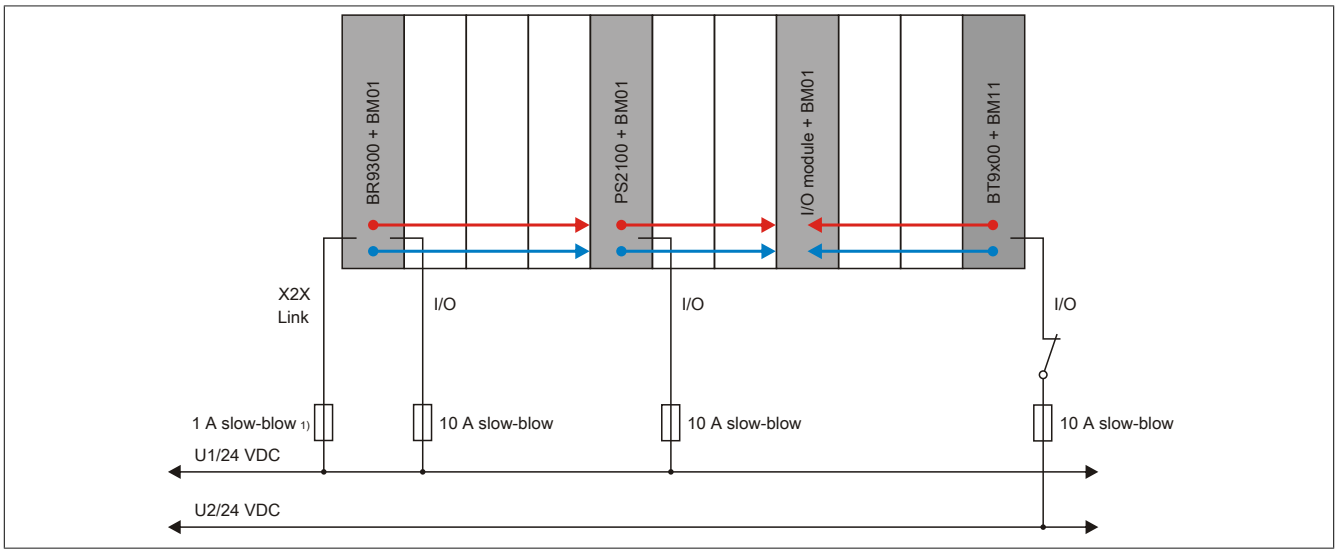

Figure 34: Protection when supplied via bus transmitter

1) Recommended for line protection.

3.20 X2X Link supply

3.20.1 Extended and redundant X2X Link supply

The X2X Link remote backplane is supplied separately from the I/O points. This ensures that the remote backplane doesn't fail if there is a power failure on the I/O side, for example with an emergency stop. After approx. 30 modules, it is necessary to "refresh" with a power supply module for X2X Link.

To achieve increased supply security, it is possible to set up a redundant X2X Link supply. To do so, the necessary X2X Link power must be determined and then covered by the corresponding quantity plus at least one additional X2X Link power supply module. This guarantees the functionality of the remote backplane even if the X2X Link supply fails.

Please note the following for the correct calculation:

- To determine the necessary X2X Link power, calculate using 75% of the power supply module's rated power during parallel operation.

Information:

This must be done for all power supply modules at the same time for a non-redundant X2X Link supply or when completely turning the X2X supply of an X20 module block on/off.

3.20.2 Example for extended X2X Link supply

It is possible to set up potential groups through the use of different supplies for the power supply modules.

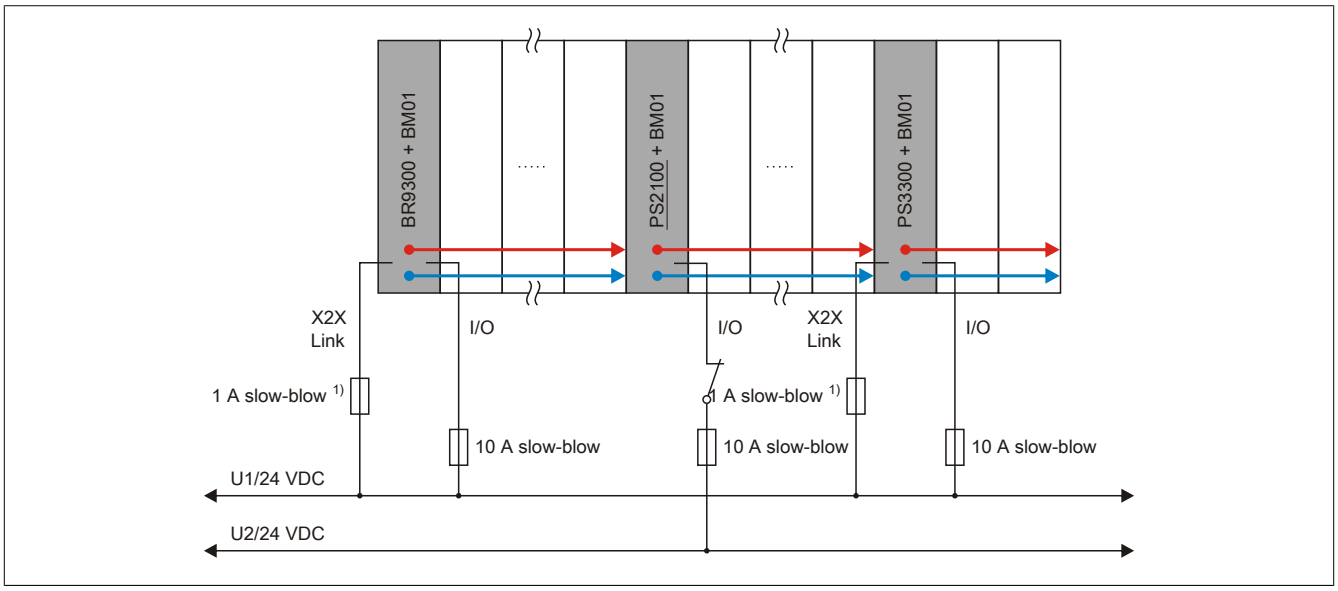

Figure 35: Example for extended X2X Link supply

1) Recommended for line protection.

The X20PS3300 power supply module supplies both the X2X Link and I/O; the X20PS2100 power supply module only supplies the I/O.

3.20.3 Example for redundant X2X Link supply

Multiple X20PS3300 power supply modules can be set up in parallel. It is possible to set up potential groups through the use of different supplies.

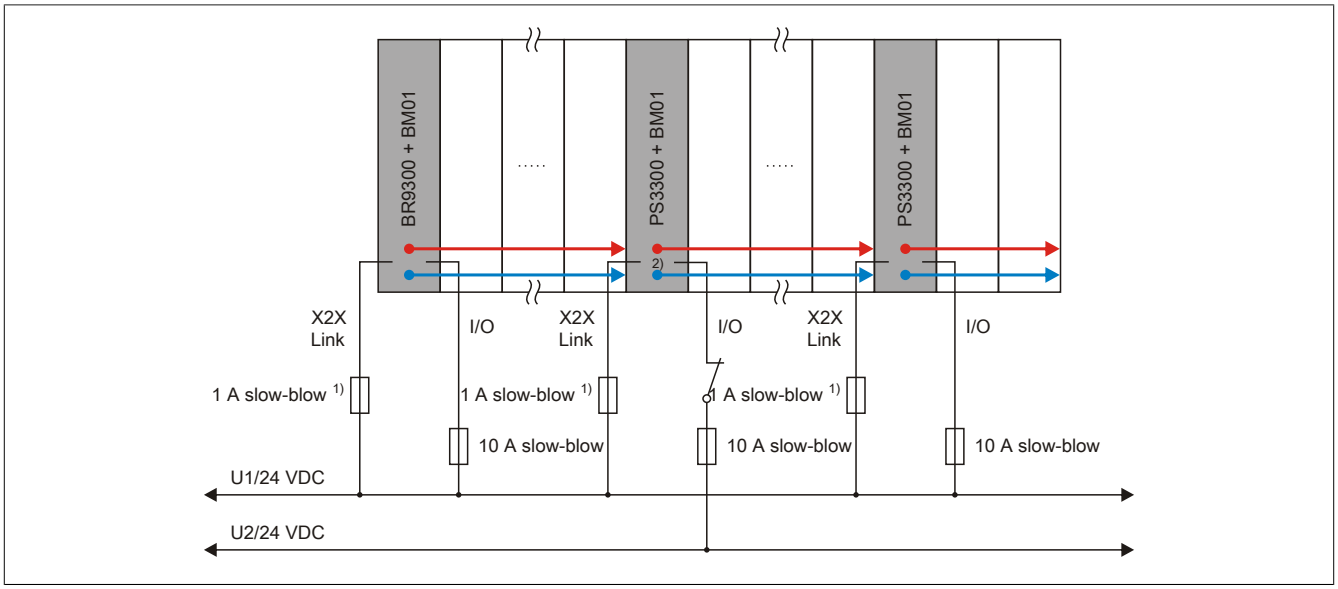

Figure 36: Example for redundant X2X Link supply

1) Recommended for line protection.
2) With separate supplies, the two reference potentials (GND_1 and GND_2) are combined via the terminal block on the PS3300.

The X20PS3300 power supply module supplies both X2X Link and the I/O.

3.21 Safe cutoff

3.21.1 General information

The operating principle "Safe cutoff of a potential group" allows the user to implement safety functions that satisfy the requirements of ISO 13849 within a B&R system when using an external safety relay.
The safety function is limited to cutting off or interrupting the power to the connected actuators.

Functionality

An external safety relay is connected to the I/O supply for the potential group. When the functional safe state is requested or a "Failsafe" state occurs, then this safety relay cuts off the I/O supply of the potential group. The power is then also cut off for all actuators connected to this potential group.

3.21.2 Scope of application / Standards referenced

The operating principle is confined to machine manufacturing applications, and therefore implicitly to the following standards:

- ISO 13849-1:2007 and ISO 13849-2:2013

Requirements of other standards are not taken into consideration.

3.21.3 Intended use

It is the user's responsibility to clarify guidelines for the use of safety-related B&R components with the respective authorities and to ensure these guidelines are met.

B&R will not assume warranty or liability for damages that occur due to:

- Improper use
- Non-observance of standards and guidelines
- Unauthorized modifications to devices, connections and settings
- Operation of unauthorized or unsuitable devices or device groups
- Failure to follow the safety notices covered in this manual
- Malfunctions caused by the external safety relay

3.21.4 Qualified personnel

Safety functionality is only permitted to be implemented by personnel with appropriate training in safety technology and knowledge of applicable regulatory and technical requirements.

Use of safety-related products is restricted to the following persons:

- Qualified personnel who are familiar with relevant safety concepts for automation technology as well as applicable standards and regulations
- Qualified personnel who plan, develop, install and commission safety equipment in machines and systems

Qualified personnel in the context of this manual's safety guidelines are those who, because of their training, experience and instruction combined with their knowledge of relevant standards, regulations, accident prevention guidelines and operating conditions, are qualified to carry out essential tasks and recognize and avoid potentially dangerous situations.

In this regard, sufficient language skills are also required in order to be able to properly understand this manual.

3.21.5 Application in the X20 system

The operating principle applies to a potential group in the X20 system. For information about how to create a potential group in the X20 system, see section 3.11 "Potential groups".

When implementing the operating principle, each X20 potential group must be supplied by a single power supply module. Only X20BM01, X20BM23 and X20BM26 modules that guarantee the interruption of the internal I/O supply to the left are permitted for use as bus modules for the power supply module. This ensures that each potential group in the X20 system will receive power from exactly one power supply module and prevents the possibility of multiple power sources.

3.21.5.1 Suitable modules

The operating principle is supported by the following X20 modules:

Module group	Module		Starting with revision
Bus modules	X20BM01	X20 power supply bus module, 24 VDC keyed, internal I/O supply interrupted to the left	D0
	X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	D0
	X20BM23	X20 power supply bus module, for X20 SafeIO power supply modules, internal I/O supply interrupted to the left	B0
	X20BM26	X20 power supply bus module, for X20 SafeIO power supply modules, with node number switch, internal I/O supply interrupted to the left	B0
Power supply modules	X20PS2100	X20 power supply module, for internal I/O supply	F0
	X20PS2110	X20 power supply module for internal I/O supply, integrated microfuse	C0
Safe power supply modules	X20SP1130	X20 safe power supply module, for internal I/O supply, 24 VDC, 10 A, with integrated safe cutoff function, be aware of the list of permitted modules in the potential group	B2
Digital outputs	X20DO2322	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, source, 3-wire connections	F0
	X20DO4322	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections	F0
	X20DO4332	X20 digital output module, 4 outputs, 24 VDC, 2 A, source, 3-wire connections	F0
	X20DO6321	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections	F0
	X20DO6322	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections	F0
	X20DO8232	X20 digital output module, 8 outputs, 12 VDC, 2 A, source, feed directly on module, 1-wire connections	E0
	X20DO8322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 1-wire connections	E0
	X20DO8332	X20 digital output module, 8 outputs, 24 VDC, 2 A, source, feed directly on module, 1-wire connections	G0
	X20DO9321	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections	E0
	X20DO9322	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections	H0
	X20DOF322	X20 digital output module, 16 outputs, 24 VDC, 0.5 A, source, 1-wire connections	C0
Digital signal processing and preparation	X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module	F0
	X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with max. 2 reference pulses, SSI absolute encoder, NetTime module	D0
	X20DS4389	X20 digital signal module, 4 digital inputs, 24 VDC, 4 digital outputs, 24 VDC, 0.1 A, oversampling I/O functions, time-triggered I/O functions, NetTime module	B0
Analog outputs	X20AO2622	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution	H0
	X20AO2632	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution	F0
	X20AO4622	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution	H0
	X20AO4632	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution	I0
Counter functions	X20DC2395	X20 digital counter module, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function	F0
	X20DC4395	X20 digital counter module, 2 SSI absolute encoder, 24 V, 2 ABR incremental encoder, 24 V, 4 AB incremental encoders, 24 V, 8 event counters or 4 PWM, local time measurement function	G0
Additional functions	X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection	F0
Motor controllers	X20MM2436	X20 PWM motor module, 24 to 39 VDC ±25%, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder	D0
	X20SM1426	X20 stepper motor module, 1 motor connection, 1 A continuous current, 1.2 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder	C0
	X20SM1436	X20 stepper motor module, module supply 24-39 VDC ±25%, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder	D0

Table 6: List of X20 modules

The operating principle of the X20 system has been tested by TÜV Süd, with the results documented under report number BE85906T.

3.21.6 General notices

3.21.6.1 Installation notes

Modules must be protected against impermissible dirt and contaminants. The maximum permissible level of dirt and contaminants is Pollution Level II as specified in the IEC 60664 standard. This can be achieved through installation in a control cabinet that provides IP54 protection.

When using the operating principle, uncoated X20 modules must not be operated in condensing relative humidity or with ambient temperatures below 0°C.

3.21.6.2 Timing

3.21.6.2.1 Worst case scenario

A maximum cutoff time of 500 ms must be assumed for the potential group for worst case scenarios. This time is needed to guarantee that energy stored within the module is discharged and the actuators are cut off in worst case scenarios. The cutoff times needed for the upstream external safety relay and actuator must also be added.

Worst case conditions for "Output = Off"

- Digital output: <5 V
- Analog output: <100 mV

3.21.6.2.2 Load-dependent cutoff time

The actual duration of cutoff can be calculated with the following formula.

$$t_{spec} = -\frac{C_{tot} * U_{in}}{I_{load}} * 2 * \ln\left(\frac{U_{off}}{U_{in}}\right)$$

t_{spec}	Actual cutoff time
C_{tot}	Total capacity of all modules in the potential group. (e.g. 10 modules 47 µF + 3 modules with 150 µF → Ctot = 920 µF)
U_{in}	Supply voltage
U_{off}	Voltage, if Output = Off
I_{load}	External load

Table 7: Parameter descriptions

Module	Module's internal capacity
X20MM2436 X20SM1426 X20SM1436	150 µF
Other modules [1)]	47 µF

1) Only modules from section 3.21.5.1 "Suitable modules".

If the result is t_{spec} = >500 ms, then the worst-case assumption from section 3.21.6.2.1 "Worst case scenario" applies.

Information:

- **The calculated load-dependent cutoff time must be verified by a test measurement!**
- **At the time a safety function is requested, there is no guarantee that the outputs used to calculate the load-dependent cutoff time are enabled. For example, if an output is disabled at the time of a request, then the respective internal capacities in the module will not be discharged in the calculated time (t_{spec}). The worst-case time of 500 ms should be taken into account in this situation. If the output is enabled from the functional application (shown in the sketch as the interval $t_{application}$) during the worst-case time (<500 ms), then the output subsequently remains enabled for the calculated time.**

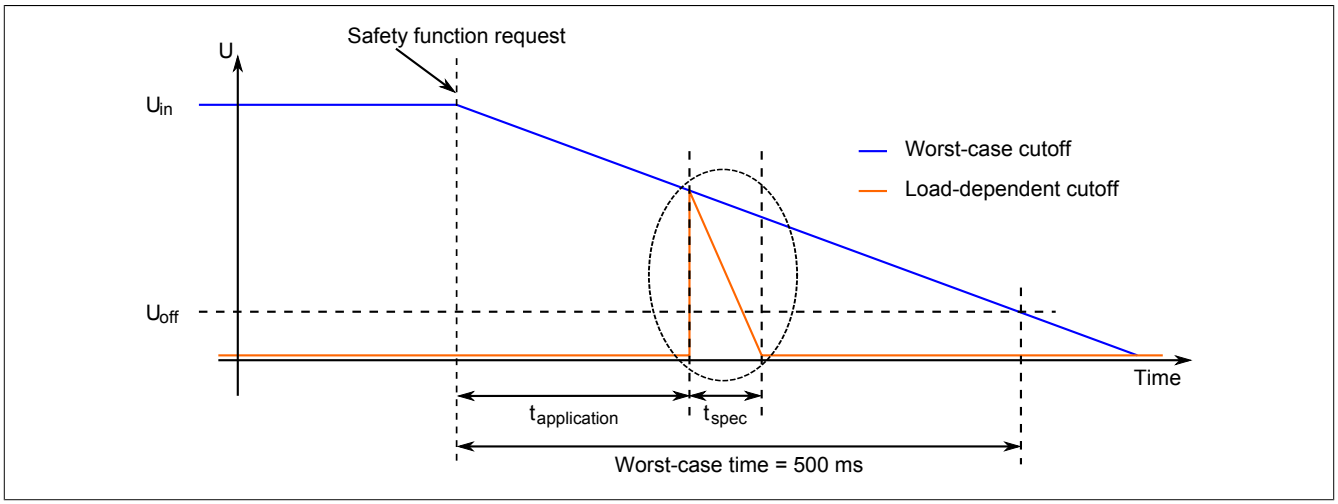

Figure 37: Output behavior following safety request

3.21.6.3 Potential group structure

The potential group can be made up only of modules in accordance with the table in section 3.21.5.1 "Suitable modules". Modules not listed in this table would compromise the "absence of feedback" of the external cutoff and therefore put the safety function at risk.

To ensure clarity and that the external cutoff is triggered when a fault occurs, installing multiple power supply sources in a potential group is not permitted.

SELV/PELV power supplies must be used for both the bus supply (X2X) and the module supply; otherwise, safety-related malfunctions can occur due to overvoltages.

For modules with isolated I/O potential for sensors and actuators, the upstream safety relay must shut off the supply for both the sensors and actuators; otherwise, energy regeneration cannot be excluded.

3.21.6.4 Circuit examples

1. One-channel without feedback

The following example shows a load being cutoff using the E-stop safety function. Only error-free actuators such as a motor or the "Enable" input of an ACOPOS / ACOPOSmulti drive may be used as the load in this case.
This type of circuit is not permitted for defective actuators such as relays since here the lack of feedback makes it impossible to detect contact sticking.

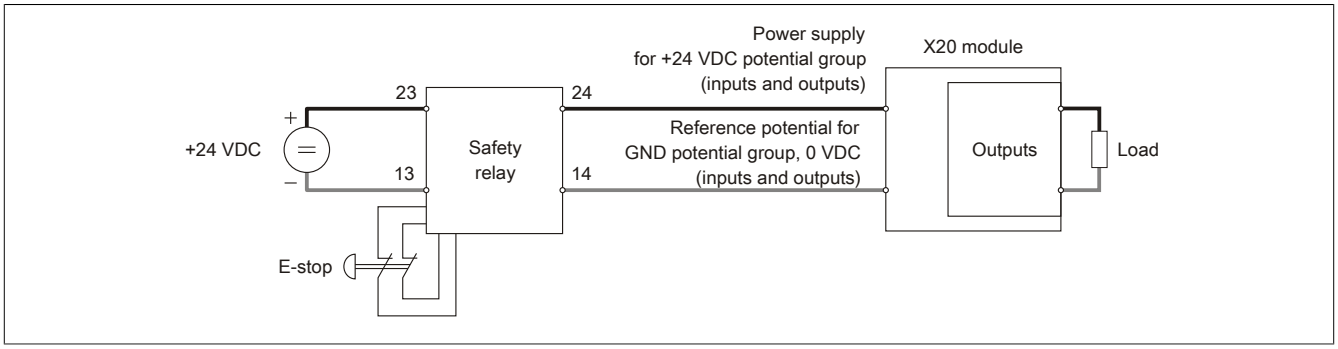

Figure 38: Circuit example 1: "One-channel without feedback"

Provided that the external components used (E-stop button, safety relay, load) satisfy the respective requirements, this example can achieve PL e (performance level as specified in ISO 13849).

2. Two-channel with feedback

The following example shows a load being cutoff using the E-stop safety function. Thanks to the feedback, errors in the actuator are detected, and with the full two-channel circuit, the cutoff is ensured even in the event of an error. Whether or not two fully isolated potential groups – as shown in the example – are necessary depends on the application and how the safety solution is designed.

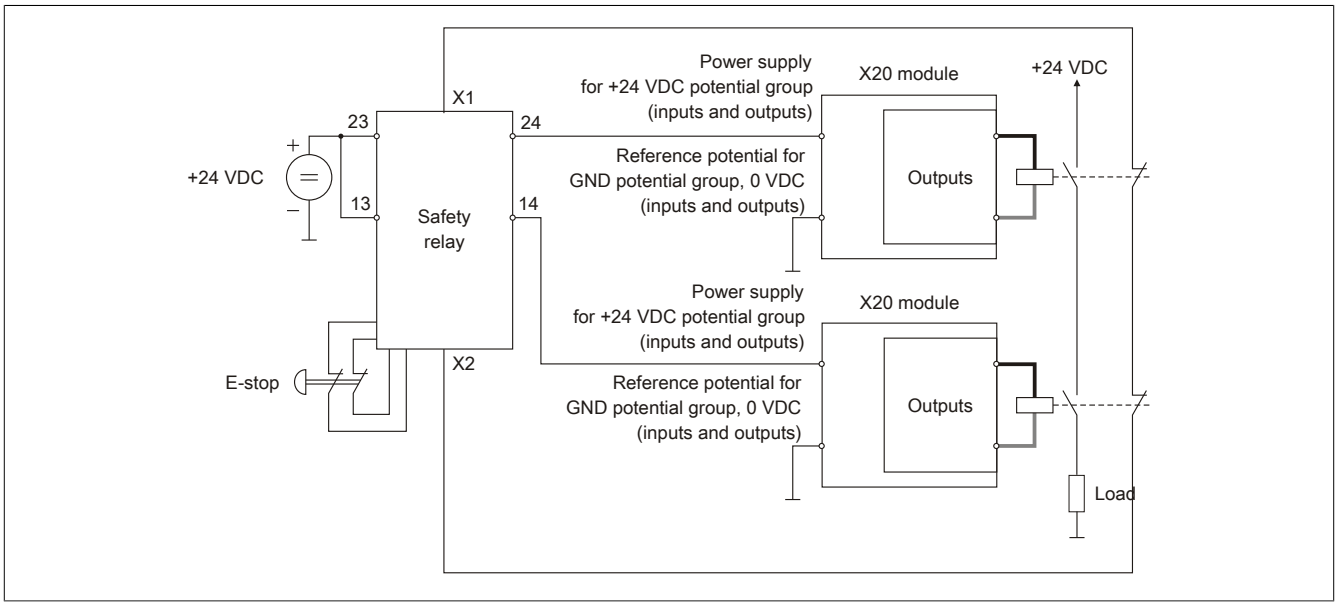

Figure 39: Circuit example 2: "Two-channel with feedback"

Provided that the external components used (E-stop button, safety relay, load) satisfy the respective requirements, this example can achieve PL e.

3. Example with X20SP1130 power supply module

The following example shows a load being cutoff using an X20SP1130 safe power supply module and an X20SI4100 safe input module together with the "E-stop" safety function.

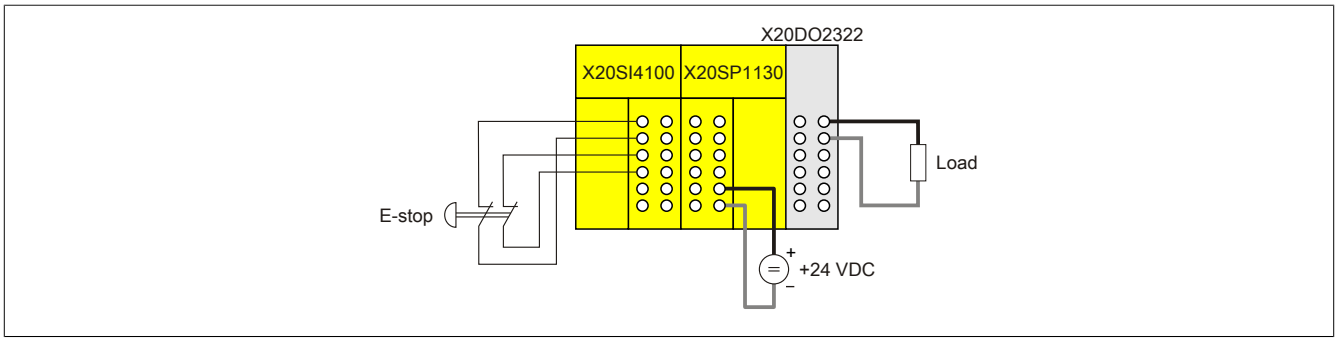

Figure 40: Circuit example 3: With X20SP1130 power supply module

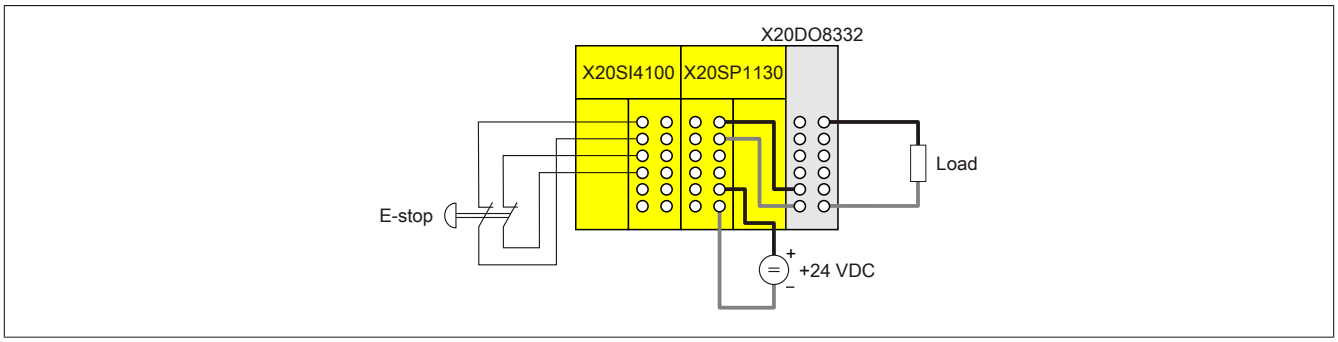

Figure 41: Circuit example 3: With X20SP1130 power supply module and X20DO8332

Provided that the external components used (E-stop button, load) satisfy the respective requirements, this example can achieve PL e.

3.21.6.5 Wiring notices

The operating principle "Safe cutoff of a potential group" only applies to the B&R modules used. All other parts of the safety chain, such as the application, upstream sensors or downstream actuators are NOT included in this principle.

For this reason, it is important to take the following points into consideration:

- Ensure proper wiring of the safety relay with the I/O supply. A short circuit between the output of the safety relay and an external 24 V voltage source can cause an unintended supply of 24 V to the internal supply voltage of the potential group. As a result, the safety function can no longer be guaranteed, which means that **ALL** of the channels in the potential group can no longer be cut off by the upstream safety switching device.
- Make sure that **ALL** of the potential group's input and output channels and the connected sensors and actuators are wired properly. A short circuit between an input or output of the potential group and an external 24 V voltage source can cause the unintended feedback of 24 V to the internal supply voltage of the potential group. As a result, the safety function can no longer be guaranteed, which means that **ALL** of the output channels in the potential group can no longer be cut off by the upstream safety relay.
- In accordance with EN ISO 13849-2:2013, Appendix D.2, Table D.4, a short circuit between any two conductors can be excluded, provided that:
    - they are permanently connected and protected against external damage (e.g. using a cable duct or armored conduit)
    - OR they are in separate plastic-sheathed cables
    - OR they are installed within an electrical enclosure (provided that both the conductors and the enclosure meet the appropriate requirements [see EN 60204-1 (IEC 60204-1)])
    - OR they are individually shielded with a ground connection

3.21.7 Safety guidelines

This section provides a summary of safety notices for the user.

Danger!

Please observe the following safety notices. Failure to observe one of the following notices can lead to loss of safety functionality and may result in serious injury.

- **The safety relay determines which category (according to ISO 13849) is achieved.**
- **When using the operating principle, it is the user's responsibility to adhere to the relevant standards and safety directives. The notices provided in sections 3.21.1 "General information" through 3.21.4 "Qualified personnel" regarding functionality, applicable standards, proper use and qualified personnel are also to be observed.**
- **The safety function is limited to cutting off or interrupting the power to connected devices. Safety functions that require actively powering on an actuator in a safe state cannot be implemented with this function.**
- **For all potentials supplying the modules, SELV/PELV power supplies must be used.**
- **The potential groups for which the operating principle is applied must only contain modules listed in the table in section 3.21.5.1 "Suitable modules".**
- **When using the operating principle with uncoated X20 modules, the modules must not be operated in condensing relative humidity or with ambient temperatures below 0°C.**
- **It is not permitted to mix modules from different systems (X20, X67) within a potential group.**
- **It is not permitted to install multiple power supply modules in a potential group (particularly with regard to power supply modules that also supply the bus supply).**
- **Ensure that the upstream safety relay is wired properly.**
- **Ensure that ALL sensors and actuators connected to the potential group are wired properly.**
- **Be aware of the maximum safety-related response time of 500 ms when shutting down the potential group. The cutoff times needed for the upstream external safety relay and actuator must also be added. Using the formulas defined in section 3.21.6.2.2 "Load-dependent cutoff time", it is possible to achieve cutoff times under 500 ms.**
- **The calculated load-dependent cutoff time must be verified by a test measurement!**
- **For modules with isolated I/O potential for sensors and actuators, the upstream safety relay must shut off the supply for both the sensors and actuators.**
- **The ground connections should be used as functional ground and not as protective ground and must not be connected to the 24 V supply voltage (GND is permitted). There must not be any protective components between the ground and the 24 V supply voltage.**

3.22 Combining X2X Link systems

3.22.1 General information

The X2X Link provides a complete remote backplane, which is used for communicating between bus modules and over the X2X Link cable. Systems based on X2X Link can be combined with one another as needed.

3.22.2 Connection overviews

The following connection overviews illustrate combinations of different systems that are based on X2X Link. The model numbers indicate which standard cables available from B&R can be used to connect with one another.

3.22.2.1 Combining X20, X67 and compact I/O system

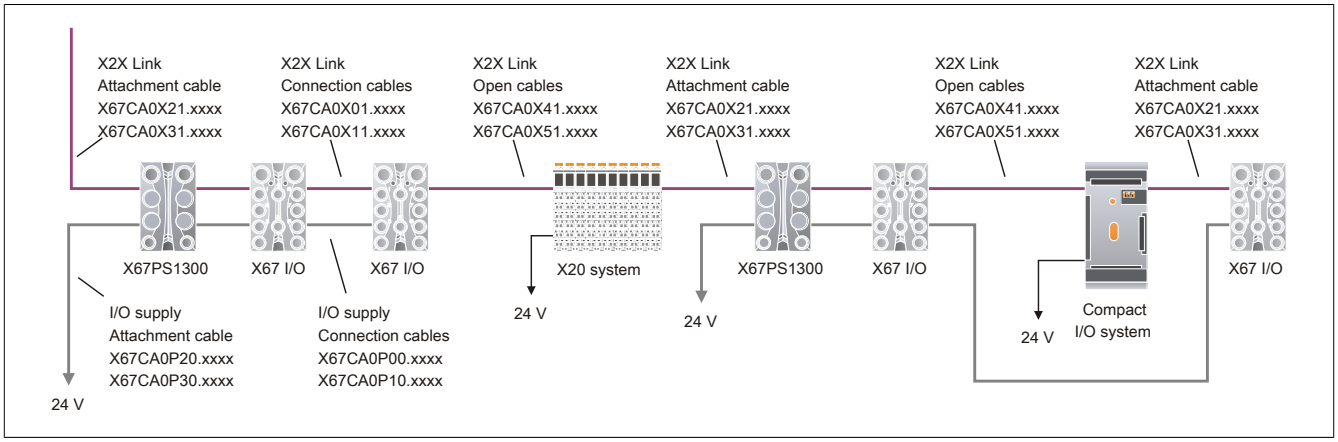

Figure 42: Connection overview - Combining X20, X67 and compact I/O system

3.22.2.2 Combining X20, X67 and valve terminal connections

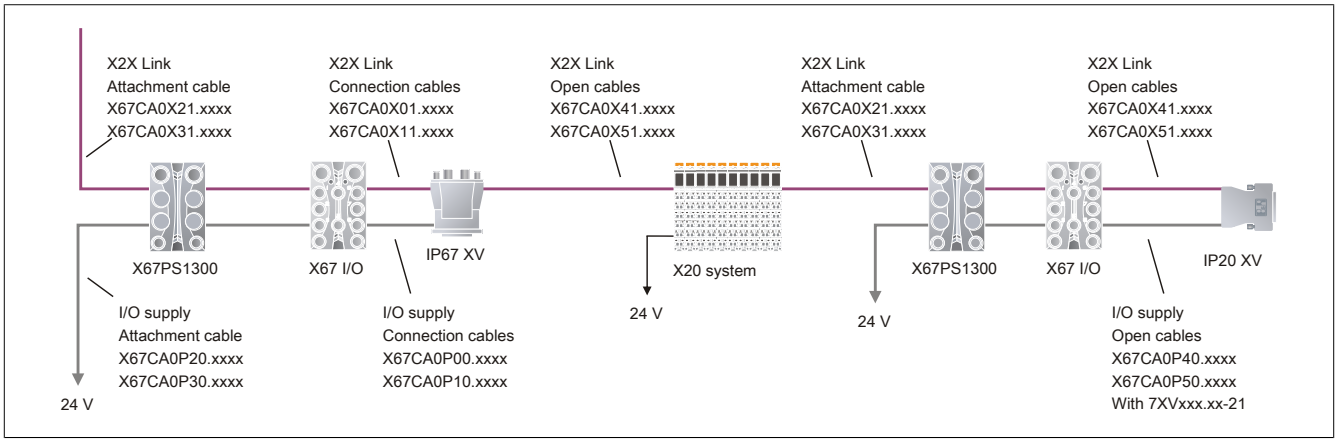

Figure 43: Connection overview - Combining X20, X67 and valve terminal connections

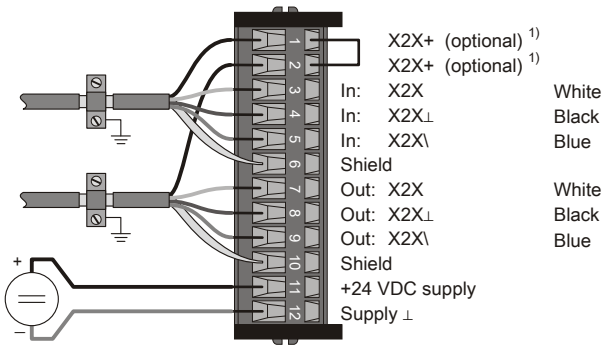
3.22.3 Connection examples

3.22.3.1 X20 system

Connection examples are listed in the module description:

- X20BR9300 bus receiver: 4.8.2.7 "Connection examples"
- X20BT9100 bus transmitter: 4.8.3.7 "Connection examples"

3.22.3.2 Compact I/O system



1) Used to forward the X2X Link supply when using IP67 modules.

3.23 Calculating the power requirements

Overview of I/O supply

The power necessary for operation is provided by the power supply modules, the X20 CPU, the bus receivers and the bus transmitters.

Module	I/O internal power	Bus power
X20CP148x, X20CP158x, X20CP358x	+240 W	+7 W
X20BR9300	+240 W	+7 W
X20PS2100	+240 W	-0.2 W
X20PS2110	+144 W	-0.2 W
X20PS3300	+240 W	+7 W
X20PS3310	+144 W	+7 W
X20PS9xxx	+240 W	+7 W

Bus transmitter

When calculating the power requirements for bus transmitters, it is important to know whether they are only being used as such or are also being used as an I/O power supply module.

Model number	I/O internal power		Bus power
	When operated as a bus transmitter	When operated as a bus transmitter and I/O power supply module	
X20BT9100	-0.1 W	+240 W	-0.5 W
X20BT9400	-0.1 W	+240 W	-0.5 W

Table 12: Overview of bus transmitter power

Information about power consumption

The power consumption of individual modules can be found on the respective technical data sheet. Information about power consumption can be found in the technical data under "General information - Power consumption".

- The value in the "Internal I/O" row refers to the internal power requirements of the I/O module covered by the 24 VDC I/O supply.
- The value specified in the "Bus" row refers to the X2X Link power balance.

These rows can be used to quickly and easily create a power balance for a certain hardware configuration. The power consumption values of individual modules should then be subtracted from the power provided by the power supply module. The sum is not permitted to be less than zero.

Information:

For a calculation example, see 3.23.1 "Example 1" and 3.23.2 "Example 2".

Embedded parameter chip

On modules with 0.01 W power requirements, it is only possible to read the embedded parameter chip if the I/O supply is also active. Information about the embedded parameter chip can be found in the 2.12 "Embedded parameter chip" section.

3.23.1 Example 1

Calculating the power requirements for the bus and 24 VDC I/O supply with the following hardware configuration:

Module	Bus power [W]	I/O-internal power [W]	I/O-external power [W]	Sensor/Actuator supply [W][1]
X20DI4371	0.14	0.59	-	12.00
X20DI2371	0.12	0.29	-	12.00
X20DO4322	0.16	0.49	48.00[2]	12.00
X20DO4322	0.16	0.49	48.00[2]	12.00
X20BT9100	0.50	0.10	-	-
Subtotal		**1.96**	**96.00**	**48.00**
Total	**1.08**		**145.96 (=1.96 + 96.00 + 48.00)**	

1) Rated power at 24 VDC and 0.5 A.
2) Rated power at 24 VDC and 100% simultaneity.

The total power to be supplied by the 24 VDC I/O power supply is 145.96 W. One power supply module is already integrated in the X20BR9300 bus receiver. The power comparison indicates that the power provided by the power supply module is sufficient.

	Bus power [W]	Power 24 VDC I/O supply [W]
X20BR9300	+7.00	+240.00[1]
Power requirements of I/O modules	-1.08	-145.96
Power requirements of all bus modules	-0.78	-
Remaining power	**+5.14**	**+94.04**

1) Rated power at 24 VDC and 10 A.

3.23.2 Example 2

The I/O modules are divided into 3 potential groups in this example:

Potential group 1	Potential group 2	Potential group 3
Digital input modules	Digital output modules	Analog input modules and temperature modules

Calculating the power requirements for the bus and 24 VDC I/O supply per potential group with the following hardware configuration:

Potential group 1				
Module	**Bus power [W]**	**I/O-internal power [W]**	**I/O-external power [W]**	**Sensor/Actuator supply [W][1]**
X20DI6371	0.15	0.88	-	-
X20DI6371	0.15	0.88	-	-
X20DI2377	0.15	0.82	-	12.00
Subtotal		**2.58**	-	**12.00**
Total	**0.45**		**14.58 (= 2.58 + 12.00)**	

1) Rated power at 24 VDC and 0.5 A.

Potential group 2				
Module	**Bus power [W]**	**I/O-internal power [W]**	**I/O-external power [W][1)]**	**Sensor/Actuator supply [W][2)]**
X20DO2322	0.13	0.33	24.00	12.00
X20DO6322	0.18	0.71	72.00	-
X20DO8332	0.22	-	-[3)]	-
Subtotal		**1.04**	**96.00**	**12.00**
Total	**0.53**		**109.04 (=1.04 + 96.00 + 12.00)**	

1) Rated power at 24 VDC and 100% simultaneity.
2) Rated power at 24 VDC and 0.5 A.
3) The power supply is integrated in the module.

Potential group 3				
Module	**Bus power [W]**	**I/O-internal power [W]**	**I/O-external power [W]**	**Sensor/Actuator supply [W]**
X20AI4622	0.01	1.10	-	-
X20AI4622	0.01	1.10	-	-
X20AT4222	0.01	1.10	-	-
X20AT2402	0.01	0.72	-	-
X20BT9100	0.50	0.10	-	-
Subtotal		**4.12**	-	-
Total	**0.54**		**4.12**	

It is then necessary to perform a power comparison between the power needed by the I/O modules and the power supplied by the power supply modules.

Potential group 1 is supplied by the supply module integrated in the X20BR9300 bus receiver. The total power supplied by the bus, including all bus modules, is 3.34 W (= 1.52 W +1.82 W). The total amount of power that must be provided for the potential group 1 via the 24 VDC I/O supply is 14.58 W.

The power comparison indicates that the power provided by the power supply module integrated in the X20BR9300 is sufficient.

Potential group 1	Bus power [W]	Power 24 VDC I/O supply [W]
X20BR9300	+7.00	+240.00[1)]
Power requirements of I/O modules	-1.52[2)]	-14.58[3)]
Power requirements of all bus modules	-1.82	-
Remaining power	**+3.66**	**+225.42**

1) Rated power at 24 VDC and 10 A.
2) Bus power to be supplied for all I/O modules (i.e. sum of the bus power of all potential groups).
3) 24 VDC I/O supply to be provided for potential group 1.

In potential groups 2 and 3, the 24 VDC I/O supply is fed via the X20PS2100 power supply module. One power supply module is needed for each potential group.

The power comparison indicates that the power provided by the X20PS2100 is sufficient.

Potential group 2		Power 24 VDC I/O supply [W]
X20PS2100		+240.00[1)]
Power requirements of I/O modules		-109.04
Remaining power		**+130.96**

1) Rated power at 24 VDC and 10 A.

Potential group 3		Power 24 VDC I/O supply [W]
X20PS2100		+240.00[1)]
Power requirements of I/O modules		-4.12
Remaining power		**+235.88**

1) Rated power at 24 VDC and 10 A.

3.24 Power supply module power loss

3.24.1 General information

Power supply modules are used to provide power to an X20 system. The power supply modules are either a separate module or part of a CPU or a bus controller.

The power consumed by the power supply modules is passed on to the X20 system, taking into consideration its own power requirements and the effectiveness of the power supplies. The data sheets for the power supply modules list their own power requirements and power loss (as maximum power consumption). With the formulas in the following sections, the exact power consumption can also be calculated. This calculation is explained using an example.

The following image shows where the power supply module uses power for its own requirements. It also shows where the power supply module uses power to supply the system and where power loss occurs.

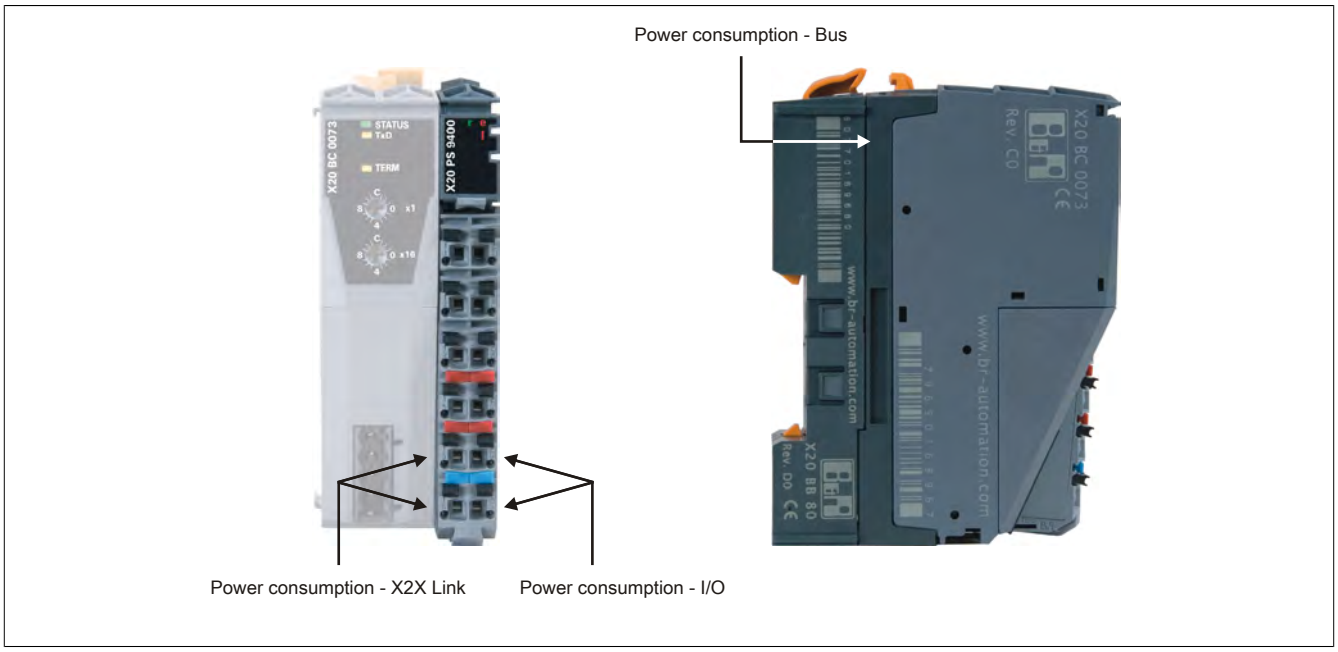

Figure 44: Power supply modules draw power at up to three supply points

3.24.2 Power supply modules without X2X Link supply

Module	Power consumption - Bus [W]	Power consumption - I/O-internal [W]	Power consumption - X67 X2X Link-internal [W]
X20PS2100	0.2	$0.1 + I_{IO}^2 \times 0.005$	-
X20PS2110	0.2	$0.1 + I_{IO}^2 \times 0.02$	-
X20BT9100	0.5	$0.1 + I_{IO}^2 \times 0.005$	-
X20BT9400	0.5	$0.1 + I_{IO}^2 \times 0.005$	$0.5 + 0.11 \times \Sigma X67$

Table 13: Power consumption of power supply modules without X2X Link supply

$I_{I/O}$ ... I/O summation current of all I/O modules supplied by this power supply module
$\Sigma X67$ ... Sum of X67 modules (max. = 8)

3.24.3 Power supply module with X2X Link supply

Module	Power consumption - Bus [W]	Power consumption - I/O-internal [W]	Power consumption - X2X Link-internal [W]
X20PS3300, X20PS9400, X20PS9500, X20CP1483, X20CP1483-1, X20CP158x, X20CP358x	0.2	$0.1 + I_{IO}^2 \times 0.005$	$0.8 + \frac{0.06 \cdot \sum P_{X2X}}{n}$
X20PS3310	0.2	$0.1 + I_{IO}^2 \times 0.02$	$0.8 + \frac{0.06 \cdot \sum P_{X2X}}{n}$
X20BR9300	0.4	$0.1 + I_{IO}^2 \times 0.005$	$0.8 + \frac{0.06 \cdot \sum P_{X2X}}{n}$
X20PS9402, X20PS9502	0.2	$0.1 + I_{IO}^2 \times 0.005$	$0.6 + 0.12 \times \Sigma P_{X2X}$

Table 14: Power consumption of power supply modules with X2X Link supply

ΣP_{X2X} ... Sum of the bus power consumption of all modules in the X20 system (compact CPU, fieldbus CPU, BC, BR, I/O, BM, BT)
n ... Number of all power supply modules in the X20 system with X2X Link supply, including X20BR9300
$I_{I/O}$ ... I/O summation current of all I/O modules supplied by this power supply module

3.24.4 Power supply module for X20 standalone devices

Module	Power consumption [W]
X20PS8002	$0.5 + 0.12 \times P_{Out}$

Table 15: Power consumption of power supply module for X20 standalone devices

P_{Out} ... Sum of power consumption values of all modules (HB) supplied by the power supply module

3.24.5 Potential distribution modules

Module	Power consumption - Bus [W]	Power consumption - I/O [W]
X20PD0011, X20PD0012	0.12	$0.15 + I_{IO}^2 \times 0.02$
X20PD0016, X20PD2113	0.12	$0.28 + I_{IO}^2 \times 0.02$

Table 16: Power consumption of potential distributor modules

$I_{I/O}$ ... PD0011, PD0012, PD0016, PD2113 with internal supply
$I_{I/O}$ corresponds to the sum of all load currents.

PD2113 with external supply (power supply module)
If the X20PD2113 module is being used as a power supply module, then $I_{I/O}$ corresponds to the summation current of all I/O modules supplied by the X20PD2113.

3.24.6 Example

Calculating the total internal power consumption of a BR9300 bus receiver with the following hardware configuration:

Module	Bus power [W]	I/O-internal power [W]
X20DI4371	0.14	0.59
X20DI2371	0.12	0.29
X20DO4322	0.16	0.49
X20DO4322	0.16	0.49
X20BT9100	0.50	0.10
Total	**1.08**	**1.96**

Two power values have to be calculated in order to determine the entire internal power consumption of the bus receiver.

- Internal X2X Link power consumption of the X20BR9300
- Internal I/O power consumption of the X20BR9300

3.24.6.1 Calculating the internal X2X Link power consumption of the X20BR9300

Bus power consumption of all modules in the X20 system

The sum of the bus power consumption from all of the modules in the X20 system is necessary in order to calculate the internal X2X Link power consumption of the X20BR9300.

The sum for the example configuration is calculated using the following formula: The bus module of the X20BR9300 does not have to be taken into account in the calculation. The power consumption of the bus module is already included with a factor of 0.8 (see formula below).

A power consumption of 0.13 W for each bus module must be included in the calculation for the 4 I/O modules and the bus transmitter.

$$\sum P_{X2X} = P_{X2XBus_{BR9300}} + \sum P_{X2XBus_{IOMod}} + \sum P_{X2XBus_{Busmod}} = 0.4 + 1.08 + 5 \cdot 0.13 = 2.13\,W$$

Internal X2X Link power consumption of the X20BR9300

The internal X2X Link power consumption of the X20BR9300 is calculated using the following formula. Since X2X Link is only supplied by the X20BR9300 bus receiver, the factor is n = 1:

$$P_{X2Xint._{BR9300}} = 0.8 + \frac{0.06 \cdot \sum P_{X2X}}{n} = 0.8 + \frac{0.06 \cdot 2.13}{1} = 0.8 + 0.13 = 0.93\,W$$

3.24.6.2 Calculating the internal I/O power consumption of the X20BR9300

The I/O summation current of all I/O modules supplied by the X20BR9300 is needed to calculate the internal I/O power consumption. The I/O summation current is composed of three parts:

- Internal power consumption of the I/O modules
- Sum of the output currents
- Sum of the actuator currents

Internal power consumption of the I/O modules

The current that results from the internal consumption of the I/O modules is calculated according to the following formula:

$$I_{IO_{int.}} = \frac{P_{IO_{int.}}}{V} = \frac{1.96}{24} = 0.082\,A$$

Sum of output and actuator currents

Two X20DO4322 modules are included in the example configuration. The following images show which outputs are wired and how high the output current and actuator current are per channel.

Connections and currents of the first X20DO4322:

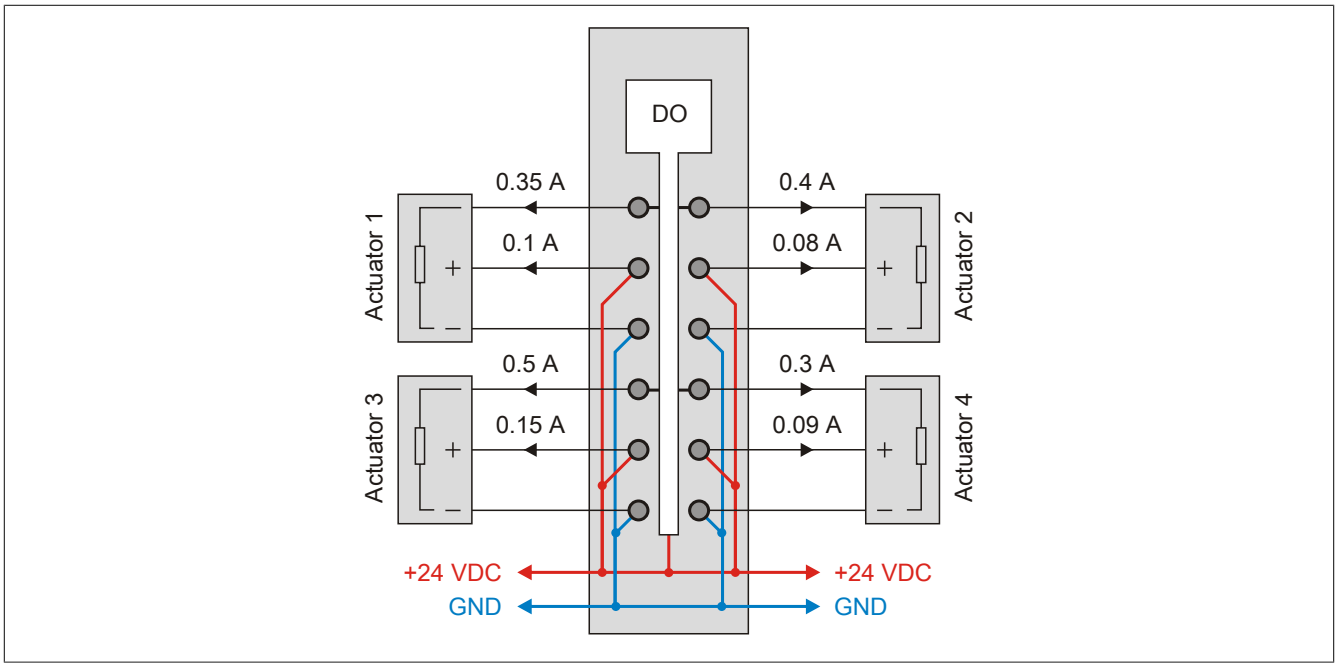

Figure 45: Connections and currents of the first X20DO4322

Connections and currents of the second X20DO4322:

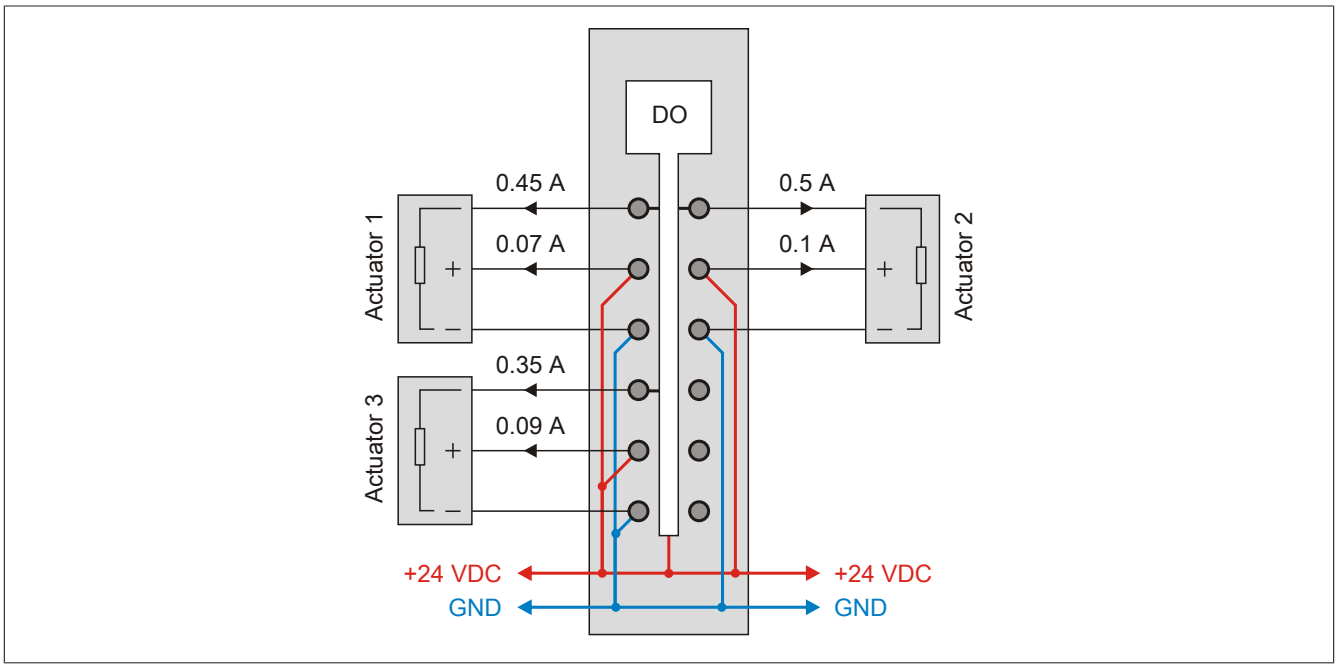

Figure 46: Connections and currents of the second X20DO4322

Calculating the sum of the output currents:

$$I_{DO} = I_{DO_1} + I_{DO_2} = 0.35 + 0.4 + 0.5 + 0.3 + 0.45 + 0.5 + 0.35 = 2.85\,A$$

Calculating the sum of the actuator currents:

$$I_{Actuator} = I_{Actuator_1} + I_{Actuator_2} = 0.1 + 0.08 + 0.15 + 0.09 + 0.07 + 0.1 + 0.09 = 0.68\,A$$

Calculating the I/O summation current

The I/O summation current is calculated from the sum of all three partial currents.

$$I_{IO} = I_{IO_{int.}} + I_{DO} + I_{Actuator} = 0.082 + 2.85 + 0.68 = 3.612\,A$$

Calculating the internal I/O power consumption of the X20BR9300

The internal I/O power consumption is calculated using the following formula:

$$P_{IOint._{BR9300}} = 0.1 + I_{IO}^2 \cdot 0.005 = 0.1 + 3.612^2 \cdot 0.005 = 0.17\,W$$

3.24.6.3 Total internal power consumption of the X20BR9300

The following 3 power values must be added together to calculate the total internal power of the X20BR9300:

- Power consumption - Bus
- Power consumption - I/O-internal
- Power consumption - X2X Link-internal

$$P_{BR9300int._{tot.}} = P_{X2XBus_{BR9300}} + P_{IOint._{BR9300}} + P_{X2Xint._{BR9300}} = 0.4 + 0.17 + 0.93 = 1.5\,W$$

Connections and currents of the second X20DO4322:

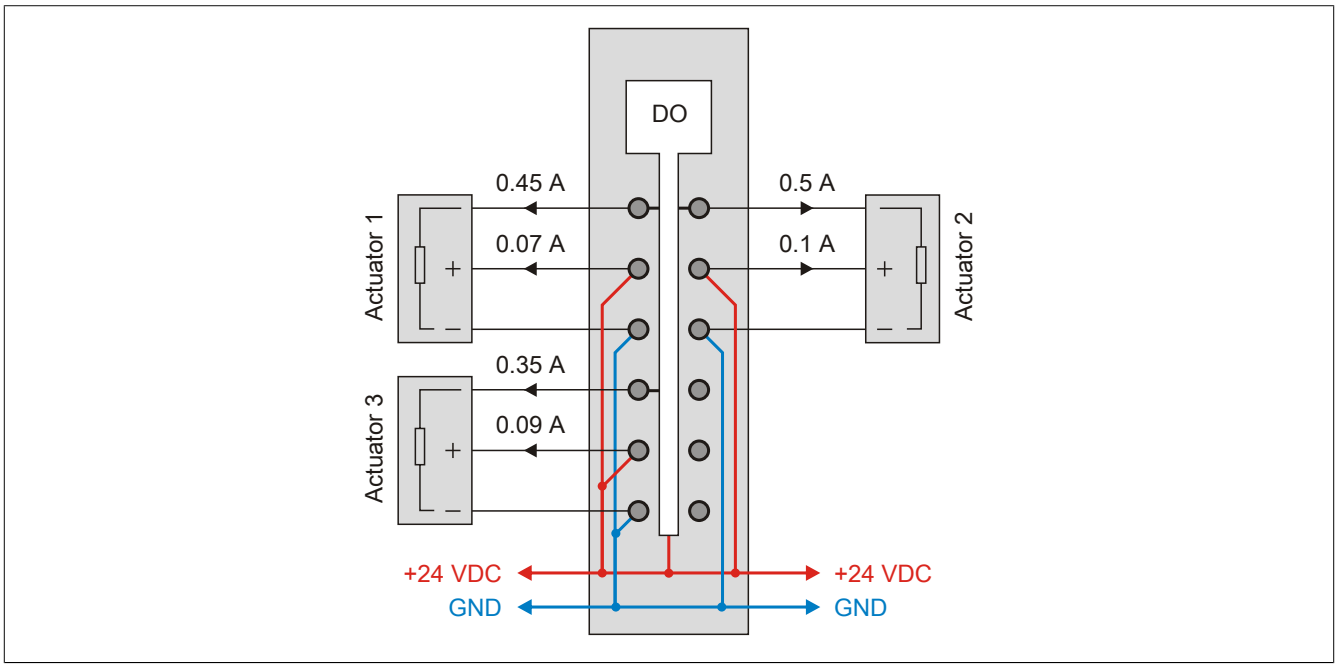

Figure 47: Connections and currents of the second X20DO4322

Calculating the sum of the output currents:

$$I_{DO} = I_{DO_1} + I_{DO_2} = 0.35 + 0.4 + 0.5 + 0.3 + 0.45 + 0.5 + 0.35 = 2.85\,A$$

Calculating the sum of the actuator currents:

$$I_{Actuator} = I_{Actuator_1} + I_{Actuator_2} = 0.1 + 0.08 + 0.15 + 0.09 + 0.07 + 0.1 + 0.09 = 0.68\,A$$

Calculating the I/O summation current

The I/O summation current is calculated from the sum of all three partial currents.

$$I_{IO} = I_{IO_{int.}} + I_{DO} + I_{Actuator} = 0.058 + 2.85 + 0.68 = 3.588\,A$$

Calculating the internal I/O power consumption of the X20BR9300

The internal I/O power consumption is calculated using the following formula:

$$P_{IO_{BR9300}} = 0.1 + I_{IO}^2 \cdot 0.005 = 0.1 + 3.588^2 \cdot 0.005 = 0.16\,W$$

4 X20 system modules

4.1 Module overview: Alphabetically

Order data	Short description
X20AI1744	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 kHz input filter
X20AI1744-3	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 Hz input filter
X20AI2222	X20 analog input module, 2 inputs, ±10 V, 13-bit converter resolution, configurable input filter
X20AI2237	X20 analog input module, 2 inputs, ±10 V, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply
X20AI2322	X20 analog input module, 2 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter
X20AI2437	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply
X20AI2438	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports HART protocol
X20AI2622	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20AI2632	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI2632-1	X20 analog input module, 2 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter
X20AI2636	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions
X20AI4222	X20 analog input module, 4 inputs, ±10 V, 13-bit converter resolution, configurable input filter
X20AI4322	X20 analog input module, 4 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter
X20AI4622	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20AI4632	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI4632-1	X20 analog input module, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI4636	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions
X20AI8221	X20 analog input module, 8 inputs, ±10 V, 13-bit converter resolution
X20AI8321	X20 analog input module, 8 inputs, 0 to 20 mA, 12-bit converter resolution
X20AIA744	X20 analog input module, 2 full-bridge strain gauge inputs, 24-bit converter resolution, 2.5 kHz input filter
X20AIB744	X20 analog input module, 4 full-bridge strain gauge inputs, 24-bit converter resolution, 2.5 kHz input filter
X20AO2437	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated
X20AO2438	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol
X20AO2622	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20AO2632	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20AO2632-1	X20 analog output module, 2 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution
X20AO4622	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20AO4632	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20AO4632-1	X20 analog output module, 4 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution
X20AO4635	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, low temperature drift
X20AP3111	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 20 mA AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3121	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 1 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3131	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 5 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3161	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 333 mV AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AT2222	X20 temperature input module, 2 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20AT2311	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.001°C, 4-wire connections
X20AT2402	X20 temperature input module, 2 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C
X20AT4222	X20 temperature input module, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20AT6402	X20 temperature input module, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C
X20ATA312	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.01 °C, 4-wire connections
X20ATA492	X20 temperature input module, 2 thermocouple inputs, type J, K, N, S, B, R, E, C, T, single channel electrically isolated, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately
X20ATB312	X20 temperature input module, 4 inputs for resistance measurement, PT100, resolution 0.01 °C, 4-wire connections
X20ATC402	X20 temperature input module, 6 thermocouple inputs, type J, K, N, S, B, R, E, C, T, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately
X20BB22	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB27	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB32	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, Slot for X20 interface module, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB37	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, Slot for X20 interface module, X20 connection, X20 locking plates X20AC0SL1/X20AC0SR1 (left and right) included
X20BB42	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB47	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included

Order data	Short description
X20BB80	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20BB81	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB82	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BC0043	X20 bus controller, 1 CANopen interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0043-10	X20 bus controller, 1 CANopen interface, FieldbusDESIGNER supported, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0053	X20 bus controller, 1 DeviceNet interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0063	X20 bus controller, 1 PROFIBUS DP interface, 9-pin DSUB connection, order bus base, power supply module and terminal block separately
X20BC0073	X20 bus controller, 1 CAN I/O interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC0087	X20 bus controller, 1 Modbus TCP or Modbus UDP interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC0088	X20 bus controller, 1 EtherNet/IP interface, integrated switch, web interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20BC00E3	X20 bus controller, 1 PROFINET RT interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC00G3	X20 bus controller, 1 EtherCAT interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20BC0143-10	X20 bus controller, 1 CANopen interface, 9-pin DSUB, FieldbusDESIGNER supported, order 1x 7AC911.9 terminal block separately Order bus base, power supply module and terminal separately
X20BC1083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC8083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC8084	X20 bus controller, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC80G3	X20 bus controller, 1 EtherNet/IP interface, supports expansion with X20 EtherCAT junction modules, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BM01	X20 power supply bus module, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM05	X20 power supply bus module, with node number switch, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous
X20BM12	X20 bus module, 240 VDC keyed, internal I/O supply continuous
X20BM15	X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous
X20BM21	X20 power supply bus module, for double-width modules, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM31	X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous
X20BM32	X20 bus module for double-width modules, 240 VAC keyed, internal I/O supply continuous
X20BR9300	X20 bus receiver, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BT9100	X20 bus transmitter, X2X Link, supply for internal I/O supply
X20BT9400	X20 bus transmitter X2X Link, feed for internal I/O supply, X2X Link supply for X67 modules, reverse polarity protection, short circuit protection, overload protection, parallel connection possible, redundancy operation possible
X20CM0985	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately.
X20CM0985-1	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay 1 A, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, additional software functions, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20CM1941	X20 resolver module, 14-bit resolver input, converter up to 12-bit ABR output
X20CM4810	X20 analog input module for vibration measurement and analysis for condition monitoring, 4 IEPE analog inputs, 51.5625 kHz sampling frequency, 24-bit converter resolution
X20CM6209	X20 diode array module, 1 A, 40 V reverse voltage, no module status data
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection
X20CP1301	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 1 GB flash drive onboard, 1 insert slot for X20 interface modules, 1 USB interface, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including power supply module, 3x X20TB1F terminal blocks, slot cover and X20 locking plate X20AC0SR1 (right) included
X20CP1381	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included

Order data	Short description
X20CP1381-RT	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, reACTION technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1382	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1382-RT	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 2 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, reACTION technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP0201	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, order bus base, power supply module and terminal block separately
X20CP0291	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately
X20CP0292	X20 compact CPU, µP 25, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 3 Ethernet interface 750 Base-T, order bus base, power supply module and terminal block separately
X20CP1483	X20 CPU, x86 100 MHz Intel compatible, 32 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1483-1	X20 CPU, x86 100 MHz Intel compatible, 64 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1584	X20 CPU, ATOM 0.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1585	X20 CPU, ATOM 1.0 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3584	X20 CPU, ATOM 0.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CP3585	X20 CPU, ATOM 1.0 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CP3586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CS1011	X20 interface module, 1 Moeller SmartWire interface
X20CS1012	X20 interface module, 1 M-Bus master interface, integrated slave supply
X20CS1013	X20 interface module, 1 DALI master interface
X20CS1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s
X20CS1030	X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s
X20CS1070	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, object buffers in both send and receive directions
X20CS2770	X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, object buffers in both send and receive directions
X20DC1073	X20 digital counter module, 1x SinCos, 1 Vss, 400 kHz input frequency, encoder monitoring, NetTime module
X20DC1176	X20 digital counter module, 1 ABR incremental encoder, 5 V 600 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1178	X20 digital counter module, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit, encoder monitoring, NetTime module
X20DC1196	X20 digital counter module, 1 ABR incremental encoders, 5 V, 600 kHz input frequency, 4x evaluation
X20DC1198	X20 digital counter module, 1 SSI absolute encoder, 5 V, 1 Mbit/s, 32-bit
X20DC11A6	X20 digital counter module, 1 ABR incremental encoder, 5 V 5 MHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1376	X20 digital counter module, 1 ABR incremental encoder, 24 V 100 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC137A	X20 digital counter module, 1x ABR incremental encoder, 24 V (differential), 300 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1396	X20 digital counter module, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20DC1398	X20 digital counter module, 1 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit
X20DC1976	X20 digital counter module, 1x ABR incremental encoder, 5 V (single ended), 250 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC2190	X20 digital counter module, ultrasonic transducer module, interfaces: EP start/stop, DPI/IP, 2 transducer rods, 4 path evaluation
X20DC2395	X20 digital counter module, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function

Order data	Short description
X20DC2396	X20 digital counter module, 2 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20DC2398	X20 digital counter module, 2 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit
X20DC4395	X20 digital counter module, 2 SSI absolute encoder, 24 V, 2 ABR incremental encoder, 24 V, 4 AB incremental encoders, 24 V, 8 event counters or 4 PWM, local time measurement function
X20DI0471	X20 digital input module, 10 inputs, 48 VDC, sink, configurable input filter, 1-wire connections
X20DI2371	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20DI2372	X20 digital input module, 2 inputs, 24 VDC, source, configurable input filter, 3-wire connections
X20DI2377	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 2 event counters 50 kHz, 3-wire connections
X20DI2653	X20 digital input module, 2 inputs, 100 to 240 VAC, 240 V keyed, 3-wire connections
X20DI4371	X20 digital input module, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20DI4372	X20 digital input module, 4 inputs, 24 VDC, source, configurable input filter, 3-wire connections
X20DI4375	X20 digital input module, 4 inputs, 24 VDC, sink, configurable input filter, open line and short circuit detection, 3-wire connections
X20DI4653	X20 digital input module, 4 inputs, 100 to 240 VAC, 240 V keyed, 2-wire connections
X20DI4760	X20 digital input module, 4 NAMUR inputs, 8.05 V
X20DI6371	X20 digital input module, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20DI6372	X20 digital input module, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections
X20DI6373	X20 digital input module, 6 inputs, 24 VDC, sink/source, all inputs floating, configurable input filter, 2-wire connections
X20DI6553	X20 digital input module, 6 inputs, 100 to 120 VAC, 240 V keyed, 1-wire connections
X20DI8371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DI9371	X20 digital input module, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DI9372	X20 digital input module, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections
X20DID371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20DIF371	X20 digital input module, 16 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DM9324	X20 digital mixed module, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source 1-wire connections
X20DO2321	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, sink, 3-wire connections
X20DO2322	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20DO2623	X20 digital output module, 2 outputs, 100-240 VAC, 1 A, source, 240 V keyed, 3-wire connections
X20DO2633	X20 digital output module, 2 triac outputs, 12 to 240 VAC, 2 A, L switching, phase angle control, 240 V keyed
X20DO2649	X20 digital output module, 2 relays, changeover contacts, 240 VAC / 5 A, 24 VDC / 5 A
X20DO4321	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, sink, 3-wire connections
X20DO4322	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20DO4331	X20 digital output module, 4 outputs, 24 VDC, 2 A, sink, 3-wire connections
X20DO4332	X20 digital output module, 4 outputs, 24 VDC, 2 A, source, 3-wire connections
X20DO4529	X20 digital output module, 4 relays, changeover contacts, 115 VAC / 0.5 A, 24 VDC / 1 A
X20DO4613	X20 digital output module, 4 triac coupler outputs, 12 to 240 VAC, 50 mA, zero-crossing detection, 240 V keyed,...
X20DO4623	X20 digital output module, 4 outputs, 100-240 VAC, 0.5 A, source, 240 V keyed, 2-wire connections
X20DO4633	X20 digital output module, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed
X20DO4649	X20 digital output module, 4 relays, N.O. contacts, 240 VAC / 5 A
X20DO6321	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections
X20DO6322	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20DO6325	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, open line and overload detection, 2-wire connections
X20DO6529	X20 digital output module, 6 relays, normally open contacts, 115 VAC / 0.5 A, 30 VDC / 1 A
X20DO6639	X20 digital output module, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A
X20DO8232	X20 digital output module, 8 outputs, 12 VDC, 2 A, source, supply directly on module, 1-wire connections
X20DO8322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DO8323	X20 digital output module, 8 outputs, 12 to 24 V, 0.5 A, sink/source, 1-wire connections, full bridge, half bridge, thermal overload protection
X20DO8331	X20 digital output module, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections
X20DO8332	X20 digital output module, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections
X20DO9321	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections
X20DO9322	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DOD322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20DOF322	X20 digital output module, 16 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module
X20DS1828	X20 digital signal module, 1 HIPERFACE interface, NetTime module
X20DS1928	X20 digital signal module, 1 EnDat 2.1/2.2 interface, NetTime module
X20DS4387	X20 digital signal module, 4x IO-Link master, 4 digital channels configurable as inputs or outputs, 3-wire connections
X20DS4389	X20 digital signal module, 4 digital inputs, 24 VDC, 4 digital outputs, 24 VDC, 0.1 A, oversampling I/O functions, time-triggered I/O functions, NetTime module
X20DS438A	X20 digital signal module, 4x I/O-Link master V1.1, can also be configured as 4x digital input or output channels, 3-wire connections
X20ET8819	X20 Ethernet analysis tool, can be expanded with active hub modules, 2x RJ45
X20HB1881	X20 hub expansion module, integrated 1-port hub, for fiber optic cable
X20HB2880	X20 hub expansion module, integrated 2-port hub, 2x RJ45
X20HB2881	X20 hub expansion module, integrated 2-port hub, for fiber optic cable
X20HB2885	X20 hub expansion module, integrated active 2-port hub, 2x RJ45
X20HB2886	X20 hub expansion module, integrated active 2-port hub, 2 fiber optic interfaces
X20HB28G0	X20 EtherCAT junction module, integrated 2-port EtherCAT junction, 2x RJ45
X20HB8815	X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45
X20HB8880	X20 base hub module, integrated 2-port hub, 2x RJ45
X20HB8884	X20 compact link selector, 2x RJ45, order bus base, power supply module and terminal block separately.

Order data	Short description
X20HB88G0	X20 EtherCAT junction (basic module), integrated 2-port EtherCAT junction, 2x RJ45
X20IF0000	X20 dummy interface module (non-functional)
X20IF1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s, electrically isolated
X20IF1030	X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated
X20IF1041-1	X20 interface module, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1043-1	X20 interface module, for DTM configuration, 1 CANopen slave interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1051-1	X20 interface module, for DTM configuration, 1 DeviceNet scanner (master) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1053-1	X20 interface module, for DTM configuration, 1 DeviceNet adapter (slave) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1061	X20 interface module, 1 PROFIBUS DP V0/V1 master interface, max. 12 Mbit/s, max. 3.5 kB input data and max. 3.5 kB output data, electrically isolated
X20IF1061-1	X20 interface module for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated
X20IF1063	X20 interface module, 1 PROFIBUS DP V0 slave interface, max. 12 Mbit/s, electrically isolated
X20IF1063-1	X20 interface module, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20IF1065	X20 interface module, 1 PROFIBUS DP V1 slave interface, max. 12 Mbit/s, electrically isolated
X20IF1072	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20IF1074	X20 interface module, for SGC, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20IF1082	X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function
X20IF1082-2	X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function
X20IF1086-2	X20 interface module, 1 POWERLINK interface, managing or controlled node, PRC function, 1 fiber optic connection
X20IF1091	X20 interface module, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF1091-1	X20 interface module, for expandable bus controller, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10A1-1	X20 interface module, for DTM configuration, 1 ASi master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10D1-1	X20 interface module, for DTM configuration, 1 EtherNet/IP scanner (master) interface, electrically isolated
X20IF10D3-1	X20 interface module, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20IF10E1-1	X20 interface module for DTM configuration, 1 PROFINET RT controller (master) interface, electrically isolated
X20IF10E3-1	X20 interface module, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20IF10G3-1	X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated
X20IF10X0	X20 interface module, 1 redundancy link interface 1000BASE-SX, CPU-CPU data synchronization module for controller redundancy
X20IF2181-2	X20 interface module, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45
X20IF2772	X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, electrically isolated, order 2x TB2105 terminal block separately
X20IF2792	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, 1 X2X Link master interface, electrically isolated, order 1x TB2105 and 1x TB704 terminal block separately
X20MM2436	X20 PWM motor module, 24 to 39 VDC ±25%, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder
X20MM3332	X20 digital motor module, 24 VDC, 3 digital outputs, full bridge (H bridge), 3 A continuous current, 5 A peak current
X20MM4331	X20 digital motor module, 24 VDC, 4 digital outputs, half bridge, 3 A continuous current, 5 A peak current
X20MM4456	X20 PWM motor module, 24 to 48 VDC ±25%, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 4 digital inputs 24 VDC, sink, configurable as incremental encoder
X20PD0011	X20 potential distributor module, 12x GND, integrated microfuse
X20PD0012	X20 potential distributor module, 12x 24 VDC, integrated microfuse
X20PD0016	X20 potential distributor module, 5x GND, 5x 24 VDC, each with 1x floating feed, integrated microfuse
X20PD2113	X20 potential distributor module, 6x GND, 6x 24 VDC, with feed option, integrated microfuse
X20PS2100	X20 power supply module, for internal I/O supply
X20PS2110	X20 supply module, for internal I/O supply, integrated microfuse
X20PS3300	X20 power supply module, for X2X Link and internal I/O supply
X20PS3310	X20 power supply module, for X2X Link and internal I/O supply, integrated microfuse
X20PS4951	X20 power supply module, for potentiometers, 4x ±10 V for potentiometer supply
X20PS8002	X20 power supply module for standalone hub and compact link selector
X20PS9400	X20 power supply module, for bus controller and internal I/O supply, X2X Link supply
X20PS9402	X20 supply module, for bus controller and internal I/O supply, X2X Link supply, supply not electrically isolated
X20PS9500	X20 supply module for compact and fieldbus CPUs and internal I/O supply, X2X Link supply
X20PS9502	X20 supply module, for compact and fieldbus CPUs and internal I/O supply, X2X Link supply, supply not electrically isolated
X20RT8001	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, reACTION technology module
X20RT8201	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, 2 analog inputs ±10 V, 500 kHz sampling frequency, 13-bit converter resolution (including sign), configurable input filter, reACTION technology module
X20SM1426	X20 stepper motor module, 1 motor connection, 1 A continuous current, 1.2 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder
X20SM1436	X20 stepper motor module, module supply 24-39 VDC ±25%, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder
X20TB06	X20 terminal block, 6-pin, 24 VDC keyed
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed
X20TB1E	X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation
X20TB1F	X20 terminal block, 16-pin, 24 VDC keyed
X20TB32	X20 terminal block, 12-pin, 240 VAC keyed
X20XC0201	X20 fieldbus CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately

Order data	Short description
X20XC0202	X20 fieldbus CPU, µP 25, 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately
X20XC0292	X20 fieldbus CPU, µP 25 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module, according to fieldbus CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately
X20ZF0000	Dummy X20 module (non-functional)
X20ZF000F	Dummy X20 module (non-functional)

4.2 Module overview: Grouped

4.2.1 CPUs

Standard CPU

Order data	Short description
X20CP1301	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 1 GB flash drive onboard, 1 insert slot for X20 interface modules, 1 USB interface, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including power supply module, 3x X20TB1F terminal blocks, slot cover and X20 locking plate X20AC0SR1 (right) included
X20CP1381	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1382	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1483	X20 CPU, x86 100 MHz Intel compatible, 32 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1483-1	X20 CPU, x86 100 MHz Intel compatible, 64 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1584	X20 CPU, ATOM 0.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1585	X20 CPU, ATOM 1.0 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP1586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20CP3584	X20 CPU, ATOM 0.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CP3585	X20 CPU, ATOM 1.0 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.
X20CP3586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.

Compact CPU

Order data	Short description
X20CP0201	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, order bus base, power supply module and terminal block separately
X20CP0291	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately
X20CP0292	X20 compact CPU, µP 25, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 3 Ethernet interface 750 Base-T, order bus base, power supply module and terminal block separately

Fieldbus CPU

Order data	Short description
X20XC0201	X20 fieldbus CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately
X20XC0202	X20 fieldbus CPU, µP 25, 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module according to fieldbus CPU base, order power supply module, bus base and terminal block separately
X20XC0292	X20 fieldbus CPU, µP 25 750 kB SRAM, 3 MB FlashPROM, support of RS232, CAN bus and interface module, according to fieldbus CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately

reACTION Technology CPU

Order data	Short description
X20CP1381-RT	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, reACTION technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1382-RT	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 2 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, reACTION technology, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included

4.2.2 Module overview: Grouped

Analog inputs

Order data	Short description
X20AI1744	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 kHz input filter
X20AI1744-3	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 Hz input filter
X20AI2222	X20 analog input module, 2 inputs, ±10 V, 13-bit converter resolution, configurable input filter
X20AI2237	X20 analog input module, 2 inputs, ±10 V, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply
X20AI2322	X20 analog input module, 2 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter
X20AI2437	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply
X20AI2438	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports HART protocol
X20AI2622	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20AI2632	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI2632-1	X20 analog input module, 2 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter
X20AI2636	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions
X20AI4222	X20 analog input module, 4 inputs, ±10 V, 13-bit converter resolution, configurable input filter
X20AI4322	X20 analog input module, 4 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter
X20AI4622	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20AI4632	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI4632-1	X20 analog input module, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20AI4636	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions
X20AI8221	X20 analog input module, 8 inputs, ±10 V, 13-bit converter resolution
X20AI8321	X20 analog input module, 8 inputs, 0 to 20 mA, 12-bit converter resolution
X20AIA744	X20 analog input module, 2 full-bridge strain gauge inputs, 24-bit converter resolution, 2.5 kHz input filter
X20AIB744	X20 analog input module, 4 full-bridge strain gauge inputs, 24-bit converter resolution, 2.5 kHz input filter
X20AP3111	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 20 mA AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3121	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 1 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3131	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 5 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20AP3161	X20 energy metering module, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 333 mV AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement

Analog outputs

Order data	Short description
X20AO2437	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated
X20AO2438	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol
X20AO2622	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20AO2632	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20AO2632-1	X20 analog output module, 2 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution
X20AO4622	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20AO4632	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20AO4632-1	X20 analog output module, 4 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution
X20AO4635	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, low temperature drift
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement

Bus controllers

Order data	Short description
X20BC0043	X20 bus controller, 1 CANopen interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0043-10	X20 bus controller, 1 CANopen interface, FieldbusDESIGNER supported, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0053	X20 bus controller, 1 DeviceNet interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0063	X20 bus controller, 1 PROFIBUS DP interface, 9-pin DSUB connection, order bus base, power supply module and terminal block separately
X20BC0073	X20 bus controller, 1 CAN I/O interface, order 1x TB2105 terminal block separately Order bus base, power supply module and terminal separately
X20BC0083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC0087	X20 bus controller, 1 Modbus TCP or Modbus UDP interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC0088	X20 bus controller, 1 EtherNet/IP interface, integrated switch, web interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20BC00E3	X20 bus controller, 1 PROFINET RT interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately.
X20BC00G3	X20 bus controller, 1 EtherCAT interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20BC0143-10	X20 bus controller, 1 CANopen interface, 9-pin DSUB, FieldbusDESIGNER supported, order 1x 7AC911.9 terminal block separately Order bus base, power supply module and terminal separately

Bus modules

Order data	Short description
X20BM01	X20 power supply bus module, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM05	X20 power supply bus module, with node number switch, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous
X20BM12	X20 bus module, 240 VDC keyed, internal I/O supply continuous
X20BM15	X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous
X20BM21	X20 power supply bus module, for double-width modules, 24 VDC keyed, internal I/O supply interrupted to the left
X20BM31	X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous
X20BM32	X20 bus module for double-width modules, 240 VAC keyed, internal I/O supply continuous

Bus receivers and transmitters

Order data	Short description
X20BR9300	X20 bus receiver, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BT9100	X20 bus transmitter, X2X Link, supply for internal I/O supply
X20BT9400	X20 bus transmitter X2X Link, feed for internal I/O supply, X2X Link supply for X67 modules, reverse polarity protection, short circuit protection, overload protection, parallel connection possible, redundancy operation possible

Counter functions

Order data	Short description
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20CM1941	X20 resolver module, 14-bit resolver input, converter up to 12-bit ABR output
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20DC1073	X20 digital counter module, 1x SinCos, 1 Vss, 400 kHz input frequency, encoder monitoring, NetTime module
X20DC1176	X20 digital counter module, 1 ABR incremental encoder, 5 V 600 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1178	X20 digital counter module, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit, encoder monitoring, NetTime module
X20DC1196	X20 digital counter module, 1 ABR incremental encoders, 5 V, 600 kHz input frequency, 4x evaluation
X20DC1198	X20 digital counter module, 1 SSI absolute encoder, 5 V, 1 Mbit/s, 32-bit
X20DC11A6	X20 digital counter module, 1 ABR incremental encoder, 5 V 5 MHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1376	X20 digital counter module, 1 ABR incremental encoder, 24 V 100 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1396	X20 digital counter module, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20DC137A	X20 digital counter module, 1x ABR incremental encoder, 24 V (differential), 300 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC1398	X20 digital counter module, 1 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit
X20DC1976	X20 digital counter module, 1x ABR incremental encoder, 5 V (single ended), 250 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module
X20DC2190	X20 digital counter module, ultrasonic transducer module, interfaces: EP start/stop, DPI/IP, 2 transducer rods, 4 path evaluation
X20DC2395	X20 digital counter module, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function
X20DC2396	X20 digital counter module, 2 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20DC2398	X20 digital counter module, 2 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit
X20DC4395	X20 digital counter module, 2 SSI absolute encoder, 24 V, 2 ABR incremental encoder, 24 V, 4 AB incremental encoders, 24 V, 8 event counters or 4 PWM, local time measurement function

Digital inputs

Order data	Short description
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20DI0471	X20 digital input module, 10 inputs, 48 VDC, sink, configurable input filter, 1-wire connections
X20DI2371	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20DI2372	X20 digital input module, 2 inputs, 24 VDC, source, configurable input filter, 3-wire connections
X20DI2377	X20 digital input module, 2 inputs, 24 VDC, sink, configurable input filter, 2 event counters 50 kHz, 3-wire connections
X20DI2653	X20 digital input module, 2 inputs, 100 to 240 VAC, 240 V keyed, 3-wire connections
X20DI4371	X20 digital input module, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20DI4372	X20 digital input module, 4 inputs, 24 VDC, source, configurable input filter, 3-wire connections
X20DI4375	X20 digital input module, 4 inputs, 24 VDC, sink, configurable input filter, open line and short circuit detection, 3-wire connections
X20DI4653	X20 digital input module, 4 inputs, 100 to 240 VAC, 240 V keyed, 2-wire connections
X20DI4760	X20 digital input module, 4 NAMUR inputs, 8.05 V
X20DI6371	X20 digital input module, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20DI6372	X20 digital input module, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections
X20DI6373	X20 digital input module, 6 inputs, 24 VDC, sink/source, all inputs floating, configurable input filter, 2-wire connections
X20DI6553	X20 digital input module, 6 inputs, 100 to 120 VAC, 240 V keyed, 1-wire connections
X20DI8371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DI9371	X20 digital input module, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DI9372	X20 digital input module, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections
X20DID371	X20 digital input module, 8 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20DIF371	X20 digital input module, 16 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20DM9324	X20 digital mixed module, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source 1-wire connections
X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module
X20RT8001	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, reACTION technology module
X20RT8201	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, 2 analog inputs ±10 V, 500 kHz sampling frequency, 13-bit converter resolution (including sign), configurable input filter, reACTION technology module

Digital inputs/outputs

Order data	Short description
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20DM9324	X20 digital mixed module, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source 1-wire connections
X20RT8001	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, reACTION technology module
X20RT8201	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, 2 analog inputs ±10 V, 500 kHz sampling frequency, 13-bit converter resolution (including sign), configurable input filter, reACTION technology module

Digital outputs

Order data	Short description
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection
X20DM9324	X20 digital mixed module, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source 1-wire connections
X20DO2321	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, sink, 3-wire connections
X20DO2322	X20 digital output module, 2 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20DO2623	X20 digital output module, 2 outputs, 100-240 VAC, 1 A, source, 240 V keyed, 3-wire connections
X20DO2633	X20 digital output module, 2 triac outputs, 12 to 240 VAC, 2 A, L switching, phase angle control, 240 V keyed
X20DO2649	X20 digital output module, 2 relays, changeover contacts, 240 VAC / 5 A, 24 VDC / 5 A
X20DO4321	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, sink, 3-wire connections
X20DO4322	X20 digital output module, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20DO4331	X20 digital output module, 4 outputs, 24 VDC, 2 A, sink, 3-wire connections
X20DO4332	X20 digital output module, 4 outputs, 24 VDC, 2 A, source, 3-wire connections
X20DO4529	X20 digital output module, 4 relays, changeover contacts, 115 VAC / 0.5 A, 24 VDC / 1 A
X20DO4613	X20 digital output module, 4 triac coupler outputs, 12 to 240 VAC, 50 mA, zero-crossing detection, 240 V keyed,...
X20DO4623	X20 digital output module, 4 outputs, 100-240 VAC, 0.5 A, source, 240 V keyed, 2-wire connections
X20DO4633	X20 digital output module, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed
X20DO4649	X20 digital output module, 4 relays, N.O. contacts, 240 VAC / 5 A
X20DO6321	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections
X20DO6322	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20DO6325	X20 digital output module, 6 outputs, 24 VDC, 0.5 A, source, open line and overload detection, 2-wire connections
X20DO6529	X20 digital output module, 6 relays, normally open contacts, 115 VAC / 0.5 A, 30 VDC / 1 A
X20DO6639	X20 digital output module, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A
X20DO8232	X20 digital output module, 8 outputs, 12 VDC, 2 A, source, supply directly on module, 1-wire connections
X20DO8322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DO8323	X20 digital output module, 8 outputs, 12 to 24 V, 0.5 A, sink/source, 1-wire connections, full bridge, half bridge, thermal overload protection
X20DO8331	X20 digital output module, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections
X20DO8332	X20 digital output module, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections
X20DO9321	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections
X20DO9322	X20 digital output module, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DOD322	X20 digital output module, 8 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20DOF322	X20 digital output module, 16 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module
X20RT8001	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, reACTION technology module
X20RT8201	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, 2 analog inputs ±10 V, 500 kHz sampling frequency, 13-bit converter resolution (including sign), configurable input filter, reACTION technology module

Digital signal processing and preparation

Order data	Short description
X20CM1201	X20 combination module, 1 AB incremental encoder, 24 V, 4 digital inputs 24 V, 4 channels 24 V configurable as inputs or outputs, flexible digital controller logic
X20DC1073	X20 digital counter module, 1x SinCos, 1 Vss, 400 kHz input frequency, encoder monitoring, NetTime module
X20DS1119	X20 multifunctional digital signal processor, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module
X20DS1319	X20 multifunctional digital signal processor, 4 digital input channels, 4 digital channels configurable as inputs or outputs, 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 2 reference pulses, SSI absolute encoder, NetTime module
X20DS1828	X20 digital signal module, 1 HIPERFACE interface, NetTime module
X20DS1928	X20 digital signal module, 1 EnDat 2.1/2.2 interface, NetTime module
X20DS4389	X20 digital signal module, 4 digital inputs, 24 VDC, 4 digital outputs, 24 VDC, 0.1 A, oversampling I/O functions, time-triggered I/O functions, NetTime module

Dummy modules

Order data	Short description
X20IF0000	X20 dummy interface module (non-functional)
X20ZF0000	Dummy X20 module (non-functional)
X20ZF000F	Dummy X20 module (non-functional)

Electronics module communication

Order data	Short description
X20CS1011	X20 interface module, 1 Moeller SmartWire interface
X20CS1012	X20 interface module, 1 M-Bus master interface, integrated slave supply
X20CS1013	X20 interface module, 1 DALI master interface
X20CS1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s
X20CS1030	X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s
X20CS1070	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, object buffers in both send and receive directions
X20CS2770	X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, object buffers in both send and receive directions

Expandable bus controllers

Order data	Short description
X20BC1083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC8083	X20 bus controller, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC8084	X20 bus controller, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20BC80G3	X20 bus controller, 1 EtherNet/IP interface, supports expansion with X20 EtherCAT junction modules, 2x RJ45, order bus base, power supply module and terminal block separately.

Hub system

Order data	Short description
X20ET8819	X20 Ethernet analysis tool, can be expanded with active hub modules, 2x RJ45
X20HB8815	X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45
X20HB8880	X20 base hub module, integrated 2-port hub, 2x RJ45
X20HB88G0	X20 EtherCAT junction (basic module), integrated 2-port EtherCAT junction, 2x RJ45

Interface module communication

Order data	Short description
X20IF1020	X20 interface module, 1 RS232 interface, max. 115.2 kbit/s, electrically isolated
X20IF1030	X20 interface module, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated
X20IF1041-1	X20 interface module, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1043-1	X20 interface module, for DTM configuration, 1 CANopen slave interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1051-1	X20 interface module, for DTM configuration, 1 DeviceNet scanner (master) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1053-1	X20 interface module, for DTM configuration, 1 DeviceNet adapter (slave) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1061	X20 interface module, 1 PROFIBUS DP V0/V1 master interface, max. 12 Mbit/s, max. 3.5 kB input data and max. 3.5 kB output data, electrically isolated
X20IF1061-1	X20 interface module for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated
X20IF1063	X20 interface module, 1 PROFIBUS DP V0 slave interface, max. 12 Mbit/s, electrically isolated
X20IF1063-1	X20 interface module, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20IF1065	X20 interface module, 1 PROFIBUS DP V1 slave interface, max. 12 Mbit/s, electrically isolated
X20IF1072	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20IF1082	X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function
X20IF1082-2	X20 interface module, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function
X20IF1086-2	X20 interface module, 1 POWERLINK interface, managing or controlled node, PRC function, 1 fiber optic connection
X20IF1091	X20 interface module, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10A1-1	X20 interface module, for DTM configuration, 1 ASi master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10D1-1	X20 interface module, for DTM configuration, 1 EtherNet/IP scanner (master) interface, electrically isolated
X20IF10D3-1	X20 interface module, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20IF10E1-1	X20 interface module for DTM configuration, 1 PROFINET RT controller (master) interface, electrically isolated
X20IF10E3-1	X20 interface module, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20IF10G3-1	X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated
X20IF10X0	X20 interface module, 1 redundancy link interface 1000BASE-SX, CPU-CPU data synchronization module for controller redundancy
X20IF2181-2	X20 interface module, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45
X20IF2772	X20 interface module, 2 CAN bus interfaces, max. 1 Mbit/s, electrically isolated, order 2x TB2105 terminal block separately
X20IF2792	X20 interface module, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, 1 X2X Link master interface, electrically isolated, order 1x TB2105 and 1x TB704 terminal block separately

Motor controllers

Order data	Short description
X20MM2436	X20 PWM motor module, 24 to 39 VDC ±25%, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder
X20MM3332	X20 digital motor module, 24 VDC, 3 digital outputs, full bridge (H bridge), 3 A continuous current, 5 A peak current
X20MM4331	X20 digital motor module, 24 VDC, 4 digital outputs, half bridge, 3 A continuous current, 5 A peak current
X20MM4456	X20 PWM motor module, 24 to 48 VDC ±25%, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 4 digital inputs 24 VDC, sink, configurable as incremental encoder
X20SM1426	X20 stepper motor module, 1 motor connection, 1 A continuous current, 1.2 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder
X20SM1436	X20 stepper motor module, module supply 24-39 VDC ±25%, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder

Other functions

Order data	Short description
X20CM0985	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately.
X20CM0985-1	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay 1 A, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, additional software functions, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately
X20CM4810	X20 analog input module for vibration measurement and analysis for condition monitoring, 4 IEPE analog inputs, 51.5625 kHz sampling frequency, 24-bit converter resolution
X20CM6209	X20 diode array module, 1 A, 40 V reverse voltage, no module status data
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement
X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection
X20DS4387	X20 digital signal module, 4x IO-Link master, 4 digital channels configurable as inputs or outputs, 3-wire connections
X20DS438A	X20 digital signal module, 4x I/O-Link master V1.1, can also be configured as 4x digital input or output channels, 3-wire connections
X20PD0011	X20 potential distributor module, 12x GND, integrated microfuse
X20PD0012	X20 potential distributor module, 12x 24 VDC, integrated microfuse
X20PD0016	X20 potential distributor module, 5x GND, 5x 24 VDC, each with 1x floating feed, integrated microfuse
X20PD2113	X20 potential distributor module, 6x GND, 6x 24 VDC, with feed option, integrated microfuse
X20PS4951	X20 power supply module, for potentiometers, 4x ±10 V for potentiometer supply

Power supplies

Order data	Short description
X20PS2100	X20 power supply module, for internal I/O supply
X20PS2110	X20 supply module, for internal I/O supply, integrated microfuse
X20PS3300	X20 power supply module, for X2X Link and internal I/O supply
X20PS3310	X20 power supply module, for X2X Link and internal I/O supply, integrated microfuse

reACTION Technology

Order data	Short description
X20RT8001	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, reACTION technology module
X20RT8201	X20 reACTION module, 4 digital inputs, 24 VDC, <1 µs, 4 digital channels, 24 VDC, 0.1 A, <1 µs, can be configured as input or output, 2 analog inputs ±10 V, 500 kHz sampling frequency, 13-bit converter resolution (including sign), configurable input filter, reACTION technology module

Redundancy systems

Order data	Short description
X20HB8884	X20 compact link selector, 2x RJ45, order bus base, power supply module and terminal block separately.

System modules for bus controllers

Order data	Short description
X20BB80	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20PS9400	X20 power supply module, for bus controller and internal I/O supply, X2X Link supply
X20PS9402	X20 supply module, for bus controller and internal I/O supply, X2X Link supply, supply not electrically isolated

System modules for compact CPUs

Order data	Short description
X20BB22	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB27	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20PS9500	X20 supply module for compact and fieldbus CPUs and internal I/O supply, X2X Link supply
X20PS9502	X20 supply module, for compact and fieldbus CPUs and internal I/O supply, X2X Link supply, supply not electrically isolated

System modules for expandable bus controllers

Order data	Short description
X20BB81	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB82	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20IF1041-1	X20 interface module, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1043-1	X20 interface module, for DTM configuration, 1 CANopen slave interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1051-1	X20 interface module, for DTM configuration, 1 DeviceNet scanner (master) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1053-1	X20 interface module, for DTM configuration, 1 DeviceNet adapter (slave) interface, electrically isolated, order 1x TB2105 terminal block separately
X20IF1091-1	X20 interface module, for expandable bus controller, 1 X2X Link master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10A1-1	X20 interface module, for DTM configuration, 1 ASi master interface, electrically isolated, order 1x TB704 terminal block separately
X20IF10D1-1	X20 interface module, for DTM configuration, 1 EtherNet/IP scanner (master) interface, electrically isolated
X20IF10D3-1	X20 interface module, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20IF10E1-1	X20 interface module for DTM configuration, 1 PROFINET RT controller (master) interface, electrically isolated
X20IF10E3-1	X20 interface module, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20IF10G3-1	X20 interface module for DTM configuration, 1 EtherCAT slave interface, electrically isolated
X20HB1881	X20 hub expansion module, integrated 1-port hub, for fiber optic cable
X20HB2880	X20 hub expansion module, integrated 2-port hub, 2x RJ45
X20HB2881	X20 hub expansion module, integrated 2-port hub, for fiber optic cable
X20PS9400	X20 power supply module, for bus controller and internal I/O supply, X2X Link supply
X20PS9402	X20 supply module, for bus controller and internal I/O supply, X2X Link supply, supply not electrically isolated

System modules for fieldbus CPUs

Order data	Short description
X20BB32	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, Slot for X20 interface module, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB37	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, Slot for X20 interface module, X20 connection, X20 locking plates X20AC0SL1/X20AC0SR1 (left and right) included
X20BB42	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB47	X20 fieldbus CPU base, for fieldbus CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, 2 slots for X20 interface modules, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20IF1074	X20 interface module, for SGC, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20PS9500	X20 supply module for compact and fieldbus CPUs and internal I/O supply, X2X Link supply
X20PS9502	X20 supply module, for compact and fieldbus CPUs and internal I/O supply, X2X Link supply, supply not electrically isolated

System modules for X20 hub system

Order data	Short description
X20BB80	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20BB81	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20BB82	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20HB1881	X20 hub expansion module, integrated 1-port hub, for fiber optic cable
X20HB2880	X20 hub expansion module, integrated 2-port hub, 2x RJ45
X20HB2881	X20 hub expansion module, integrated 2-port hub, for fiber optic cable
X20HB28G0	X20 EtherCAT junction module, integrated 2-port EtherCAT junction, 2x RJ45
X20PS8002	X20 power supply module for standalone hub and compact link selector
X20PS9400	X20 power supply module, for bus controller and internal I/O supply, X2X Link supply
X20PS9402	X20 supply module, for bus controller and internal I/O supply, X2X Link supply, supply not electrically isolated

System modules for X20 redundancy systems

Order data	Short description
X20HB2885	X20 hub expansion module, integrated active 2-port hub, 2x RJ45
X20HB2886	X20 hub expansion module, integrated active 2-port hub, 2 fiber optic interfaces

Temperature measurement

Order data	Short description
X20AT2222	X20 temperature input module, 2 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20AT2311	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.001°C, 4-wire connections
X20AT2402	X20 temperature input module, 2 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C
X20AT4222	X20 temperature input module, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20AT6402	X20 temperature input module, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C
X20ATA312	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.01 °C, 4-wire connections
X20ATA492	X20 temperature input module, 2 thermocouple inputs, type J, K, N, S, B, R, E, C, T, single channel electrically isolated, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately
X20ATB312	X20 temperature input module, 4 inputs for resistance measurement, PT100, resolution 0.01 °C, 4-wire connections
X20ATC402	X20 temperature input module, 6 thermocouple inputs, type J, K, N, S, B, R, E, C, T, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately

Terminal blocks

Order data	Short description
X20TB06	X20 terminal block, 6-pin, 24 VDC keyed
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed
X20TB1E	X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation
X20TB1F	X20 terminal block, 16-pin, 24 VDC keyed
X20TB32	X20 terminal block, 12-pin, 240 VAC keyed

4.3 Analog input modules

Analog input modules convert measured values (voltages, currents) into numerical values, which can be processed by the PLC.

In the PLC, analog data is always in 16-bit 2s complement regardless of the resolution. Therefore, the resolution of the module used does not have to be taken into consideration when creating an application program.

Every channel on an analog input module has a status LED.

4.3.1 Brief information

Product ID	Short description	on page
X20AI1744	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 kHz input filter	132
X20AI1744-3	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 Hz input filter	132
X20AI2222	X20 analog input module, 2 inputs, ±10 V, 13-bit converter resolution, configurable input filter	148
X20AI2237	X20 analog input module, 2 inputs, ±10 V, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply	157
X20AI2322	X20 analog input module, 2 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter	174
X20AI2437	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply	183
X20AI2438	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports HART protocol	199
X20AI2622	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter	252
X20AI2632	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions	263
X20AI2632-1	X20 analog input module, 2 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter	288
X20AI2636	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions	313
X20AI4222	X20 analog input module, 4 inputs, ±10 V, 13-bit converter resolution, configurable input filter	344
X20AI4322	X20 analog input module, 4 inputs, 0-20 mA / 4-20 mA, 12-bit converter resolution, configurable input filter	353

X20cAI4632-1	X20 analog input module, coated, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions	399
X20cAP3121	X20 energy metering module, coated, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 1 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed	510

4.3.2 X20AI1744, X20AI1744-3

4.3.2.1 General Information

The X20AI1744 and X20AI1744-3 modules work with both 4-line and 6-line strain gauge cells. If a 6-line strain gauge cell is connected, the line compensation no longer functions. This module concept requires compensation in the measurement system. This compensation eliminates the absolute uncertainty in the measurement circuit, suchas component tolerances, effective bridge voltage, or zero offset. The measurement precision refers to the absolute (compensated) value, which will only change as a result of changes in the operating temperature.

The AI1744 analog input module is available in two versions:

Model number	Description
X20AI1744	The module is equipped with a 5kHz input filter for fast signal sequences. It therefore also allows high frequency signals and disturbances to pass through.
X20AI1744-3	This version is equipped with a slow 5Hz input filter. It is therefore suitable for slow signal sequences and provides good suppression of high frequency disturbance signals.

- 1 full-bridge strain gauge input
- Data output rate can be set from 2.5 Hz to 7.5 kHz
- Special operating modes (synchronous mode and multiple sampling)

4.3.2.2 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI1744	X20 analog input module, 1 full-bridge strain gauge input, 24-bit converter resolution, 5 kHz input filter

Table 17: X20AI1744, X20AI1744-3 - Order data

4.3.2.3 Technical data

Product ID	X20AI1744	X20AI1744-3
Short description		
I/O module	1 full-bridge strain gauge input	
General information		
B&R ID code	0x1CDE	0xA4EF
Status indicators	Channel status, operating status, module status	
Diagnostics		
Module run/error	Yes, using status LED and software	
Open line	Yes, using status LED and software	
Input	Yes, using status LED and software	
Power consumption		
Bus	0.01 W	
Internal I/O	1.25 W	
Additional power dissipation caused by the actuators (resistive) [W]	Max. 0.36 W [1)]	
Electrical isolation		
Bus - Analog input	Yes	
Bus - Bridge supply voltage	Yes	
Channel - I/O supply	No	
Certification		
CE	Yes	
cULus	Yes	
KC	Yes	
GOST-R	Yes	
Full-bridge strain gauge		
Strain gauge factor	±2 to ±256 mV/V, configurable using software	

Table 18: X20AI1744, X20AI1744-3 - Technical data

Product ID	X20AI1744	X20AI1744-3
Connection	4- or 6-wire connections [2]	
Input type	Differential, used to evaluate a full-bridge strain gauge	
Digital converter resolution	24-bit	
Conversion time	Depends on the configured data output rate	
Data output rate	2.5 - 7500 samples per second, configurable using software (f_{DATA})	
Input filter		
Cutoff frequency	5 kHz	5 Hz
Orderliness	3	
Slope	60 dB	
ADC filter characteristics	Sigma-Delta, see section "Filter characteristics of the Sigma-Delta ADC"	
Operating range / Measurement sensor	85 to 5000 Ω	
Influence of cable length	The shielded, twisted pair cable should be as short as possible and run separately to the sensor (isolated from load circuit) without intermediate terminals	
Input protection	RC protection	
Input current	690 nA	
Common-mode range	0 to 3 VDC Permissible input voltage range (with regard to the potential strain gauge GND) on the inputs "Input +" and "Input -"	
Isolation voltage between input and bus	500 V_{eff}	
Conversion procedure	Sigma-Delta	
Output of the digital value		
Broken bridge supply line	Value approaches 0	
Broken sensor line	Value approaches ±end value (Status bit "open circuit" in register *Module status* is set)	
Valid value range	0x007FFFFF to 0xFF800001	
Strain gauge supply		
Voltage	5.5 VDC / max. 65 mA [3]	
Short circuit protection, overload protection	Yes	
Voltage drop for short circuit protection	Max. 0.2 VDC at 65 mA	
Quantization		
LSB value (16-bit)		
2 mV/V	336 nV	
4 mV/V	671 nV	
8 mV/V	1.343 µV	
16 mV/V	2.686 µV	
32 mV/V	5.371 µV	
64 mV/V	10.74 µV	
128 mV/V	21.48 µV	
256 mV/V	42.97 µV	
LSB value (24-bit)		
2 mV/V	1.31 nV	
4 mV/V	2.62 nV	
8 mV/V	5.25 nV	
16 mV/V	10.49 nV	
32 mV/V	20.98 nV	
64 mV/V	41.96 nV	
128 mV/V	83.92 nV	
256 mV/V	167.85 nV	
Temperature coefficient		
Rev. ≤D1	30 ppm/°C	
Rev. ≥E0	10 ppm/°C	
Operating conditions		
Mounting orientation		
Horizontal	Yes	
Vertical	Yes	
Installation at altitudes above sea level		
0 to 2000 m	No limitations	
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m	
Protection in accordance with EN 60529	IP20	
Environmental conditions		
Temperature		
Operation		
Horizontal installation	0 to 55°C	
Vertical installation	0 to 50°C	
Derating	-	
Storage	-25 to 70°C	
Transport	-25 to 70°C	

Table 18: X20AI1744, X20AI1744-3 - Technical data

Product ID	X20AI1744	X20AI1744-3
Relative humidity		
Operation	5 to 95%, non-condensing	
Storage	5 to 95%, non-condensing	
Transport	5 to 95%, non-condensing	
Mechanical characteristics		
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately	
Spacing	12.5 $^{+0.2}$ mm	

Table 18: X20AI1744, X20AI1744-3 - Technical data

1) Depends on the full-bridge strain gauge used
2) With 6-wire connections, line compensation does not function. (See section "Connection examples")
3) The maximum current of 90 mA is permitted up to an operating temperature of 45°C.

4.3.2.4 Status LEDs

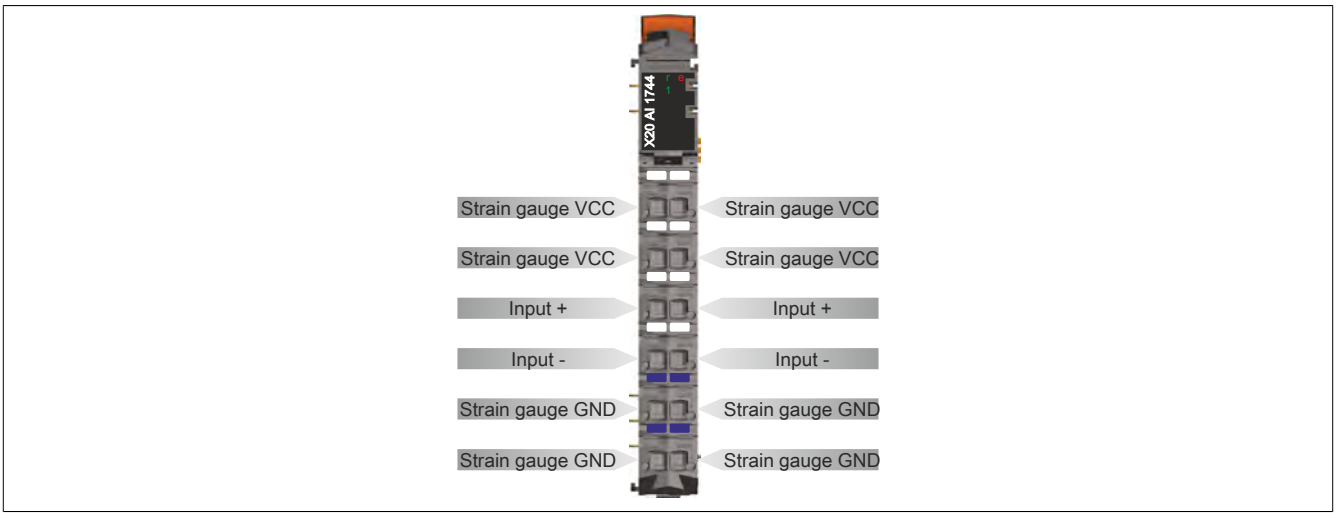
The status LEDs are identical on the X20AI1744 and X20AI1744- 3 modules.

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Image	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Error or reset status
	1	Green	Off	Possible causes: • Open line • Sensor is unplugged • Converter is busy
			On	Analog/digital converter running, value OK

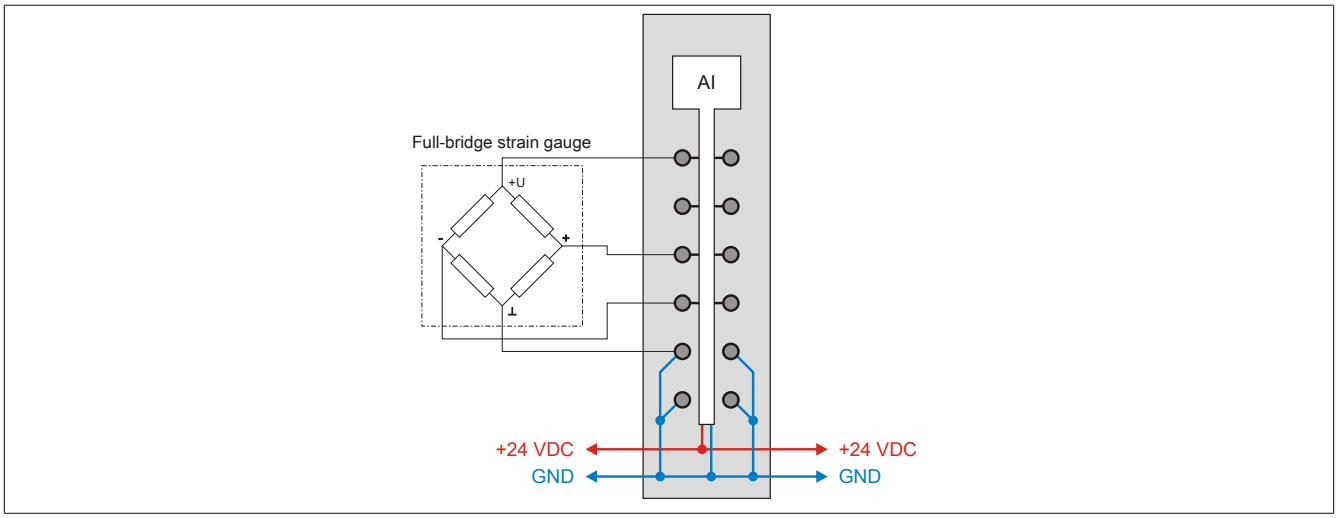
4.3.2.5 Pinout

The pinouts are identical on the X20AI1744 and X20AI1744- 3 modules.



4.3.2.6 Connection examples

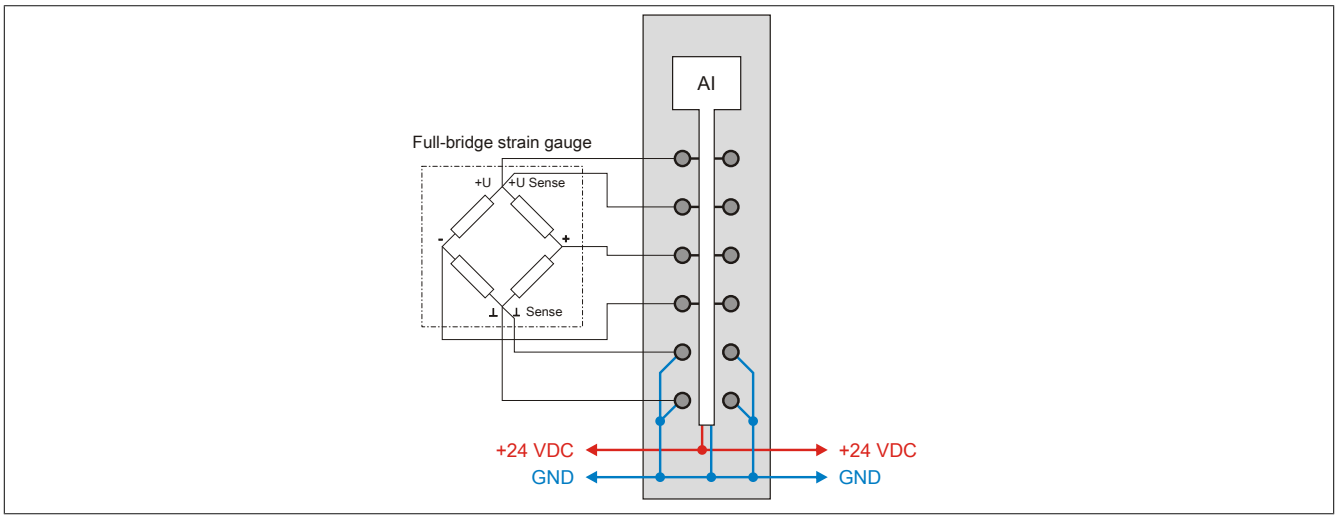
Full-bridge strain gauge with 4-line connection



Full-bridge strain gauge with 6-line connection

Precision can be improved by using strain gauge cells with feedback of the bridge voltage. The additional sensor lines with the strain gauge bridge supply compensate for the thermal resistance change of the feed lines. If a 6-line strain gauge cell is connected to the module, the sense lines are bypassed by the 4 internally linked strain gauge VCC connections (i.e. strain gauge GND). For this reason, the line compensation no longer functions. The measurement precision is therefore affected by changes in operating temperature. Longer cable lengths and smaller cable cross-sections also increase the potential for errors in the measurement system.

In order to reduce cable resistance, the sense lines should be connected in parallel with the strain gauge bridge supply lines. Optimal signal quality can be obtained by using a shielded twisted pair cable. The connections for the strain gauge supply lines, the sensor lines, and the bridge differential voltage lines should each use one twisted pair cable.



Parallel connection of 2 full-bridge strain gauges with 4-line connections

For parallel connection of full-bridge strain gauges, please refer to the manufacturer's guidelines.

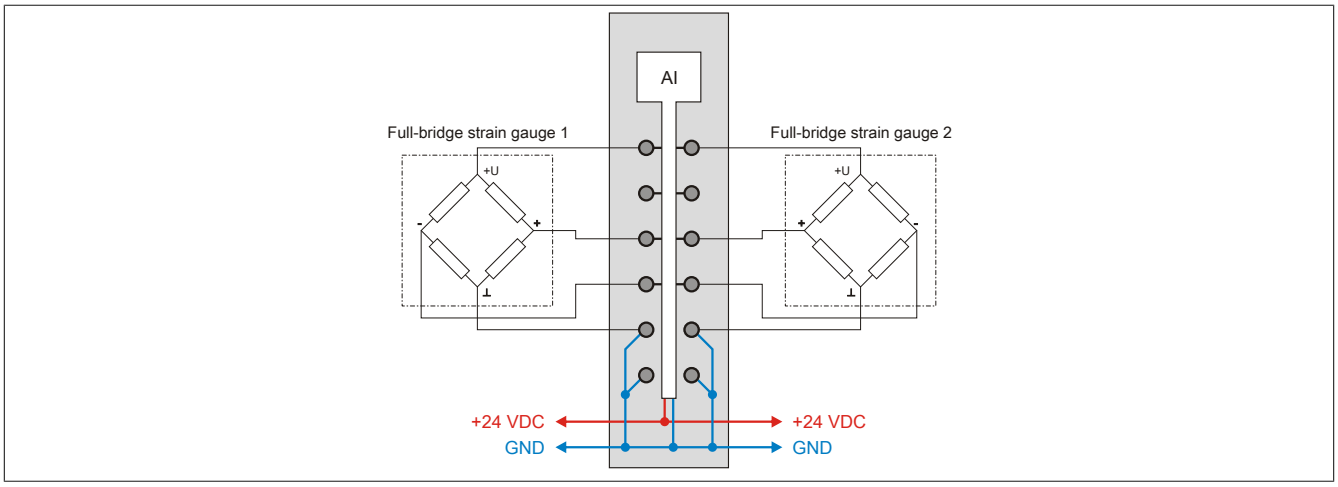


Figure 48: Connection example - Parallel connection of 2 full-bridge strain gauges

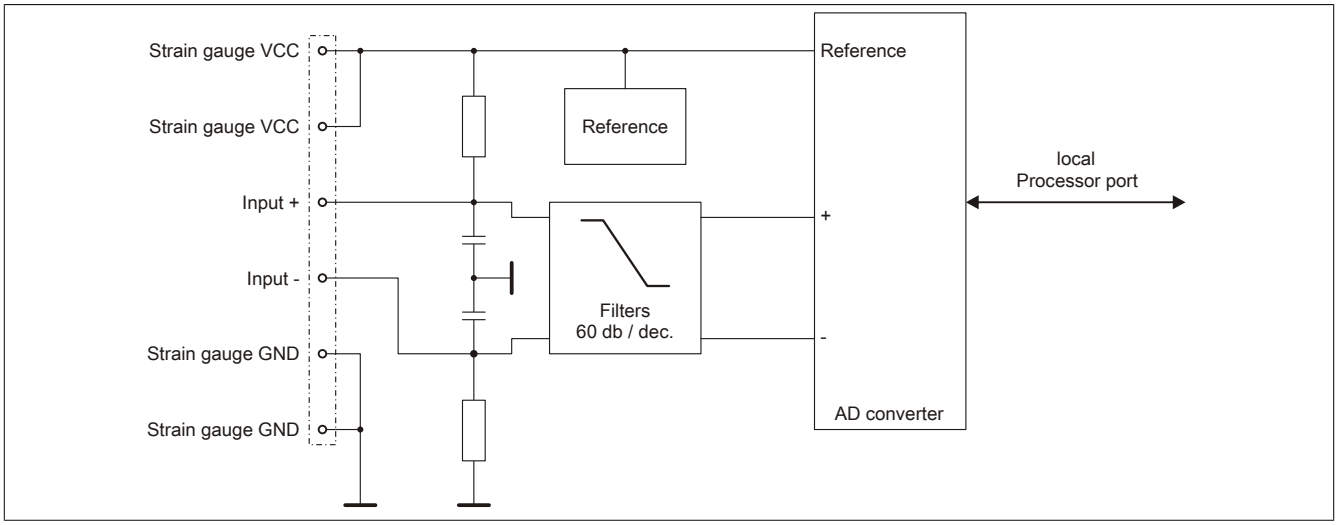
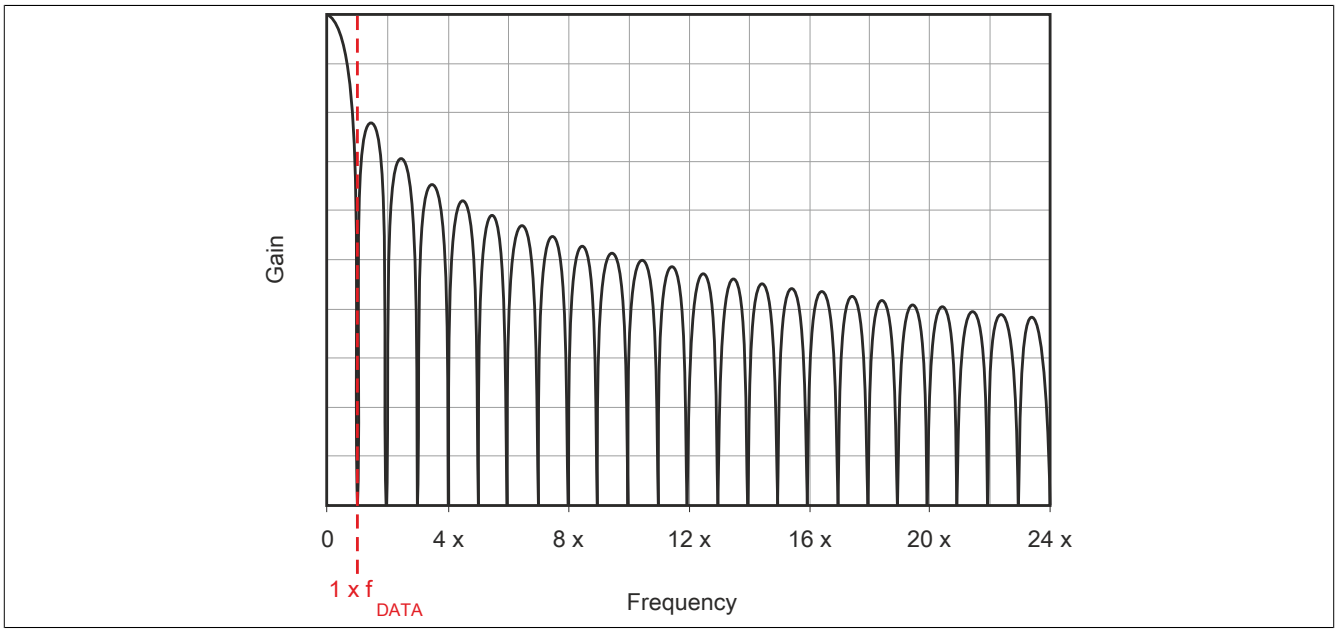
When connecting 3 or more full-bridge strain gauges in parallel, two lines must be connected together in an X20 terminal block.

4.3.2.7 Input circuit diagram



4.3.2.8 Filter characteristics of the Sigma-Delta ADC



4.3.2.9 Effective resolution of the AD converter

The AD converter on the AI1744 provides a 24 bit measurement value. However, the actual attainable noise-free resolution is always less than 24 bit. This "effective resolution" depends on the data rate and measurement range.

Example:

Because of the conversion method, a data rate of 2.5 Hz and a specified measurement area of 2 mV/V result in an effective resolution of 18.7 bits:

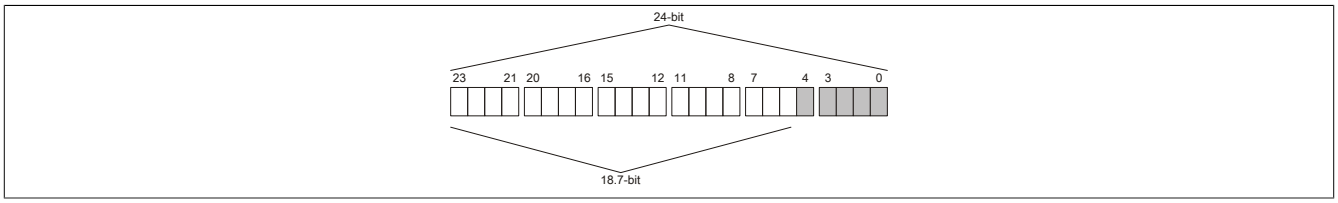


Figure 49: Example for the effective resolution of the AD converter

The low-order bits (grayed out) contain only noise instead of valid values and must therefore not be evaluated.

With the multiple sampling function model, only the highest 16 bits are made available.

4.3.2.10 Calculation example / Quantization

In a weighing application, the corresponding weight located on the connected load cell should be determined from the value derived from the X20AI1744.

The characteristics of the strain gauge load cell are as follows:

- Rated load: 1000 kg
- Bridge factor: 4 mV/V

The value for the positive full-scale deflection at a specified rated load of 1000kg is derived from the bridge factor of the strain gauge load cell (multiplication with the bridge supply voltage from the AI1744 module):

4 mV/V × 5.5 V = 22 mV

With a simple Rule of Three calculation, the corresponding value can be calculated (as seen in the table) from weight to the converter value and vice versa. This simplified theoretical approach is only valid for an ideal measurement system. Calibration of the entire measurement system is recommended because not only the X20AI1744 module, but particularly the strain gauge bridges feature tolerances (offset, gain). When taring, the gradient offset is recalculated and the gain of the linear equation is determined when standardized. In addition to the calculation displayed in the table, these calculations must also be carried out in the application.

24 bit value from the X20AI1744		Quantization	Corresponding weight
0x007F FFFF	8,388,607	22.0 mV	1000 kg
0x0000 0001	1	2.62 nV	0.119 g
0x0000 20C3	8,387	22.0 µV	1 kg
0x0001 0000	65,536	171.9 µV	7.81 kg

Table 19: X20AI1744 - Calculation example / Quantization

The values for each LSB can be found in the technical data of the X20AI1744, under "Quantization" (1 LSB in reference to 16 bit and 1 LSB in reference to 24 bit).

4.3.2.11 Register description

4.3.2.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.2.11.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
2	StatusInput01	USINT	•			
4	AnalogInput01	DINT	•			
16	ConfigOutput01	USINT				•
18	ConfigCycletime01	UINT				•
32	AdcClkFreqShift01[1)]	USINT				•

1) **X20AI744**: from firmware version 8 / upgrade 1.3.0.0; **X20AI744-3**: from firmware version 8 / upgrade 1.2.0.0

4.3.2.11.3 Function model 1 - Multiple sampling

In this function model, the AD converter is operated in synchronization with X2X Link using a fixed ADC cycle time (configurable as 50 or 100 µs).

The module returns between 3 and 10 measured values per X2X cycle depending on the configuration. With an X2X cycle time of 400 µs and ADC cycle time of 50 µs, exactly 8 measurements are performed and the module can return 8 values (strain gauge value 01 to strain gauge value 08).

If a longer cycle time is used, the values returned correspond to the last measurements. If using an X2X cycle time that is not a whole number multiple of the ADC cycle time, then the conversion cannot be synchronized with X2X Link. In this case, the module outputs the invalid value 0x8000.

Example 1

With an X2X cycle time of 800 µs, 16 measurements are performed per X2X cycle. The first 6 measured values are discarded; the last 10 measured values are provided by the module.

With a shorter X2X cycle time, the number of measured values should not exceed the number of measurements that can actually be made. All other measured values are invalid (0x8000). To minimize the load on X2X Link, it is possible to disable unneeded registers (see "Number of measurement values").

Example 2

If using an X2X cycle time of 300 µs, it is possible to perform 6 measurements per X2X cycle if the ADC cycle time equals 50 µs. For this reason, only the first 6 registers are valid. The registers for the 7th through 10th measured value (AnalogInput07 to AnalogInput08) should be disabled by setting "Number of measured values" to "6 measured values" in the I/O configuration.

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
2	StatusInput01	USINT	•			
1534 + N * 4	AnalogInput0N (N = 1 to 10)	INT	•			
1600	ConfigOutput01 (X20AI1744) ConfigGain01_MultiSample (X20AI1744-3)	USINT				•
1603	ConfigCycletime01_MultiSample	USINT				•

4.3.2.11.4 Function model 254 - Bus Controller

In the bus controller function model, the module behaves as it does in the standard function model, with the exception that it is not synchronized to the X2X Link even if Synchronous mode is activated in the ADC configuration register. Instead, the module behaves as if the set ADC cycle time is not a factor or multiple of the X2X cycle time and attempts to maintain the set ADC cycle time as precisely as possible.

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
2	StatusInput01	USINT	•			
4	AnalogInput01	DINT	•			
16	ConfigOutput01	USINT				•
18	ConfigCycletime01	UINT				•
32	AdcClkFreqShift01[1)]	USINT				•

1) **X20AI744**: from firmware version 8 / upgrade 1.3.0.0; **X20AI744-3**: from firmware version 8 / upgrade 1.2.0.0

4.3.2.11.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.2.11.5 Register for "Standard" and "Bus Controller" function model

4.3.2.11.5.1 Module status

Name:
StatusInput01

The current state of the module is indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AD converter values	0	ADC value is valid
		1	ADC value is invalid
1	Line monitoring	0	OK
		1	Open line
2	Only valid in synchronous mode	0	ADC runs synchronous to the X2X Link
		1	ADC does not run synchronous to the X2X Link
3 - 7	Reserved	-	

4.3.2.11.5.2 Strain gauge value

Name:
AnalogInput01

This register contains the raw value determined by the A/D converter for the full-bridge strain gauge with 24-bit resolution.

Data type	Values	Information
DINT	0x007FFFFF to 0xFF800001	Valid value range
	0x007FFFFF	Overrun
	0xFF800001	Underflow
	0xFF800000	Invalid value

Effective resolution

In principle, the effective resolution of the A/D converter is dependent on the data rate and the measurement range (see "Effective resolution of the AD converter").

The following table shows how the effective resolution (in bits), or the effective value range of the strain gauge value depend on the module configuration (data rate, measurement area).

	Measurement range							
	±16 mV/V		±8 mV/V		±4 mV/V		±2 mV/V	
Data rate f_{DATA} [Hz]	Bits	Range of values	Bits	Range of values	Bits	Range of values	Bits	Range of values
2.5	21.3	±1,290,000	20.8	±912,000	19.7	±425,000	18.7	±212,000
5	20.7	±851,000	20.3	±645,000	19.3	±322,000	18.3	±161,000
10	20.4	±691,000	19.9	±490,000	18.9	±244,000	17.9	±122,000
15	20.1	±562,000	19.3	±320,000	18.7	±212,000	17.7	±106,000
25	19.7	±425,000	19.2	±301,000	18.5	±185,000	17.5	±92,000
30	19.6	±397,000	19.0	±262,000	18.1	±140,000	17.1	±72,000
50	19.4	±346,000	18.8	±230,000	17.9	±122,000	16.9	±61,000
60	19.3	±320,000	18.8	±230,000	17.8	±114,000	16.8	±57,000
100	19.1	±280,000	18.5	±185,000	17.4	±86,000	16.4	±43,000
500	18.0	±130,000	17.3	±80,000	16.3	±40,000	15.3	±20,000
1000	17.2	±75,000	16.5	±46,000	15.6	±25,000	14.6	±12,000
2000	16.6	±49,600	16.1	±35,000	15.3	±20,000	14.3	±10,000
3750	16.2	±37,600	15.7	±26,600	14.7	±13,000	13.7	±6,600
7500	15.8	±28,500	15.3	±20,200	14.4	±10,800	13.4	±5,400

Table 20: Effective resolution of the strain gauge value in bits for the measurement range 2 to 16 mV/V

	Measurement range							
	±256 mV/V		±128 mV/V		±64 mV/V		±32 mV/V	
Data rate f_{DATA} [Hz]	Bits	Range of values	Bits	Range of values	Bits	Range of values	Bits	Range of values
2.5	23	±4,194,000	22.6	±3,179,000	22.1	±2,248,000	21.7	±1,703,000
5	22.3	±2,582,000	22.4	±2,767,000	21.9	±1,957,000	21.3	±1,291,000
10	22.3	±2,582,000	22	±2,097,000	21.6	±1,589,000	21	±1,049,000

		1	Extended measurement range (32 to 256 mV/V)[2)]
7	Reserved	0	(must be 0)

1) ADC is operated synchronously with the X2X Link, if possible; beginning with firmware 2
2) Starting with Firmware Version 4

Synchronous mode

Beginning with firmware version 2, the analog/digital converter (ADC) on the X20AI1744 module can be operated and read synchronously with the X2X Link. Synchronous mode is activated by selecting the respective operating mode in the *ADC configuration* register. A time between 200 and 2,000 µs must also be set in the *ADC cycle time* register. If this time is a whole number factor or multiple of the configured cycle time of the X2X Link, then the ADC is synchronously read with the X2X Link.

Information:

The ADC cycle time must be ≥1/4 of the X2X cycle time.

The bit 2 in *Module Status* is set (i.e. ADC does not run synchronously), ...

- ... if the configured ADC cycle time cannot be synchronized with the X2X Link.
- ... if the module is still in the settling phase.

Jitter, dead time and settling time:

Jitter	
ADC cycle times <1500 µs	Max. ±1 µs
ADC cycle times >1500 µs	Max. ±4 µs
Dead time on the X2X Link	$50\ \mu s + \frac{\text{X2X cycle time}}{128}$
Settling time	
Firmware Version ≤	Max. 150 x ADC cycle time
Firmware Version ≥5	150 x X2X cycle time

Table 22: Jitter, dead time and settling time

The settling time corresponds to the time needed until the AD converter can be operated after activating the synchronous mode or following conversion of the ADC cycle time.

4.3.2.11.5.4 ADC cycle time

Name:
ConfigCycletime01

This register is only used in "Synchronous mode". If synchronous mode is enabled in the ADC configuration, then the module attempts to operate the ADC synchronously to the X2X Link (based on the ADC cycle time specified in this register). It is necessary for the X2X Link cycle time and the ADC cycle time to have a certain relationship. The following conditions must be adhered to:

1 ADC cycle time ≥ 1/4 X2X cycle time
2 ADC cycle time corresponds to a whole number factor or multiple of the X2X cycle time
3 ADC cycle time must be in the range from 50 to 2000 µs

Data type	Value
UINT	50 to 2000

4.3.2.11.5.5 ADC clock frequency shift

Name:
AdcClkFreqShift01

In rare cases, X20AI1744 connected to neighboring slots can influence one another. This can result in temporary, minimal deviations in measurement values. This can only occur if the SigmaDelta ADCs on the neighboring X20AI1744 modules are operated at exactly the same clock frequency.

In most cases, these clock frequencies vary slightly due to part variances. When they are the same however, this register on the X20AI1744 provides a safe way for an application to prevent this type of mutual influence.

Data type	Value
SINT	-128 to 127

This register can be used to vary the clock frequency in increments of 200 ppm. Setting values from -50 to 50 cover a range of -10000 ppm to 10000 ppm. This corresponds with -1% to 1%.

Values beyond this range will cause activation of a default mode. The frequency shift is derived from the from the last 2 digits of the serial number by the X20AI1744 firmware. This saves time that would otherwise be needed for programming, provided that the last two digits of the serial numbers on the neighboring modules are not the same

Register value	Frequency shift in ppm	Example of a sampling rate[1)]
127	((SerialNo. modulo 100) - 50) * (-200) ppm	Based on the serial number
...	...	...
51	((SerialNo. modulo 100) - 50) * (-200) ppm	Based on the serial number
50	10000	505
49	9800	504.9
...	...	...
2	400	500.2
1	200	500.1
0	0	500
-1	-200	499.9
-2	-400	499.8
...	...	...
-50	-10000	495
-51	((SerialNo. modulo 100) - 50) * (-200) ppm	Based on the serial number
...	...	...
-128	((SerialNo. modulo 100) - 50) * (-200) ppm	Based on the serial number

Table 23: Frequency shift of the ADC clock

1) Nominal sampling rate of 500 samples per second

IMPORTANT:

As shown in the table above, shifting the ADC clock frequency will equally shift the ADC sampling rate. Shifting the ADC clock frequency too much can cause problems with disturbance suppression particularly when a very specific sampling rate has been defined to suppress existing disturbances (e.g: 50 Hz to suppress the 50 Hz hum). Also see "Filter characteristics of the Sigma-Delta ADC".
It's situations like this where the option to manually shift the frequency in the I/O configuration or ASIOACC library should be utilized rather than relying on the default frequency shift that is based on the serial number.

A frequency shift like the one shown below would be sufficient to prevent modules from influencing one another and would not cause any noticeable difference to the filter characteristics.

Slot	1	2	3	4	5	6	...
ADC clock frequency shift	0	2	-1	1	-2	0	...

Information:

- **This register has no effect in synchronous mode because the firmware regulates the ADC clock frequency in such a way that the ADC conversion cycle is synchronous with the X2X cycle.**
- **When writing to this register using the ASIOACC library, only the lowest value byte of the written value is accepted. For example, the value 256 (=0x100) is identical to the value 0 (=0x00).**

4.3.2.11.6 Register for "Multiple Sampling" function model

4.3.2.11.6.1 Module status

Name:
StatusInput01

The current state of the module is indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AD converter values	0	ADC value is valid
		1	ADC value is invalid
1	Line monitoring	0	OK
		1	Open line An open line was found during at least one measurement in this X2X cycle. This bit is reset if all measurements are OK after correcting this error, i.e. it does not have to be acknowledged.
2	Synchronous mode	0	ADC runs synchronous to the X2X Link
		1	ADC does not run synchronous to the X2X Link
3 - 7	Reserved	-	

4.3.2.11.6.2 Strain gauge value - Multiple

Name:
AnalogInput01 to AnalogInput10

This register contains the raw value determined by the ADC for the full-bridge strain gauge with 16-bit resolution. The module returns between 3 and 10 measured values per X2X cycle depending on the configuration.

Effective resolution

In principle, the effective resolution of the AD converter is dependent on the data rate and the measurement range (see "Effective resolution of the AD converter").

The following table shows how the effective resolution (in bits), or the effective value range of the strain gauge value depend on the module configuration (data rate, measurement area).

Measurement range							
±16mV/V		±8mV/V		±4mV/V		±2mV/V	
Bits	Scope	Bits	Scope	Bits	Scope	Bits	Scope
15.4	22,000	14.6	12,000	13.8	7,000	12.8	4,000

Table 24: Effective resolution of the strain gauge value in bits for the measurement range 2 to 16 mV/V

Measurement range							
±256mV/V		±128mV/V		±64mV/V		±32mV/V	
Bits	Scope	Bits	Scope	Bits	Scope	Bits	Scope
17.1	70,000	16.7	53,000	16.4	43,000	15.9	31,000

Table 25: Effective resolution of the strain gauge value in bits for the measurement range 32 to 256 mV/V

4.3.2.11.6.3 ADC configuration

Name:
ConfigOutput01 (X20AI1744)
ConfigGain01_MultiSample (X20AI1744-3)

The measurement range for the AD converter can be configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Standard measurement range (bit 2 = 0)	00	16 mV/V
		01	8 mV/V
		10	4 mV/V
		11	2 mV/V
	Extended measurement range (bit 2 = 1)[1)]	00	256 mV/V
		01	128 mV/V
		10	64 mV/V
		11	32 mV/V
2		0	Standard measurement range (2 to 16 mV/V)
		1	Extended measurement range (32 to 256 mV/V)[1)]
3 - 7	Reserved	0	(must be 0)

1) Starting with Firmware Version 4. In the standard measurement range (2 to 16 mV/V), open-circuit detection works reliably at all adjustable data rates. In the extended measurement range (32 to 256 mV/V), open-circuit detection does not work reliably (because of the variable input impedance of the amplifier in relation to the set data rate).

4.3.2.11.6.4 ADC cycle time

Name:
ConfigCycletime1_MultiSample

This register can be used to configured the ADC cycle time.

In order for multisampling to work, the X2X cycle time must be divisible by the ADC cycle time (i.e. results in a whole number).

Data type	Value	Information
USINT	0	50 µs (default)
	1	100 µs
	2 - 255	Reserved

4.3.2.11.6.5 Number of measurement values

If the X2X cycle time is too short, then bot all 10 measurements can be performed. To reduce the load on X2X Link, it makes sense to only transfer as many values as measurements that can be made. This is why it is possible to configure the number of measured values to be transferred (see "Function model 1 - Multiple sampling").

Example: ADC cycle time 50 µs

X2X cycle time	Number of measurement values to be transferred
250 µs	5
300 µs	6
350 µs	7
400 µs	8
450 µs	9
≥500 µs	10

Example: ADC cycle time 100 µs

X2X cycle time	Number of measured values to be transferred
300 µs	3
400 µs	4
500 µs	5
600 µs	6
700 µs	7
800 µs	8
900 µs	9
≥1 ms	10

4.3.2.11.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.3.2.11.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

There is no limitation and no simple dependency on the bus cycle time. In the "Standard" function model, the I/O update time is defined by the register 4.3.2.11.5.3 "ADC configuration" and 4.3.2.11.5.4 "ADC cycle time".
In the "Multiple Sampling" function model, the update time is 50 µs.

4.3.3 X20AI2222

4.3.3.1 General information

The module is equipped with 2 inputs with 13-bit (including sign) digital converter resolution. It can be used to capture voltage signals in the range from ±10 V.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs ±10 V
- 13-bit digital converter resolution

4.3.3.2 Order data

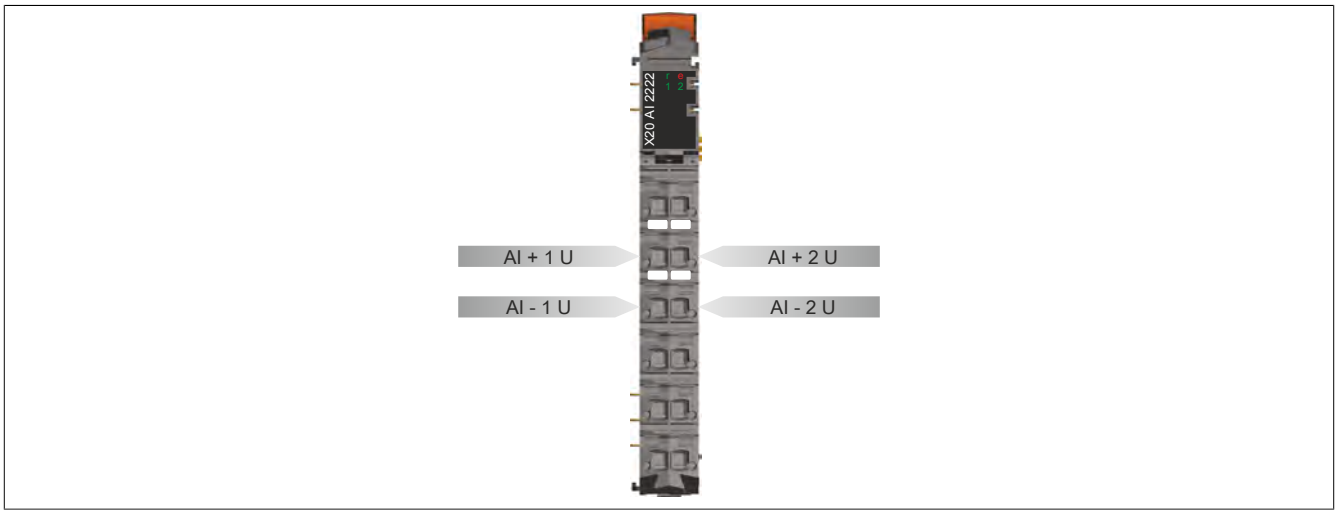
4.3.3.4 LED status indicators

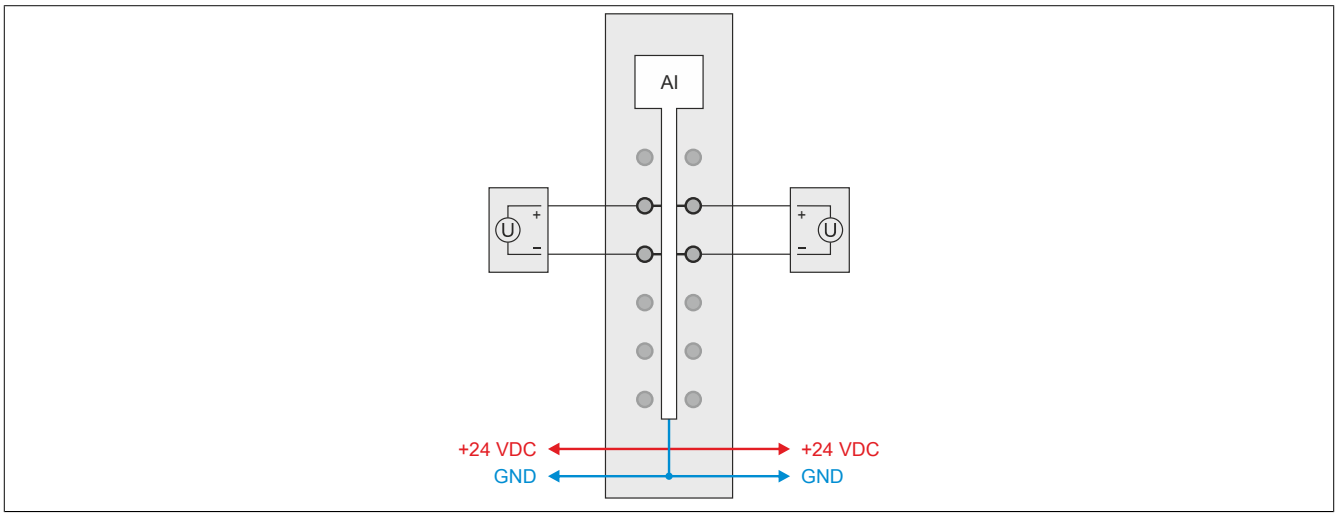
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	Open line or sensor is disconnected
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

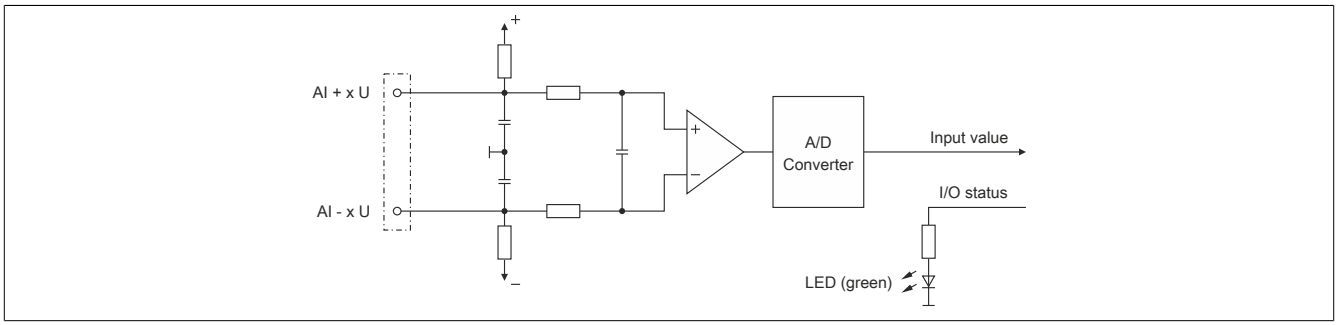
4.3.3.5 Pinout



4.3.3.6 Connection example



4.3.3.7 Input circuit diagram



4.3.3.8 Register description

4.3.3.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.3.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
16	Configuring the input filter	USINT				•
20	Lower limit value	INT				•
22	Upper limit value	INT				•
Analog signal - Communication						
0	AnalogInput01	INT	•			
2	AnalogInput02	INT	•			
30	Input status	USINT	•			

4.3.3.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
16	-	Configuring the input filter	USINT				•
20	-	Lower limit value	INT				•
22	-	Upper limit value	INT				•
Analog signal - Communication							
0	0	AnalogInput01	INT	•			
2	2	AnalogInput02	INT	•			
30	-	Input status	USINT		•		

1) The offset specifies the position of the register within the CAN object.

4.3.3.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.3.8.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.3.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput02

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal -10 to 10 VDC

4.3.3.8.6 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be >500 µs. Filtering is disabled for shorter cycle times.

If the input filter is active, then the scan rate for the channels is measured in ms. The time offset between the channels is 200 µs. The conversion takes place asynchronously to the network cycle.

4.3.3.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

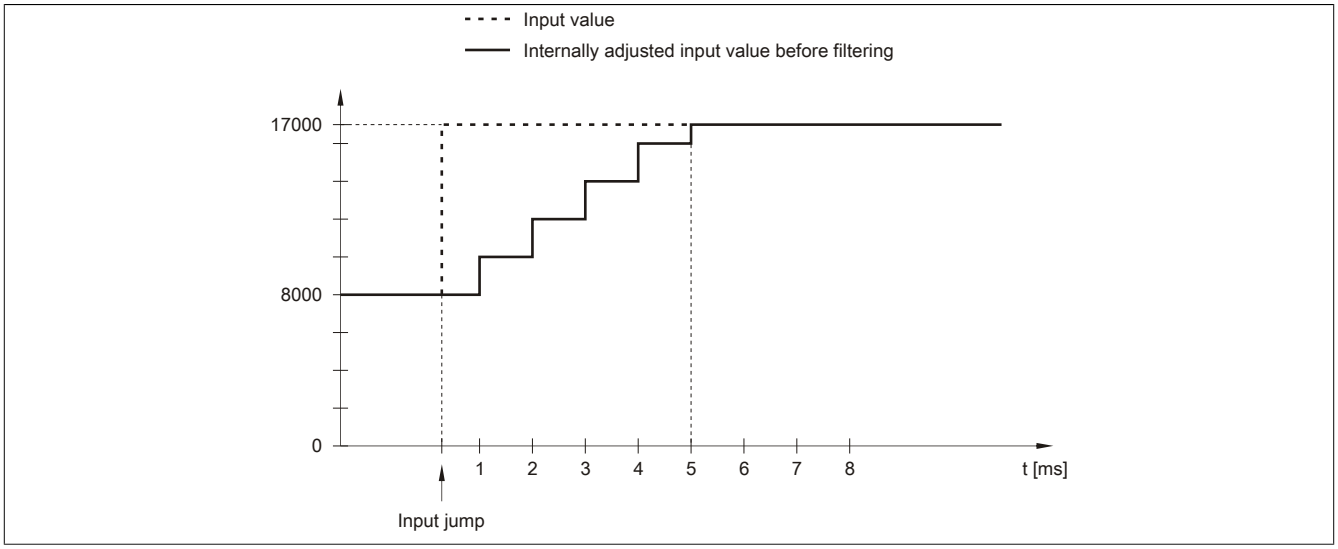


Figure 50: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

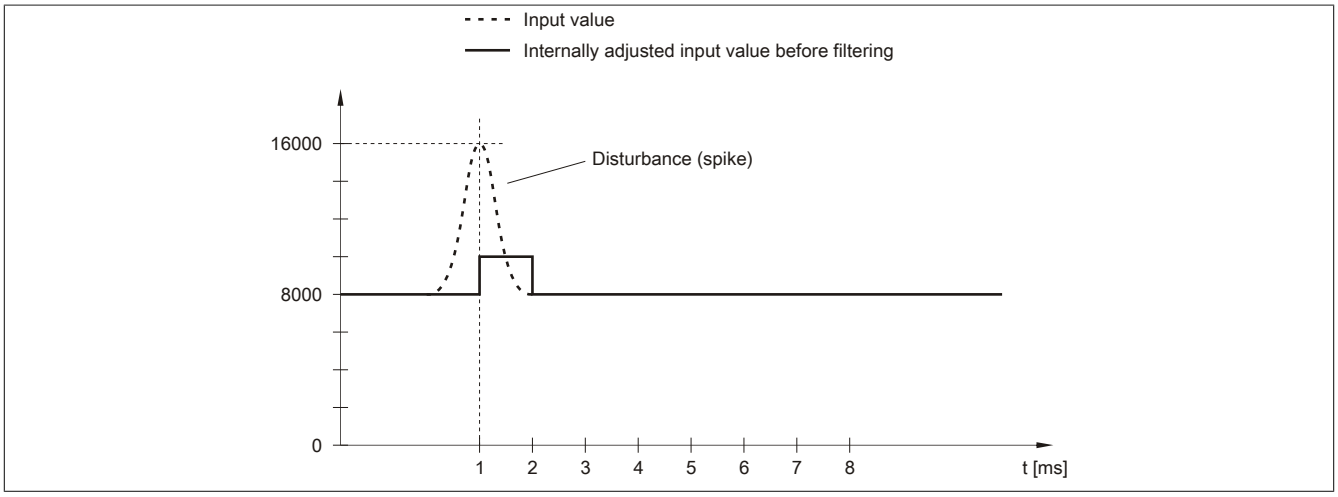

Figure 51: Adjusted input value for disturbance

4.3.3.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

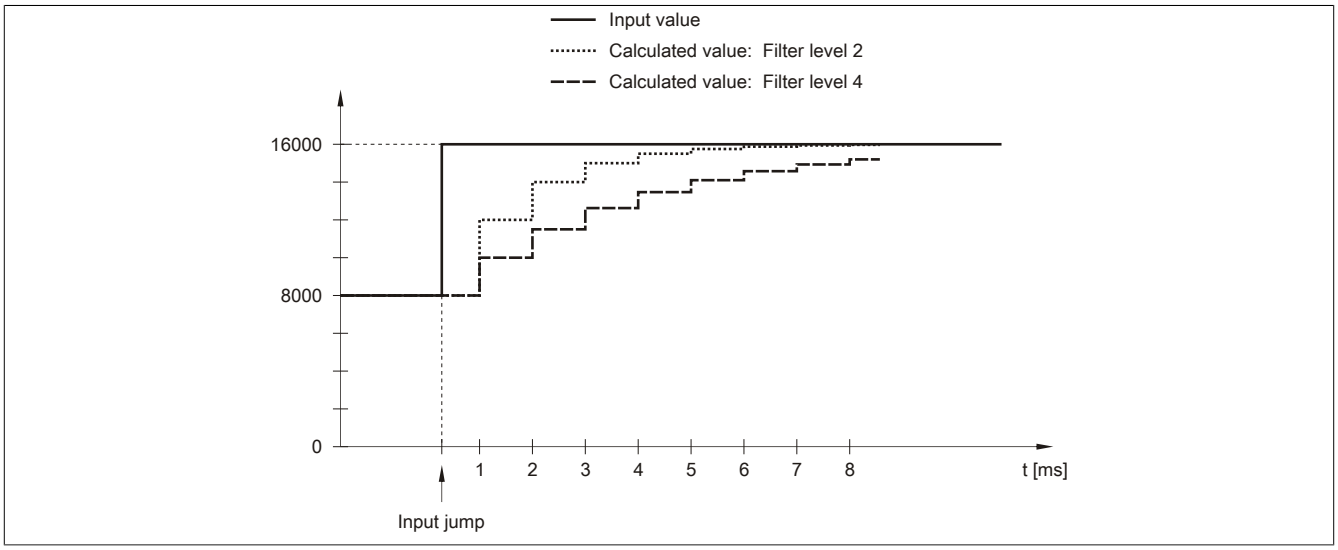

Figure 52: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

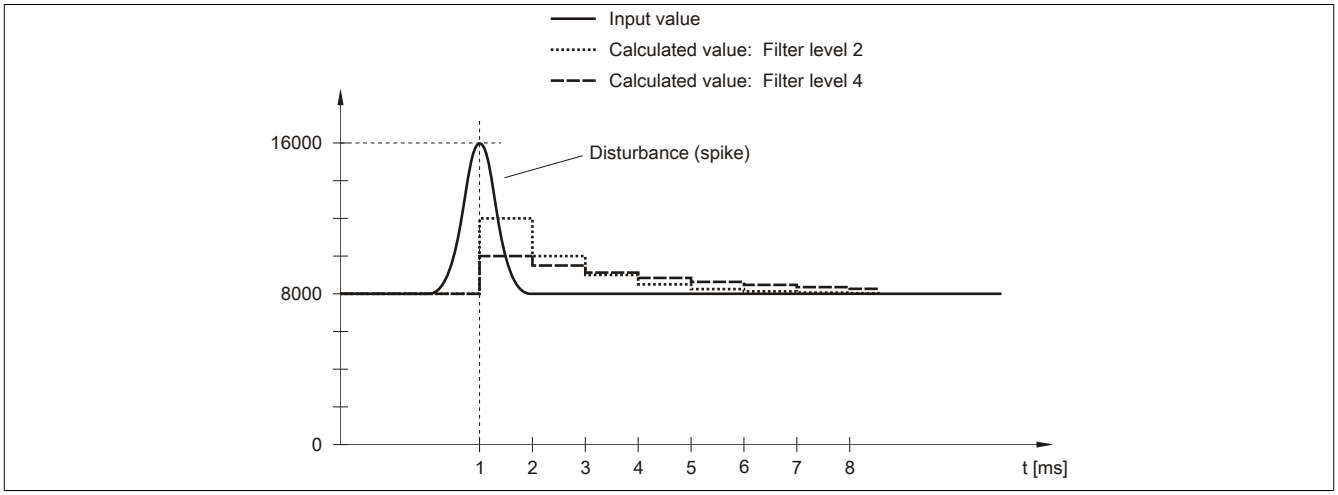

Figure 53: Calculated value during disturbance

4.3.3.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.3.8.8 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of -32768 corresponds to the minimum default value of -10 VDC.

Keep in mind that this setting applies to all channels!

4.3.3.8.9 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at +10 VDC.

Keep in mind that this setting applies to all channels!

4.3.3.8.10 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

4.3.3.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.3.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Inputs without filtering	300 µs for all inputs
Inputs with filtering	1 ms

4.3.4 X20AI2237

4.3.4.1 General information

The module is equipped with 2 voltage measurement inputs with 16-bit digital converter resolution.

Each voltage input has its own sensor supply. The two channels with their respective sensor supplies are electrically isolated from each other.

- 2 analog voltage inputs
- Electrically isolated analog channels
- Electrically isolated sensor supplies
- 16-bit digital converter resolution
- Very high sampling rate

4.3.4.4 LED status indicators

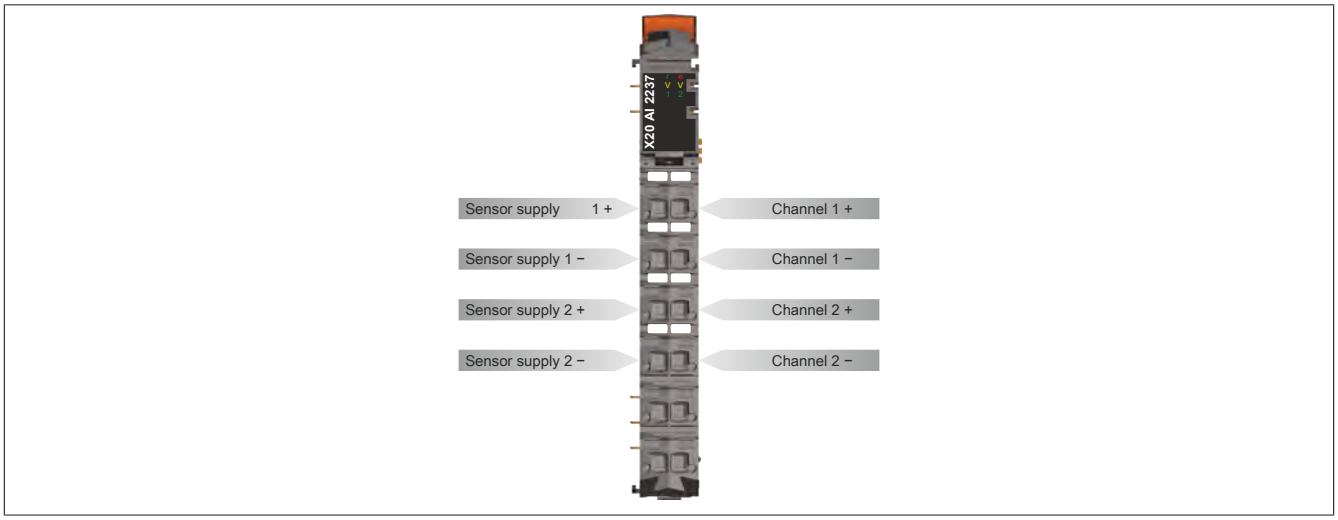
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	**Operating state**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
	Module status			
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	Sensor supply			
	V	Yellow	Off	Module supply not connected or overload
			On	Sensor supply in its normal operating range
	Analog input			
	1 - 2	Green	Off	Indicates one of the following cases: • No power to module • Channel disabled • Open line
			Single flash	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

4.3.4.5 Pinout

Shielded twisted pair cables should be used to minimize coupling disturbances. Use either one cable for each channel or a multiple twisted pair cable for both channels.

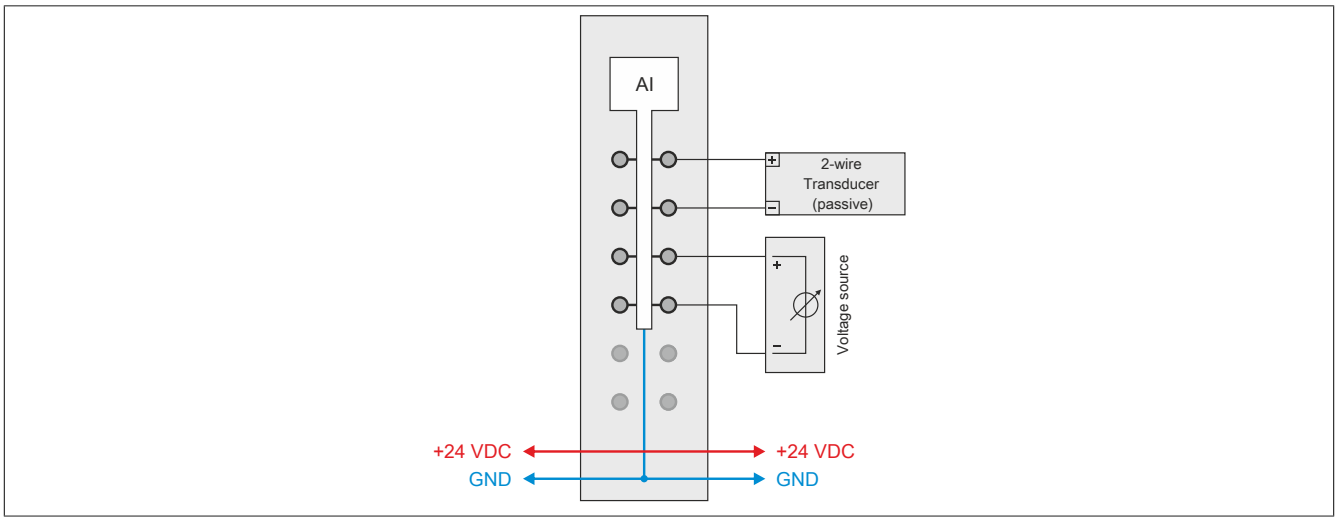


4.3.4.6 Connection examples

2-wire connections

A 2-wire connection can be implemented as follows:

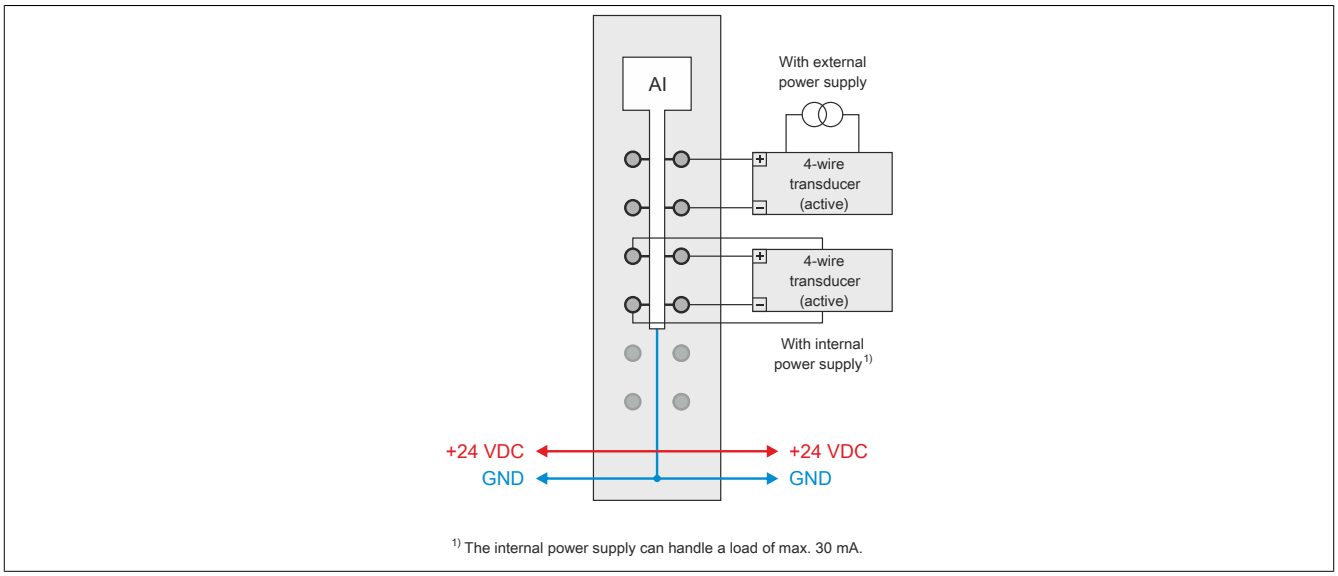
- 2-wire transducer
- Active voltage source



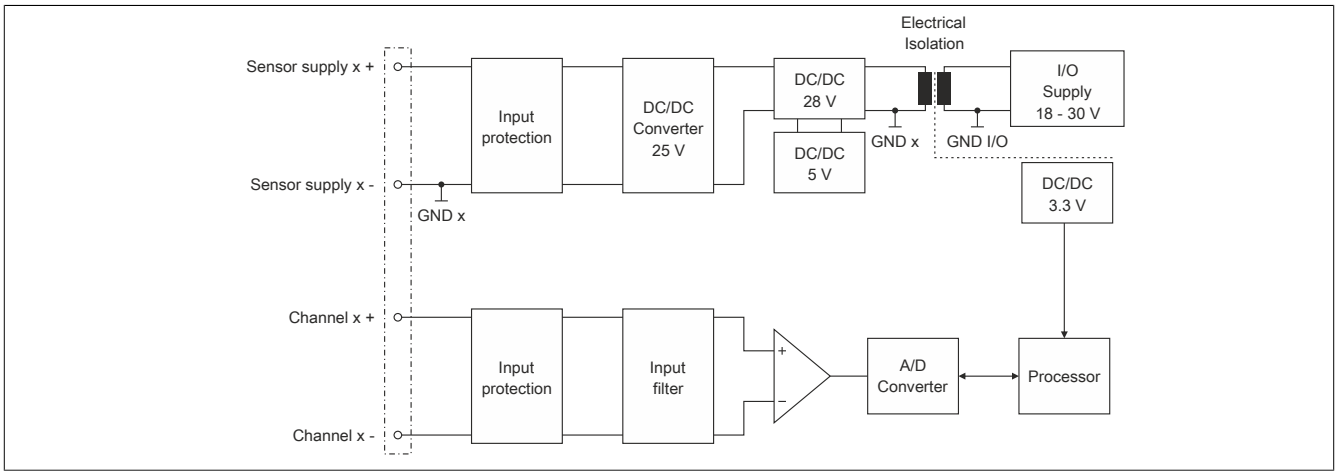
4-wire connections

A 4-wire connection can be implemented as follows:

- 4-wire transducer with external supply
- 4-wire transducer supplied by the module

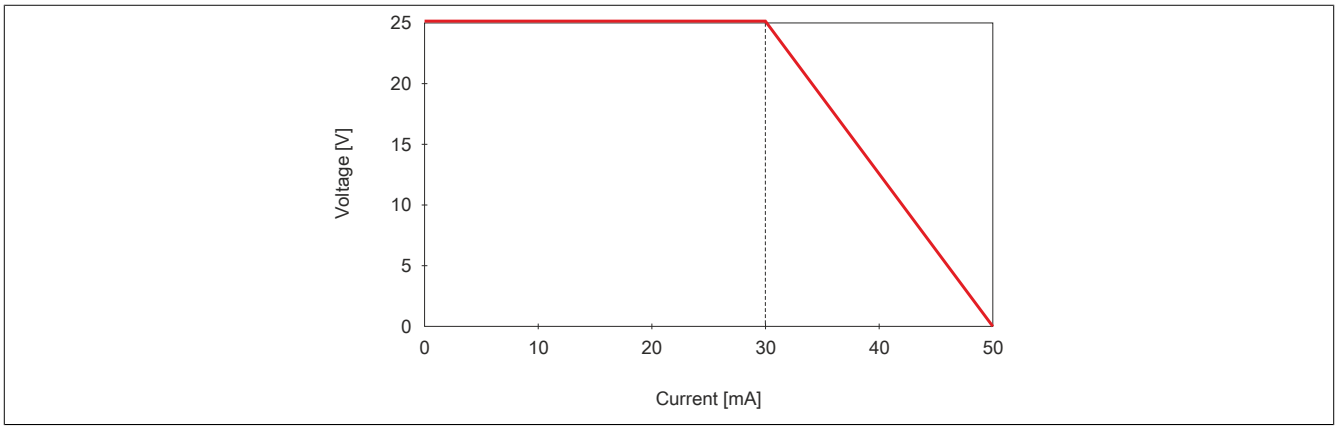


4.3.4.7 Input circuit diagram



4.3.4.8 Behavior in the event of short circuit

In the event of a short circuit, the output current for the sensor supply is limited according to the following diagram.



4.3.4.9 Register description

4.3.4.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.4.9.2 Function model 0 - default

Register	Name	Data type	Read		Write

1) The offset specifies the position of the register within the CAN object.

4.3.4.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.4.9.4 General information

The module provides 2 electrically isolated channels. Each channel can read an electrical voltage signal in the ±10 V range and supply the signal encoder with 24 VDC.

4.3.4.9.5 Analog input - Configuration

Each channel is configured and enabled separately. First, the user must set the scaling of the input value and select a replacement value strategy. Depending on the requirements of the application, the user can also set user-defined limit values and define an input filter.

Scaling

The module's A/D converter works with a resolution of 16 bits (±15 bits). This allows the input value of ±10 V to be mapped using ±32767 steps. To simplify implementation, the user can configure scaling to ±10000 steps. The conversion value corresponds to the voltage in mV, and with a resolution of more than 14 bits (±13 bits) is still precise enough for the many different application that use this technology.

Replacement value strategy

The detected voltage is evaluated in order to ensure the quality of the read value. For example, if a logically impermissible voltage value or an open line is detected, the limit monitor triggers an appropriate response.

The response is determined by the replacement value strategy selected by the user. With the option "Replace with static value", the user defines two values that replace the converted value when the upper and lower limits are exceeded. The alternative "Retain last valid value" keeps the last validated value. However, the evaluation for this option takes more time. Depending on the "preparation interval", the value currently being read may be delayed.

Limit Value Monitoring

In addition to the qualitative evaluation of the input, the module also provides the option of adapting the range of permitted values to the requirements of the application. The registers 4.3.4.9.5.3 "UpperLimit" and 4.3.4.9.5.4 "LowerLimit" can be used to place additional restrictions on the permitted upper and lower limit. When this feature is used, the selected replacement value strategy is implemented according to the new limits.

4.3.4.9.5.1 Input filter

Analog input signals can experience brief disturbances caused by external factors (EMC). The ADC's high sampling rate allows you to filter out these types of signal peaks without hindering the application processes.

2 configuration points are available for interpolating the input signal:

- 4.3.3.8.6.1 "Input ramp limitation"
- 4.3.3.8.6.2 "Filter level"

Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

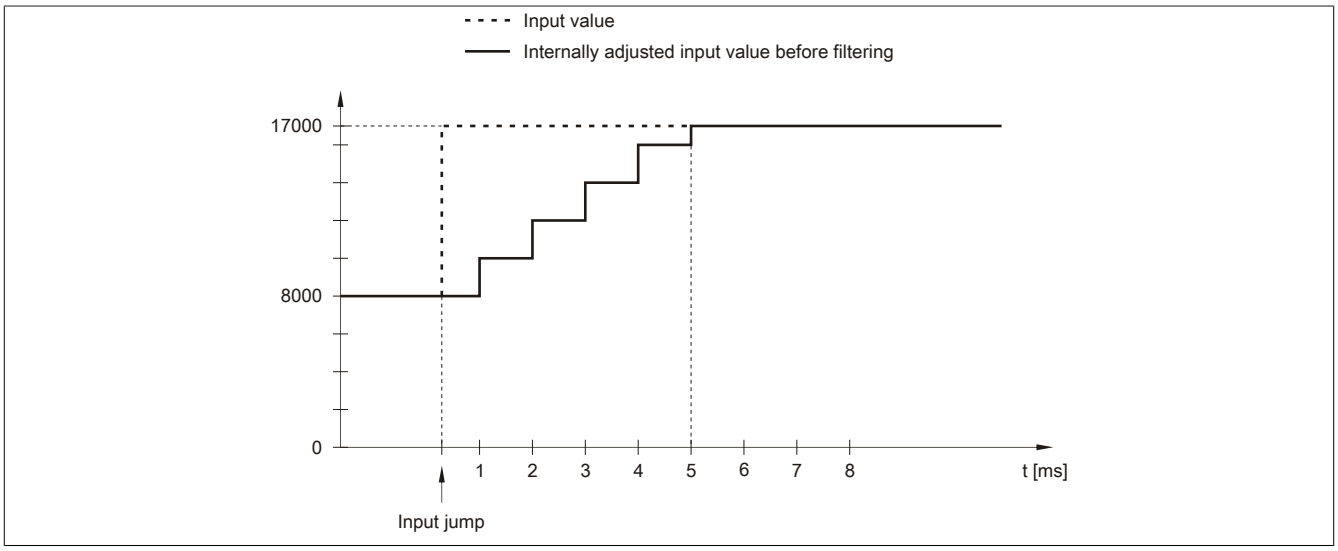

Figure 54: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

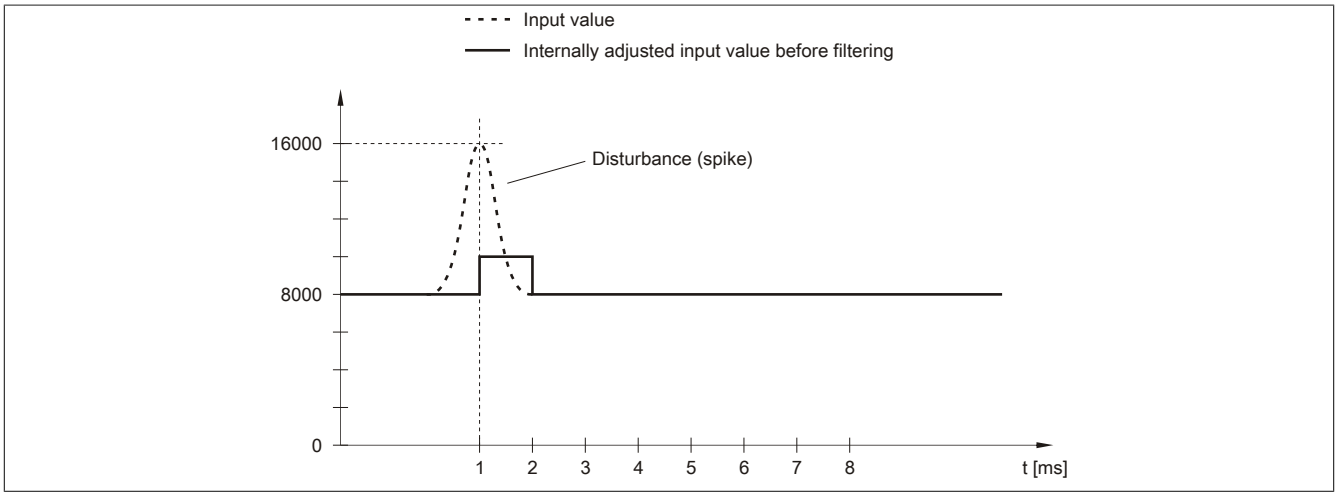

Figure 55: Adjusted input value for disturbance

Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

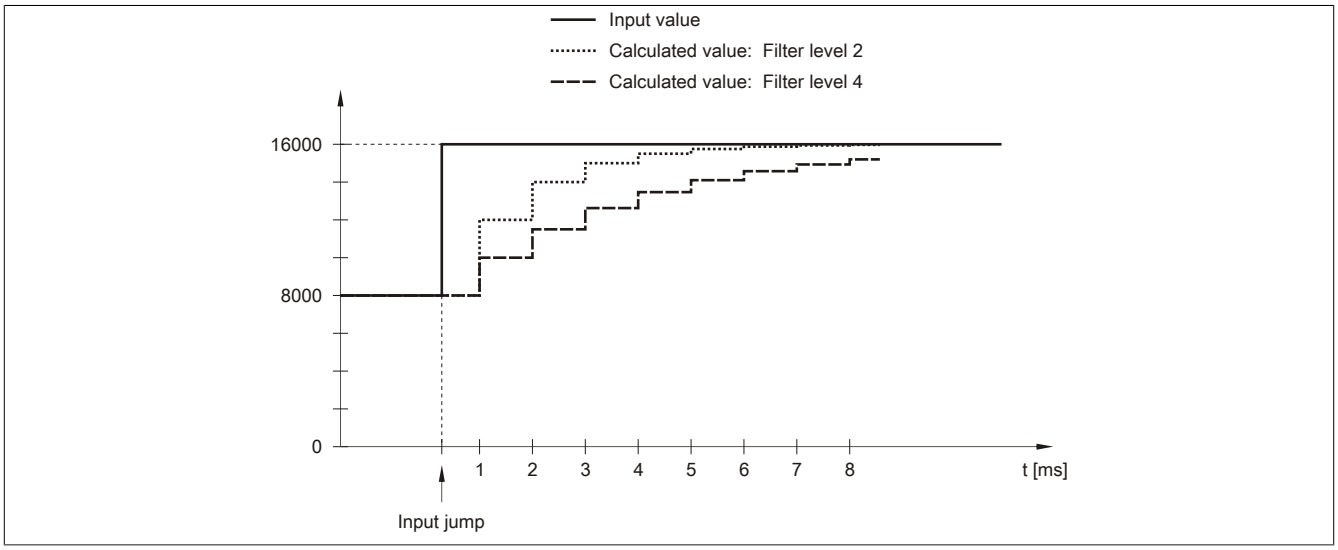

Figure 56: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

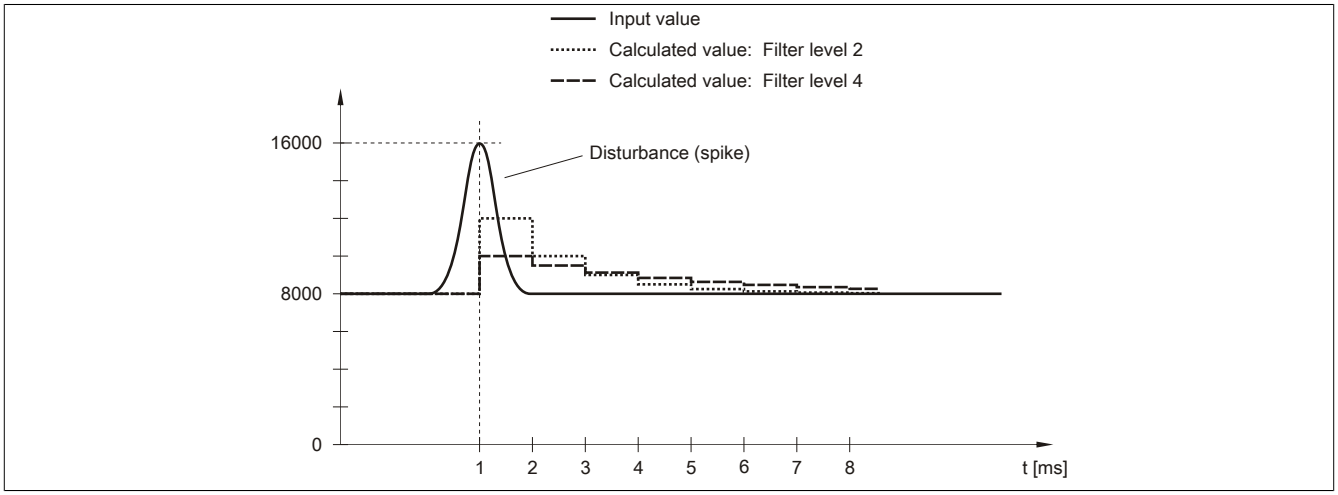

Figure 57: Calculated value during disturbance

Configuring filters

Name:
AnalogFilter01 to AnalogFilter02

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.4.9.5.2 Channel parameters

Name:
AnalogMode01 to AnalogMode02

These registers are used to predefine the operating parameters that the module will be using for the respective channel. Each channel must be enabled individually and can be configured and operated independently.

Information:

Different limit values must be configured for any display normalizing that needs to take place.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel (on/off)	0	Disabled
		1	Enabled
1	Limit exceeded	0	Disabled
		1	Enabled
2	Lower limit violation	0	Disabled
		1	Enabled
3	Reserved	0	
4	Replacement value strategy	0	Replace with static value
		1	Retain last valid value
5	Measured value scaling	0	±32767 (resolution: 16-bit)
		1	±10000 (resolution: >14-bit)
6 - 15	Reserved	0	

4.3.4.9.5.3 Upper limit value

Name:
UpperLimit01 to UpperLimit02

If the value range needs to be restricted further, this register can be used to enter new user-specific upper limit values.

Data type	Value
INT	-32767 to 32767
	-10000 to 10000

Information:

The defined limit values must take the configured scaling into consideration.

4.3.4.9.5.4 Lower limit value

Name:
LowerLimit01 to LowerLimit02

If the value range needs to be restricted further, this register can be used to enter new user-specific lower limit values.

Data type	Value
INT	-32767 to 32767
	-10000 to 10000

Information:

The defined limit values must take the configured scaling into consideration.

4.3.4.9.5.5 Hysteresis

Name:
Hysteres01 to Hysteres02

If the user-specific limit values are being used, then a hysteresis range should also be defined. These registers configure how far a limit value can be exceeded before a response is triggered.
The error status is cleared when the scaled input value once again passes the limit by at least the hysteresis value in the permitted direction.

Data type	Value
INT	-32767 to 32767
	-10000 to 10000

Information:

The hysteresis value must take the scaling into consideration.

4.3.4.9.5.6 Upper replacement value

Name:
ReplacementUpper01 to ReplacementUpper02

This register is used to define the static values to be displayed instead of the current measured value when the limit is violated.

Data type	Value
INT	-32767 to 32767

4.3.4.9.5.7 Lower replacement value

Name:
ReplacementLower01 to ReplacementLower02

This register is used to define the lower static values to be displayed instead of the current measured value when the limit is violated.

Data type	Value
INT	-32767 to 32767

4.3.4.9.5.8 Preparation time for the measured values

Name:
PreparationInterval01 to PreparationInterval02

If the last valid measured value should be kept when violating the limit value, then PreparationInterval must be defined. The measured values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measured value acquired 2 preparation intervals ago is constantly output.

Data type	Value	Information
UINT	0 to 65535	in 0.1 ms

Functionality:
Measured values are continuously converted and stored to measured value memory depending on the configured input filter. The current contents of the measured value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measured value memory are passed to the buffer.
If the check turns up an impermissible value, then the contents of the measured value memory are discarded. The copy direction between output and buffer memory reverses and the last valid value continues to be output.

Information:

If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured conversion rate of the A/D converter.

"Application" Value being measured (analog)	
↓	Condition: - Conversion interval (A/D converter) elapsed
"Measured value memory" Measured value (digital)	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Buffer" Last valid value	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Output memory" Next-to-last valid/ displayed value	

4.3.4.9.5.9 Delaying error messages

Name:
ErrorDelay01 to ErrorDelay02

This register specifies the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measured value deviations, for example.

Data type	Value
UINT	0 to 65535

4.3.4.9.5.10 Time for composite error bit

Name:
SumErrorDelay01 to SumErrorDelay02

This register can be used to set the time that an error must remain pending before the composite error bit is set.

Data type	Value
UINT	0 to 65535

4.3.4.9.6 Analog input - Communication

The measured voltage data can be obtained via 2 different registers: The unevaluated measured value contains the scaled converter value. The evaluated measured value also takes the limit values and the configured replacement value strategy into consideration.

4.3.4.9.6.1 Analog input values - Original values

Name:
AnalogInput01 to AnalogInput02

These registers are used to indicate the actual input values after standardization.

Data type	Value
INT	-32767 to 32767
	-10000 to 10000

4.3.4.9.6.2 Analog input values - Limited

Name:
AnalogInput01 to AnalogInput02

This register is used to indicate the values of the Analog input values - Original values register. In addition, the settings for limit value monitoring and replacement value strategy are applied to this register.

Data type	Value
INT	-32767 to 32767
	-10000 to 10000

4.3.4.9.6.3 Sample time

Name:
Sampletime01 to Sampletime02

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

4.3.4.9.6.4 Status of the inputs

Name:
AnalogStatus01 to AnalogStatus02
UnderflowAnalogInput01 to UnderflowAnalogInput02
OverflowAnalogInput01 to OverflowAnalogInput02
OpenLineAnalogInput01 to OpenLineAnalogInput02
SumErrorAnalogInput01 to SumErrorAnalogInput02
SensorErrorAnalogInput01 to SensorErrorAnalogInput02
IoSuppErrorAnalogInput01 to IoSuppErrorAnalogInput02

The current error status of the module channels is displayed in this register, regardless of the configured replacement value strategy. Some error information may be delayed according to the previously configured condition.

Setting "Format of status information" in Automation Studio allows you to specify whether the status information is transferred as USINT or bitwise.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	UnderflowAnalogInput01 or 02	0	Value equals lower limit
		1	Below lower limit value
1	OverflowAnalogInput01 or 02	0	Value equals upper limit
		1	Above upper limit value
2	OpenLineAnalogInput01 or 02	0	No open line detected
		1	Open line detected
3	Reserved	0	
4	SumErrorAnalogInput01 or 02	0	No error detected
		1	Composite error detected
5	Reserved	0	
6	SensorErrorAnalogInput01 or 02	0	Sensor voltage OK
		1	Sensor load too high
7	IoSuppErrorAnalogInput01 or 02	0	Module voltage OK
		1	Energy supply not permitted

UnderflowAnalogInput

The signal underflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.4.9.5.9 "ErrorDelay" register).

OverflowAnalogInput

The signal overflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.4.9.5.9 "ErrorDelay" register).

SumErrorAnalogInput

This error information derives from the status of individual errors and is only activated after the configurable delay time has passed [ms] (see 4.3.4.9.5.10 "SumErrorDelay" register). Linking this error information to an application makes it possible to hide temporary temperature value overflows and underflows, for example.

SensorErrorAnalogInput

In addition to the analog input, the module also provides the option of supplying the connected encoder with 24 VDC. If the input impedance for the sensor is too high, however, the integrated voltage supply will fail.

IoSuppErrorAnalogInput

This error is activated immediately as soon as the module detects that the necessary supply voltage is no longer being provided (<20 VDC).

4.3.4.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.4.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.3.5 X20AI2322

4.3.5.1 General information

The module is equipped with 2 inputs with 12-bit digital converter resolution. It is possible to select between the two current ranges 0 to 20 mA and 4 to 20 mA.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs, 0 to 20 mA or 4 to 20 mA
- 12-bit digital converter resolution

4.3.5.2 Order data

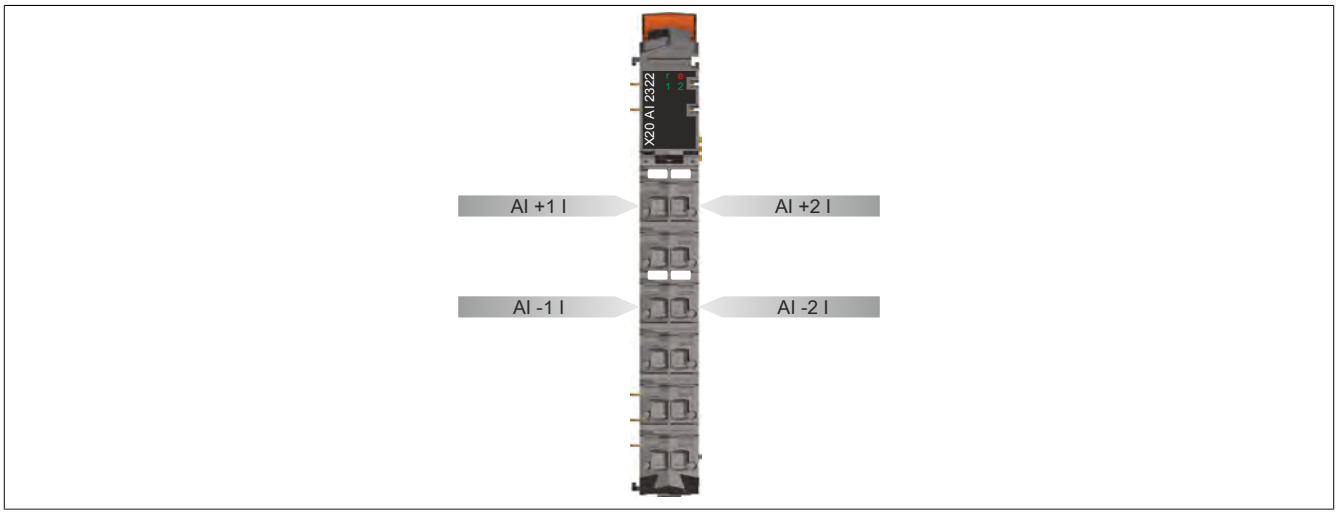
4.3.5.4 LED status indicators

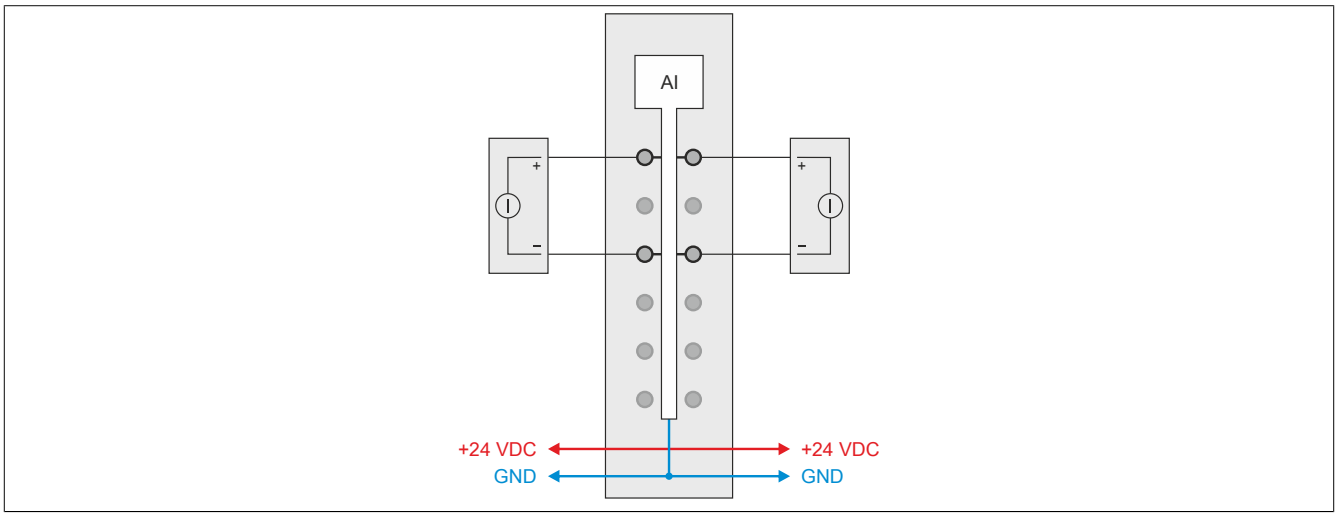
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green	Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

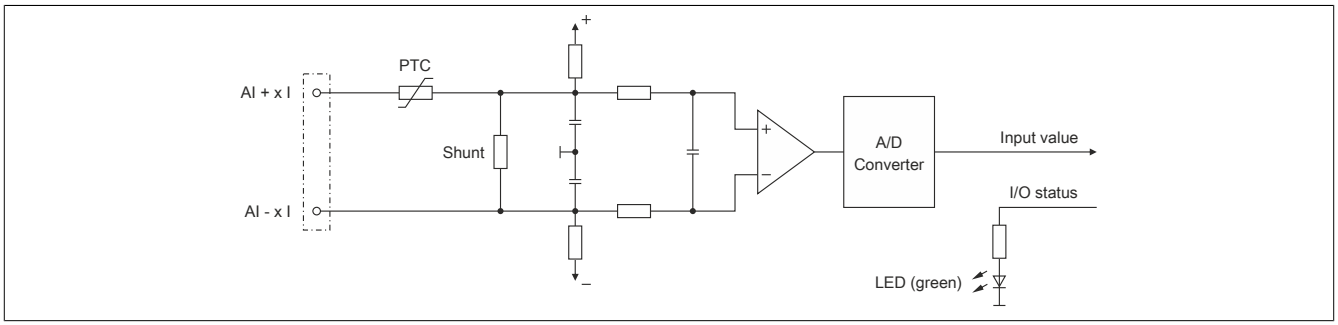
4.3.5.5 Pinout



4.3.5.6 Connection example



4.3.5.7 Input circuit diagram



4.3.5.8 Register description

4.3.5.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.5.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
16	Configuring the input filter	USINT				●
18	Channel type	USINT				●
20	Lower limit value	INT				●
22	Upper limit value	INT				●
Analog signal - Communication						
0	AnalogInput01	INT	●			
2	AnalogInput02	INT	●			
30	Input status	USINT	●			

4.3.5.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
16	-	Configuring the input filter	USINT				●
18	-	Channel type	USINT				●
20	-	Lower limit value	INT				●
22	-	Upper limit value	INT				●
Analog signal - Communication							
0	0	AnalogInput01	INT	●			
2	2	AnalogInput02	INT	●			
30	-	Input status	USINT		●		

1) The offset specifies the position of the register within the CAN object.

4.3.5.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.5.8.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.5.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput02

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	0 to 32767	Current signal 0 to 20 mA or 4 to 20 mA

4.3.5.8.6 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be >500 µs. Filtering is disabled for shorter cycle times.

If the input filter is active, then the scan rate for the channels is measured in ms. The time offset between the channels is 200 µs. The conversion takes place asynchronously to the network cycle.

4.3.5.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

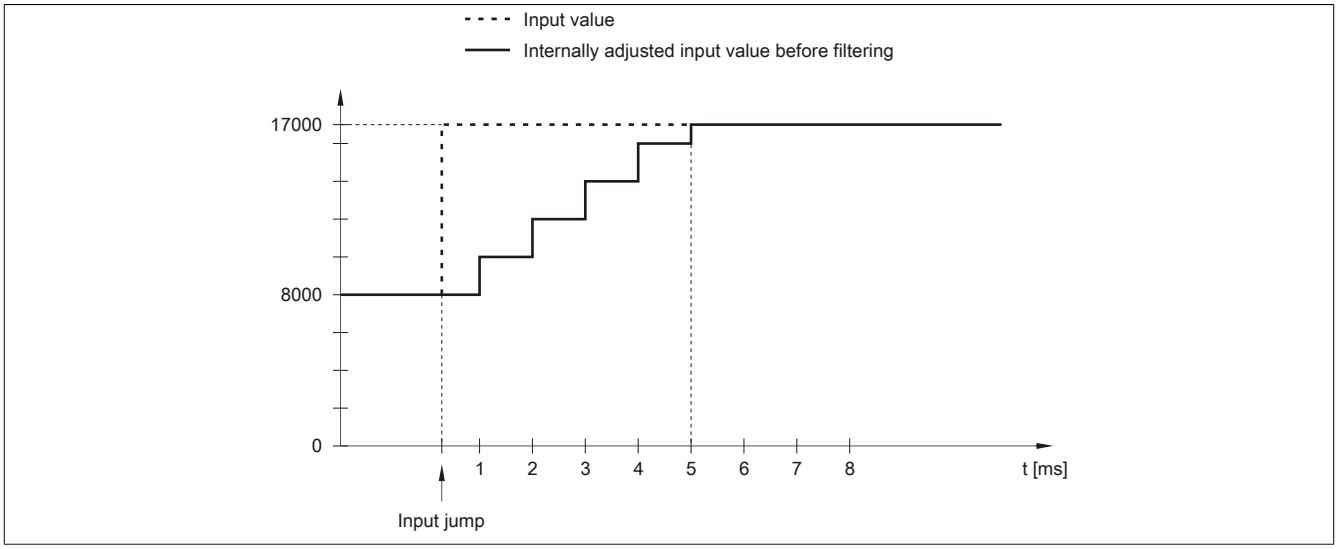


Figure 58: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

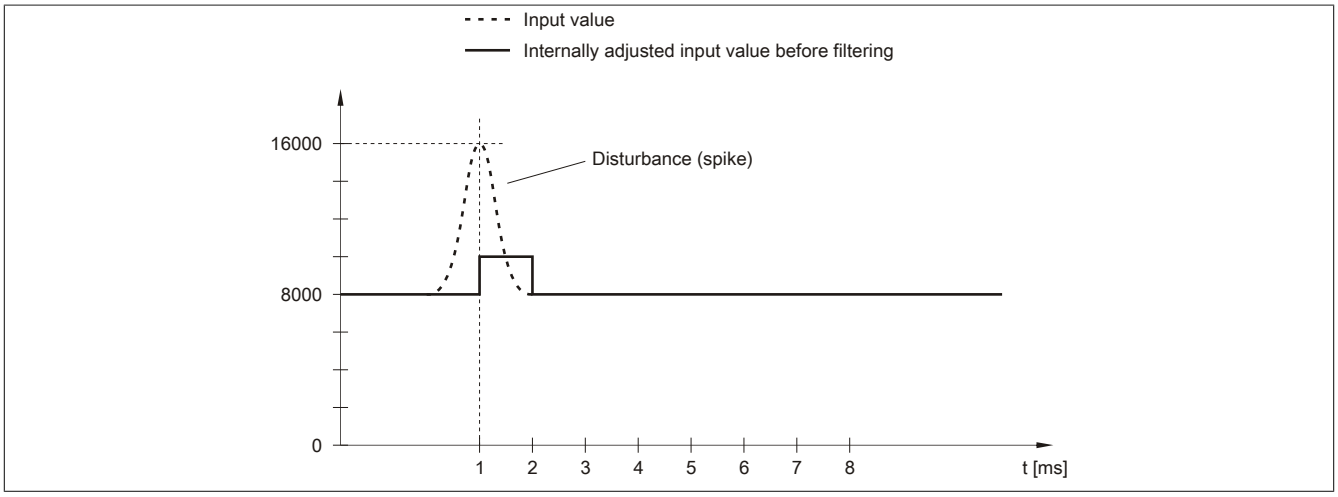

Figure 59: Adjusted input value for disturbance

4.3.5.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

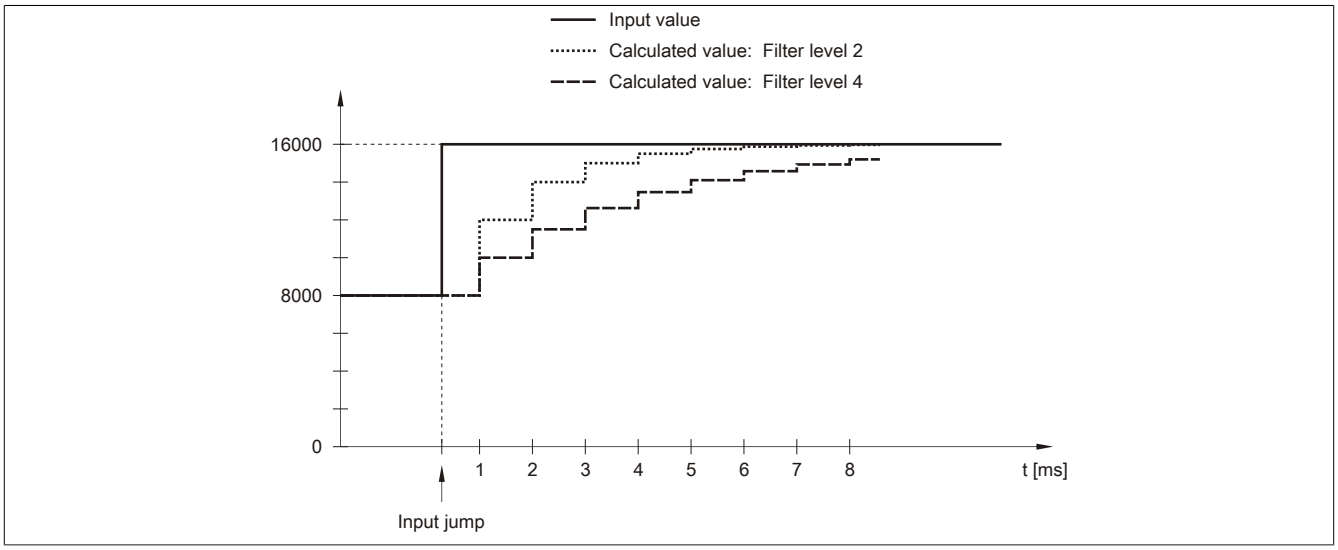

Figure 60: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

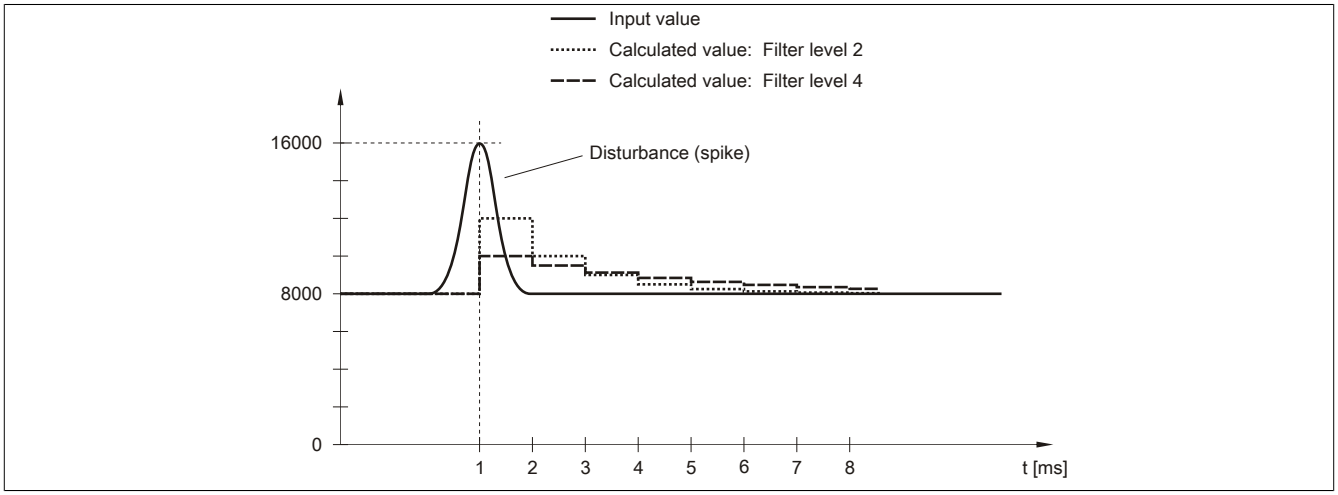

Figure 61: Calculated value during disturbance

4.3.5.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.5.8.8 Channel type

Name:
ConfigOutput02

This register can be used to set the range of the current signal. This is determined by how they are configured. The following input signals can be set:

- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	1	
2 - 3	Reserved	0	
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
5	Channel 2: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
6 - 7	Reserved	0	

4.3.5.8.9 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

- **When configured as 0 to 20 mA, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Keep in mind that this setting applies to all channels!

4.3.5.8.10 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at 20 mA.

Keep in mind that this setting applies to all channels!

4.3.5.8.11 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
4 - 7	Reserved	0	

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)	
	0 to 20 mA	4 to 20 mA
Upper limit value exceeded	+32767 (0x7FFF)	
Lower limit value exceeded	0	-8191 (0xE001)

4.3.5.8.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.5.8.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Inputs without filtering	300 µs for all inputs
Inputs with filtering	1 ms

4.3.6 X20AI2437

4.3.6.1 General information

The module is equipped with 2 current measurement inputs with 16-bit digital converter resolution.

Each current measurement input has its own sensor supply. The two channels with their respective sensor supplies are electrically isolated from each other. The user can select between the two measurement ranges 4 to 20 mA and 0 to 25 mA.

- 2 analog current measurement inputs
- Electrically isolated analog channels
- Electrically isolated sensor supplies
- 16-bit digital converter resolution

4.3.6.2 Order data

Model number	Short description	Figure
	Analog inputs

Table 33: X20AI2437 - Technical data

1) To reduce power dissipation, B&R recommends leaving unused inputs open.
2) Sensor supply
3) Ta min.: 0°C
   Ta max.: See environmental conditions
4) Based on the current measured value.
5) Based on the 25 mA measurement range.

4.3.6.4 LED status indicators

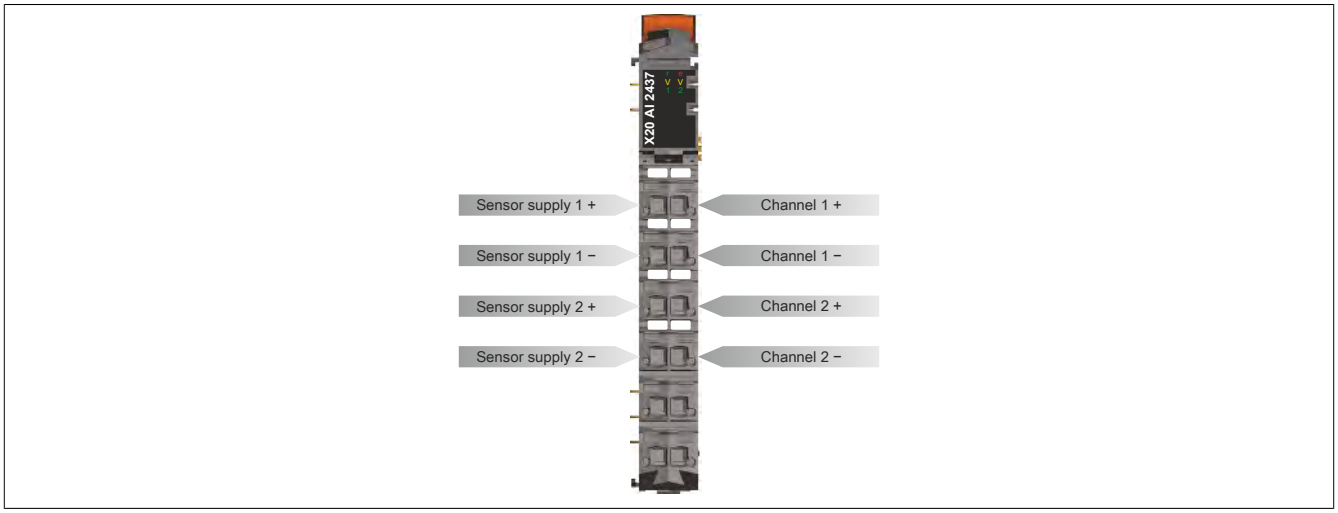
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	**Operating state**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
	Module status			
	e	Red	Off	No power to module or everything OK
			Single flash	A conversion error has occurred. This status is output along with a double flash on the channel LED of the analog input where the error occurs.
			On	Error or reset status
	Sensor supply			
	V	Yellow	Off	Overload
			On	Sensor supply in its normal operating range
	Analog input			
	1 - 2	Green	Off	Indicates one of the following cases: • No power to module • Channel disabled • Open line
			Single flash	Input signal overflow or underflow
			Double flash	A conversion error has occurred. A single flash is output on the red "e" module status LED.
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

4.3.6.5 Pinout

Shielded twisted pair cables should be used to minimize coupling disturbances. Use either one cable for each channel or a multiple twisted pair cable for both channels.

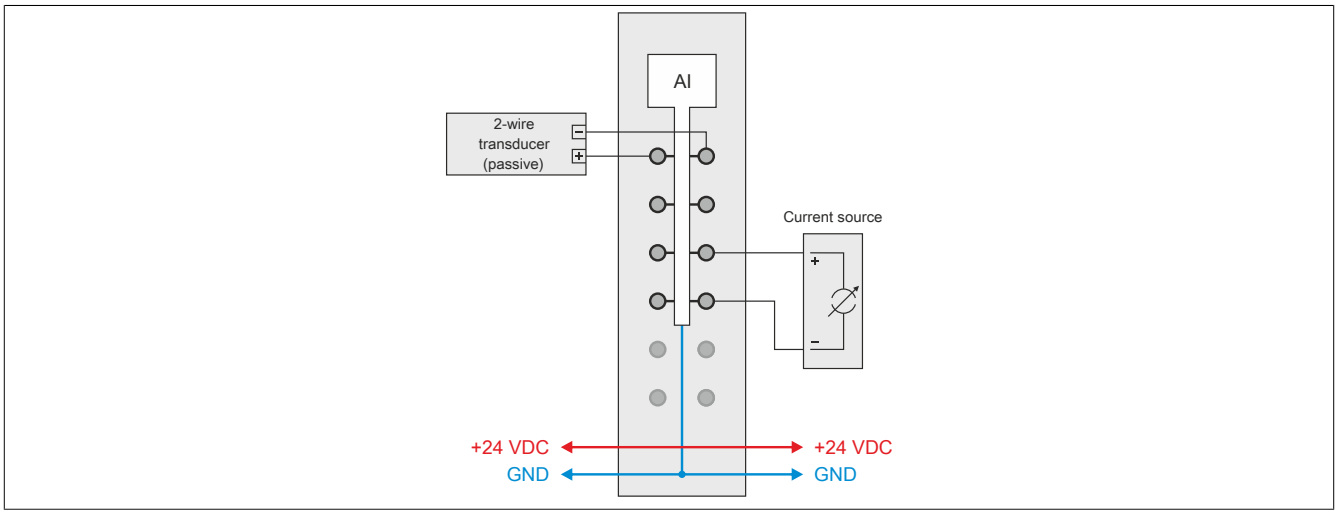


4.3.6.6 Connection examples

2-wire connections

A 2-wire connection can be implemented as follows:

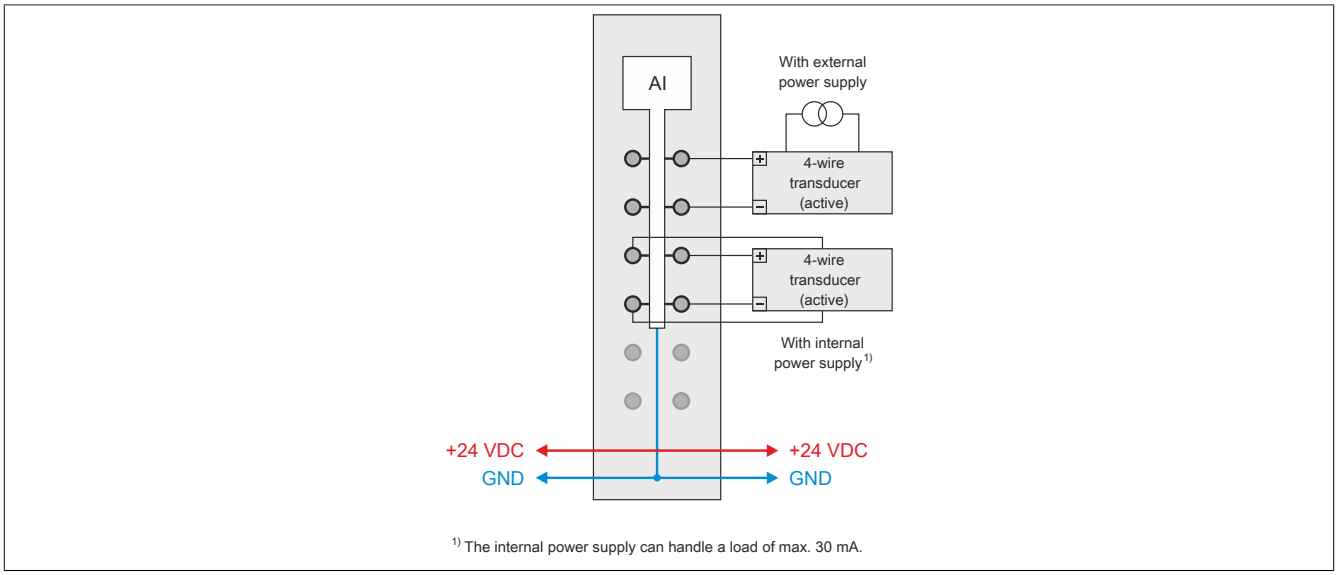
- 2-wire transducer
- Active current source



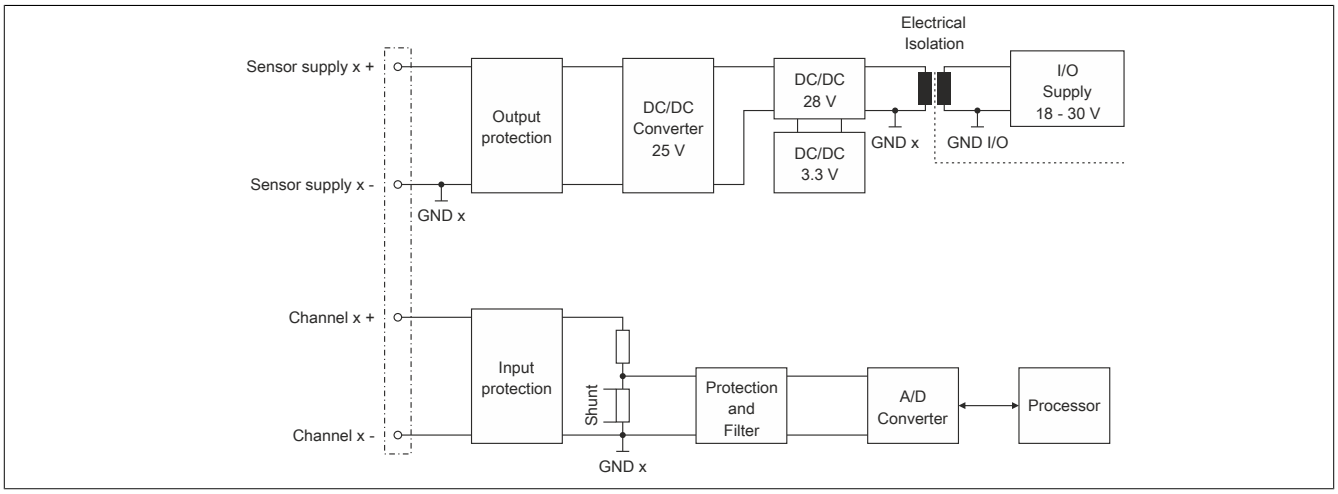
4-wire connections

A 4-wire connection can be implemented as follows:

- 4-wire transducer with external supply
- 4-wire transducer supplied by the module

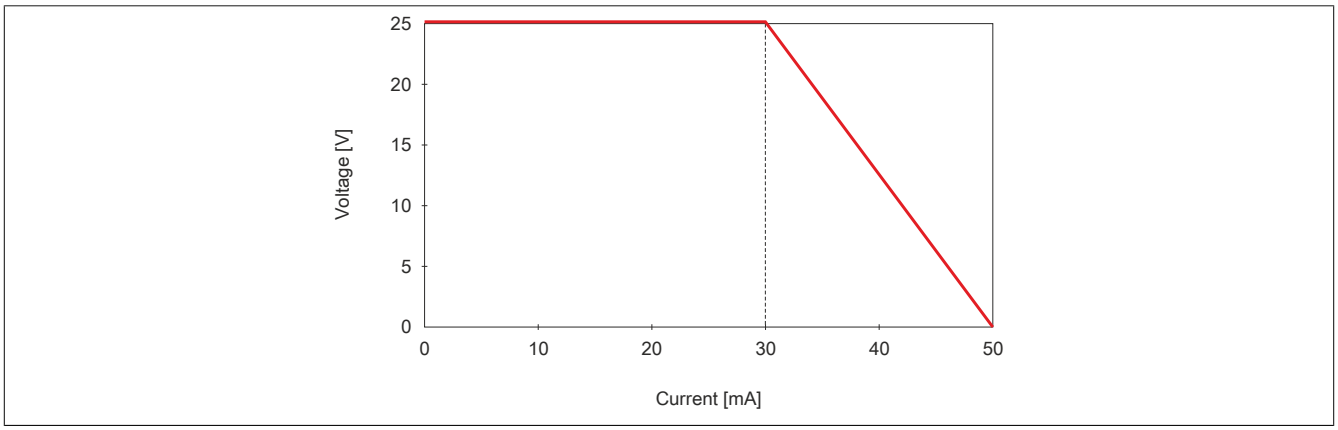


4.3.6.7 Input circuit diagram



4.3.6.8 Behavior in the event of short circuit

In the event of a short circuit, the output current for the sensor supply is limited according to the following diagram.



4.3.6.9 Register description

4.3.6.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.6.9.2 Function model 0 - default

1) The offset specifies the position of the register within the CAN object.

4.3.6.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.6.9.4 General information

The module is equipped with 2 independent electrically isolated channels. Both channels can be used to read in an analog signal. All registers necessary for this have a dual design so that the channels can be configured and operated independently of one another.
The current input signals (0 to 25 mA) can be displayed in different formats.

Specific features:

- Channels electrically isolated
- Internal supply with short circuit protection <30 mA per channel
- Configurable filter (default 50 Hz)
- Selective line monitoring can be enabled for: open line (<2 mA), underflow (<3.6 mA) or overflow (>21 mA) of a configurable threshold
- Selectable error strategy: Replacement value for the respective threshold (default) or use the last valid value

4.3.6.9.5 Analog signal - Configuration

How the analog signal is displayed can be adapted to the requirements of the application. Separate configuration registers per channel are available to aid in this.

4.3.6.9.5.1 Channel parameters

Name:
AnMode_1 to AnMode_2

These registers are used to predefine the operating parameters that the module will be using for the respective channel. Each channel must be enabled individually and can be configured and operated independently.

Information:

Different limit values must be configured for any display normalizing that needs to take place.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel	0	Channel 0x turned off
		1	Channel 0x enabled (bus controller default setting)
1	Open line detection	0	Open line monitoring turned off
		1	Open line monitoring enabled (bus controller default setting)
2	Underflow detection	0	Underflow detection turned off
		1	Underflow detection enabled (bus controller default setting)
3	Replacement value strategy	0	Use replacement values when an error occurs (bus controller default setting)
		1	Keep the last valid converted value
4 - 5	Normalization	00	Displays 0 to 25 mA as 0 to 32767
		01	Displays 0 to 25 mA as 0 to 25000 [µA] (bus controller default setting)
		10	Displays 4 to 20 mA as 0 to 32767
		11	Displays 0 to 25 mA as 0 to 65535
6 - 15	Reserved	-	

4.3.6.9.5.2 Sample rate

Name:
Samplerate_1 to Samplerate_2

A sample rate can be configured for both analog inputs independently of one another. The following formula for this parameter is derived using the desired sampling frequency:

Sample rate for A/D converter = (4920000/1024)/sampling frequency

Data type	Value	
UINT	4 to 1023	Sample rate **Examples of configurable values** 960 ... 200 ms ... 5 Hz 480 ... 100 ms ... 10 Hz 320 ... 66.7 ms ... 15 Hz 192 ... 40 ms ... 25 Hz 160 ... 33.3 ms ... 30 Hz 96 ... 20 ms ... 50 Hz (bus controller default setting) 80 ... 16.7 ms ... 60 Hz 48 ... 10 ms ... 100 Hz 9 ... 2 ms ... 500 Hz 4 ... 1 ms ... 1000 Hz

Setting to 1000 Hz will result in jitter when acquiring measured values. Jitter-free operation is possible up to 960 Hz (sample rate setting = 5).

4.3.6.9.5.3 Limit value for open line detection

Name:
OpenLoopLimit_1 to OpenLoopLimit_2

The limit value for the respective analog input must be set when open circuit monitoring is enabled and if required by the configured normalization.

Data type	Value	Information
INT	-32767 to 32767	Open circuit limit value
UINT	0 to 65535	Open circuit limit value

If limit value monitoring is active, the corresponding error status is output after a configured delay when falling below this value. Using a default value of 2000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 2000
- Displays 0 to 25 mA as 0 to 32767: 2621, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -4096, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 5243, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.4 Lower limit value

Name:
LowerLimit_1 to LowerLimit_2

If the value range needs to be restricted further, this register can be used to enter new user-specific lower limit values.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The limit value must be set for the respective analog input depending on the configured normalization. After the configured delay time has passed, the corresponding error status is given if the respective value is overrun or underrun. When this error state occurs, the "AnalogInput0x" channel is evaluated according to the replacement value strategy. Using a default value of 3600 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 3600
- Displays 0 to 25 mA as 0 to 32767: 4718, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -819, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 9437, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.5 Upper limit value

Name:
UpperLimit_1 to UpperLimit_2

If the value range needs to be restricted further, this register can be used to enter new user-specific upper limit values.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The limit value must be set for the respective analog input depending on the configured normalization. After the configured delay time has passed, the corresponding error status is given if the respective value is overrun or underrun. When this error state occurs, the AnalogInput0x channel is evaluated according to the replacement value strategy. Using a default value of 21000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 21000
- Displays 0 to 25 mA as 0 to 32767: 27524, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 32767, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 55049, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.6 Hysteresis

Name:
Hysteres_1 to Hysteres_2

If the user-specific limit values are being used, then a hysteresis range should also be defined. These registers configure how far a limit value can be exceeded before a response is triggered.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The hysteresis value must be set for the respective analog input depending on the configured normalization. The error status is cleared if the actual analog value changes by at least this hysteresis value from the limit value in the allowed direction. Using a default value of 100 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 100
- Displays 0 to 25 mA as 0 to 32767: 131, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 156, limit value = [µA] * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 262, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.7 Lower replacement value

Name:
ReplacementLower_1 to ReplacementLower_2

This register is used to define the lower static values to be displayed instead of the current measured value when the lower limit is violated.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

If the replacement strategy "Use replacement values when an error occurs" is enabled, the replacement value must be set for the respective analog input taking the configured normalization into account as well. When an overflow or underflow error status occurs, the "AnalogInput0x" channel is replaced with the corresponding value. Using a default value of 3600 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 3600
- Displays 0 to 25 mA as 0 to 32767: 4718, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -819, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 9437, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.8 Upper replacement value

Name:
ReplacementUpper_1 to ReplacementUpper_2

This register is used to define the static values to be displayed instead of the current measured value when the upper limit is violated.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

If the replacement strategy "Use replacement values when an error occurs" is activated, the replacement value must be set for the respective analog input taking the configured normalization into account as well. When an overflow or underflow error status occurs, the AnalogInput0x channel is replaced with the corresponding value. Using a default value of 21000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 21000
- Displays 0 to 25 mA as 0 to 32767: 27524, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 32767, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 55049, limit value = ([µA] * 65535) / 25000

4.3.6.9.5.9 Delaying error messages

Name:
ErrorDelay_1 to ErrorDelay_2

This register specifies the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measured value deviations, for example.

Data type	Value	Information
UINT	0 to 10	Error formation delay in conversion cycles
	2	Default value

4.3.6.9.5.10 Time for composite error bit

Name:
SumErrorDelay_1 to SumErrorDelay_2

This register specifies the time in milliseconds that one of the individual error bits must be pending until the composite error status bit is set.

Data type	Value	Information
UINT	0 to 65535	Composite error bit delay in ms
	4000	Default value

4.3.6.9.5.11 Preparation time for the measured values

Name:
PreparationInterval01 to PreparationInterval02

If the last valid measured value should be kept when violating the limit value, then PreparationInterval must be defined. The measured values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measured value acquired 2 preparation intervals ago is constantly output.

Data type	Value	Information
UINT	0 to 65535	in 0.1 ms

Functionality:
Measured values are continuously converted and stored to measured value memory. The current contents of the measured value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measured value memory are passed to the buffer.
If the check turns up an impermissible value, then the contents of the measured value memory are discarded. The copy direction between output and buffer memory reverses and the last valid value continues to be output.

Information:

If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured conversion rate of the A/D converter.

"Application" Value being measured (analog)	
↓	Condition: - Conversion interval (A/D converter) elapsed
"Measured value memory" Measured value (digital)	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Buffer" Last valid value	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Output memory" Next-to-last valid/ displayed value	

4.3.6.9.6 Analog signal - Communication

4.3.6.9.6.1 Analog input values - Limited

Name:
AnalogInput01 to AnalogInput02

These registers take the values from the 4.3.6.9.6.2 "Analog input values - Original values" registers and use them to generate the evaluated input values. The configured auxiliary functions are applied to form these values.

Data type	Value	Information
INT	0 to 25000	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 4 to 20 mA
UINT	0 to 65535	Normalizing option 0 to 25 mA

Predefining values and timing
The value 0 (null) is output to the "AnalogInput" registers until a signal short circuit or converter error causes the value to be changed.

The timing for acquiring measured values is determined by the converter hardware and the set sampling rate. The two channels are converted independently of each other and are not synchronized with the X2X Link.

Conversion time
Channel 0x sampling rate

4.3.6.9.6.2 Analog input values - Original values

Name:
Measurand01 to Measurand02

The normalized input values are transferred to these registers. Depending on the normalization selected, the value range and the data type can be adapted to the requirements of the application.

Data type	Value	Information
INT	0 to 25000	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 4 to 20 mA
UINT	0 to 65535	Normalizing option 0 to 25 mA

4.3.6.9.6.3 Sample time

Name:
AnalogSampletime01 to AnalogSampletime02

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

4.3.6.9.6.4 Status of the inputs

Name:
AnalogStatus01 to AnalogStatus02
UnderflowAnalogInput01 to UnderflowAnalogInput02
OverflowAnalogInput01 to OverflowAnalogInput02
OpenLineAnalogInput01 to OpenLineAnalogInput02
ConversionErrorAnalogInput01 to ConversionErrorAnalogInput02
SumErrorAnalogInput01 to SumErrorAnalogInput02
SensorErrorAnalogInput01 to SensorErrorAnalogInput02
IoSuppErrorAnalogInput01 to IoSuppErrorAnalogInput02

The current error status of the module channels is displayed in this register, regardless of the configured replacement value strategy. Some error information may be delayed according to the previously configured condition.

Setting "Format of status information" in Automation Studio allows you to specify whether the status information is transferred as USINT or bitwise.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	UnderflowAnalogInput01 or 02	0	No error
		1	Underflow on Channel 0x
1	OverflowAnalogInput0101 or 02	0	No error
		1	Overflow on Channel 0x
2	OpenLineAnalogInput0101 or 02	0	No error
		1	Open line on Channel 0x
3	ConversionErrorAnalogInput01 or 02	0	No error
		1	Conversion error on Channel 0x
4	SumErrorAnalogInput0101 or 02	0	No error
		1	Composite error on Channel 0x
5	Reserved	-	
6	SensorErrorAnalogInput01 or 02	0	No error
		1	Sensor error on Channel 0x
7	IoSuppErrorAnalogInput01 or 02	0	No error
		1	I/O supply error on Channel 0x

UnderflowAnalogInput

The signal underflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.6.9.5.9 "ErrorDelay" register).

OverflowAnalogInput01

The signal overflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.6.9.5.9 "ErrorDelay" register).

OpenLineAnalogInput01

Depending on the configuration, measurement information is checked for values <2 mA (4.3.6.9.5.3 "OpenLoopLimit" register) to detect a failure signal. Open line detection takes place using a configurable hysteresis value (default: 100 µA, 4.3.6.9.5.6 "Hysteresis" register). It is possible to disable open line detection ("AnalogMode" (4.3.6.9.5.1 "AnalogMode" register) to suppress alarms when hardware is not present. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (4.3.6.9.5.9 "ErrorDelay" register).

ConversionErrorAnalogInput

This error status is triggered when the hardware exceeds the conversion time.

SumErrorAnalogInput01

This error information derives from the statuses of individual errors and is only activated after the configurable delay time has passed [ms] (see 4.3.6.9.5.10 "SumErrorDelay" register). Linking this error information to an application makes it possible to hide temporary temperature value overflows and underflows, for example.

SensorErrorAnalogInput

This error is activated immediately after a fault is detected in the internal sensor supply.

IoSuppErrorAnalogInput

This error is activated immediately as soon as the module detects that the necessary supply voltage is no longer being provided (<20 VDC).

4.3.6.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.6.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.3.7 X20(c)AI2438

4.3.7.1 General information

The module is equipped with 2 current measurement inputs with 16-bit digital converter resolution. It supports the HART communication standard for data transfer, parameter configuration and diagnostics.

Each current measurement input has its own sensor supply. The two channels with their respective sensor supplies are electrically isolated from each other. The user can select between the two measurement ranges 4 to 20 mA and 0 to 25 mA.

- 2 analog current measurement inputs
- Integrated HART protocol
- Supports HART variables
- Electrically isolated analog channels
- Electrically isolated sensor supplies
- 16-bit digital converter resolution

4.3.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.3.7.3 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI2438	X20 analog input module, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports HART protocol	
X20cAI2438	X20 analog input module, coated, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports the HART protocol	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous

Table 35: X20AI2438, X20cAI2438 - Technical data

1) To reduce power dissipation, B&R recommends leaving unused inputs open.
2) Sensor supply
3) Ta min.: 0°C
   Ta max.: See environmental conditions
4) Based on the current measured value.
5) Based on the 25 mA measurement range.

4.3.7.5 LED status indicators

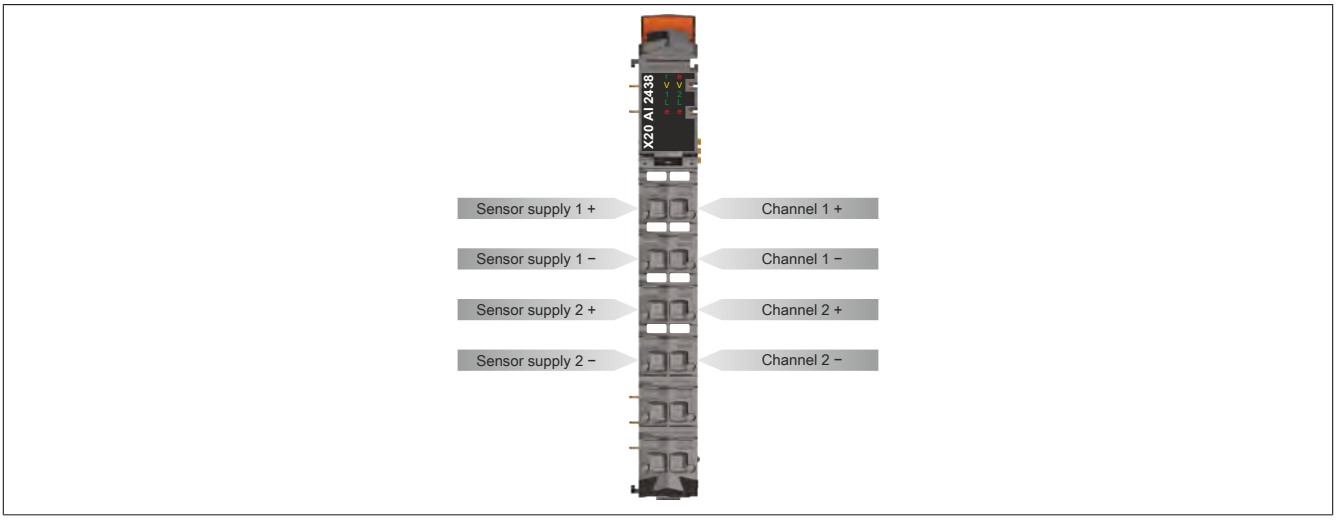
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	**Operating state**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
	Module status			
	e	Red	Off	No power to module or everything OK
			Single flash	A conversion error has occurred. This status is output along with a double flash on the channel LED of the analog input where the error occurs.
			On	Error or reset status
	Sensor supply			
	V	Yellow	Off	Module supply not connected or overload
			On	Sensor supply in its normal operating range
	Analog input			
	1 - 2	Green	Off	Indicates one of the following cases: • No power to module • Channel disabled • Open line
			Single flash	Input signal overflow or underflow
			Double flash	A conversion error has occurred. A single flash is output on the red "e" module status LED.
			On	Analog/digital converter running, value OK
	HART link			
	L	Green	Off	Indicates one of the following cases: • No power to module • HART disabled for the respective channel
			Flickering	Carrier signal active (DCD or RTS)
	HART error			
	e	Red	Off	Indicates one of the following cases: • Communication taking place without errors • No power to module • HART disabled for the respective channel
			On	Communication error

1) Depending on the configuration, a firmware update can take up to several minutes.

4.3.7.6 Pinout

Shielded twisted pair cables should be used to minimize coupling disturbances. Use either one cable for each channel or a multiple twisted pair cable for both channels.

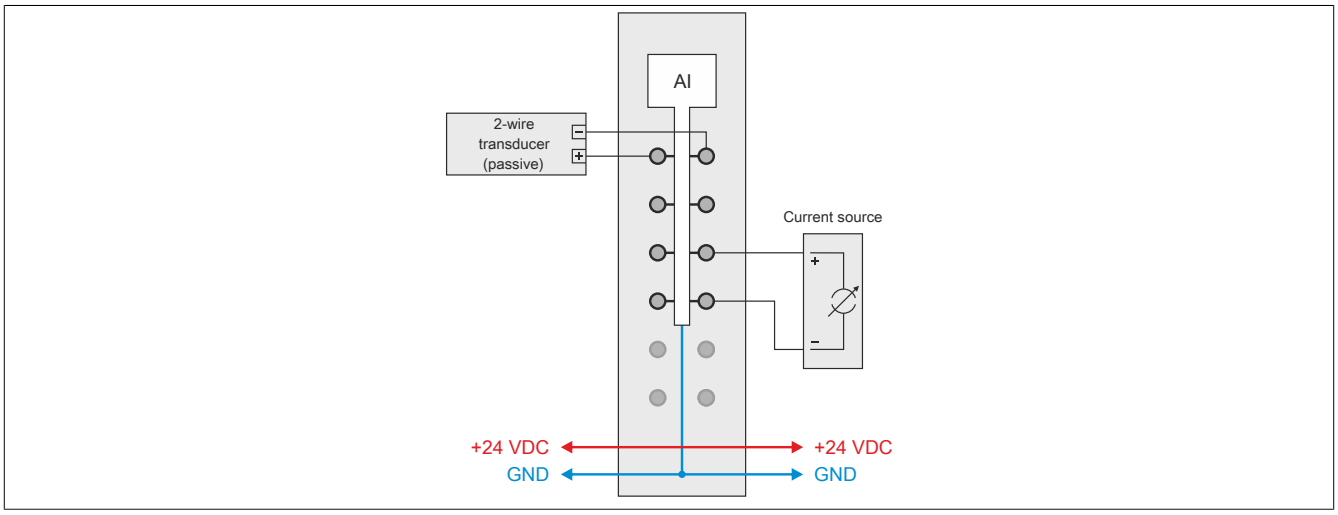


4.3.7.7 Connection examples

2-wire connections

A 2-wire connection can be implemented as follows:

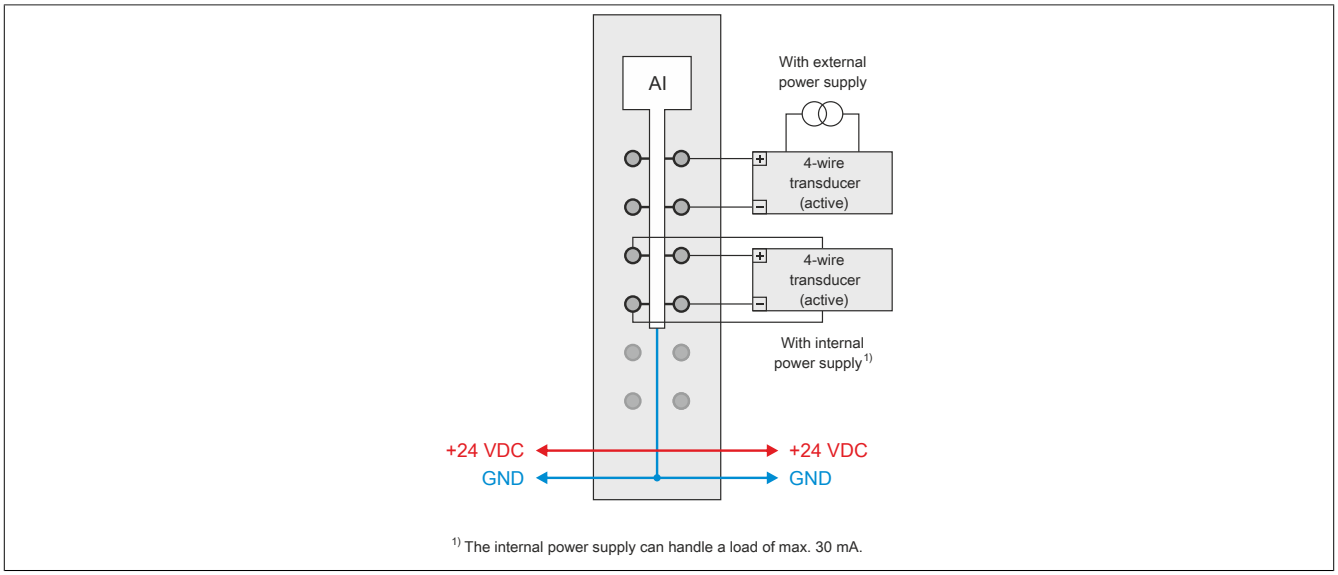
- 2-wire transducer
- Active current source



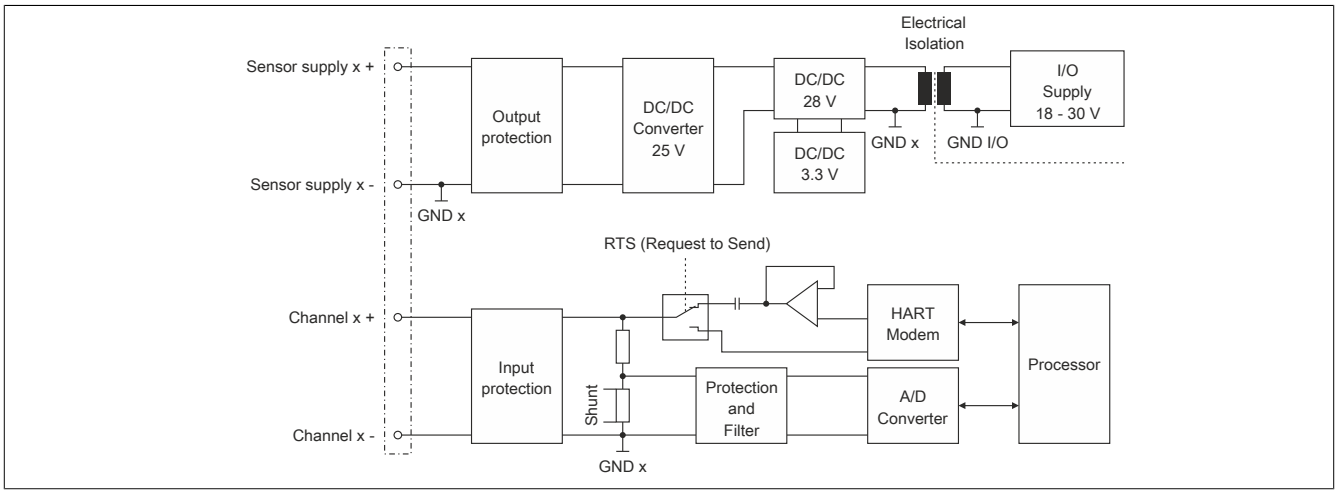
4-wire connections

A 4-wire connection can be implemented as follows:

- 4-wire transducer with external supply
- 4-wire transducer supplied by the module

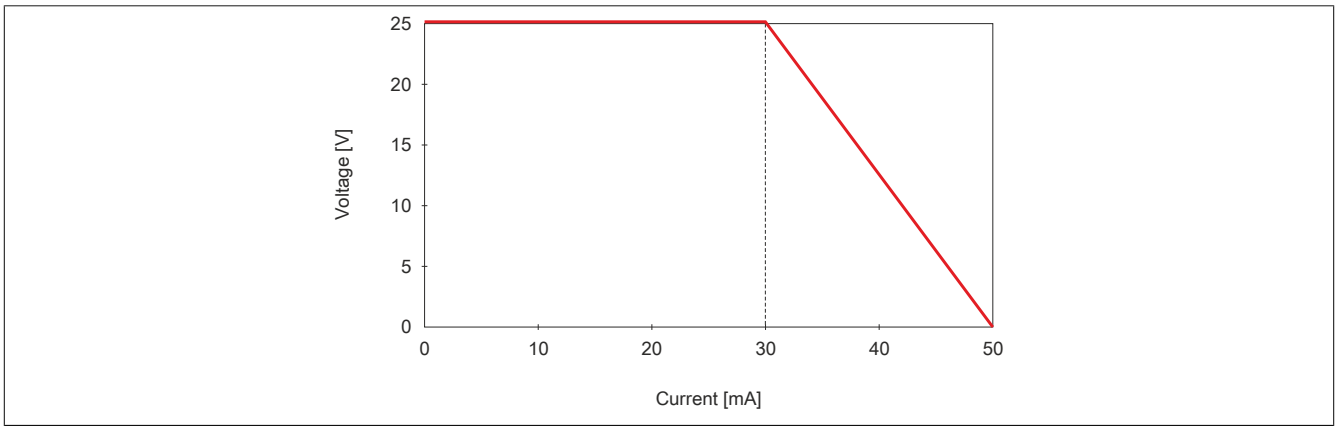


4.3.7.8 Input circuit diagram



4.3.7.9 Behavior in the event of short circuit

In the event of a short circuit, the output current for the sensor supply is limited according to the following diagram.



4.3.7.10 Register description

4.3.7.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.7.10.2 Register overview - Function model 0 (standard)

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic

1) The offset specifies the position of the register within the CAN object.

4.3.7.10.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.3.7.10.4 General information

This module is equipped with two independent electrically isolated channels with integrated HART modems. Both channels can be used to read in an analog signal and handle HART communication. All registers necessary for this have a dual design so that the channels can be configured and operated independently of one another.
The current input signals (0 to 25 mA) can be displayed in various formats and used as conventional analog inputs. The integrated HART modems retrieve digital information from the memory on the HART slave using the same physical lines that modulate the HART signals.

When using the 0 to 25 mA current input variant, the module is conceived as a HART master for 2 channels (loops), with FSK modulation of the HART protocol and sensor supply for max. 4 slaves per channel.

Each channel can use one of the following connection variants:

- Connection of one HART node (point-to-point) with evaluation of the analog signal and output of 4 HART process variables OR
- Connection of up to 15 HART nodes in multidrop mode with output of the primary HART variable from activated nodes

Specific features:

- Channels electrically isolated
- Up to 4 or 15 HART input variables per channel
- Configurable sampling rate (input filter) to transfer HART and analog signal without interference (default: 50 Hz or 20 ms)
- Internal supply with short circuit protection <30 mA per channel
- Selective line monitoring can be enabled for: open line (<2 mA), underflow (<3.6 mA) or overflow (>21 mA) of a configurable threshold
- Selectable error strategy (static replacement value or retention of the last permitted value)
- Cyclic "HART status" polling (HART command 0), the status information received is made available for channel diagnostics
- Compatible with an additional secondary master in the HART network (module acts as the primary master)
- "HART communication error bit" (shows loss of HART connection if a connection had already been established successfully)
- Optional: Burst mode for one node per channel
- Optional: Cyclic polling of "HART variables" (HART command 3 or 9)
- Optional: Sensor supply for max. 4 nodes per channel in the multidrop variant
- Optional: Flatstream functionality (module acts as bridge for HART packets)

4.3.7.10.5 Analog signal - Configuration

How the analog signal is displayed can be adapted to the requirements of the application. Separate configuration registers per channel are available to aid in this.

4.3.7.10.5.1 Channel parameters

Name:
AnMode_1 to AnMode_2

These registers are used to predefine the operating parameters that the module will be using for the respective channel. Each channel must be enabled individually and can be configured and operated independently.

Information:

Different limit values must be configured for any display normalizing that needs to take place.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel	0	Channel 0x turned off
		1	Channel 0x enabled (bus controller default setting)
1	Open line detection	0	Open line monitoring turned off
		1	Open line monitoring enabled (bus controller default setting)
2	Underflow detection	0	Underflow detection turned off
		1	Underflow detection enabled (bus controller default setting)
3	Replacement value strategy	0	Use replacement values when an error occurs (bus controller default setting)
		1	Keep the last valid converted value
4 - 5	Normalization	00	Displays 0 to 25 mA as 0 to 32767
		01	Displays 0 to 25 mA as 0 to 25000 [µA] (bus controller default setting)
		10	Displays 4 to 20 mA as 0 to 32767
		11	Displays 0 to 25 mA as 0 to 65535
6 - 15	Reserved	-	

4.3.7.10.5.2 Sample rate

Name:
Samplerate_1 to Samplerate_2

A sample rate can be configured for both analog inputs independently of one another. The following formula for this parameter is derived using the desired sampling frequency:

Sample rate for A/D converter = (4920000/1024)/sampling frequency

Data type	Value	
UINT	4 to 1023	Sample rate **Examples of configurable values** 960 ... 200 ms ... 5 Hz 480 ... 100 ms ... 10 Hz 320 ... 66.7 ms ... 15 Hz 192 ... 40 ms ... 25 Hz 160 ... 33.3 ms ... 30 Hz 96 ... 20 ms ... 50 Hz (bus controller default setting) 80 ... 16.7 ms ... 60 Hz 48 ... 10 ms ... 100 Hz 9 ... 2 ms ... 500 Hz 4 ... 1 ms ... 1000 Hz

The fastest sample rate of 10 ms for the analog inputs is predefined by the cutoff frequency of the hardware filter. When using HART communication, however, a sample rate not faster than 100 ms is recommended.

4.3.7.10.5.3 Limit value for open line detection

Name:
OpenLoopLimit_1 to OpenLoopLimit_2

The limit value for the respective analog input must be set when open circuit monitoring is enabled and if required by the configured normalization.

Data type	Value	Information
INT	-32767 to 32767	Open circuit limit value
UINT	0 to 65535	Open circuit limit value

If limit value monitoring is active, the corresponding error status is output after a configured delay when falling below this value. Using a default value of 2000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 2000
- Displays 0 to 25 mA as 0 to 32767: 2621, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -4096, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 5243, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.4 Preparation time for the measured values

Name:
PreparationInterval01 to PreparationInterval02

If the last valid measured value should be kept when violating the limit value, then PreparationInterval must be defined. The measured values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measured value acquired 2 preparation intervals ago is constantly output.

Data type	Value	Information
UINT	0 to 65535	in 0.1 ms

Functionality:
Measured values are continuously converted and stored to measured value memory. The current contents of the measured value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measured value memory are passed to the buffer.
If the check turns up an impermissible value, then the contents of the measured value memory are discarded. The copy direction between output and buffer memory reverses and the last valid value continues to be output.

Information:

If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured conversion rate of the A/D converter.

"Application" Value being measured (analog)	
↓	Condition: - Conversion interval (A/D converter) elapsed
"Measured value memory" Measured value (digital)	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Buffer" Last valid value	
↓	Condition: - PreparationInterval elapsed - Measured value permissible
"Output memory" Next-to-last valid/ displayed value	

4.3.7.10.5.5 Lower replacement value

Name:
ReplacementLower_1 to ReplacementLower_2

This register is used to define the lower static values to be displayed instead of the current measured value when the lower limit is violated.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

If the replacement strategy "Use replacement values when an error occurs" is enabled, the replacement value must be set for the respective analog input taking the configured normalization into account as well. When an overflow or underflow error status occurs, the "AnalogInput0x" channel is replaced with the corresponding value. Using a default value of 3600 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 3600
- Displays 0 to 25 mA as 0 to 32767: 4718, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -819, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 9437, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.6 Upper replacement value

Name:
ReplacementUpper_1 to ReplacementUpper_2

This register is used to define the static values to be displayed instead of the current measured value when the upper limit is violated.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

If the replacement strategy "Use replacement values when an error occurs" is activated, the replacement value must be set for the respective analog input taking the configured normalization into account as well. When an overflow or underflow error status occurs, the AnalogInput0x channel is replaced with the corresponding value. Using a default value of 21000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 21000
- Displays 0 to 25 mA as 0 to 32767: 27524, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 32767, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 55049, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.7 Lower limit value

Name:
LowerLimit_1 to LowerLimit_2

If the value range needs to be restricted further, this register can be used to enter new user-specific lower limit values.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The limit value must be set for the respective analog input depending on the configured normalization. After the configured delay time has passed, the corresponding error status is given if the respective value is overrun or underrun. When this error state occurs, the "AnalogInput0x" channel is evaluated according to the replacement value strategy. Using a default value of 3600 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 3600
- Displays 0 to 25 mA as 0 to 32767: 4718, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: -819, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 9437, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.8 Upper limit value

Name:
UpperLimit_1 to UpperLimit_2

If the value range needs to be restricted further, this register can be used to enter new user-specific upper limit values.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The limit value must be set for the respective analog input depending on the configured normalization. After the configured delay time has passed, the corresponding error status is given if the respective value is overrun or underrun. When this error state occurs, the AnalogInput0x channel is evaluated according to the replacement value strategy. Using a default value of 21000 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 21000
- Displays 0 to 25 mA as 0 to 32767: 27524, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 32767, limit value = (([µA] * 1.31068) - 5242.72) * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 55049, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.9 Hysteresis

Name:
Hysteres_1 to Hysteres_2

If the user-specific limit values are being used, then a hysteresis range should also be defined. These registers configure how far a limit value can be exceeded before a response is triggered.

Data type	Value
INT	-32767 to 32767
UINT	0 to 65535

The hysteresis value must be set for the respective analog input depending on the configured normalization. The error status is cleared if the actual analog value changes by at least this hysteresis value from the limit value in the allowed direction. Using a default value of 100 µA, the following values and formulas result for this parameter:

- Displays 0 to 25 mA as 0 to 25000: 100
- Displays 0 to 25 mA as 0 to 32767: 131, limit value = ([µA] * 32767) / 25000
- Displays 4 to 20 mA as 0 to 32767: 156, limit value = [µA] * 1.5625
- Displays 0 to 25 mA as 0 to 65535: 262, limit value = ([µA] * 65535) / 25000

4.3.7.10.5.10 Delaying error messages

Name:
ErrorDelay_1 to ErrorDelay_2

This register specifies the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measured value deviations, for example.

Data type	Value	Information
UINT	0 to 10	Error formation delay in conversion cycles
	2	Default value

4.3.7.10.5.11 Time for composite error bit

Name:
SumErrorDelay_1 to SumErrorDelay_2

This register specifies the time in milliseconds that one of the individual error bits must be pending until the composite error status bit is set.

Data type	Value	Information
UINT	0 to 65535	Composite error bit delay in ms
	4000	Default value

4.3.7.10.6 Analog signal - Communication

4.3.7.10.6.1 Analog input values - Limited

Name:
AnalogInput01 to AnalogInput02

These registers take the values from the 4.3.6.9.6.2 "Analog input values - Original values" registers and use them to generate the evaluated input values. The configured auxiliary functions are applied to form these values.

Data type	Value	Information
INT	0 to 25000	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 4 to 20 mA
UINT	0 to 65535	Normalizing option 0 to 25 mA

Predefining values and timing
The value 0 (null) is output to the "AnalogInput" registers until a signal short circuit or converter error causes the value to be changed.

The timing for acquiring measured values is determined by the converter hardware and the set sampling rate. The two channels are converted independently of each other and are not synchronized with the X2X Link.

Conversion time
Channel 0x sampling rate

4.3.7.10.6.2 Analog input values - Original values

Name:
Measurand01 to Measurand02

The normalized input values are transferred to these registers. Depending on the normalization selected, the value range and the data type can be adapted to the requirements of the application.

Data type	Value	Information
INT	0 to 25000	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 0 to 25 mA
	0 to 32,767	Normalizing option 4 to 20 mA
UINT	0 to 65535	Normalizing option 0 to 25 mA

4.3.7.10.6.3 Sample time

Name:
AnalogSampletime01 to AnalogSampletime02

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

4.3.7.10.6.4 Status of the inputs

Name:
AnalogStatus01 to AnalogStatus02
UnderflowAnalogInput01 to UnderflowAnalogInput02
OverflowAnalogInput01 to OverflowAnalogInput02
OpenLineAnalogInput01 to OpenLineAnalogInput02
ConversionErrorAnalogInput01 to ConversionErrorAnalogInput02
SumErrorAnalogInput01 to SumErrorAnalogInput02
SensorErrorAnalogInput01 to SensorErrorAnalogInput02
IoSuppErrorAnalogInput01 to IoSuppErrorAnalogInput02

The current error status of the module channels is displayed in this register, regardless of the configured replacement value strategy. Some error information may be delayed according to the previously configured condition.

Setting "Format of status information" in Automation Studio allows you to specify whether the status information is transferred as USINT or bitwise.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	UnderflowAnalogInput01 or 02	0	No error
		1	Underflow on Channel 0x
1	OverflowAnalogInput0101 or 02	0	No error
		1	Overflow on Channel 0x
2	OpenLineAnalogInput0101 or 02	0	No error
		1	Open line on Channel 0x
3	ConversionErrorAnalogInput01 or 02	0	No error
		1	Conversion error on Channel 0x
4	SumErrorAnalogInput0101 or 02	0	No error
		1	Composite error on Channel 0x
5	Reserved	-	
6	SensorErrorAnalogInput01 or 02	0	No error
		1	Sensor error on Channel 0x
7	IoSuppErrorAnalogInput01 or 02	0	No error
		1	I/O supply error on Channel 0x

UnderflowAnalogInput

The signal underflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.6.9.5.9 "ErrorDelay" register).

OverflowAnalogInput01

The signal overflow error status is indicated here according to the configuration. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (see 4.3.6.9.5.9 "ErrorDelay" register).

OpenLineAnalogInput01

Depending on the configuration, measurement information is checked for values <2 mA (4.3.6.9.5.3 "OpenLoopLimit" register) to detect a failure signal. Open line detection takes place using a configurable hysteresis value (default: 100 µA, 4.3.6.9.5.6 "Hysteresis" register). It is possible to disable open line detection ("AnalogMode" (4.3.6.9.5.1 "AnalogMode" register) to suppress alarms when hardware is not present. This error information is enabled as a multiple of the conversion cycle only after the configurable delay time has passed (4.3.6.9.5.9 "ErrorDelay" register).

ConversionErrorAnalogInput

This error status is triggered when the hardware exceeds the conversion time.

SumErrorAnalogInput01

This error information derives from the statuses of individual errors and is only activated after the configurable delay time has passed [ms] (see 4.3.6.9.5.10 "SumErrorDelay" register). Linking this error information to an application makes it possible to hide temporary temperature value overflows and underflows, for example.

SensorErrorAnalogInput

This error is activated immediately after a fault is detected in the internal sensor supply.

IoSuppErrorAnalogInput

This error is activated immediately as soon as the module detects that the necessary supply voltage is no longer being provided (<20 VDC).

4.3.7.10.7 HART

HART (Highway Addressable Remote Transducer) is a protocol for communicating with intelligent field devices. It was developed in order to more efficiently use the infrastructure for transferring analog signals. The digital HART notifications are modulated to the analog signal using Frequency Shift Keying (FSK). HART can thus use the same physical line as the analog signal without influencing the original function.
HART slaves are able to determine different process data independently and prepare HART concordantly. This protocol supports polling of the value of a process variable as well as its unit and status. Field devices usually supply their information after the master requests it. In newer revisions, it is also possible to transfer configuration data.

There are two different types of HART networks. In a *point-to-point* network, only one slave is connected to a HART master. Here, the analog signal and the HART signal can be transferred over the same line. Managing several slaves with HART requires what is known as a *multidrop* network. Here, each HART slave is assigned and identified by a unique address. Classic analog signals cannot be clearly traced in bus systems. As a result, the HART protocol does not support analog information transfers in multidrop networks up to and including HART Revision 5.

4.3.7.10.7.1 HART - Configuration

HART modules are analog modules equipped with a HART modem. For each channel, a separate HART network can be managed by the module, which acts as a primary master. Once configured successfully, the HART information is stored in the module where it can then be used by the PLC.

The number of HART slaves must be specified in the configuration.
If only one slave is connected to the HART channel, then it is part of a point-to-point network. The module can then prepare up to four process variables from the connected slave.
Multidrop mode allows up to 15 HART slaves to be connected. The primary process variable from each slave is then retrieved.

HartNodeCnt

Name:
HartCodeCnt_1 to HartCodeCnt_2

These registers tell the module how many HART slaves are connected to a channel.

Information:

If a slave is not connected to one of the HART channels, the value "0" should be defined in this register. This shortens the I/O update time and avoids superfluous error messages.

Data type	Value	Information	
USINT	0	HART communication disabled for this channel	
	1	Point-to-point	Standard HART communication (bus controller default)
	2 to 15	Multidrop	Number of HART slave nodes

HartBurstNode

Name:
HartBurstNode_1 to HartBurstNode_2

In addition to the type of network, the user can also choose from two different types of communication behavior. Conventional HART communication relies on polling. The module requests the data from the individual HART slaves and receives the corresponding information from each slave as a response. If a HART node should be queried in short time intervals, the user can configure burst mode for channels on one node. In this case, the slave transmits the node's information cyclically without constant prompting from the master.
The "HartBurstNode" registers are therefore used to enter the node numbers (short address) for the channels whose information should be retrieved using burst mode. Burst mode itself is enabled with the "HartMode" register.

Data type	Value	Information	
USINT	0 to 15	Point-to-point	0 (bus controller default)

HartMode

Name:
HartMode_1 to HartMode_2

The user can use these registers to configure the communication behavior of each of the HART channels. Generally, the HART nodes are polled individually. This register can still be used to start or stop burst mode when needed. In burst mode, a node transmits its information cyclically instead of continuously. As a result, the HART standard allows the simultaneous usage of both burst mode and polling.

Information:

To retrieve information with burst mode, theHartBurstNode register must be configured correctly.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Slave polling mode	0	Polling mode enabled (Bus Controller Default)
		1	Polling mode disabled
1	Start slave burst mode	0	No response to burst (bus controller default)
		1	Enables burst mode in the HartBurstNode node
2	Stop slave burst mode	0	No response to burst (bus controller default)
		1	Disables burst mode, if enabled
3 - 7	Reserved	-	

4.3.7.10.7.2 HART - Communication

Once the configuration has been completed, the information is retrieved automatically and transferred to the module's registers. A separate register in the module is implemented for each piece of information. HART modules are designed to retrieve up to 15 pieces of information per channel. The module reads in the data, stores it in temporary memory and prepares it for retrieval. When the X2X master accesses the module registers, it is irrelevant whether the HART data originates from a point-to-point network or a multidrop network.

Overview of internal module mapping

	Point-to-point network (1 HART slave)	*Multidrop network (2 to 15 HART slaves)*
(Pv)Input_01	Primary piece of information from HART node 1	Primary piece of information from HART node 1
(Pv)Input_02	Secondary piece of information from HART node 1	Primary piece of information from HART node 2
...	...	...
(Pv)Input_04	Quaternary piece of information from HART node 1	Primary piece of information from HART node 4
(Pv)Input_05	Reserved	Primary piece of information from HART node 5
...	...	...
(Pv)Input_15	Reserved	Primary piece of information from HART node 15

The HART specifications stipulates that information from a HART node be split into various pieces. The value of a process variable is stored to the respective "PvInput" register and has a size of 4 bytes (REAL) in accordance with the HART specification. Due to the length limitation of 30 bytes on the X2X link, there are restrictions to the number of possible cyclic variables. It is recommended to only transfer a maximum of 2 "PvInput" registers cyclically to the X2X master. All other information should be transferred in a different way. To access HART information, the user can choose from among the following methods:

- Data points that are configured to be transferred cyclically are read once per bus cycle. This method allows information to be exchanged between the module and the X2X master in real time. Nevertheless, the length limitation may prevent all data from being retrieved within one cycle.
- If the AsIOAcc library is used, information is retrieved acyclically only when it is needed, i.e. communication can be adapted to the application running on the X2X master. In this way, all of the necessary module registers on the X2X link can be polled despite the length limitation.
  This method of information exchange is not real-time capable.
- HART modules are equipped with a FlatStream interface. When using FlatStream communication, the module acts a bridge between the X2X master and the HART slave, i.e. the X2X master communicates directly with the HART slave (see section "FlatStream communication""FlatStream communication").
  FlatStream communication is also not real-time capable. It allows unrestricted access to the HART slave. The user must have sufficient knowledge of the HART protocol command set as well as the capabilities of the HART slave device.

PvInput

Name:
PvInput_01 to PvInput_15
PvInput_01_01 to PvInput_01_15
PvInput_02_01 to PvInput_02_15

These registers return the current value of the process variable that has been read.

Information:

These registers are of data type REAL, which means that the available bytes on the X2X Link are filled more quickly when operated cyclically. If information from several slave nodes is needed, it must be retrieved acyclically or using Flatstream .

Data type	Value	Information
REAL	IEEE745 SPF	32-bit data type with valid value
	0x7FA00000	Not a number (NaN) with invalid value

PvUnit

Name:
PvUnit_01 to PvUnit_15
PvUnit_01_01 to PvUnit_01_15
PvUnit_02_01 to PvUnit_02_15

These registers return a HART-specific code that specifies the unit for the measured value. The coding for this is established in the HART specification.

Data type	Value
USINT	See description of the HART slave See HART specification

PvSampleTime

Name:
PvSampleTime01 to PvSampleTime02
PvSampleTime01_01 to PvSampleTime01_15
PvSampleTime02_01 to PvSampleTime02_15

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

This refers to the point in time when the HART master receives the slave's response. This is a way to check whether new HART information has been read since the last X2X cycle.

Information:

The cycle times of a HART network are relatively long so that it is not possible to reliably determine when the measured value is retrieved with just this information.

PvNodeComStatus

Name:
PvNodeComStatus01 to PvNodeComStatus02
PvNodeComStatus01_01 to PvNodeComStatus01_15
PvNodeComStatus02_01 to PvNodeComStatus02_15

These registers return information about whether a value that has been read is valid. According to the HART specification, this type of status register consists of two parts. The high byte stores the "response code" and the low byte the "field device status". This makes it possible to check the current status of a read process variable.

These registers can be checked before further processing information in temporary storage. If the current value is 0x0000, an error was not detected during the HART transfer and the information from the checked node can be used. If a different value is present, the situation in the HART network should be checked. This can be done using an extension register, for example.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Quality - Node information 2 to n	0	Digital measured value okay
		1	Measured value outside the permitted range
1	Quality - Node information 1	0	Digital measured value okay
		1	Measured value outside the permitted range
2	Limit violation	0	Parameter okay
		1	Invalid measured value(s) or encoder supply value
3	Static analog signal	0	Normal value change/fluctuation
		1	Constant analog value of Node 1 slave
4	Additional status information (only supported by a few slaves)	0	Not available
		1	Available (only using Flatstream command #48)
5	Restart	0	Normal operation
		1	Field device restarts
6	Device ID	0	Unchanged
		1	Changed
7	Device error	0	Measured value okay
		1	Questionable measured value information
8 - 14	Response code, if relevant	x	See **HART-specific response code**
15	Error - Communication	0	Error-free communication (response code irrelevant)
		1	Faulty communication (response code relevant)

HART-specific response code (excerpt):

0x82 … Receive buffer overflow 0x88 … Checksum incorrect 0x90 … Faulty protocol structure 0xA0 … Overrun 0xC0 … Parity not allowed 0xFF … Timeout	If a HART communication error occurs, the response code is written. Bit 15 is always set.

Retrieving information that has been read

After the node data has been transferred to the module registers, the information can be retrieved from the module. A separate register in the module is implemented for each piece of information.

PvCountHartRequest

The "PvCountHartRequest" registers are increased once the module is ready to transmit a message to the corresponding channel.

Data type	Value
UINT	0 to 65535

PvCountHartTimeout

The "PvCountHartTimeout" registers are increased if the slave exceeds the maximum permitted time before responding to the module's request.

Data type	Value
UINT	0 to 65535

PvCountHartRxError

The "PvCountHartRxError" registers are increased if communication errors occur on Layer 1 of the OSI model (e.g. transmission error as per parity bit).

Data type	Value
UINT	0 to 65535

PvCountHartFrameError

The "PvCountHartFrameError" registers are increased if communication errors occur on Layer 2 of the OSI model (e.g. faulty telegram structure).

Data type	Value
UINT	0 to 65535

PvNodeFound

Name:
PvNodeFound01 to PvNodeFound02

These registers provide information about which nodes were detected on which channel (slave identified successfully).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
1	Node 2 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
...		...	
13	Node 14 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
14	Node 15 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
15	Reserved	-	

PvNodeError

Name:
PvNodeError01 to PvNodeError02

These registers contain the HART communications error bits. These bits are set if the connection to a node was established successfully but the node at some point no longer responds as it should (e.g. the HART slave exceeds the configured timeout / number of retries).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
1	Node 2 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
...		...	
13	Node 14 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
14	Node 15 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
15	Reserved	-	

4.3.7.10.7.3 Extended configuration

The additional configuration registers are specified values when the module is started. In most systems, the user does not need to make any adjustments here. Register values should only be changed if HART network communication is not taking place satisfactorily.

HartNodeDisable

Name:
HartNodeDisable_1 to HartNodeDisable_2

These registers are intended for things like maintenance. They make it possible to cut off configured HART nodes to suppress error messages for a certain period of time. During normal operation, the configured nodes must be switched active to guarantee that the procedure runs smoothly.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Enabled (bus controller default setting)
		1	Disabled
1	Node 2 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
...		...	
13	Node 14 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
14	Node 15 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
15	Reserved	-	

HartProtTimeOut

Name:
HartProtTimeOut_1 to HartProtTimeOut_2

These registers specify the time span within which the slave must respond for the response to be valid.

Data type	Values [ms]	Information
UINT	0 to 65535	Bus controller default: 256 [ms]

HartProtRetry

Name:
HartProtRetry_1 to HartProtRetry_2

These registers determine how many times the master retries a request if it receives an invalid response or no response at all.

Data type	Value	Information
UINT	0 to 65535	Bus controller default: 3 attempts

HartPreamble

Name:
HartPreamble_1 to HartPreamble_2

The length of the preamble can be set in these registers. The preamble is used to synchronize the receiver to the transmitter. The longer the declared preamble, the less chance that a communication error will occur. Nevertheless, a useful signal is not transmitted during synchronization so the preamble should be kept as short as possible.

Data type	Value	Information
UINT	5 to 20	Bus controller default: 20

4.3.7.10.8 FlatStream communication

4.3.7.10.8.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

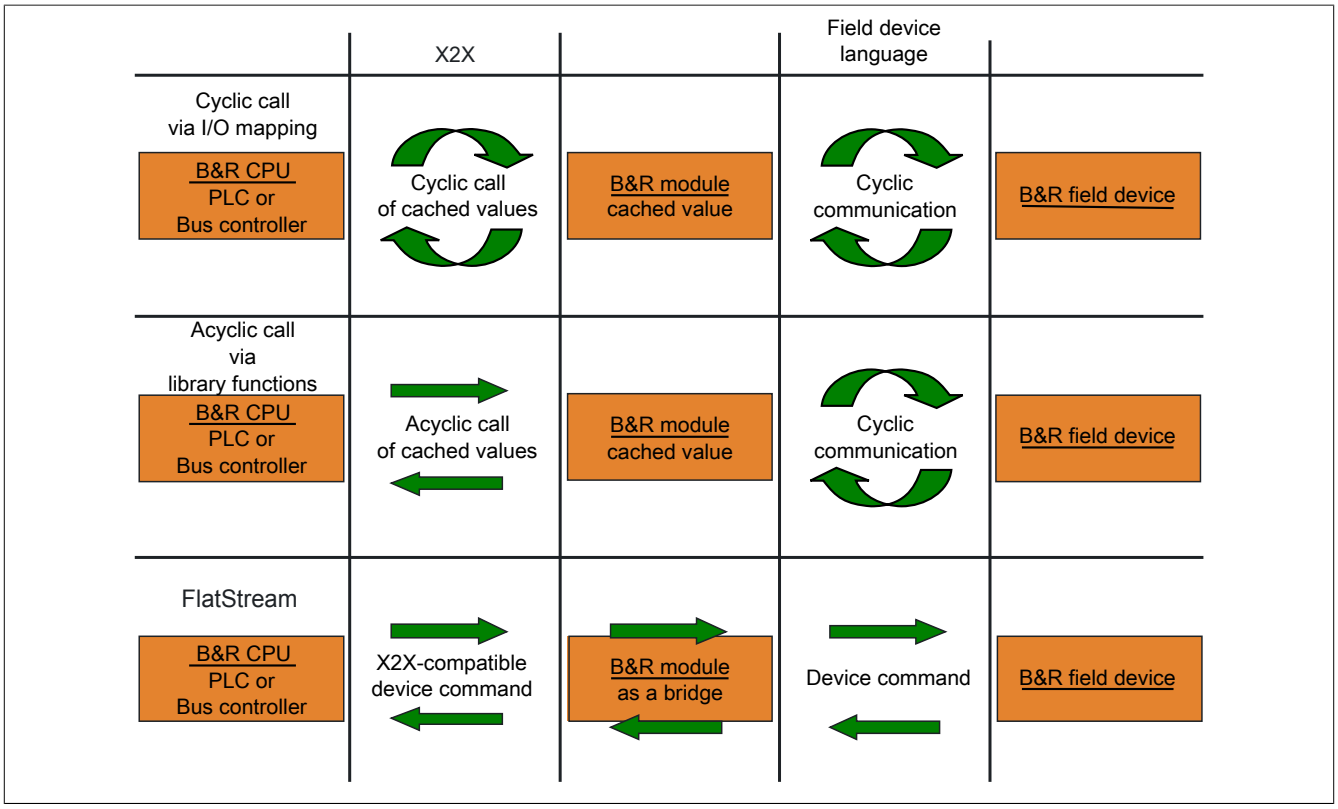

Figure 62: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.3.7.10.8.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.3.7.10.8.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

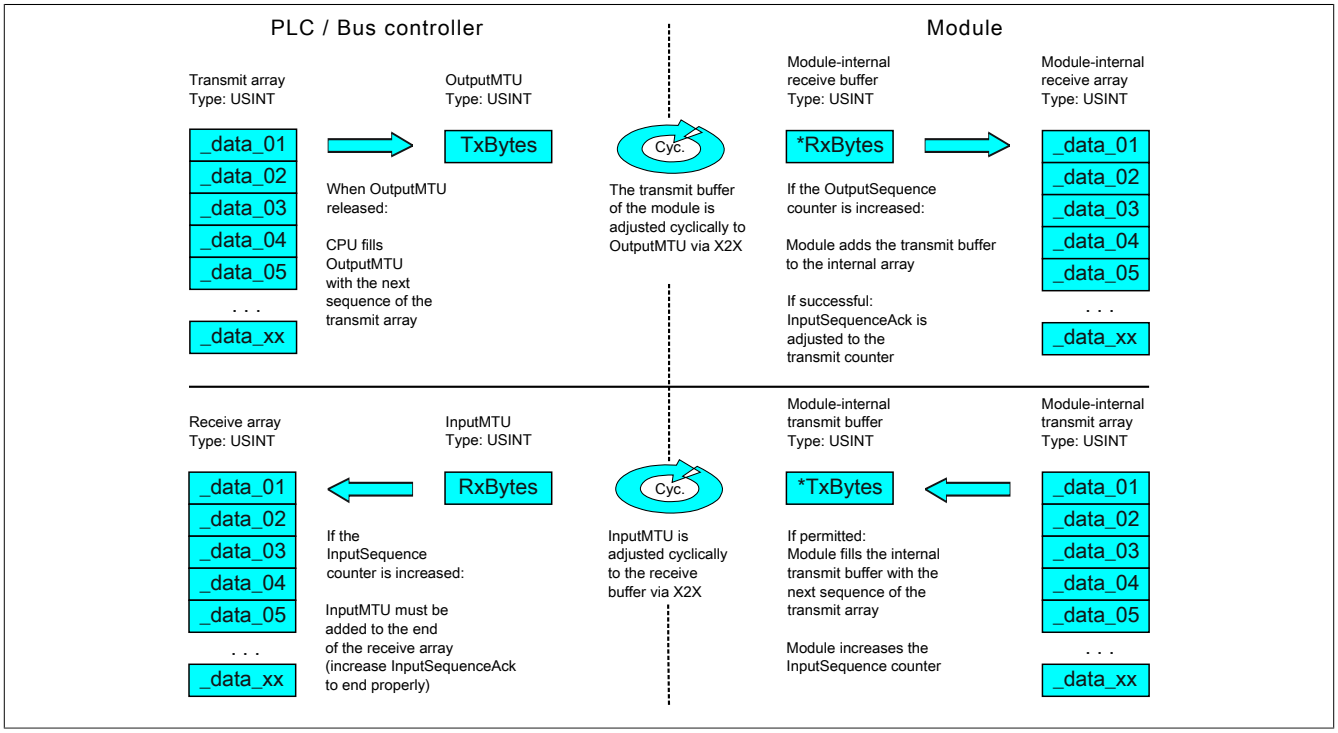

Figure 63: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.3.7.10.8.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

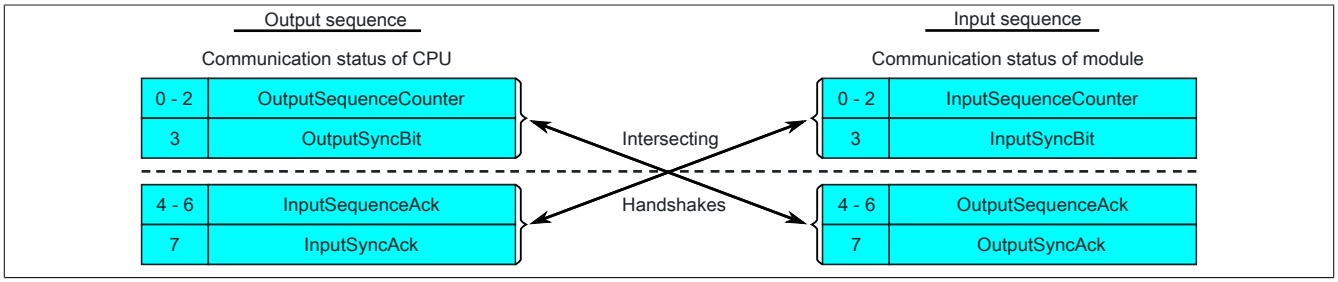

Figure 64: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

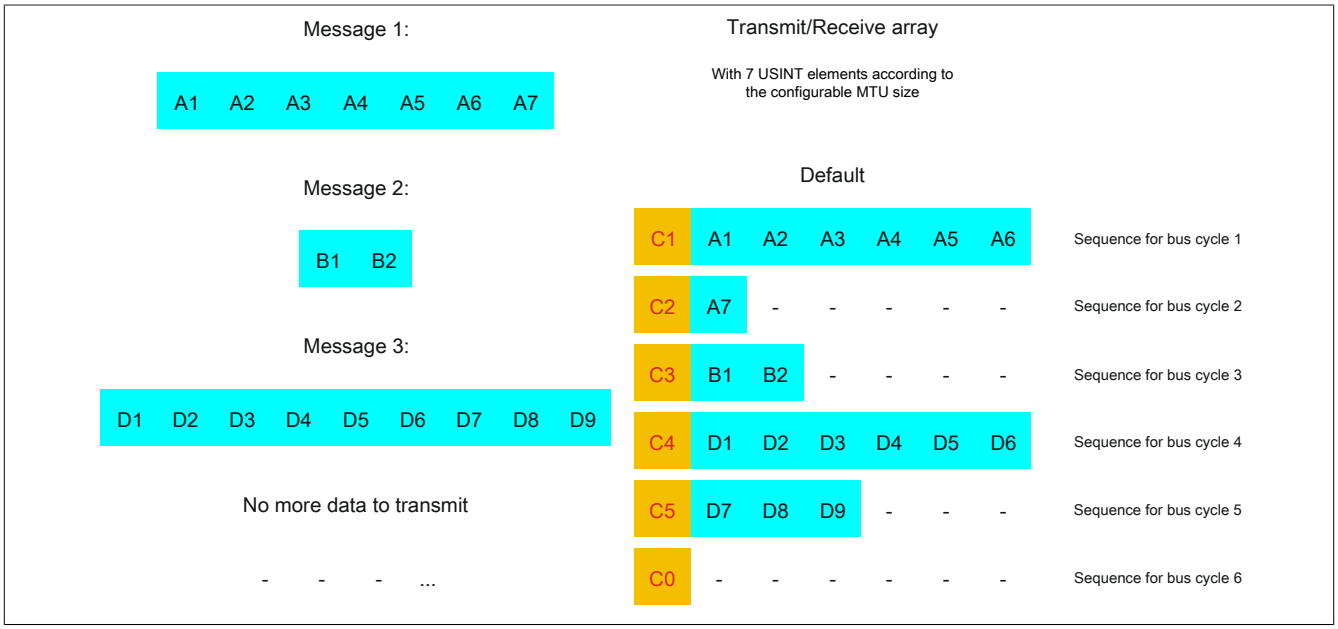

Figure 65: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 36: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 37: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

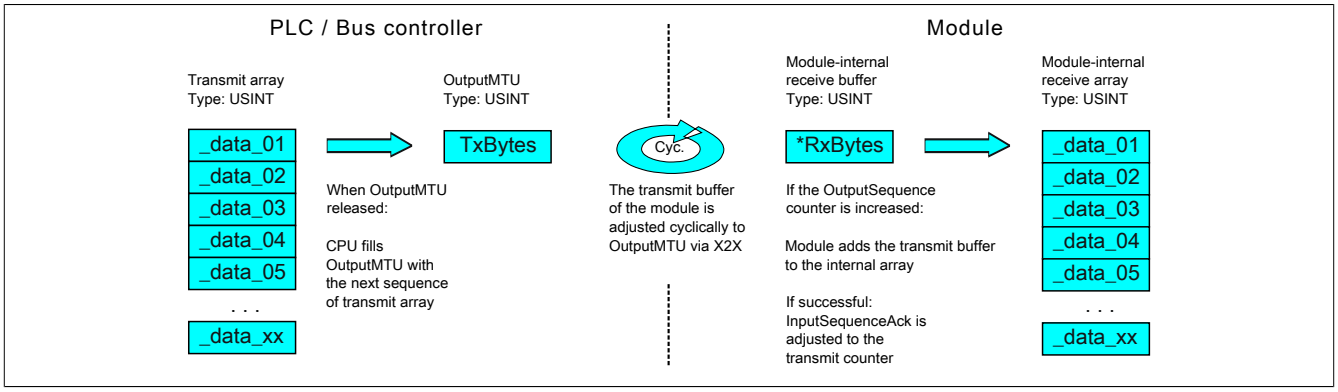

Figure 66: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

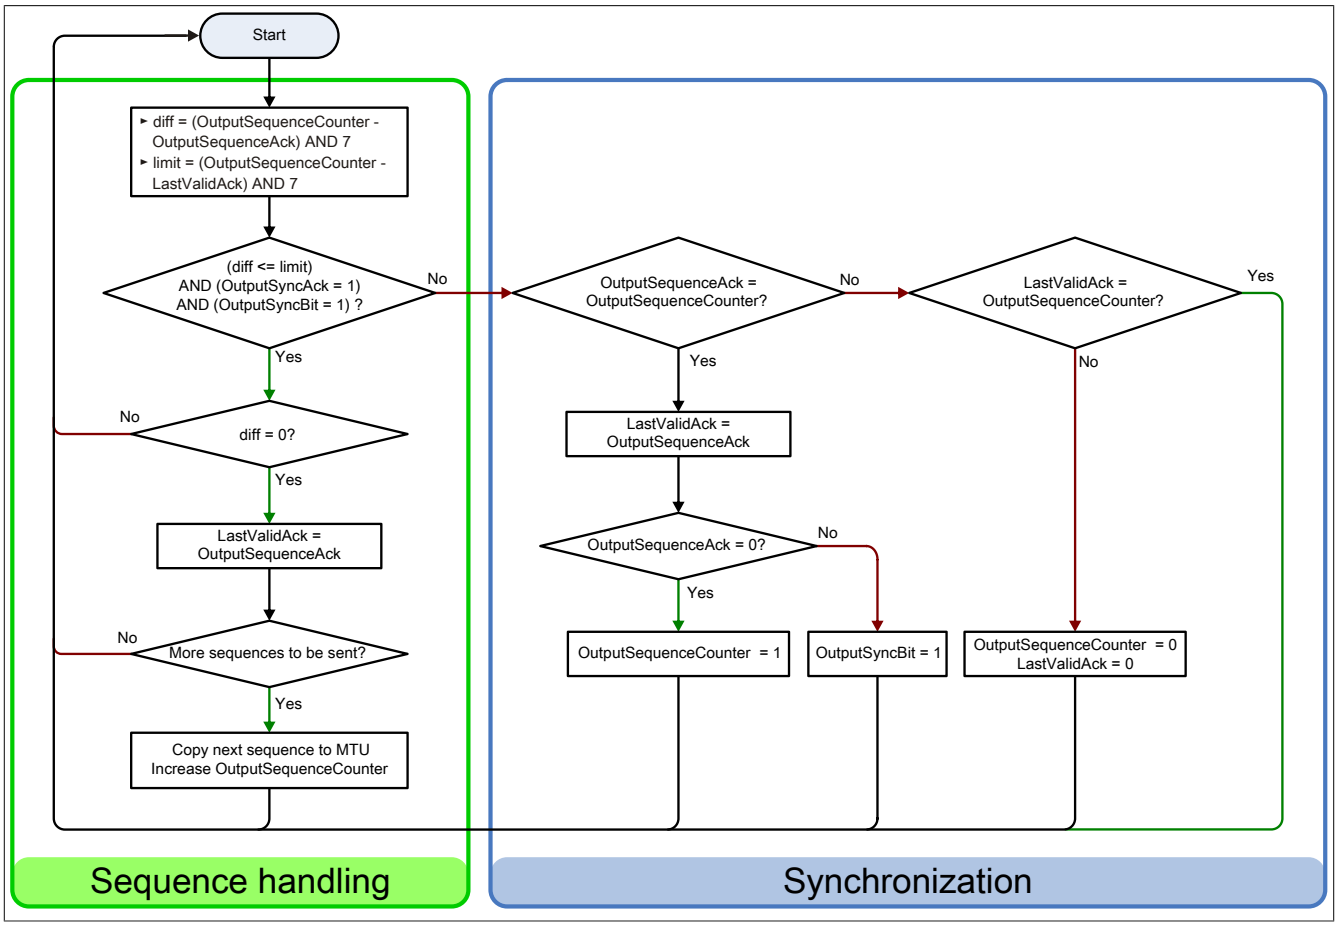

Figure 67: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

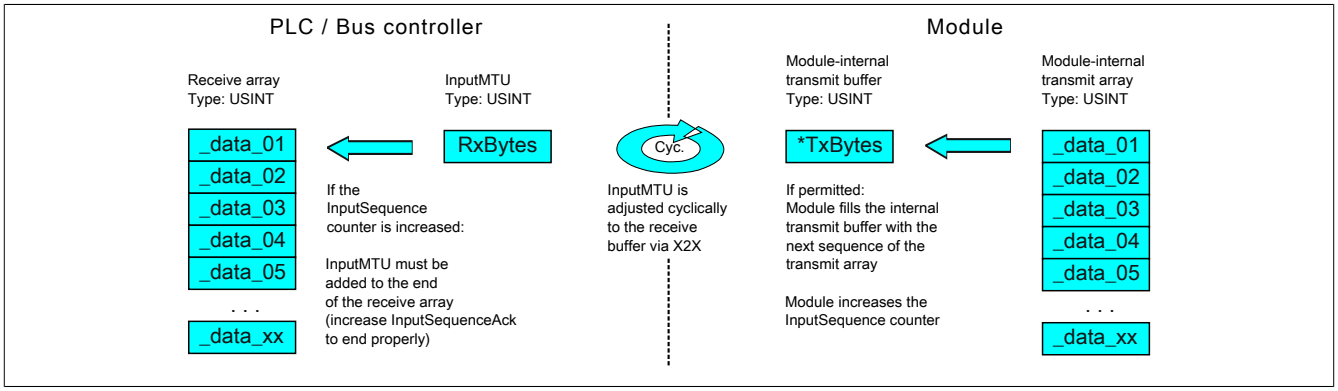

Figure 68: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

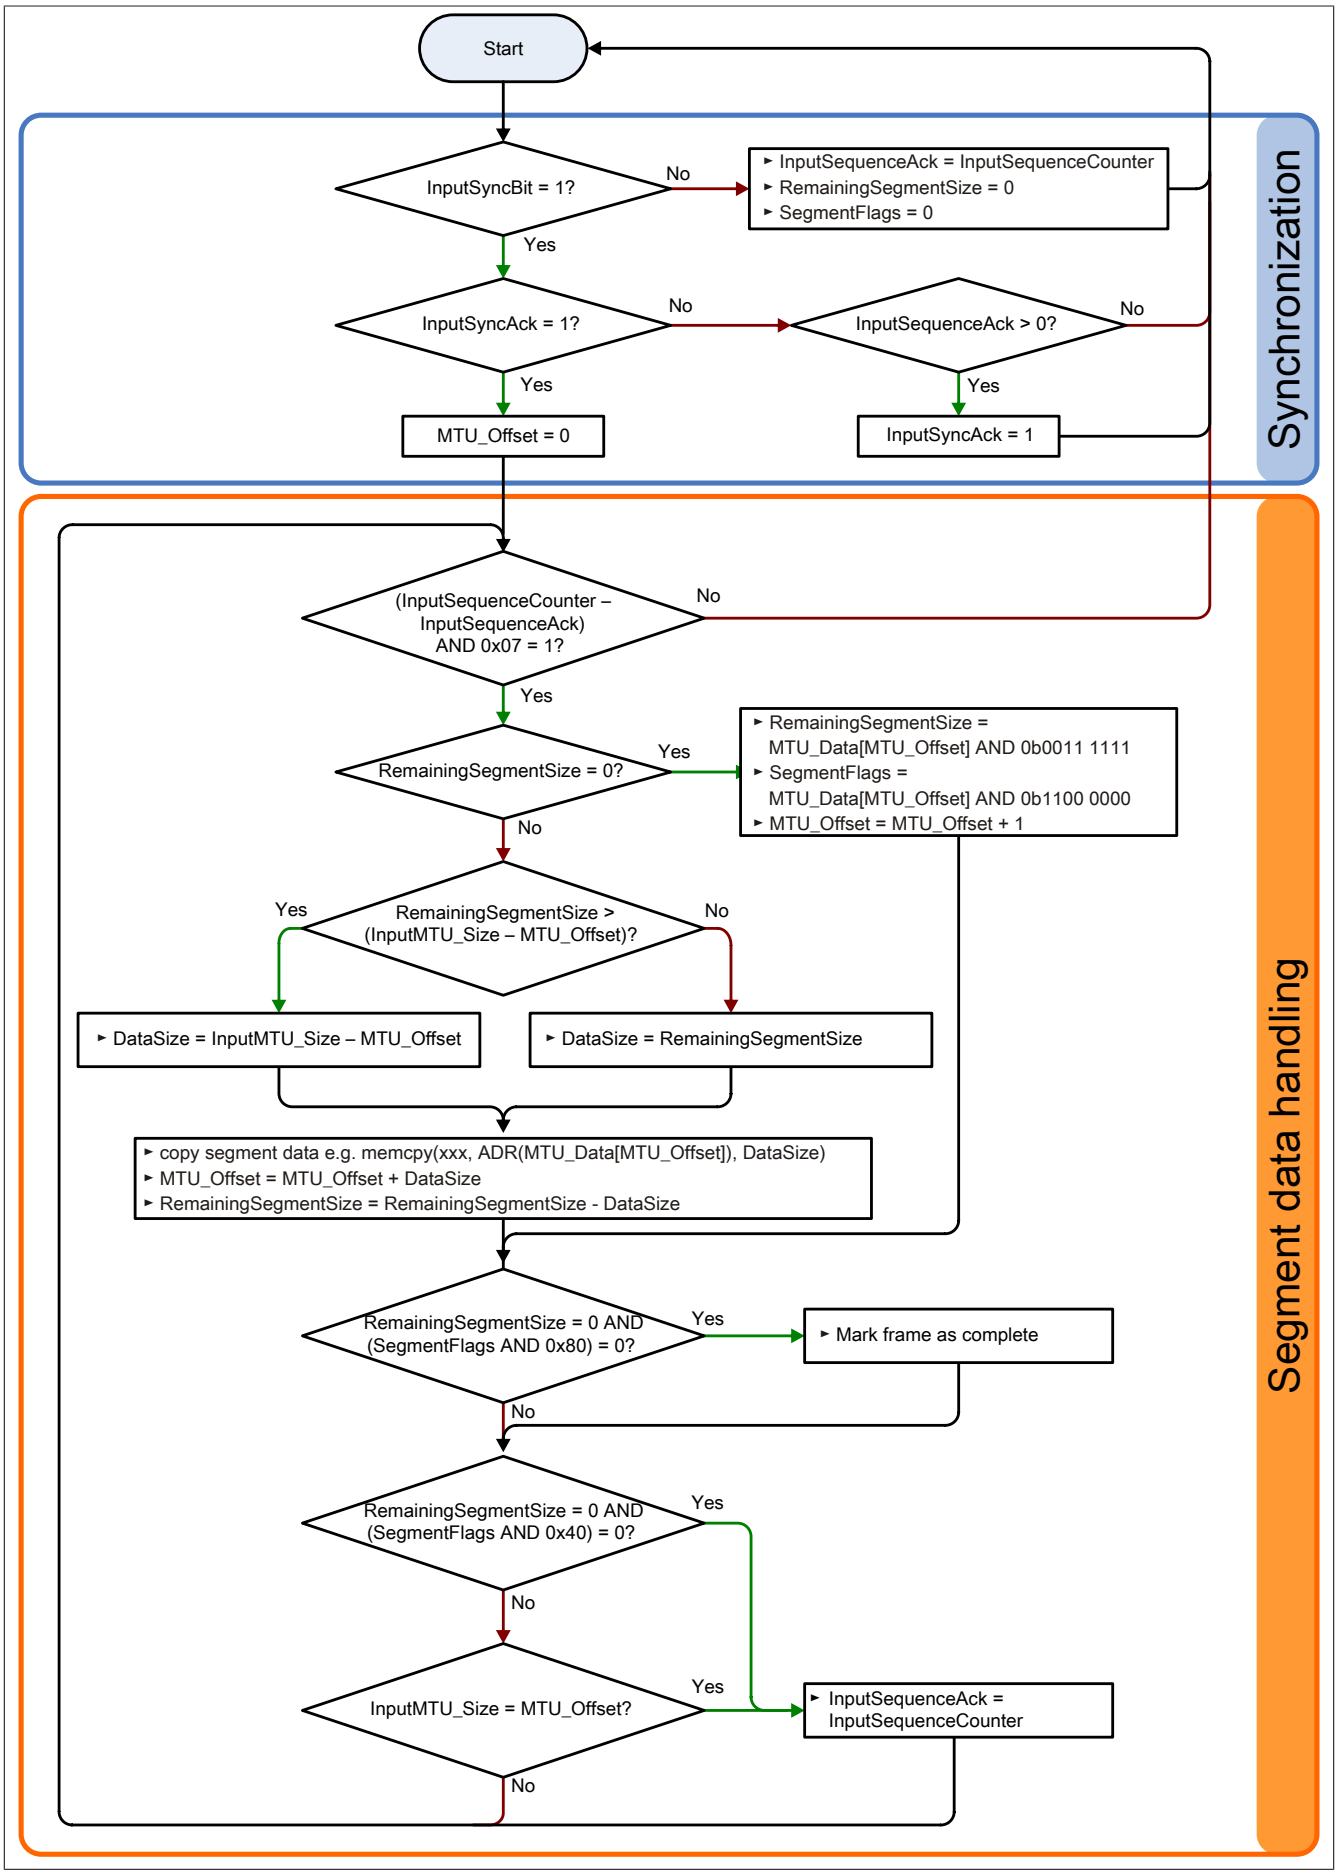

Figure 69: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

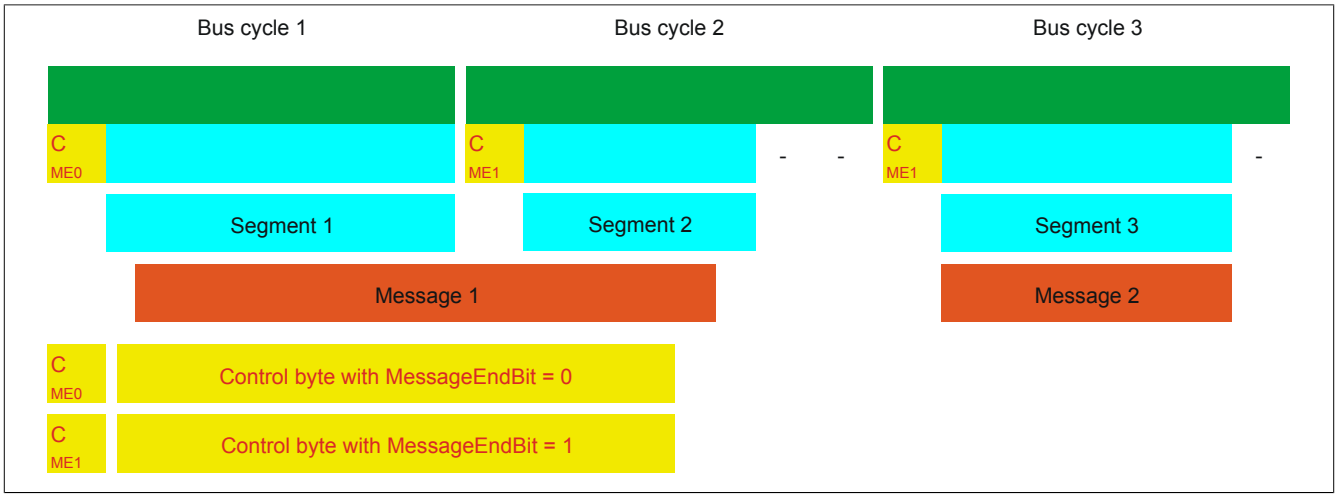

Figure 70: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

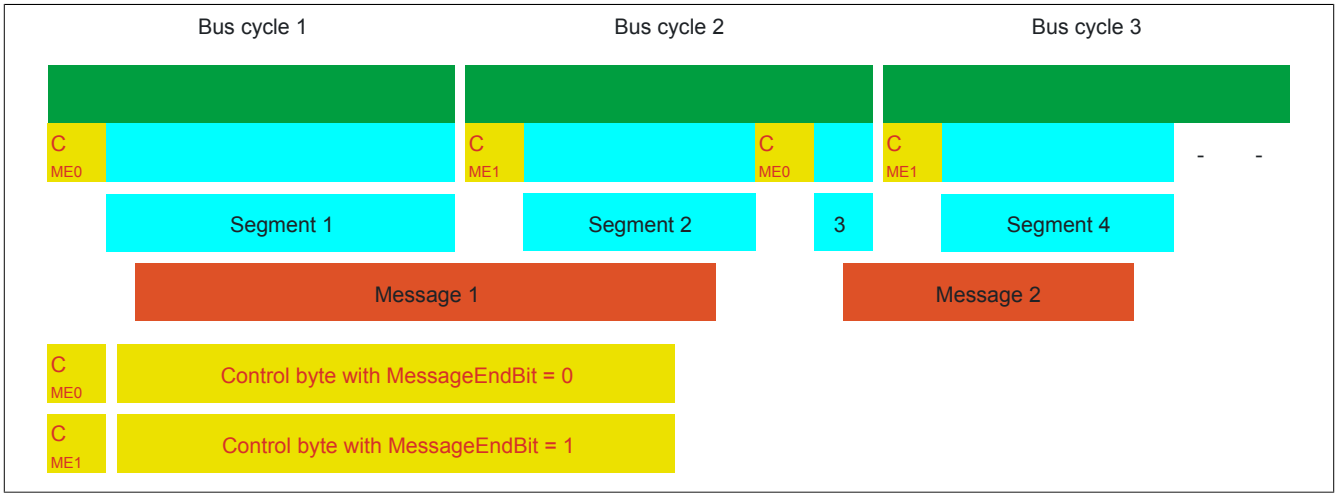

Figure 71: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

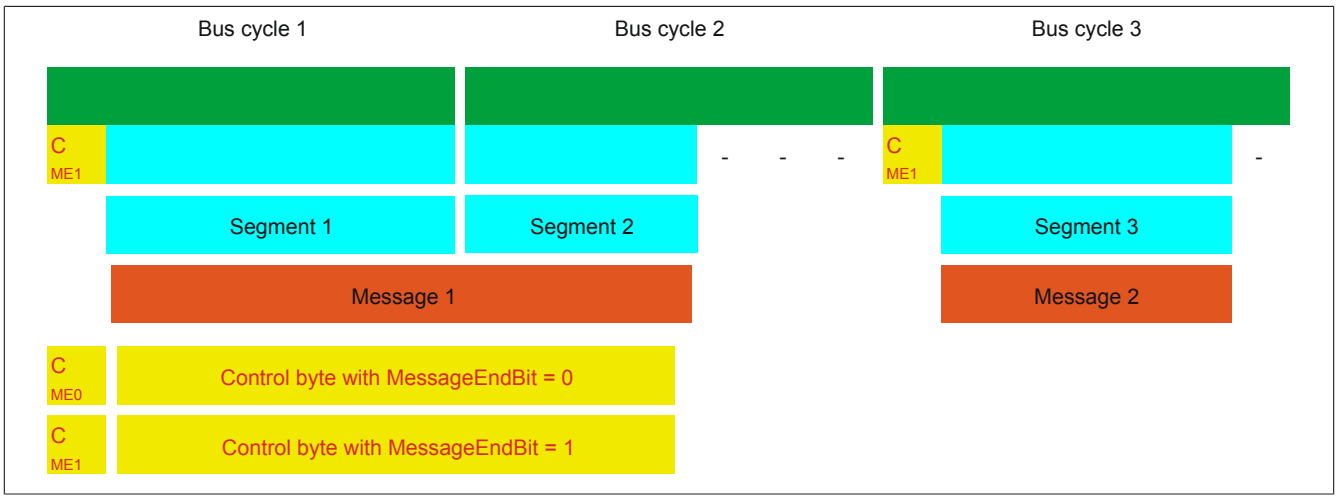

Figure 72: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

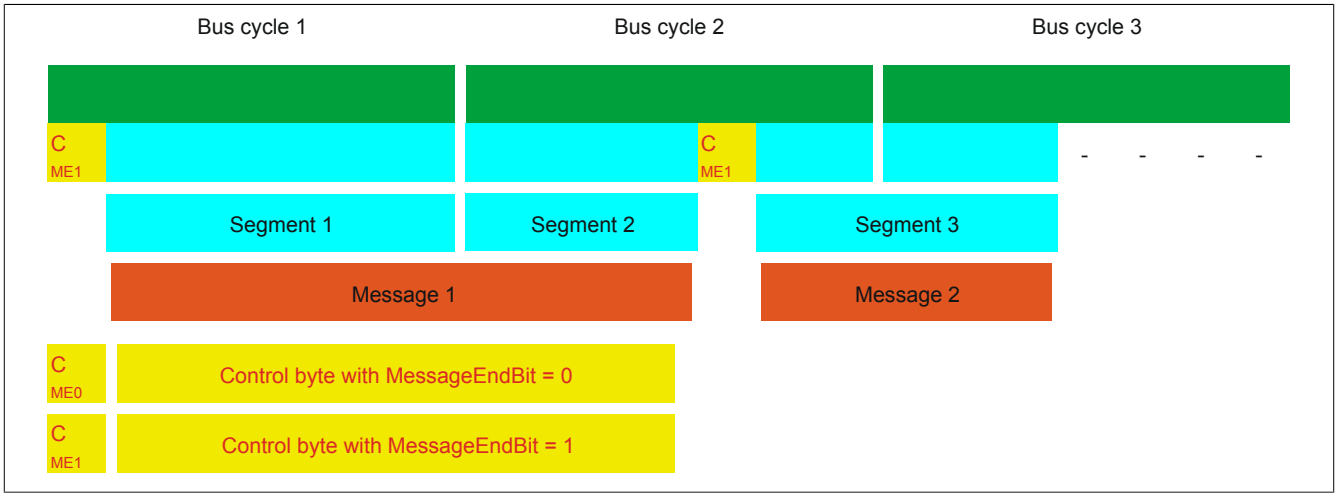

Figure 73: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

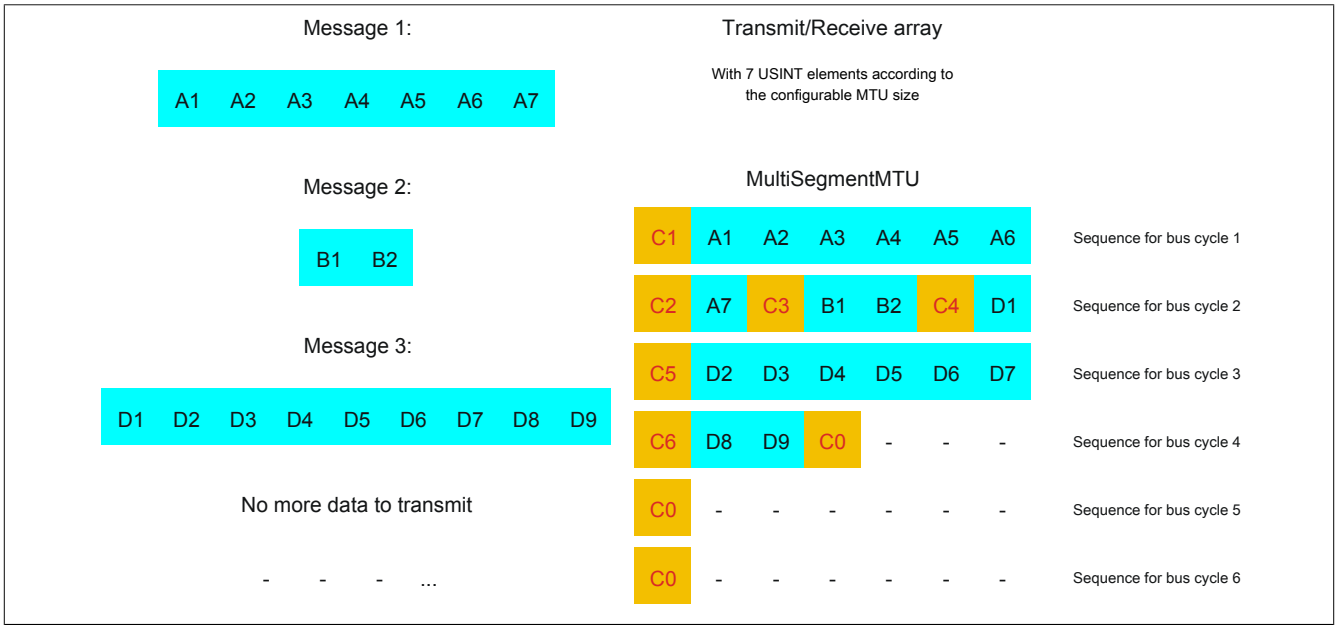

Figure 74: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 38: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 39: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

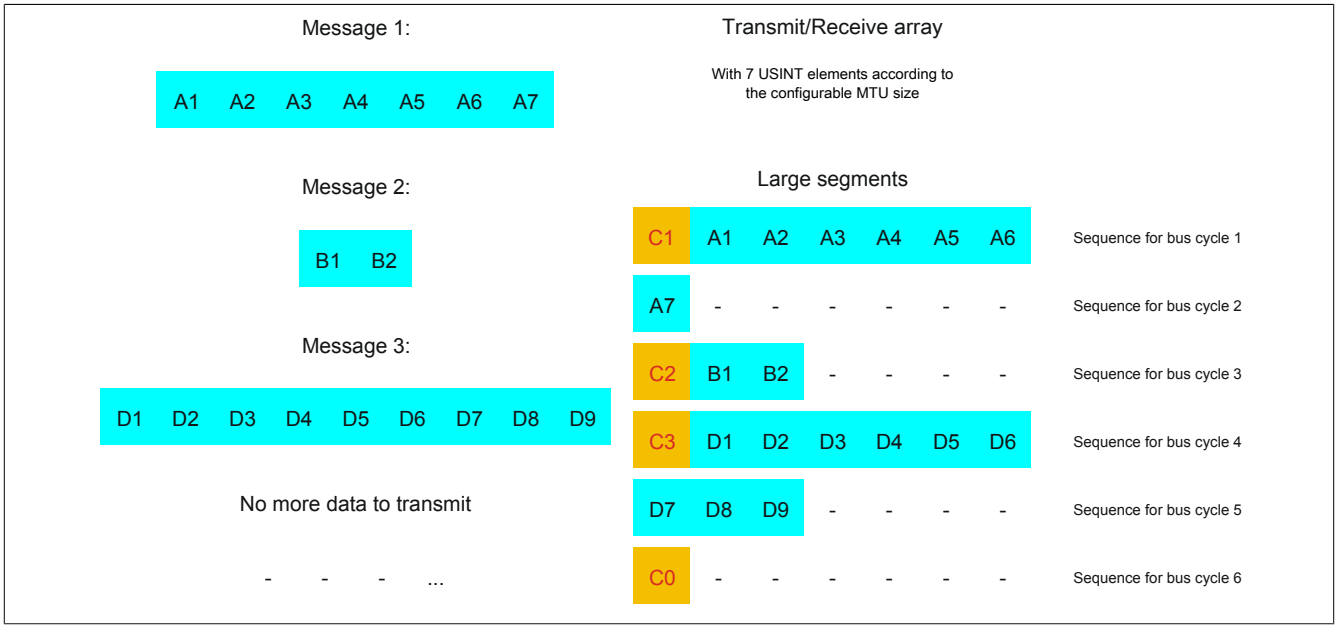

Figure 75: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 40: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

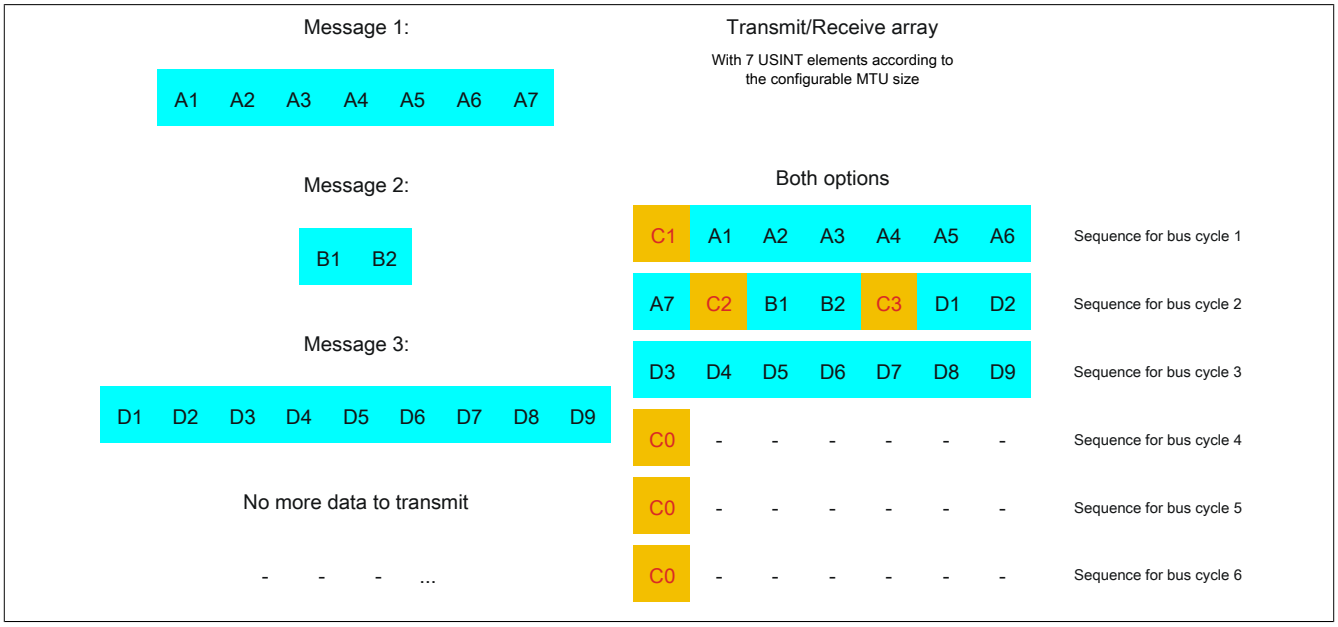

Figure 76: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 41: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.3.7.10.8.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

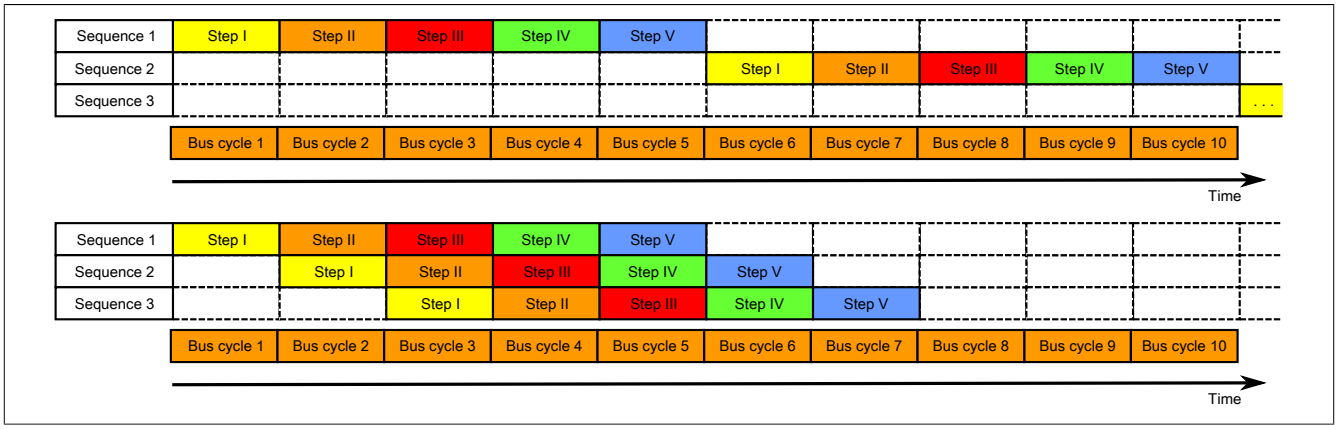

Figure 77: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

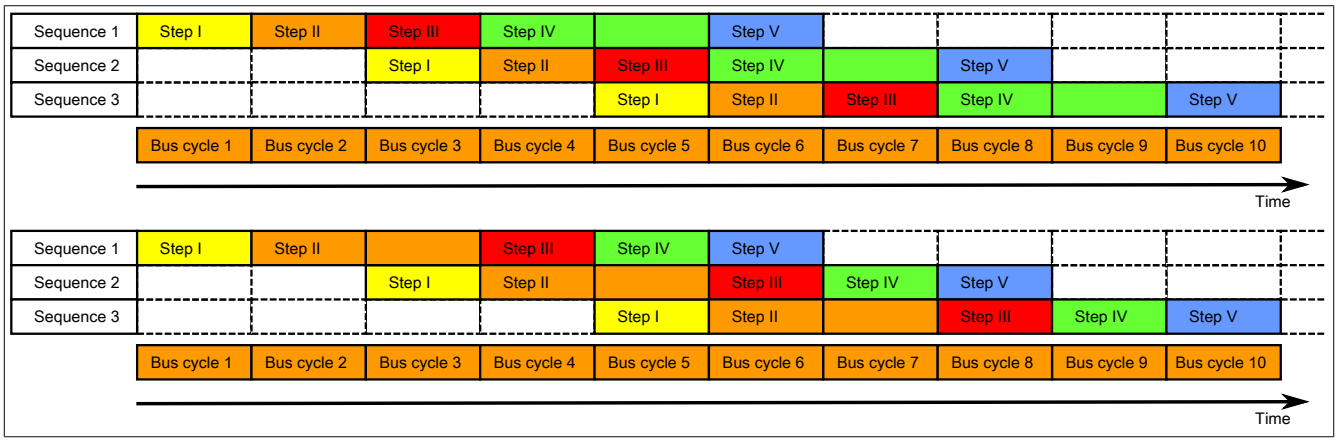

Figure 78: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

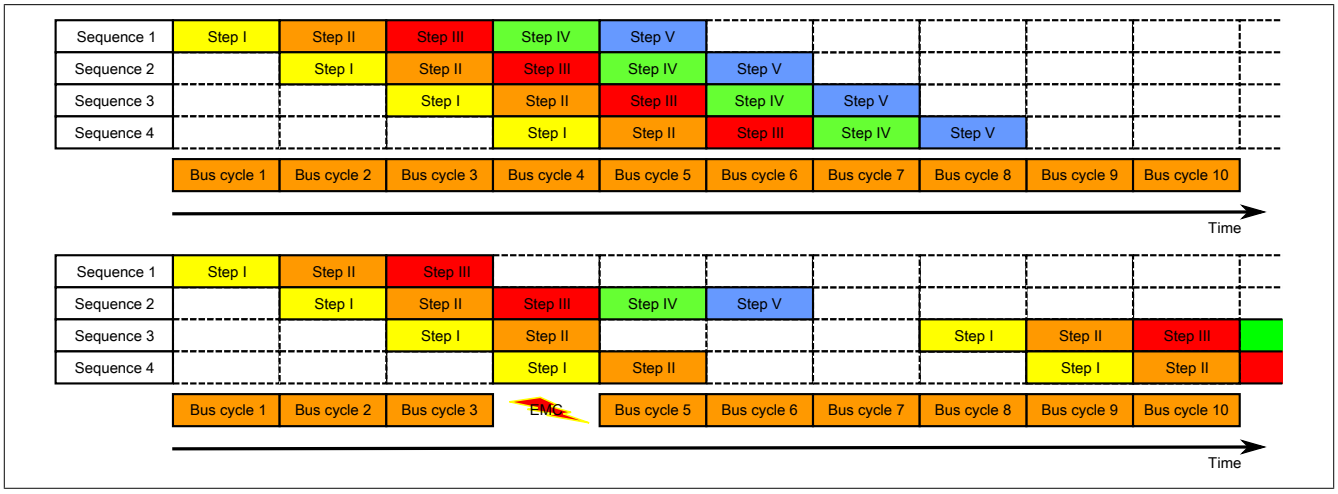

Figure 79: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.3.7.10.9 HART with Flatstream

When using Flatstream communication, the module acts as a bridge between the X2X master and an intelligent field device connected to the module. Flatstream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

HART is considered a master-slave network where half-duplex communication takes place asynchronously. Various features have been included to ensure that signals are transmitted without errors.
For example, the user can increase the length of the preamble, thus making the transmission more secure. However, this also has an effect on the percentage of payload data and overhead.

Additional information about HART can be found at www.HARTcomm.org.

How it works

The module has two independent channels. When using Flatstream , the channel number must therefore be specified. The general structure of a Flatstream frame is extended as follows.

Input/Output sequence	Tx/Rx bytes		
(unchanged)	Control byte (unchanged)	Channel number	HART frame (without preamble and checksum)

HART frame with Flatstream					
Startup	ADDR	CMD	BCNT	(STS)	(DATA)

Startup	Start identification
ADDR	Address within the HART network
CMD	HART command
BCNT	Byte counters (number of remaining bytes)
*STS	Status of the last command received. Information about the working mode of the HART Slave and communication errors (if supported, return data from the HART Slave)
*DATA	Data (if necessary for the command)

Examples of HART commands

Command	Function
0x00	Read slave ID
0x03	Read current value and up to four variables
0x09	Read up to four variables including status
0x21	Read variables

4.3.7.10.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.7.10.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Analog inputs	1 ms

Minimum I/O update time for HART communication	
Point-to-point	500 ms
Multidrop	Number of stations * 1000 ms

4.3.8 X20AI2622

4.3.8.1 General information

The module is equipped with 2 inputs with 13-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs
- Either current or voltage signal possible
- 13-bit digital converter resolution

4.3.8.2 Order data

Table 43: X20AI2622 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.
5) Based on the 20 mA measurement range.

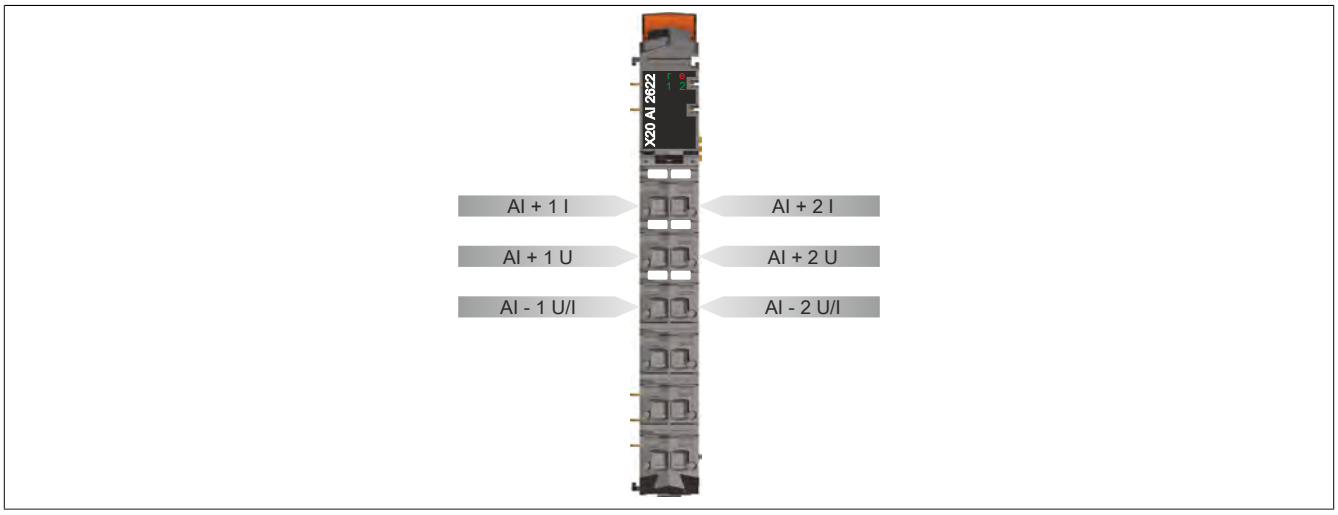
4.3.8.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

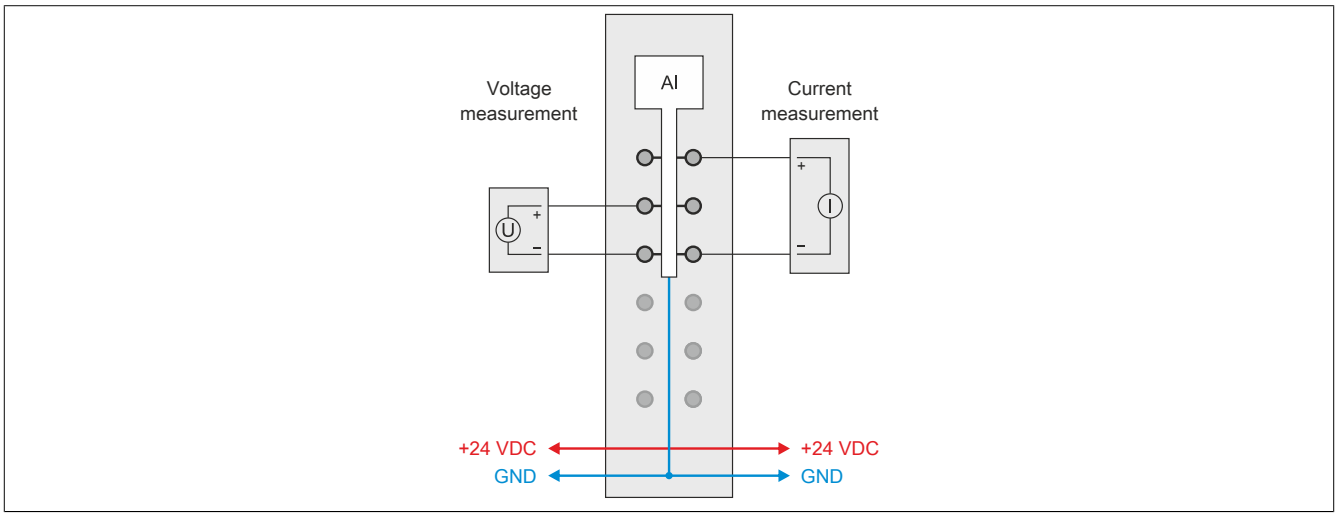
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	Open line[1] or sensor is disconnected
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

1) Open line detection only possible when measuring voltage.

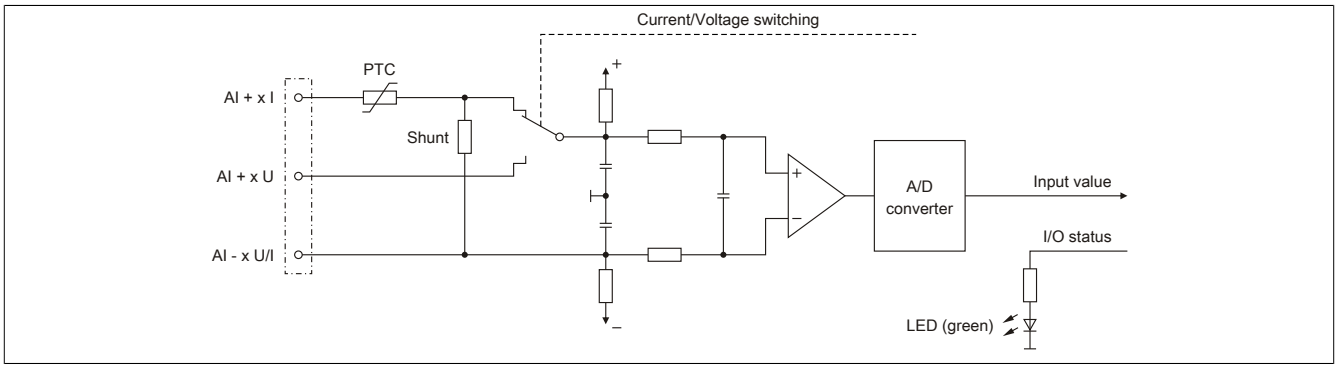
4.3.8.5 Pinout



4.3.8.6 Connection example



4.3.8.7 Input circuit diagram



4.3.8.8 Register description

4.3.8.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.8.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
16	ConfigOutput01	USINT				•
18	ConfigOutput02	USINT				•
20	ConfigOutput03	INT				•
22	ConfigOutput04	INT				•
Communication						
0	AnalogInput01	INT	•			
2	AnalogInput02	INT	•			
30	StatusInput01	USINT	•			

4.3.8.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
16	-	ConfigOutput01	USINT				•
18	-	ConfigOutput02	USINT				•
20	-	ConfigOutput03	INT				•
22	-	ConfigOutput04	INT				•
Communication							
0	0	AnalogInput01	INT	•			
2	2	AnalogInput02	INT	•			
30	-	StatusInput01	USINT		•		

1) The offset specifies the position of the register within the CAN object.

4.3.8.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.8.8.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.8.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput02

The analog input value are mapped to this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA

4.3.8.8.6 Input filter

This module is equipped with a configurable input filter. The minimum X2X cycle time must be >500 µs. Filtering is disabled for shorter X2X cycle times.

If the input filter is active, then the channels are scanned in 1 ms cycles. The time offset between the channels is 200 µs. Conversion is performed acyclically to the X2X cycle.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

4.3.8.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

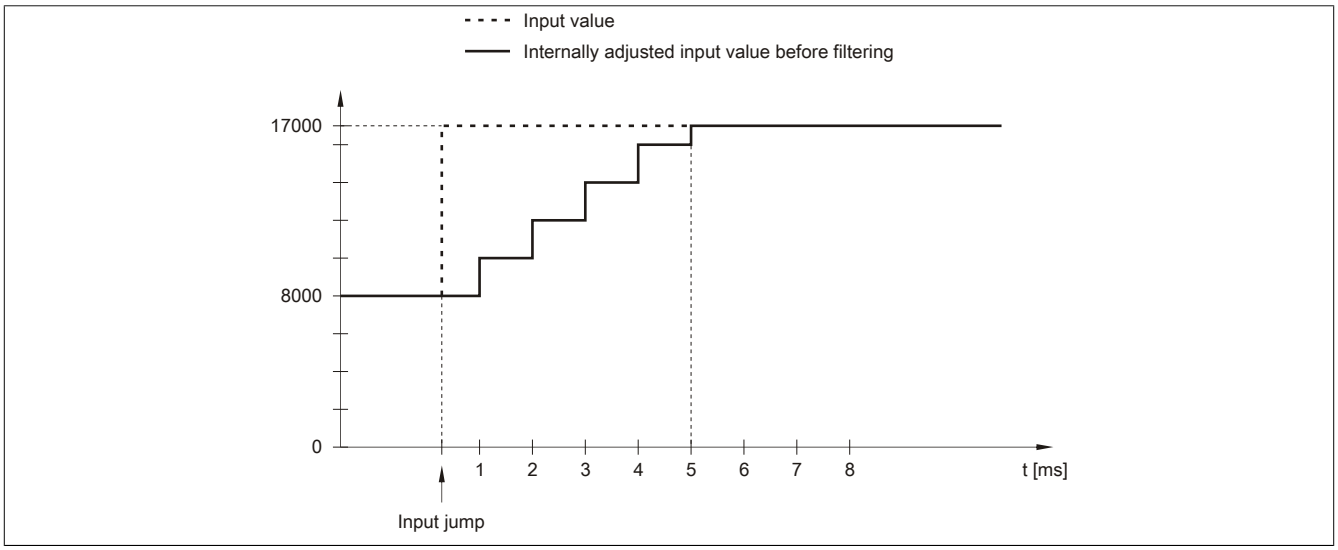


Figure 80: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

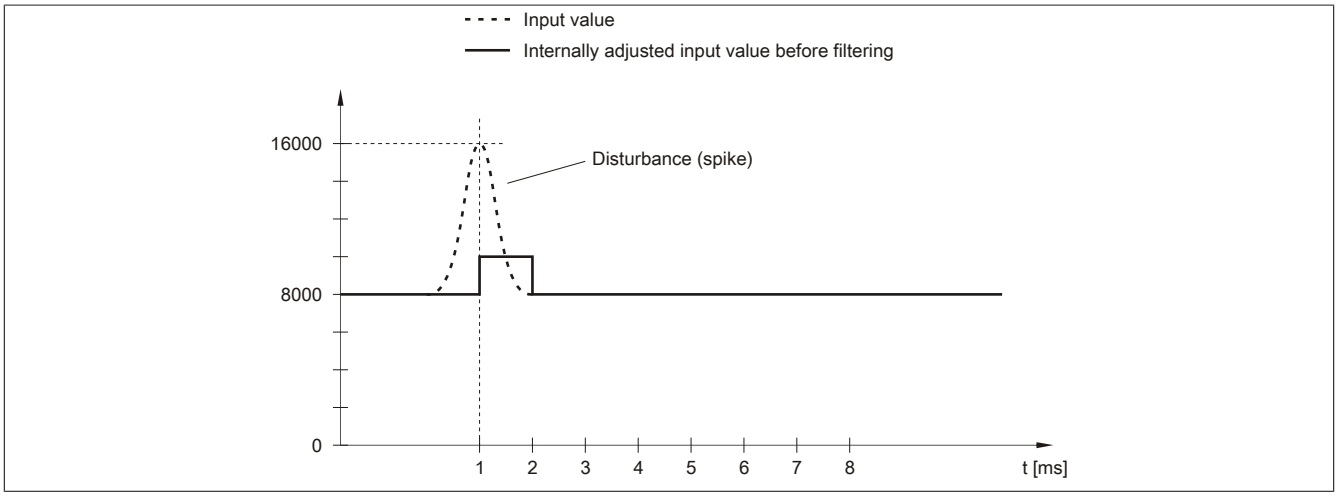

Figure 81: Adjusted input value for disturbance

4.3.8.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

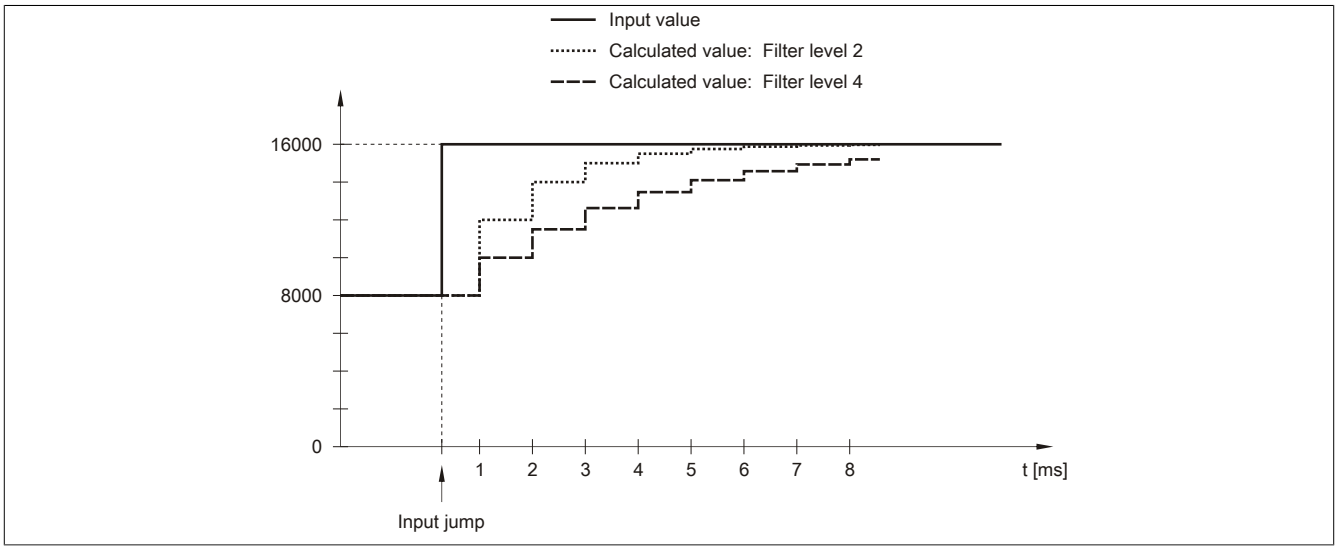

Figure 82: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

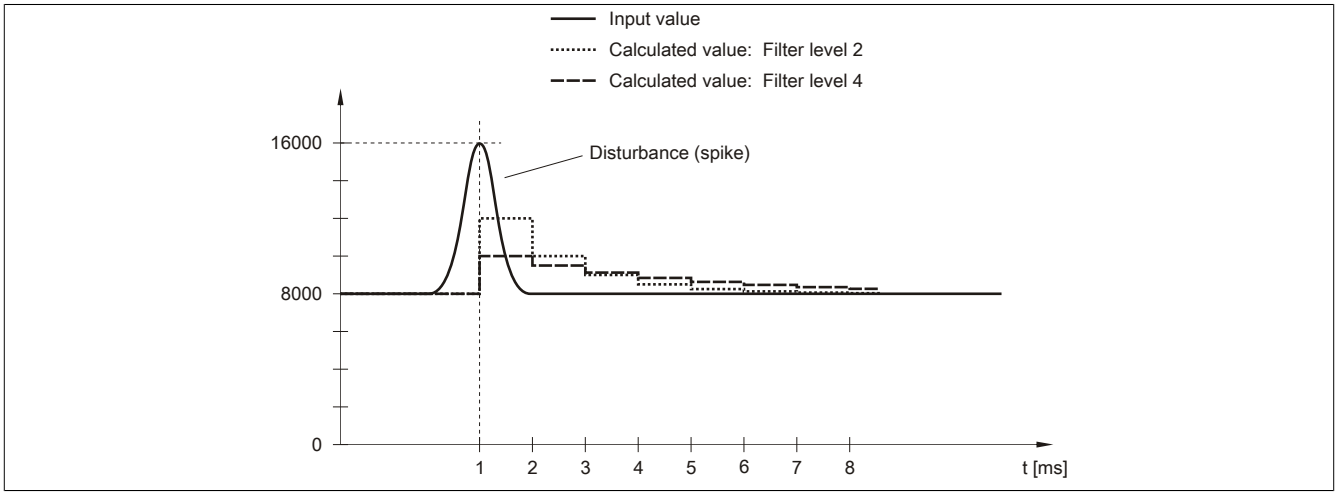

Figure 83: Calculated value during disturbance

4.3.8.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.8.8.8 Channel type

Name:
ConfigOutput02

This register can be used to define the type and range of signal measurement.

Each channel is capable of handling either current or voltage signals. This differentiation is made using multiple connection terminal points and an integrated switch in the module. The switch is automatically activated by the module depending on the specified configuration. The following input signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 4
1	Channel 2	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 5
2 - 3	Reserved	0	
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
5	Channel 2: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
6 - 7	Reserved	0	

4.3.8.8.9 Limit values

The input signal is monitored at the upper and lower limit values. These must be defined according to the operating mode:

Limit value (default)	Voltage signal ±10 V		Current signal 0 to 20 mA		Current signal 4 to 20 mA	
Upper maximum limit value	+10 V	+32767 (0x7FFF)	20 mA	+32767 (0x7FFF)	20 mA	+32767 (0x7FFF)
Lower minimum limit value	-10 V	-32767 (0x8001)	0 mA	0[1)]	4 mA	0[2)]

1) The analog value is limited down to 0.
2) The analog value is limited down to 0 at currents <4 mA. The status bit for the lower limit is set.

Other limit values can be defined if necessary. Limit values are valid for all channels and activated automatically by writing to the limit value registers. From this point on, the analog values will be monitored and limited according to the new limits. The results of monitoring are displayed in the status register.

Examples of limit value settings

Application case	Limit value settings
Current signal: 4 to 20 mA	A negative limit value must be configured in order to measure values <4 mA with a current signal of 4 to 20 mA: 0 mA is equal to a value of -8192 (0xE000).
Mixed voltage and current signal	The configured limit values are valid for all channels. Mixed operation (voltage and current signal) therefore requires a compromise. The following configuration has proven effective: Upper limit = +32767, lower limit = -32767 This makes it possible to also measure negative voltage values. A lower limit value of 0 would limit the voltage value to 0.
Current signal on all channels	All channels are configured for measuring current. The limit value setting in Automation Studio is not adjusted automatically. That means that +32767 is configured as the upper limit value and -32767 as the lower limit value. The necessary changes must be made by the user, e.g. lower limit value = 0

4.3.8.8.9.1 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

- **The default value of -32768 corresponds to the minimum default value of -10 VDC.**
- **When configured as 0 to 20 mA, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Information:

Keep in mind that this setting applies to all channels!

4.3.8.8.9.2 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value of 20 mA or +10 VDC.

Information:

Keep in mind that this setting applies to all channels!

4.3.8.8.10 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message. The following states are monitored depending on the settings:

Value	Voltage signal ±10 V	Current signal 0 to 20 mA	Current signal 4 to 20 mA
0	No error	No error	No error
1	Lower limit value exceeded	Default setting The input value has a lower limit of 0x0000. Underflow monitoring is therefore not necessary. After lower limit value change The input value is limited to the configured value. The status bit is set when the lower limit value is passed.	Lower limit value exceeded
2	Upper limit value exceeded	Upper limit value exceeded	Upper limit value exceeded
3	Open line	-	-

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

4.3.8.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.8.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Inputs without filtering	300 µs for all inputs
Inputs with filtering	1 ms

4.3.9 X20AI2632

4.3.9.1 General information

The module is equipped with 2 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs
- Either current or voltage signal possible
- 16-bit digital converter resolution
- Simultaneous input conversion
- Very fast conversion time

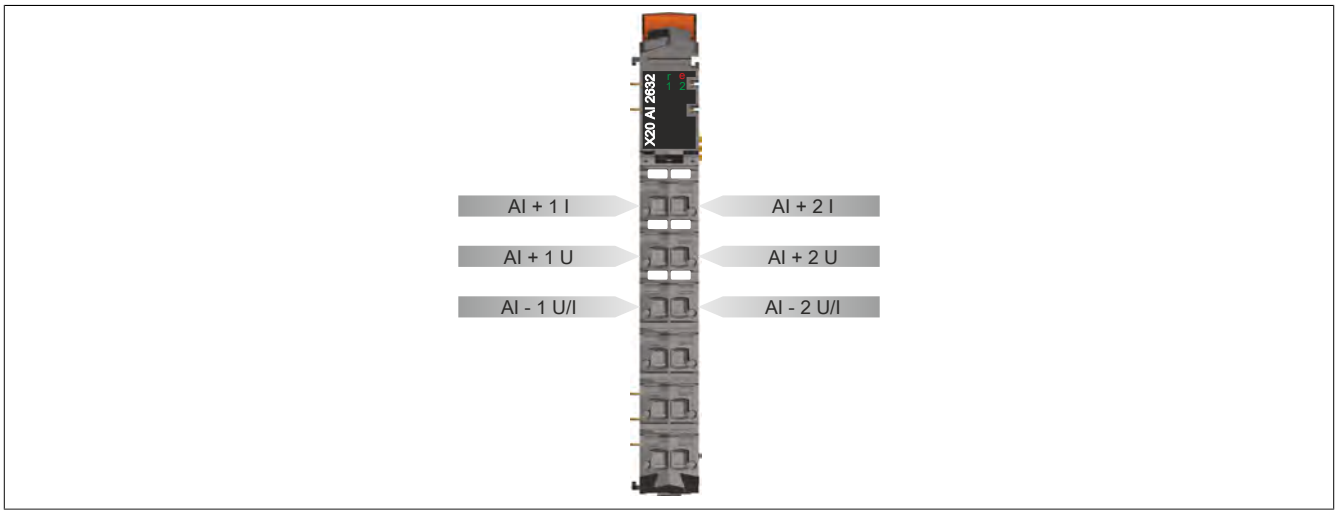
			On	Error or reset status
			Double flash	System error: • Violation of the scan time • Synchronization error
	1 - 2	Green	Off	Open line2) or sensor is disconnected
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

4.3.9.5 Pinout



4.3.9.6 Connection example

To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules

1) The offset specifies the position of the register within the CAN object.

4.3.9.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.9.8.4 Configuration

This module is equipped with analog inputs with connected 16-bit A/D converters. Each of the inputs can be configured separately from one another either on the voltage or current input for the following areas:

- Permitted voltage: ±10 V
- Permitted current: 0 to 20 mA

4.3.9.8.4.1 Channel configuration

Name:
ConfigOutput01 for channel 01
ConfigOutput06 for channel 02

The individual inputs for processing the current or voltage signal are configured in these registers. This configuration must be made in addition to using the correct terminal block pins.

Filtering, analysis and error monitoring (bits 4 to 6) can only be used if the channel is enabled (bit 7 = 0).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Terminal selector	0	Voltage terminal for ±10 VDC
		1	Current terminal for 0 to 20 mA
1	Gain selector	0	Voltage ±10 VDC
		1	Current 0 to 20 mA
2 - 3	Reserved	-	
4	Filtering active	0	Inactive
		1	Active
5	Minimum/Maximum analysis active	0	Inactive
		1	Active
6	Error monitoring active	0	Inactive
		1	Active
7	Enables channel	0	Channel enabled
		1	Channel disabled

4.3.9.8.4.2 Sampling and conversion

The analog signal is sampled in 2 steps.

- **Conversion task**
  The A/D converter digitalizes the inputs signals for the enabled inputs once per conversion cycle. Then the results are available internally in the module. To ensure that this process is executed without delays, the corresponding task will be handled with very high priority.
  The timespan needed for conversion results from the set sampling time.
- **Processing task**
  The converted A/D converter values are further processed according to the user settings (filtering, scaling, limit values, error statistics, min/max analysis, hysteresis comparison). The task for this process has low priority. The timespan needed for further processing depends on the configured functions and is the second portion of the sampling time.

Cycle time violation

In normal operation, further processing is triggered after each conversion. The conversion and sampling tasks run synchronous to one another. If the predefined sampling time is not sufficient to convert all enabled channels and complete the configured functions, a cycle time violation occurs.

Sampling time

Name:
ConfigOutput24

The sampling time is set to µs in this register. This makes it possible to improve the sampling cycle (resolution = 1 µs). The lowest configurable cycle time is 50 µs.

Data type	Value	Function
UINT	50 to 10,000	Default value = 100

Information:

Values that are too low for the cycle time will result in cycle time violations.

4.3.9.8.4.3 Filtering (optional)

If filtering is enabled in the 4.3.9.8.4.1 "Channel configuration" register, the basic data of the A/D converter is filtered per channel. The following registers are available to specify the filter order and respective cutoff frequency for configuring the low-pass filter:

- "Filter order"
- "Filter cutoff frequency"

Filter order

Name:
ConfigOutput26 for channel 1
ConfigOutput28 for channel 2

The filter order is specified in this register. The "Filter cutoff frequency" register is used to configure the respective cutoff frequency of the filter.

Data type	Value
USINT	1 to 4

Internal filter orders greater than 1 are implemented as cascaded first-order filters. Since the filter is calculated in the sampling cycle, the filter characteristics are directly related to the settings for the sampling cycle time.

Calculating the cutoff frequency of an nth-order filter:

yn = a * xn + b * y(n-1)

Approximate calculation

a = Sampling time / (Sampling time + 1/Cutoff frequency)

b = 1 - a

Filter cutoff frequency

Name:
ConfigOutput27 for channel 1
ConfigOutput29 for channel 2

The cutoff frequency of the respective filter is configured in these registers.

Data type	Value	Description
UINT	1 to 65,535	Cutoff frequency in hertz

Information:

The highest cutoff frequency is limited by the Nyquist Shannon sampling theorem (based on the sampling cycle time). The system does not check for violations of this sampling theorem.

4.3.9.8.4.4 Scaling (optional)

Scaling A/D converter data is an option for the user. The following registers are available for this:

- "User-defined gain" (= ku)
- "User-defined offset" (= du)

Scaling calculation:

Scaled value = k * A/C value + d

Gain $k = k_{Calibration} * ku$

Offset $d = d_{Calibration} + du$

The value has to be limited since it can exceed the 16-bit constraints. To provide the greatest degree of flexibility, limiting is possible using the registers "Minimum limit value" and "Maximum limit value".

User-defined gain

Name:
ConfigOutput04 for channel 1
ConfigOutput09 for channel 2

The user-defined gain for the A/D converter data of the respective physical channel can be specified in these registers.

The value 65,536 (0x10000) corresponds to a gain of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

User-defined offset

Name:
ConfigOutput05 for channel 1
ConfigOutput10 for channel 2

The user-defined offset for the A/D converter data of the respective physical channel can be specified in this register.

The value 65,536 (0x10000) corresponds to an offset of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.3.9.8.4.5 User-defined limit values

If the application requires a limitation of the range of values, then the user can define his own limit values. These values will also be use for the module's error statistics. The following registers are available for this:

- "Minimum limit value"
- "Maximum limit value"

Information:

32-bit numbers are used inside the module. A limit value violation can therefore also be determined if the permitted range of values was defined from -32768 to 32767.

Minimum limit value

Name:
ConfigOutput02 for channel 1
ConfigOutput07 for channel 2

The minimum limit value is configured in this register. This limit value is also used as the lower value in the error statistics (see register "Counter for range exceeded violations (neg.)").

Data type	Value
INT	-32768 to 32767

Maximum limit value

Name:
ConfigOutput03 for channel 1
ConfigOutput08 for channel 2

The maximum limit value is configured in this register. This limit value is also used as the upper value in the error statistics (see register "Counter for range exceeded violations (pos.)").

Data type	Value
INT	-32768 to 32767

4.3.9.8.5 Communication - General

The module's analog inputs convert current and voltage values with 16-bit resolution. This information can be used by the application with the help of the registers listed here.

4.3.9.8.5.1 Analog inputs

Name:
AnalogInput01 to AnalogInput02

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 to 20 mA

4.3.9.8.5.2 Sampling cycle counter

Name:
SampleCycleCounter

The number of times the input signal has been sampled is provided in this register.

Data type	Value
UINT	0 to 65535

4.3.9.8.5.3 Error monitoring and counters

Channel status

Name:
Channel01OK to Channel02OK
SyncStatus
ConvertionCycle

This register collects error messages synchronously with the network cycle. Temporary error states that were registered in a conversion cycle remain active for at least 2 network cycles. In order to receive detailed error information, the corresponding error counters and X2X network events should also be observed.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OK	0	OK
		1	Errors
1	Channel02OK	0	OK
		1	Errors
2 - 5	Reserved	-	
6	SyncStatus[1)]	0	OK
		1	Not synchronized
7	ConvertionCycle[2)]	0	OK
		1	Errors

1) Identical to bit 0 of the registers "Synchronization error counter".
2) Identical to bit 0 of the registers "Counter for faulty sampling cycles".

Synchronization error counter

Name:
SynchronizationViolationErrorCounter

This register counts how often the conversion task was triggered more than 5 µs after the next-coming X2X cycle. In this case, the module is considered being no longer synchronized with X2X Link.

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for faulty sampling cycles

Name:
SampleCycleViolationErrorCounter

This register is used to indicate the number of cycle time violations that have occurred thus far. A cycle time violation occurs if the conversion tasks initiates a sampling task before the last sampling cycle has finished. See 4.3.9.8.4.2 "Sampling and conversion".

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Range violation (neg. and pos.)

Name:
Channel01underflow to Channel02underflow
Channel01overflow to Channel02overflow

This register indicates whether a range violation (pos. and/or neg.) of the limit values defined in the registers "Minimum limit value" and "Maximum limit value" has occurred. The individual bits in this register are identical to the values of the lowest bits in the registers "Counter for range exceeded violations (neg.)" and "Counter for range exceeded violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01underflow	0	No error
		1	Range exceeded (.neg) on channel 1
1	Channel02underflow	0	No error
		1	Range exceeded (.neg) on channel 2
2 - 3	Reserved	-	
4	Channel01overflow	0	No error
		1	Range exceeded (.pos) on channel 1
5	Channel02overflow	0	No error
		1	Range exceeded (.pos) on channel 2
6 - 7	Reserved	-	

Working range violation (pos.)

Name:
Channel01OutofRange to Channel02OutofRange

This register indicates whether the input value exceeds the module's maximum measurement range. The individual bits in this register are identical to the values of the lowest bits in the register "Counter for work range violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutofRange	0	No error
		1	Working range violation (pos.) of channel 1
1	Channel02OutofRange	0	No error
		1	Working range violation (pos.) of channel 2
2 - 7	Reserved	-	

Counter for work range violations (pos.)

Name:
CH01OutofRange to CH02OutofRange

Errors outside of the module's maximum possible measurement range are indicated in this register. These errors lead to full-scale deflection of the A/D converter.

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.9.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (neg.)

Name:
CH01Underflow to CH02Underflow

This register indicates range exceeded violations (neg.) of the value configured in the register "Minimum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.9.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (pos.)

Name:
CH01Overflow to CH02Overflow

This register indicates range exceeded violations (pos.) of the value configured in the register "Maximum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.9.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

4.3.9.8.6 Additional analysis functions

In addition to sampling the analog input signal, this module can also be used to perform additional analysis of the values obtained.

- **Limit value analysis**
  If limit value analysis has been enabled for a channel, the sampled minimum and maximum values are latched internally in the module. A measurement period can be triggered using the control byte. When the respective configured edge is generated by the application, the limit values from the previous measurement period are displayed and the internal latch register is reset.
- **Recording sampled values**
  If recording sampled values has been enabled for a channel, then the sampled values are additionally recorded in the module's internal FIFO memory. If the configured event occurs, the contents of the FIFO memory are transmitted to the application.

Information:

It is only possible to use the recording of sampled values if the module is operated on an X2X master that is an SG4 CPU.

4.3.9.8.6.1 Trigger condition on falling edge

Name:
ConfigOutput21

This register configures whether the falling edge is used to trigger the trace and determination of the input value in the register 4.3.9.8.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	No trigger
		1	Falling edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Falling edge determines input value of channel 1
5	MinMaxStart02	0	No determination
		1	Falling edge determines input value of channel 2
6 - 7	Reserved	0	

4.3.9.8.6.2 Trigger condition on rising edge

Name:
ConfigOutput22

This register configures whether the rising edge is used to trigger the trace and determination of the input value in the register 4.3.9.8.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Rising edge does not initiate trigger
		1	Rising edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Rising edge determines input value of channel 1
5	MinMaxStart02	0	No determination
		1	Rising edge determines input value of channel 2
6 - 7	Reserved	0	

4.3.9.8.6.3 Analysis control byte

Name:
TraceTrigger01
MinMaxStart01 to MinMaxStart02

The trace function and determination of the minimum/maximum input values can be started in this register.
Whether the rising and/or falling edge is used to trigger the functions can be configured using the registers 4.3.9.8.6.1 "Trigger condition on falling edge" and 4.3.9.8.6.2 "Trigger condition on rising edge".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Does not initiate trigger/trace
		1	Initiates trigger/trace
1 - 3	Reserved	-	
4	MinMaxStart01	0	Determination not initiated
		1	Initiates determination of input value of channel 1
5	MinMaxStart02	0	Determination not initiated
		1	Initiates determination of input value of channel 2
6 - 7	Reserved	-	

Information:

To reduce the cyclic data transfer, this register combines the trace and limit value determination functions.

4.3.9.8.6.4 Analysis status byte

Name:
MinMaxStart01Readback to MinMaxStart02Readback

The currently requested module-internal analyses can be checked in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	MinMaxStart01Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
5	MinMaxStart02Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
6 - 7	Reserved	-	

4.3.9.8.7 Limit values

Limit value analysis must be enabled for the desired channel. See 4.3.9.8.4.1 "Channel configuration". The sampled value of the channel is then compared to the minimum and maximum values that are stored internally in the module. If a new measurement period is initiated with the 4.3.9.8.6.3 "Analysis control byte" register, then the values of the previous measurement period can be read from the respective registers intended for this.

4.3.9.8.7.1 Minimum input values

Name:
MinInput01 to MinInput02

The minimum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.9.8.7.2 Maximum input values

Name:
MaxInput01 to MaxInput02

The maximum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.9.8.7.3 Limit value trigger counter

Name:
CH01MinMaxLatchCounter to CH02MinMaxLatchCounter

The number of valid events that trigger a new measurement period for the limit value analysis is counted in this register.

Data type	Value
UINT	0 to 65535

4.3.9.8.8 Trace

If the module is operated on a SG4 CPU, the digitalized input values are recorded by the module. The module must be operated in "Supervised" mode in order to use the trace function.

Recording must be enabled for the desired channel. The enable bits can then control the recording at runtime. The sampled values are recorded in the module's internal FIFO memory.

If the previously defined state occurs on the channel, the contents of the FIFO memory are transmitted to the application. Whether the FIFO memory continued to be filled depends on how recording is configured.

Information:

The trace mechanism can only be used if the module is connected directly to the CPU, not if it is operated behind a bus controller.

4.3.9.8.8.1 Enable recording

Name:
TraceChannelEnable

The respective channel is enabled for the trace with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Channel disabled
		1	Channel enabled
1	Channel 2	0	Channel disabled
		1	Channel enabled
2 - 7	Reserved	-	

4.3.9.8.8.2 Number of values to be recorded

Name:
TraceSampleDepth

16 kB are available on the module for the trace. The FIFO memory limitation means that a maximum of 8192 analog values can be recorded. This memory is divided up equally among the enabled channels. The actual number of maximum possible recordings therefore depends on the number of channels enabled for trace:

1 channel enabled: Up to 8192 recordings
2 channels enabled: Up to 4096 recordings per channel

Data type	Value	Function
UINT	2 to 8192	Default value = 1024

4.3.9.8.8.3 Recording priority

Name:
ConfigOutput25

The priority of the trace can be increased with this register.

Data type	Value	Function
USINT	3	Standard (default value)
	6	Trace priority higher than X2X Link communication

4.3.9.8.8.4 Starting a recording

Name:

TraceEnable01

This register starts the recording according to the specifications for edge control or the comparator.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceEnable01	0	Disables the trace function
		1	Enables the trace function
1 - 7	Reserved	-	

4.3.9.8.8.5 Recording status

Name:
TraceEnabled
TraceWriteActive
TraceReadActive
ReadyForTrigger
TriggerActive
TraceOk
TraceError

The status of the trace is represented in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	TraceEnabled	0	Trace inactive
		1	Trace active
1	Reserved	-	
2	TraceWriteActive	0	Data not recorded
		1	Data recorded
3	TraceReadActive	0	Data not output/read
		1	Data output/read
4	ReadyForTrigger	0	Not ready for triggering
		1	Ready for triggering
5	TriggerActive	0	No trigger active or already executed
		1	Trigger active
6	TraceOk	0	Overflow or inactive
		1	No overflow
7	TraceError	0	No error or inactive
		1	Trace buffer full

4.3.9.8.8.6 Free trace buffer

Name:
FreeBufferSize

Specifies the available FIFO memory area in bytes for the trace

Data type	Value
UINT	0 to 65535

4.3.9.8.8.7 Counter for trace triggers

Name:
TriggerCount

The number of trigger events that have occurred since "starting the trace" is indicated in this register.

Data type	Value
UINT	0 to 65535

4.3.9.8.8.8 Counter for faulty recording triggers

Name:
TriggerFailCount

Counts the trigger events for which the trace could not be performed.

Data type	Value
UINT	0 to 65535

4.3.9.8.8.9 Comparator for trigger conditions

In order to adapt the trace as closely as possible to the requirements of the application, the trace function can also be controlled using the comparator. Threshold values (hysteresis) can be defined within the permitted range of values to do so. 2 status bits are then generated for each enabled channel:

- **InRange bit**
  The InRange status is "1" if the measured value falls within the defined limits.
  The InRange status is "0" if the measured value falls outside the defined limits.
- **Threshold value bit**
  The threshold value bit is "1" if the measured value exceeds the upper threshold value.
  The threshold value bit is "0" if the measured value falls below the lower threshold value.

The InRange and threshold value bits for all channels are grouped together in the lower-value byte of the "Hysteresis status of the channels" register. In addition, the states of the previous sampling are stored in the higher-value byte.

The 4 status messages of each channel can be linked according to the following logic via a logical connective mask using AND or OR operators and used as a trace trigger:

```
delta = (Current_HysteresisStatus ^ NominalValues) // Different between current status and preset
cond = delta & Selected_HysteresisStatusBits // Eliminate irrelevant status messages
cond = Selected_HysteresisStatusBits (Current_HysteresisStatus ^ NominalValues)
if ((0 == (cond & ~LogicalOperators)) &&
(0 != (~cond & LogicalOperators))) { => Generate trigger event}
```

	Corresponds to register:
Selected_HysteresisStatusBits	cfgComp_EnableMask
Current_HysteresisStatus	CompStateCollection
Nominal values	cfgComp_NominalState
Logical operators	cfgComp_ConditionTypeMask

Lower limit value for hysteresis

Name:
cfgComp_LowLimitCh01 to cfgComp_LowLimitCh02

The lower limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Upper limit value for hysteresis

Name:
cfgComp_HighLimitCh01 to cfgComp_HighLimitCh02

The upper limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Hysteresis status of the channels

Name:
CompStateCollection

The hysteresis status of the input channels for the current and last cycle are represented in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
2	Channel02 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
3	Channel02 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
10	Channel02 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
11	Channel02 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
12 - 15	Reserved	-	

Comparison state of the channels

Name:
cfgComp_NominalState

The desired comparison state for the hysteresis status is indicated in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
2	Channel02 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
3	Channel02 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
10	Channel02 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
11	Channel02 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
12 - 15	Reserved	-	

Information:

This is a "whitelist", i.e. the trace starts as soon as the current status message takes on the state predefined here.

One or more matches will be necessary depending on the selection of the relevant hysteresis status bits and logical connective operators.

Selecting the relevant hysteresis status bits

Name:
cfgComp_EnableMask

This register selects which status bits of the hysteresis comparison should be used to generate the trigger.

For more information about using this register, see 4.3.9.8.8.9 "Comparator for trigger conditions".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
1	Channel01 InRange status in the current cycle	0	Do not use
		1	Use for generation
2	Channel02 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
3	Channel02 InRange status in the current cycle	0	Do not use
		1	Use for generation
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
9	Channel01 InRange status in the last cycle	0	Do not use
		1	Use for generation
10	Channel02 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
11	Channel02 InRange status in the last cycle	0	Do not use
		1	Use for generation
12 - 15	Reserved	-	

Logical connective operators for hysteresis status bits

Name:
cfgComp_ConditionTypeMask

The desired state operators with which the status bits are linked to one another to generate a trigger are selected in this register.

At least one OR operation must be configured, but it does not necessarily have to be located on a channel configured with "1" in the "Selecting the relevant hysteresis status bits" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
1	Channel01 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
2	Channel02 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
3	Channel02 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
9	Channel01 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
10	Channel02 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
11	Channel02 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
12 - 15	Reserved	-	

4.3.9.8.8.10 Time-offset trace

Additional conditions for shifting the starting and stopping points can be defined if the trace should be chronologically offset to the trigger.

Starting the trace

Name:
TraceTriggerStart

The starting position is defined relative to the configured trigger condition in this register. Positive values mean that the trace takes place x samples after the trigger condition. Negative values mean that the trace takes place x samples before the trigger condition.

The value -32768 performs the trace without regard for the configured trigger condition. If the trace memory is completely full, then the oldest recorded value is overwritten (FIFO principle).

"Trace start" in the I/O configuration or the registers 4.3.9.8.6.1 "Trigger condition on falling edge" and 4.3.9.8.6.2 "Trigger condition on rising edge" determine whether a positive, negative or any edge must be triggered.

Data type	Value	Information
INT	-32767 to 32767	
	-32768	Continuous trace without a stopping point

Stopping the trace

Name:
TraceTriggerStop

The stopping position is defined relative to the configured trigger condition in this register.

- When configuring an early trigger event, this value refers to the trigger event.
- When configuring a delayed trigger event, this value refers to the starting event.

Data type	Value
UINT	0 to 65535

4.3.9.8.9 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.3.9.8.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard priority	200 µs
High priority with trace function	300 µs

4.3.9.8.11 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.10 X20AI2632-1

4.3.10.1 General information

The module is equipped with 2 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs
- Either current or voltage signal possible
- Extended signal range
- 16-bit digital converter resolution
- Simultaneous input conversion
- Very fast conversion time

4.3.10.2 Order data

Model number	Short description	Figure

Spacing	12.5$^{+0.2}$ mm

Table 47: X20AI2632-1 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 22 V measurement range.
5) Based on the 22 mA measurement range.

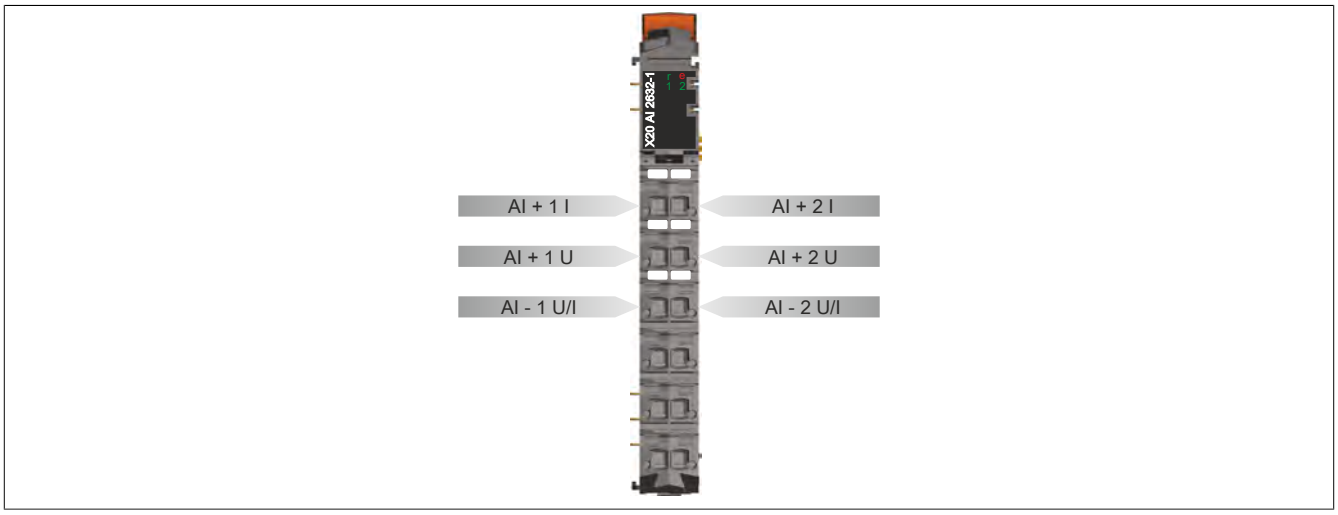
4.3.10.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)1)
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	System error: • Violation of the scan time • Synchronization error
	1 - 2	Green	Off	Open line2) or sensor is disconnected
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

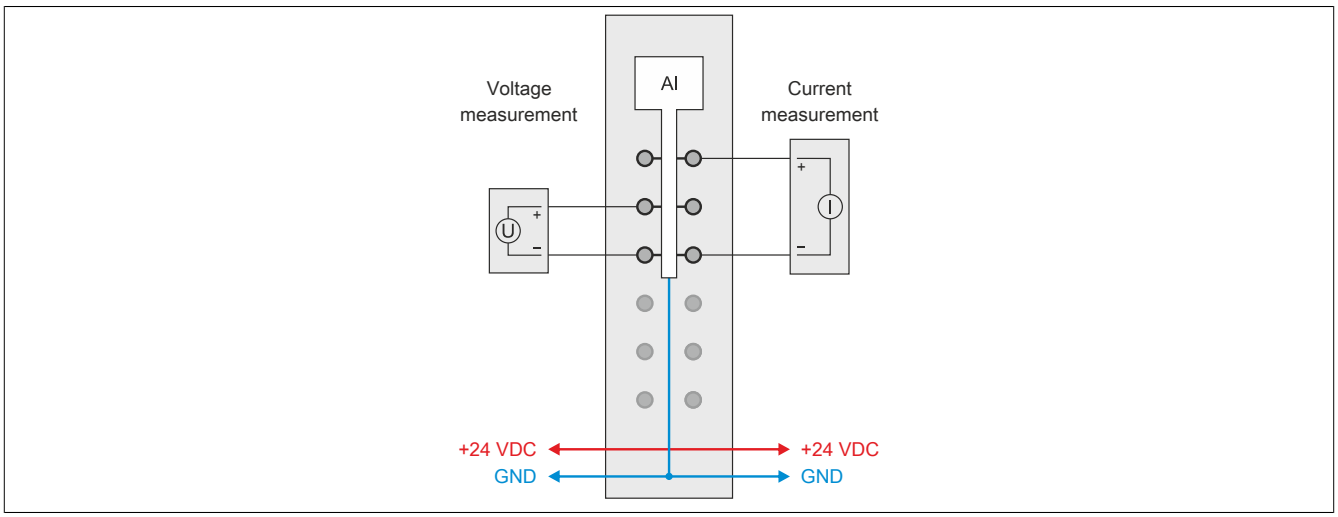
4.3.10.5 Pinout



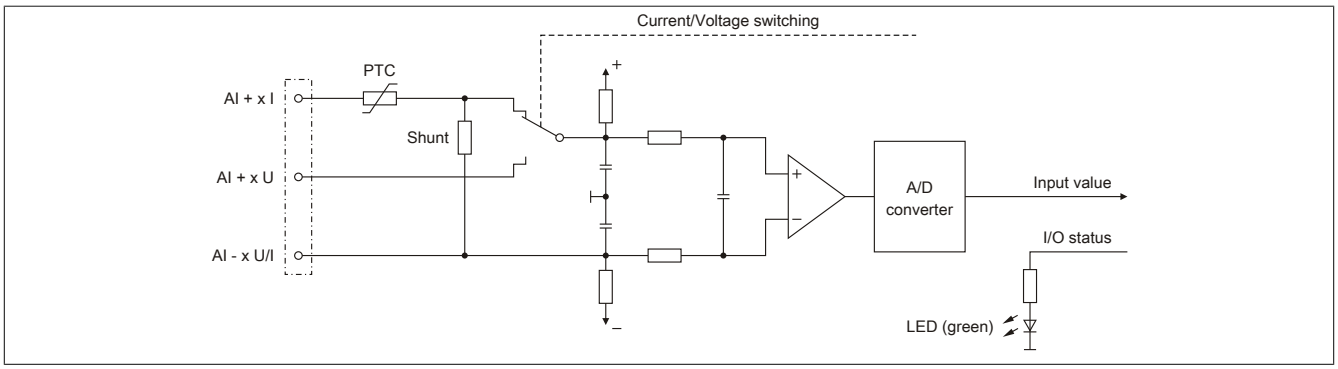
4.3.10.6 Connection example

To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules



4.3.10.7 Input circuit diagram



4.3.10.8 Register description

4.3.10.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

4.3.10.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.10.8.4 Configuration

This module is equipped with analog inputs with connected 16-bit A/D converters. Each of the inputs can be configured separately from one another either on the voltage or current input for the following areas:

- Permitted voltage: ±11 V at 20 Ω
- Permitted current: 22 mA (maximum 40 mA) (<400 Ω)

4.3.10.8.4.1 Channel configuration

Name:
ConfigOutput01 for channel 01
ConfigOutput06 for channel 02

The individual inputs for processing the current or voltage signal are configured in these registers. This configuration must be made in addition to using the correct terminal block pins.

Filtering, analysis and error monitoring (bits 4 to 6) can only be used if the channel is enabled (bit 7 = 0).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Terminal selector	0	Voltage terminal for ±11 VDC
		1	Current terminal for 0 to 22 mA
1	Gain selector	0	Voltage ±11 VDC
		1	Current 0 to 22 mA
2 - 3	Reserved	-	
4	Filtering active (only if bit 7 = 0)	0	Inactive
		1	Active
5	Minimum/Maximum analysis active (only if bit 7 = 0)	0	Inactive
		1	Active
6	Error monitoring active (only if bit 7 = 0)	0	Inactive
		1	Active
7	Enables channel	0	Channel enabled
		1	Channel disabled

4.3.10.8.4.2 Sampling and conversion

The analog signal is sampled in 2 steps.

- **Conversion task**
  The A/D converter digitalizes the inputs signals for the enabled inputs once per conversion cycle. Then the results are available internally in the module. To ensure that this process is executed without delays, the corresponding task will be handled with very high priority.
  The timespan needed for conversion results from the set sampling time.
- **Processing task**
  The converted A/D converter values are further processed according to the user settings (filtering, scaling, limit values, error statistics, min/max analysis, hysteresis comparison). The task for this process has low priority. The timespan needed for further processing depends on the configured functions and is the second portion of the sampling time.

Cycle time violation

In normal operation, further processing is triggered after each conversion. The conversion and sampling tasks run synchronous to one another. If the predefined sampling time is not sufficient to convert all enabled channels and complete the configured functions, a cycle time violation occurs.

Sampling time

Name:
ConfigOutput24

The sampling time is set to µs in this register. This makes it possible to improve the sampling cycle (resolution = 1 µs). The lowest configurable cycle time is 50 µs.

Data type	Value	Function
UINT	50 to 10,000	Default value = 100

Information:

Values that are too low for the cycle time will result in cycle time violations.

4.3.10.8.4.3 Filtering (optional)

If filtering is enabled in the 4.3.10.8.4.1 "Channel configuration" register, the basic data of the A/D converter is filtered per channel. The following registers are available to specify the filter order and respective cutoff frequency for configuring the low-pass filter:

- "Filter order"
- "Filter cutoff frequency"

Filter order

Name:
ConfigOutput26 for channel 1
ConfigOutput28 for channel 2

The filter order is specified in this register. The "Filter cutoff frequency" register is used to configure the respective cutoff frequency of the filter.

Data type	Value
USINT	1 to 4

Internal filter orders greater than 1 are implemented as cascaded first-order filters. Since the filter is calculated in the sampling cycle, the filter characteristics are directly related to the settings for the sampling cycle time.

Calculating the cutoff frequency of an nth-order filter:

yn = a * xn + b * y(n-1)

Approximate calculation

a = Sampling time / (Sampling time + 1/Cutoff frequency)

b = 1 - a

Filter cutoff frequency

Name:
ConfigOutput27 for channel 1
ConfigOutput29 for channel 2

The cutoff frequency of the respective filter is configured in these registers.

Data type	Value	Description
UINT	1 to 65,535	Cutoff frequency in hertz

Information:

The highest cutoff frequency is limited by the Nyquist Shannon sampling theorem (based on the sampling cycle time). The system does not check for violations of this sampling theorem.

4.3.10.8.4.4 Scaling (optional)

Scaling A/D converter data is an option for the user. The following registers are available for this:

- "User-defined gain" (= ku)
- "User-defined offset" (= du)

Scaling calculation:

Scaled value = k * A/C value + d

Gain $k = k_{Calibration} * ku$

Offset $d = d_{Calibration} + du$

The value has to be limited since it can exceed the 16-bit constraints. To provide the greatest degree of flexibility, limiting is possible using the registers "Minimum limit value" and "Maximum limit value".

User-defined gain

Name:
ConfigOutput04 for channel 1
ConfigOutput09 for channel 2

The user-defined gain for the A/D converter data of the respective physical channel can be specified in these registers.

The value 65,536 (0x10000) corresponds to a gain of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

User-defined offset

Name:
ConfigOutput05 for channel 1
ConfigOutput10 for channel 2

The user-defined offset for the A/D converter data of the respective physical channel can be specified in this register.

The value 65,536 (0x10000) corresponds to an offset of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.3.10.8.4.5 User-defined limit values

If the application requires a limitation of the range of values, then the user can define his own limit values. These values will also be use for the module's error statistics. The following registers are available for this:

- "Minimum limit value"
- "Maximum limit value"

Information:

32-bit numbers are used inside the module. A limit value violation can therefore also be determined if the permitted range of values was defined from -32768 to 32767.

Minimum limit value

Name:
ConfigOutput02 for channel 1
ConfigOutput07 for channel 2

The minimum limit value is configured in this register. This limit value is also used as the lower value in the error statistics (see register "Counter for range exceeded violations (neg.)").

Data type	Value
INT	-32768 to 32767

Maximum limit value

Name:
ConfigOutput03 for channel 1
ConfigOutput08 for channel 2

The maximum limit value is configured in this register. This limit value is also used as the upper value in the error statistics (see register "Counter for range exceeded violations (pos.)").

Data type	Value
INT	-32768 to 32767

4.3.10.8.5 Communication - General

The module's analog inputs convert current and voltage values with 16-bit resolution. This information can be used by the application with the help of the registers listed here.

4.3.10.8.5.1 Analog input channels

Name:
AnalogInput01 to AnalogInput02

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal ±11 VDC
	0 to 32,767	Current signal 0 to 22 mA

4.3.10.8.5.2 Sampling cycle counter

Name:
SampleCycleCounter

The number of times the input signal has been sampled is provided in this register.

Data type	Value
UINT	0 to 65535

4.3.10.8.5.3 Error monitoring and counters

Channel status

Name:
Channel01OK to Channel02OK
SyncStatus
ConvertionCycle

This register collects error messages synchronously with the network cycle. Temporary error states that were registered in a conversion cycle remain active for at least 2 network cycles. In order to receive detailed error information, the corresponding error counters and X2X network events should also be observed.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OK	0	OK
		1	Errors
1	Channel02OK	0	OK
		1	Errors
2 - 5	Reserved	-	
6	SyncStatus[1)]	0	OK
		1	Not synchronized
7	ConvertionCycle[2)]	0	OK
		1	Errors

1) Identical to bit 0 of the registers "Synchronization error counter".
2) Identical to bit 0 of the registers "Counter for faulty sampling cycles".

Synchronization error counter

Name:
SynchronizationViolationErrorCounter

This register counts how often the conversion task was triggered more than 5 µs after the next-coming X2X cycle. In this case, the module is considered being no longer synchronized with X2X Link.

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for faulty sampling cycles

Name:
SampleCycleViolationErrorCounter

This register is used to indicate the number of cycle time violations that have occurred thus far. A cycle time violation occurs if the conversion tasks initiates a sampling task before the last sampling cycle has finished. See 4.3.9.8.4.2 "Sampling and conversion".

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Range violation (neg. and pos.)

Name:
Channel01underflow to Channel02underflow
Channel01overflow to Channel02overflow

This register indicates whether a range violation (pos. and/or neg.) of the limit values defined in the registers "Minimum limit value" and "Maximum limit value" has occurred. The individual bits in this register are identical to the values of the lowest bits in the registers "Counter for range exceeded violations (neg.)" and "Counter for range exceeded violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01underflow	0	No error
		1	Range exceeded (.neg) on channel 1
1	Channel02underflow	0	No error
		1	Range exceeded (.neg) on channel 2
2 - 3	Reserved	-	
4	Channel01overflow	0	No error
		1	Range exceeded (.pos) on channel 1
5	Channel02overflow	0	No error
		1	Range exceeded (.pos) on channel 2
6 - 7	Reserved	-	

Working range violation (pos.)

Name:
Channel01OutofRange to Channel02OutofRange

This register indicates whether the input value exceeds the module's maximum measurement range. The individual bits in this register are identical to the values of the lowest bits in the register "Counter for work range violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutofRange	0	No error
		1	Working range violation (pos.) of channel 1
1	Channel02OutofRange	0	No error
		1	Working range violation (pos.) of channel 2
2 - 7	Reserved	-	

Counter for work range violations (pos.)

Name:
CH01OutofRange to CH02OutofRange

Errors outside of the module's maximum possible measurement range are indicated in this register. These errors lead to full-scale deflection of the A/D converter.

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.10.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (neg.)

Name:
CH01Underflow to CH02Underflow

This register indicates range exceeded violations (neg.) of the value configured in the register "Minimum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.10.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (pos.)

Name:
CH01Overflow to CH02Overflow

This register indicates range exceeded violations (pos.) of the value configured in the register "Maximum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.10.8.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

4.3.10.8.6 Additional analysis functions

In addition to sampling the analog input signal, this module can also be used to perform additional analysis of the values obtained.

- **Limit value analysis**
  If limit value analysis has been enabled for a channel, the sampled minimum and maximum values are latched internally in the module. A measurement period can be triggered using the control byte. When the respective configured edge is generated by the application, the limit values from the previous measurement period are displayed and the internal latch register is reset.
- **Recording sampled values**
  If recording sampled values has been enabled for a channel, then the sampled values are additionally recorded in the module's internal FIFO memory. If the configured event occurs, the contents of the FIFO memory are transmitted to the application.

Information:

It is only possible to use the recording of sampled values if the module is operated on an X2X master that is an SG4 CPU.

4.3.10.8.6.1 Trigger condition on falling edge

Name:
ConfigOutput21

This register configures whether the falling edge is used to trigger the trace and determination of the input value in the register 4.3.9.8.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	No trigger
		1	Falling edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Falling edge determines input value of channel 1
5	MinMaxStart02	0	No determination
		1	Falling edge determines input value of channel 2
6 - 7	Reserved	0	

4.3.10.8.6.2 Trigger condition on rising edge

Name:
ConfigOutput22

This register configures whether the rising edge is used to trigger the trace and determination of the input value in the register 4.3.9.8.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Rising edge does not initiate trigger
		1	Rising edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Rising edge determines input value of channel 1
5	MinMaxStart02	0	No determination
		1	Rising edge determines input value of channel 2
6 - 7	Reserved	0	

4.3.10.8.6.3 Analysis control byte

Name:
TraceTrigger01
MinMaxStart01 to MinMaxStart02

The trace function and determination of the minimum/maximum input values can be started in this register.
Whether the rising and/or falling edge is used to trigger the functions can be configured using the registers 4.3.9.8.6.1 "Trigger condition on falling edge" and 4.3.9.8.6.2 "Trigger condition on rising edge".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Does not initiate trigger/trace
		1	Initiates trigger/trace
1 - 3	Reserved	-	
4	MinMaxStart01	0	Determination not initiated
		1	Initiates determination of input value of channel 1
5	MinMaxStart02	0	Determination not initiated
		1	Initiates determination of input value of channel 2
6 - 7	Reserved	-	

Information:

To reduce the cyclic data transfer, this register combines the trace and limit value determination functions.

4.3.10.8.6.4 Analysis status byte

Name:
MinMaxStart01Readback to MinMaxStart02Readback

The currently requested module-internal analyses can be checked in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	MinMaxStart01Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
5	MinMaxStart02Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
6 - 7	Reserved	-	

4.3.10.8.7 Limit values

Limit value analysis must be enabled for the desired channel. See 4.3.10.8.4.1 "Channel configuration". The sampled value of the channel is then compared to the minimum and maximum values that are stored internally in the module. If a new measurement period is initiated with the 4.3.9.8.6.3 "Analysis control byte" register, then the values of the previous measurement period can be read from the respective registers intended for this.

4.3.10.8.7.1 Maximum input values

Name:
MaxInput01 to MaxInput02

The maximum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.10.8.7.2 Minimum input values

Name:
MinInput01 to MinInput02

The minimum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.10.8.7.3 Limit value trigger counter

Name:
CH01MinMaxLatchCounter to CH02MinMaxLatchCounter

The number of valid events that trigger a new measurement period for the limit value analysis is counted in this register.

Data type	Value
UINT	0 to 65535

4.3.10.8.8 Trace

If the module is operated on a SG4 CPU, the digitalized input values are recorded by the module. The module must be operated in "Supervised" mode in order to use the trace function.

Recording must be enabled for the desired channel. The enable bits can then control the recording at runtime. The sampled values are recorded in the module's internal FIFO memory.

If the previously defined state occurs on the channel, the contents of the FIFO memory are transmitted to the application. Whether the FIFO memory continued to be filled depends on how recording is configured.

Information:

The trace mechanism can only be used if the module is connected directly to the CPU, not if it is operated behind a bus controller.

4.3.10.8.8.1 Enable recording

Name:
TraceChannelEnable

The respective channel is enabled for the trace with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Channel disabled
		1	Channel enabled
1	Channel 2	0	Channel disabled
		1	Channel enabled
2 - 7	Reserved	-	

4.3.10.8.8.2 Number of values to be recorded

Name:
TraceSampleDepth

16 kB are available on the module for the trace. The FIFO memory limitation means that a maximum of 8192 analog values can be recorded. This memory is divided up equally among the enabled channels. The actual number of maximum possible recordings therefore depends on the number of channels enabled for trace:

1 channel enabled: Up to 8192 recordings
2 channels enabled: Up to 4096 recordings per channel

Data type	Value	Function
UINT	2 to 8192	Default value = 1024

4.3.10.8.8.3 Recording priority

Name:
ConfigOutput25

The priority of the trace can be increased with this register.

Data type	Value	Function
USINT	3	Standard (default value)
	6	Trace priority higher than X2X Link communication

4.3.10.8.8.4 Starting a recording

Name:

TraceEnable01

This register starts the recording according to the specifications for edge control or the comparator.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceEnable01	0	Disables the trace function
		1	Enables the trace function
1 - 7	Reserved	-	

4.3.10.8.8.5 Recording status

Name:
TraceEnabled
TraceWriteActive
TraceReadActive
ReadyForTrigger
TriggerActive
TraceOk
TraceError

The status of the trace is represented in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	TraceEnabled	0	Trace inactive
		1	Trace active
1	Reserved	-	
2	TraceWriteActive	0	Data not recorded
		1	Data recorded
3	TraceReadActive	0	Data not output/read
		1	Data output/read
4	ReadyForTrigger	0	Not ready for triggering
		1	Ready for triggering
5	TriggerActive	0	No trigger active or already executed
		1	Trigger active
6	TraceOk	0	Overflow or inactive
		1	No overflow
7	TraceError	0	No error or inactive
		1	Trace buffer full

4.3.10.8.8.6 Free trace buffer

Name:
FreeBufferSize

Specifies the available FIFO memory area in bytes for the trace

Data type	Value
UINT	0 to 65535

4.3.10.8.8.7 Counter for trace triggers

Name:
TriggerCount

The number of trigger events that have occurred since "starting the trace" is indicated in this register.

Data type	Value
UINT	0 to 65535

4.3.10.8.8.8 Counter for faulty recording triggers

Name:
TriggerFailCount

Counts the trigger events for which the trace could not be performed.

Data type	Value
UINT	0 to 65535

4.3.10.8.8.9 Comparator for trigger conditions

In order to adapt the trace as closely as possible to the requirements of the application, the trace function can also be controlled using the comparator. Threshold values (hysteresis) can be defined within the permitted range of values to do so. 2 status bits are then generated for each enabled channel:

- **InRange bit**
  The InRange status is "1" if the measured value falls within the defined limits.
  The InRange status is "0" if the measured value falls outside the defined limits.
- **Threshold value bit**
  The threshold value bit is "1" if the measured value exceeds the upper threshold value.
  The threshold value bit is "0" if the measured value falls below the lower threshold value.

The InRange and threshold value bits for all channels are grouped together in the lower-value byte of the "Hysteresis status of the channels" register. In addition, the states of the previous sampling are stored in the higher-value byte.

The 4 status messages of each channel can be linked according to the following logic via a logical connective mask using AND or OR operators and used as a trace trigger:

```
delta = (Current_HysteresisStatus ^ NominalValues) // Different between current status and preset
cond = delta & Selected_HysteresisStatusBits // Eliminate irrelevant status messages
cond = Selected_HysteresisStatusBits (Current_HysteresisStatus ^ NominalValues)
if ((0 == (cond & ~LogicalOperators)) &&
(0 != (~cond & LogicalOperators))) { => Generate trigger event}
```

	Corresponds to register:
Selected_HysteresisStatusBits	cfgComp_EnableMask
Current_HysteresisStatus	CompStateCollection
Nominal values	cfgComp_NominalState
Logical operators	cfgComp_ConditionTypeMask

Lower limit value for hysteresis

Name:
cfgComp_LowLimitCh01 to cfgComp_LowLimitCh02

The lower limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Upper limit value for hysteresis

Name:
cfgComp_HighLimitCh01 to cfgComp_HighLimitCh02

The upper limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Hysteresis status of the channels

Name:
CompStateCollection

The hysteresis status of the input channels for the current and last cycle are represented in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
2	Channel02 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
3	Channel02 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
10	Channel02 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
11	Channel02 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
12 - 15	Reserved	-	

Comparison state of the channels

Name:
cfgComp_NominalState

The desired comparison state for the hysteresis status is indicated in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
2	Channel02 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
3	Channel02 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
10	Channel02 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
11	Channel02 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
12 - 15	Reserved	-	

Information:

This is a "whitelist", i.e. the trace starts as soon as the current status message takes on the state predefined here.

One or more matches will be necessary depending on the selection of the relevant hysteresis status bits and logical connective operators.

Selecting the relevant hysteresis status bits

Name:
cfgComp_EnableMask

This register selects which status bits of the hysteresis comparison should be used to generate the trigger.

For more information about using this register, see 4.3.9.8.8.9 "Comparator for trigger conditions".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
1	Channel01 InRange status in the current cycle	0	Do not use
		1	Use for generation
2	Channel02 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
3	Channel02 InRange status in the current cycle	0	Do not use
		1	Use for generation
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
9	Channel01 InRange status in the last cycle	0	Do not use
		1	Use for generation
10	Channel02 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
11	Channel02 InRange status in the last cycle	0	Do not use
		1	Use for generation
12 - 15	Reserved	-	

Logical connective operators for hysteresis status bits

Name:
cfgComp_ConditionTypeMask

The desired state operators with which the status bits are linked to one another to generate a trigger are selected in this register.

At least one OR operation must be configured, but it does not necessarily have to be located on a channel configured with "1" in the "Selecting the relevant hysteresis status bits" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
1	Channel01 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
2	Channel02 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
3	Channel02 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
4 - 7	Reserved	-	
8	Channel01 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
9	Channel01 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
10	Channel02 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
11	Channel02 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
12 - 15	Reserved	-	

4.3.10.8.8.10 Time-offset trace

Additional conditions for shifting the starting and stopping points can be defined if the trace should be chronologically offset to the trigger.

Starting the trace

Name:
TraceTriggerStart

The starting position is defined relative to the configured trigger condition in this register. Positive values mean that the trace takes place x samples after the trigger condition. Negative values mean that the trace takes place x samples before the trigger condition.

The value -32768 performs the trace without regard for the configured trigger condition. If the trace memory is completely full, then the oldest recorded value is overwritten (FIFO principle).

"Trace start" in the I/O configuration or the registers 4.3.9.8.6.1 "Trigger condition on falling edge" and 4.3.9.8.6.2 "Trigger condition on rising edge" determine whether a positive, negative or any edge must be triggered.

Data type	Value	Information
INT	-32767 to 32767	
	-32768	Continuous trace without a stopping point

Stopping the trace

Name:
TraceTriggerStop

The stopping position is defined relative to the configured trigger condition in this register.

- When configuring an early trigger event, this value refers to the trigger event.
- When configuring a delayed trigger event, this value refers to the starting event.

Data type	Value
UINT	0 to 65535

4.3.10.8.9 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.3.10.8.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard priority	200 µs
High priority with trace function	300 µs

4.3.10.8.11 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.11 X20AI2636

4.3.11.1 General information

The module is equipped with 2 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections. With the oversampling function, up to 16 analog values per channel can be recorded.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog inputs
- Current or voltage signal configuration for the entire module
- 16-bit digital converter resolution
- Minimum conversion time of 40 µs for all inputs
- The conversion time for the entire module can be configured in 0.02 µs steps.
- Maximum 14 samples (16-bit) for the entire module per X2X Link cycle
- Oversampling: Up to 16 analog values per channel (internal)
- Timestamp for the last conversion of an X2X Link cycle

4.3.11.2 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI2636	X20 analog input module, 2 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions	
	Required accessories	
	Bus modules

Spacing	12.5+0.2 mm

Table 49: X20AI2636 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals.
2) Based on the current measured value.
3) Based on the 20 V measurement range.
4) Based on the 20 mA measurement range.

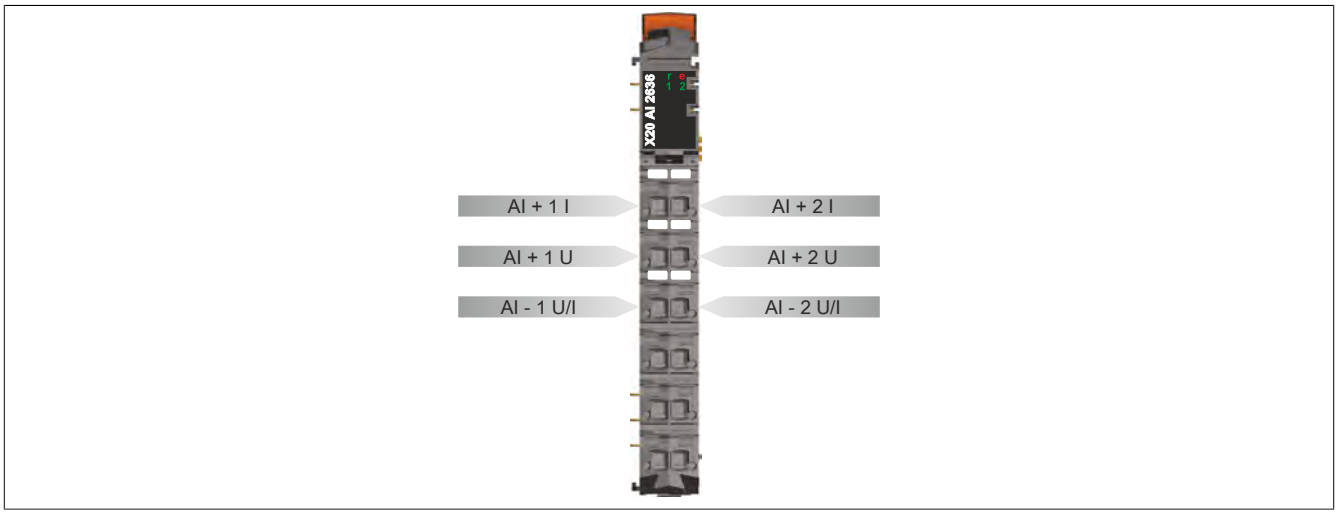
4.3.11.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)1)
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	System error: • Violation of the scan time • Synchronization error
	1 - 2	Green	Off	Open line2) or sensor is disconnected
			Blinking	Channel error: Underflow, overflow or broken connection
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

4.3.11.5 Pinout



4.3.11.6 Connection example

To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules

4.3.11.8.3 Function model 254

The "Bus controller" function model has the following limitations compared to the "Standard" function model:

- No oversampling function since consistency is not possible when operating CAN-based bus controllers due to the limited data range
- The sampling cycle time is set to 100 µs.
- No timestamp function
- A range of logical functions is available for processing the physical values right on the module:
  - Output of physical values (standard)
  - Addition of two channels with scaling
  - Integral addition of two channels with scaling
  - Multiplication of two channels with scaling
  - Integral multiplication of two channels with scaling

1) The offset specifies the position of the register within the CAN object.

4.3.11.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.11.8.4 General information

There is a difference on the module between physical (default) and logical values:

Physical or default values
The conversion results are transferred to the higher-level system after being scaled and filtered. They are not processed further.

Logical values
The physical values can be further processed with mathematical functions and comparators. In addition, another logical channel can be used as a starting point to further process a logical function.

4.3.11.8.5 Operating mode - Oversampling

The input values are recorded with a configurable sampling cycle time and saved with timestamp to the internal physical data buffer. This data range can then be read out in the cyclic data transfer using a configurable data length.

The recording and transmission system for the logical channels is identical to that for the physical channels. The functions of the logical channels are also executed in the configured sampling cycle time and saved with timestamp to the logical data buffer. The values can also be read out from here using configurable cyclic data points.

The defined sampling cycle time may not be sufficient for the sum of all physical and logical functions if using fast X2X Link cycle times, however. If influencing the physical sampling is not permitted, then a prescaler can be used to slow down the logical processing.

Information:

The ability to adjust the sampling cycle time as needed on the module means there is basically no synchronization with X2X Link, regardless of whether standard inputs or an oversampling function is configured.

If synchronization is required, then the configured sampling cycle time must be a multiple of the X2X Link cycle time!

4.3.11.8.5.1 Analog oversampling

When using analog oversampling, the enabled channels are stored in the module within a configurable time frame independently of the X2X cycle. Space is available for 16 analog values per physical and logical channel.

These samplings are are numbered from 1 to 16 for the registers. The conversions or calculations of individual channels with the same number (i.e. sample line 1 to 16, e.g. PhysCh01Sample**10**, PhysCh02Sample**10**, etc.) are derived from the same sampling cycle or logical computing cycle and therefore have the same timestamp.

The timestamp refers to the newest data value, i.e. always to sample line 1. If a timestamp for older data points is needed, it needs to be back-calculated in the application using the sampling cycle time configured on the module. The prescaler must also be taken into account for logical channels.

Calculation example

Sample line	Calculation	
1	Timestamp	**Newest value**
2	Timestamp - Sampling cycle time	
3	Timestamp - 2 * Sampling cycle time	
4	Timestamp - 3 * Sampling cycle time	
...	...	
10	Timestamp - 9 * Sampling cycle time	
...	...	
16	Timestamp - 15 * Sampling cycle time	**Oldest value**

How the buffer is organized can be seen from this. This is not a FIFO buffer but a static buffer that the values are pushed through. Sample line 1 always contains the newest values, the next line the second newest, all the way up to sample line 16, which contains the oldest values.

The sample counter is a circular counter, with the number of new sample lines derived from the value of the last transfer cycle.

Example

A difference of 3 to the last transfer cycle means:

The data in sample line 1 and all subsequent data from the previous transfer cycle is now shifted in the current cycle beginning with sample line 4. Sample lines 1 through 3 contain the new values for further processing by the application. Sample lines 14 through 16 from the last transfer cycle are no longer in the buffer.

4.3.11.8.5.2 Comparator oversampling

When using comparator oversampling, the results of the enabled channels are stored in the module within a configurable time frame independently of the X2X cycle. 16 bits of memory space are available per logical channel.

These samplings (i.e. event bits) are consecutively numbered from 1 to 8 and 9 to 16 for the two registers. The results of individual channels with the same number (i.e. sample line 1 to 16, e.g. for channel 1 LogicCh01Sample**16_9** and LogicCh01Sample**8_1**) are derived from the same sampling cycle or logical computing cycle and therefore have the same timestamp.

The timestamp refers to the newest data value, i.e. always to sample line 1 (i.e. bit 0 in the LogicCh01Sample8_1 register). If a timestamp for older comparator results is needed, it needs to be back-calculated in the application using the sampling cycle time configured on the module. The prescaler must also be taken into account.

Calculation example

Sample line	(register name)	Calculation	
1	(LogicCh01Sample8_1 bit 0)	Timestamp	**Newest value**
2	(LogicCh01Sample8_1 bit 1)	Timestamp - Sampling cycle time	
3	(LogicCh01Sample8_1 bit 2)	Timestamp - 2 * Sampling cycle time	
4	(LogicCh01Sample8_1 bit 3)	Timestamp - 3 * Sampling cycle time	
...			
10	(LogicCh01Sample16_9 bit 1)	Timestamp - 9 * Sampling cycle time	
...			
16	(LogicCh01Sample16_9 bit 7)	Timestamp - 15 * Sampling cycle time	**Oldest value**

How the buffer is organized can be seen from this. This is not a FIFO buffer but a static buffer that the values are pushed through. Sample line 1 always contains the newest values, the next line the second newest, all the way up to sample line 16, which contains the oldest values.

The sample counter is a circular counter, with the number of new sample lines derived from the value of the last transfer cycle.

Example

A difference of 3 to the last transfer cycle means:

The comparator result in sample line 1 and all subsequent data from the previous transfer cycle is now shifted in the current cycle beginning with sample line 4. Sample lines 1 through 3 contain the new bit values for further processing by the application. Sample lines 14 through 16 from the last transfer cycle are no longer in the buffer.

Data transfer

The analog conversion rate / sampling cycle time can be considerably faster than the X2X Link cycle. Saved analog or comparator data can be transferred to the higher-level system synchronously and consistently.

In the application, it's important that the relationship between cyclic data points, the sampling cycle time on the module and the transfer time is sufficient to read all of the new data points on the higher-level system.

The sample counter can be used to check how many data values are actually new since the last transfer cycle. If the counter difference to the previous cycle is larger than the number of existing cyclic data points, then values have been overlooked and the system needs to be adjusted.

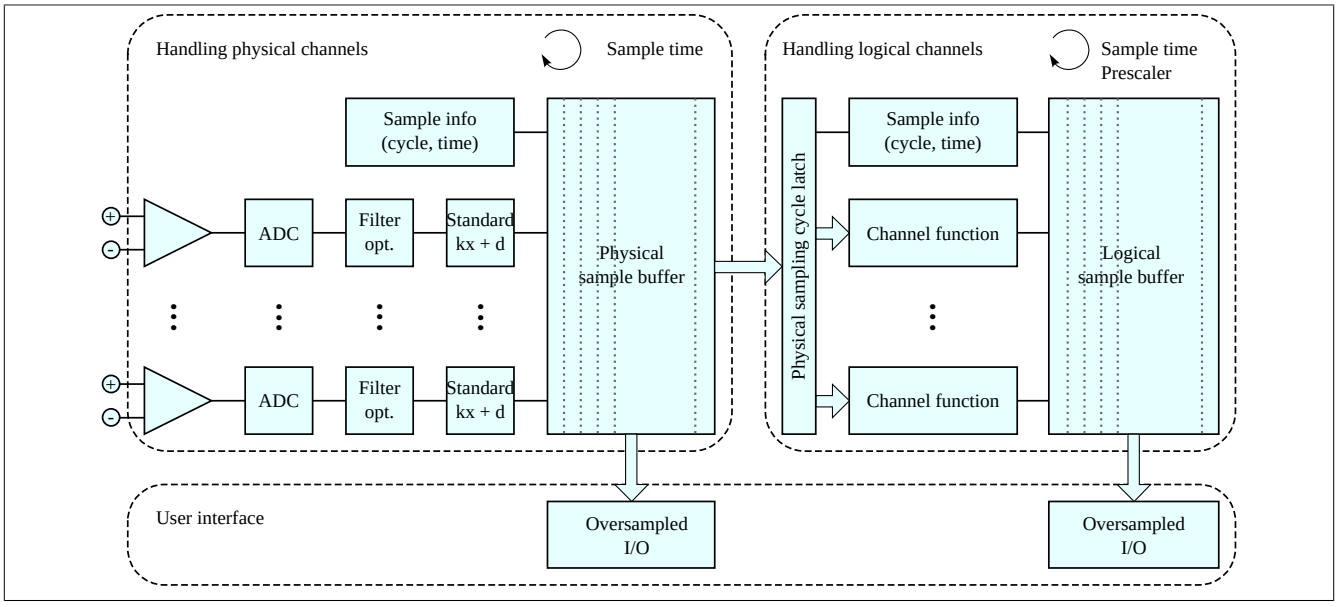
The general guideline is that a cyclic data point should be configured more than is actually required computing-wise.

Example with synchronous settings

- Sampling cycle time = 50 µs
- X2X Link cycle time = 500 µs

Samples 1 to 10 of a channel are possible to calculate in this example. Sample 11 should also be configured as a cyclic data point, however.
The reason for this is the possible jitter in the module caused by interruptions, e.g. from the X2X Link transfer. For the current cycle, this can mean that only 9 new values are available and that 11 values will have to be transferred in the next cycle.

For logical comparator functions, this problem doesn't exist since the maximum number is always transferred in the cycle data range.



4.3.11.8.6 Bus controller operating mode

The input values are recorded with a configurable sampling cycle time and saved with timestamp to the internal physical data buffer. Only the newest value will be transferred in the next possible bus cycle.

Limitations in the bus controller function model:

- No oversampling function since consistency is not possible due to the limited data range
- Sampling cycle time configured to 100 µs by default
- Range of logical functions available for processing physical values directly on the module
- Timestamp not available

4.3.11.8.7 "AnalogInput" registers

Name:
AnalogInput01 to AnalogInput02

This module can be configured and operated as a normal analog input module without logical auxiliary functions. The physical values from the last sampling cycle are used as input values in this case.

The module is operated as a normal analog input module in the bus controller function model. Nevertheless, it is still possible to connect each input channel directly to a logical function. The analog data on the bus controller is mapped using the calculation abilities of the logical channels and configured automatically (see 4.3.11.8.14.2 "Operation in the bus controller function model ").

Analog input values are displayed as signed 16-bit values depending on the configured operating mode.

Data type	Value	Information
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 mA to 20 mA

Information:

It is important to note that the oversampling function is not available in the bus controller function model due to the amount of data and lack of consistency!

4.3.11.8.8 Physical sampling

This module has a data buffer with 16 entries for each of the physical input channels. This buffer is processed according to the configured sampling cycle time.

A maximum of only 30 bytes is available for cyclic transfer on the X2X bus, however. Minus the status and sample counter, this allows only a selection of 14 samples (with a 16-bit data width) from the physical and logical buffer to be transferred.
Data loss can therefore occur with an imprecise selection and configuration.

Example

Displaying continuous sample lines.

- Sampling cycle time = 100 µs
- X2X cycle time = 500 µs

Sample line 1	PhysCh0xSample1
Sample line 2	PhysCh0xSample2
Sample line 3	PhysCh0xSample3
Sample line 4	PhysCh0xSample4
Sample line 5	PhysCh0xSample5
Sample line 6	PhysCh0xSample6
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 2	New values in sample line 1 and sample line 2
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5

Information:

It is important to note that the sample counter refers to the update of the sample lines in the data buffer and not to the number of values transferred cyclically.

Displaying each second sample line to bridge a higher recording duration:

- Sampling cycle time = 100 µs
- X2X cycle time = 1000 µs

Sample line 1	PhysCh0xSample1
Sample line 3	PhysCh0xSample3
Sample line 5	PhysCh0xSample5
Sample line 7	PhysCh0xSample7
Sample line 9	PhysCh0xSample9
Sample line 11	PhysCh0xSample11
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 3	New values in sample line 1 and sample line 3
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5
...	
Difference SampleCount = 9	New values in sample line 1 to sample line 9

4.3.11.8.8.1 "PhysChSample" registers

Name:
PhysCh01Sample1 to PhysCh01Sample16
PhysCh02Sample1 to PhysCh02Sample16

These registers are the physical buffer registers of the analog channels. 16 registers are available for each channel. Sample 1 is the newest value; sample 16 is the oldest.

Data type	Value	Information
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 mA to 20 mA

4.3.11.8.8.2 "PhysSampleCount" register

Name:
PhysSampleCount

This register is an integer counter that is increased as soon as the module has saved a new physical sample line. The number of new sample lines is calculated from the difference to the previous cycle.

Data type	Value
SINT	-128 to 127
INT	-32,768 to 32,767

4.3.11.8.8.3 "PhysTimestamp" register

Name:
PhysTimestamp

This register returns the timestamp of the values currently being determined as signed values in µs. This data point is the timestamp of the physical sample line 1.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.11.8.9 Logical sampling

The module has a data buffer with 16 entries for each of the 6 logical channels. This buffer is processed according to the configured sampling cycle time. In addition, it's also possible to adjust the logical execution cycle using a prescaler for the sampling cycle time.

A maximum of only 30 bytes is available for cyclic transfer on the X2X bus, however. Minus the status and sample counter, this allows only a selection of 14 samples (with a 16-bit data width) from the physical and logical buffer to be transferred. For the logical channels, it is also possible to configure a 32-bit data width.
Data loss can therefore occur with an imprecise selection and configuration.

Example

Displaying continuous sample lines.

- Sampling cycle time = 100 µs
- X2X cycle time = 500 µs

Sample line 1	LogicCh0xSample1
Sample line 2	LogicCh0xSample2
Sample line 3	LogicCh0xSample3
Sample line 4	LogicCh0xSample4
Sample line 5	LogicCh0xSample5
Sample line 6	LogicCh0xSample6
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 2	New values in sample line 1 and sample line 2
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5

Information:

It is important to note that the sample counter refers to the update of the sample lines in the data buffer and not to the number of values transferred cyclically.

Displaying each second sample line to bridge a higher recording duration:

- Sampling cycle time = 100 µs
- X2X cycle time = 1000 µs

Sample line 1	LogicCh0xSample1
Sample line 3	LogicCh0xSample3
Sample line 5	LogicCh0xSample5
Sample line 7	LogicCh0xSample7
Sample line 9	LogicCh0xSample9
Sample line 11	LogicCh0xSample11
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 3	New values in sample line 1 and sample line 3
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5
...	
Difference SampleCount = 9	New values in sample line 1 to sample line 9

4.3.11.8.9.1 "LogicChSample" registers

Name:
LogicCh01Sample1 to LogicCh01Sample16
...
LogicCh06Sample1 to LogicCh06Sample16

These registers are the buffer registers of the logical input channels. 16 registers are available for each channel. Sample 1 is the newest value; sample 16 is the oldest.

Calculated values are displayed as signed 16- or 32-bit values depending on the register being used.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.11.8.9.2 "LogicChSample16_9" registers

Name:
LogicCh01Sample16_9 to LogicCh06Sample16_9

These registers are used to represent the results of samples 9 to 16 of the logical digital comparator for the logical channels. Each of these bits corresponds to a sample line, with sample 9 the newest and Sample 16 the oldest comparator comparison. The results of samples 1 to 8 are represented in 4.3.11.8.9.3 ""LogicChSample8_1" registers".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator result	x	Sample 9
...	...		
7	Comparator result	x	Sample 16

4.3.11.8.9.3 "LogicChSample8_1" registers

Name:
LogicCh01Sample8_1 to LogicCh06Sample8_1

These registers are used to represent the results of samples 1 to 8 of the logical digital comparator for the logical channels. Each of these bits corresponds to a sample line, with sample 1 the newest and Sample 8 the oldest comparator comparison. The results of samples 9 to 16 are represented in 4.3.11.8.9.2 ""LogicChSample16_9" registers".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator result	x	Sample 1
...	...		
7	Comparator result	x	Sample 8

4.3.11.8.9.4 "LogicSampleCount" register

Name:
LogicSampleCount

This register is an integer counter that is increased as soon as the module has saved a new logical sample line. The number of new sample lines is calculated from the difference to the previous cycle.

Data type	Value
SINT	-128 to 127
INT	-32,768 to 32,767

4.3.11.8.9.5 "LogicTimestamp" register

Name:
LogicTimestamp

This register returns the timestamp of the values currently being determined as signed 2 or 4-byte values in µs. This data point is the timestamp of the logical sample line 1.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.11.8.10 System configuration

The following registers are used to configure the module's system settings.

4.3.11.8.10.1 Register "CfO_BaseConfig"

Name:
CfO_BaseConfig

This register can be used to configure settings for handling logical oversampling and data acquisition.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	"Display configuration for logical values active/inactive" in the AS I/O configuration	0	Inactive
		1	Active
1	"Logical handling priority" in the AS I/O configuration	0	Low
		1	High
2 - 3	Reserved	-	
4	"Physical input mode" in the AS I/O configuration	0	Newest value
		1	Referenced value (reference = prescaled system timer)
5	"Logical input mode" in the AS I/O configuration	0	Newest value
		1	Referenced value (reference = prescaled system timer)
6 - 7	Reserved	-	

Priority of logical oversampling

- Low priority setting
  Logical and physical buffers are not processed in the same context. If the calculation time that results in the logical oversampling is higher than the configured sampling cycle time, this setting and a prescaler > 1 can be used to split up the logical processing over several sampling cycles. In this way, the sample lines of the physical and logical oversampling are not automatically acquired or calculated at the same point in time. If the prescaler is configured incorrectly, the logical oversampling cannot be processed successfully.
- High priority setting
  Logical and physical buffers are processed in the same context. The sample lines of the physical and logical oversampling are acquired and calculated at the same point in time. It must be possible to execute all configured functions in the configured sampling cycle time; otherwise, a cycle time violation will occur and the configuration must be changed accordingly. Configuring the logical prescaler doesn't have any effect here; only the data traffic in the logical oversampling is limited.

Current or referenced values for logical or physical oversampling

In a system being used to capacity, jitter in the sampling cycle on the module can also be caused by the necessary processing of functions (X2X Link operation, logical and physical oversampling) when the cycle time is set to synchronous. This results in a varying number of sample lines in the same time period. For this reason, more samples should also be configured in the cyclic image than are actually necessary to compute.

- Current values setting
  Passing on the sample lines to the higher-level system takes place as quickly as possible, with fewer or more sample lines possibly occurring.
- Referenced values setting
  This setting minimizes jitter and makes it possible to expect a constant number of new sample lines per cycle when configured optimally. With regard to response time, however, delays of several sampling cycles may occur.

4.3.11.8.10.2 Register "CfO_CycleTime"

Name:
CfO_CycleTime
"Physical sample time" in the AS I/O configuration.

This register configures the module's sampling cycle time. The format is a 16.16-bit unsigned 4-byte value, with the high word representing the integer part of the µs value and the low word the decimal places. The decimal places allow a closer alignment to the X2X cycle time. The absolute resolution is 1 µs.

Input value = Time in µs * 65536 data type

Data type	Value	Information
UDINT	2,621,440 to 2,147,483,647	40 µs to 32 ms sampling cycle time
	6,553,600	100 µs (default value)

4.3.11.8.10.3 Register "CfO_Prescaler"

Name:
CfO_Prescaler

This register contains the prescaler for configuring the logical channel processing time. The actual logical cycle time will be calculated from the multiple of the sampling cycle time that is defined here. If a very short sampling cycle time is required for physical samples, then the module load can be reduced using the second time base for the logical samples.

Data type	Value	Information
UINT	1 to 10	Multiple of the physical sampling cycle for logical processing
	0	Default value in the standard function model
	2	Default value in the bus controller function model

4.3.11.8.10.4 Register "CfO_SyncOffset"

Name:
CfO_SyncOffset
"Synchronization offset" in the AS I/O configuration.

The system cycle can be offset in 1 µs steps in this register.

Data type	Value	Information
UINT	-32,768 to 32,767	Synchronization offset in µs (default = 0)

4.3.11.8.11 Scaling

Analog input channels are naturally aligned and normalized when delivered (gain = k, offset = d). In addition, user-defined normalization is also available (gain = ku, offset = du). The calculation is optimized by grouping the factors together.

Normalization calculation:

nom = k * RawValue + d

k = k * ku

d = k * d + du

The values calculated here are limited to 16 bits.

4.3.11.8.11.1 "CfO_UserGainCh" registers

Name:
CfO_UserGainCh01 to CfO_UserGainCh02
"Configuration channel 0x / gain" in the AS I/O configuration

These registers are used to configure the gain for the respective channel. The format is a 16.16-bit signed 4-byte value, with the high word the integer part and the low word the decimal places.

Input value = Gain ku * 65536

The value 0x10000 corresponds to a gain of 1.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Gain
	65,535	= 1 (default value)

4.3.11.8.11.2 "CfO_UserOffsetCh" registers

Name:
CfO_UserOffsetCh01 to CfO_UserOffsetCh02
"Configuration channel 0x / offset" in the AS I/O configuration

These registers are used to configure the offset for the respective channel. The format is a 16.16-bit signed 4-byte value, with the high word the integer part and the low word the decimal places.

Input value = Offset du * 65536

The value 0x10000 corresponds to an offset of 1.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Offset (default = 0)

4.3.11.8.12 Input filter

This module is equipped with an individually configurable input filter for each channel. The following filters can be selected:

- 1st-order low pass
- 2nd-order low pass
- 2nd-order IIR

The cutoff frequency can be configured for the 1st-order and 2nd-order low pass filters. The coefficients Alpha0, Alpha1, Alpha2, Beta1 and Beta2 must be configured for the IIR filter.

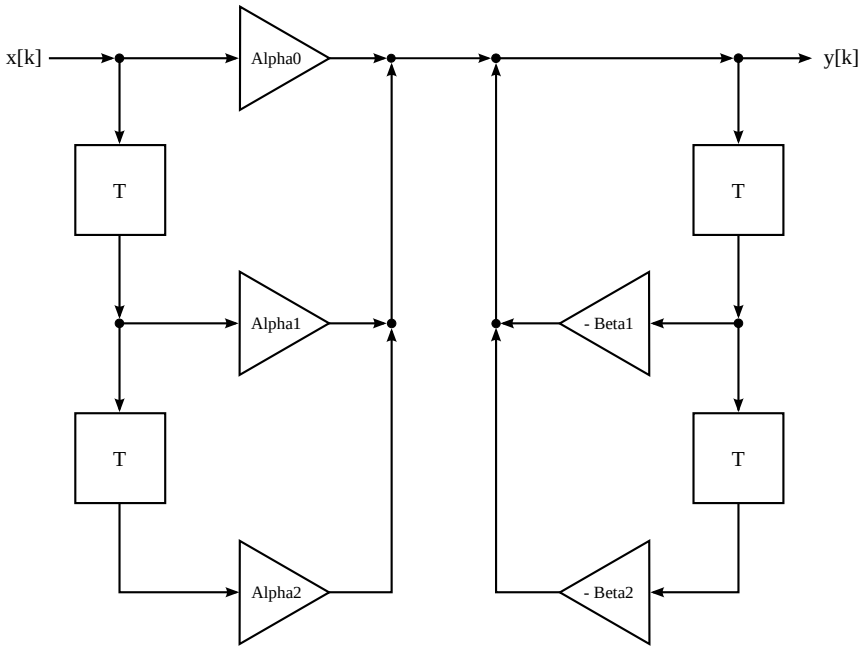
4.3.11.8.12.1 "CfO_AlphaCh" and "CfO_BetaCh" registers

Name:
CfO_Alpha0Ch01 to CfO_Alpha0Ch02
CfO_Alpha1Ch01 to CfO_Alpha1Ch02
CfO_Alpha2Ch01 to CfO_Alpha2Ch02
CfO_Beta1Ch01 to CfO_Beta1Ch02
CfO_Beta1Ch01 to CfO_Beta1Ch02

These registers are used to configure the coefficients for the IIR filter.

Image as a z-transfer function

The 2nd-order z-transfer function is specified in coefficient form (denominator polynomial Beta1, Beta2 and numerator polynomial Alpha0, Alpha1, Alpha2). The transfer method is calculated with the sampling cycle time.



Data type	Value	
DINT	-2,147,483,648 to 2,147,483,647	IIR filter coefficient (default = 0)

4.3.11.8.12.2 "CfO_CutOffFrequCh" register

Name:
CfO_CutOffFrequCh01 to CfO_CutOffFrequCh02

These registers are used to configure the limit frequency in hertz for a 1st- or 2nd-order low pass for the corresponding channel.

Data type	Value	Information
UINT	0 to 65535	Limit frequency for 1st- or 2nd-order low pass [Hz] (default = 0)

4.3.11.8.13 Physical configuration

4.3.11.8.13.1 "CfO_ModeCh" registers

Name:
CfO_ModeCh01 to CfO_ModeCh02

The operating mode for each physical channel can be configured in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Connection configuration **This value must be set the same for each register!**	000	Voltage signal
		111	Current signal
3 - 7	Reserved	0	
8 - 10	Operating mode	000	Channel disabled
		001	No filtering
		010	2nd-order IIR (configurableAlpha and Beta coefficients)
		011	1st-order low pass (configurable limit frequency)
		100	2nd-order low pass (configurable limit frequency)
		101 to 111	Reserved
11 - 15	Reserved	0	

4.3.11.8.14 Logical configuration

4.3.11.8.14.1 Operation in the standard function model

6 logical channels are available on the module. Each channel can be configured with one of the following functions:

- Addition of two channels with scaling
- Integral addition of two channels with scaling
- Multiplication of two channels with scaling
- Integral multiplication of two channels with scaling
- Comparator function of two channels
- Hysteresis comparator of one channel

With logical oversampling, 32-bit data points are available in addition to 16-bit data points due to the possible calculated results. The AS I/O configuration or data point mapping can be opened to select which one to use.

If there is no need to use 32-bit data points, or if this would lead to too large of a limitation in the number of data points, scaling can be used to limit the range to 16 bits.

The buffer depth for the digital comparator is also able to handle 16 results. Since these are Boolean results, these 16 bits are compressed into 2-byte data points and transferred that way.

Addition

This function can be used to determine the sum or difference of two channels. To determine the difference, negative scaling needs to be configured for the channel.

Calculation

Sample line = (Channel 1 * Scaling 1) + (Channel 2 * Scaling 2)

The addition calculation is handled internally as a 32-bit value in 16.16 format; the data from the source channels is evaluated as integers (applied to the high word), with decimal places possible as a result of scaling. When displayed as a logical 32-bit result, these decimal places are visible. When displayed as a 16-bit value, only the integral high word is used.

Example

Channel 1 = 2000
Channel 2 = 1000
Both scalings = 1

Results

3000.x = (2000.x * 1,0) + (1000.x * 1.0)
32-bit representation = 196608000 = 0xBB80000
16-bit representation = 3000 = 0xBB8

Information:

The maximum value channel 1 can take on is 32767; otherwise, an addition overflow occurs. If values greater than 32767 are possible, the value range must be limited with scaling.

Integral of addition

This function can be used in the application to establish the average value of the channels or to calculate the deviation/difference between two channels over n samples. In each cycle, the channels are added together first; then the result is added to the previous value and saved in the current sample line. Depending on the result data type being used (16-bit or 32-bit), eventually the continuous integration will cause the calculation to overflow after n samples. Because the result value is signed, it is important to set the number n of samples small enough so that the integration is less than half of the value range. If this is done, determining the average value can be carried out despite an overflow.

Calculation

Sample line result = Integral ((Channel 1 * Scaling 1) + (Channel 2 * Scaling 2))

The addition calculation is handled internally as a 32-bit value in 16.16 format; the data from the source channels is evaluated as integers (applied to the high word), with decimal places possible as a result of scaling. When displayed as a logical 32-bit result, these decimal places are visible. When displayed as a 16-bit value, only the integral high word is used.

Example

Channel 1 = 2000
Channel 2 = 1000
Both scalings = 1

Results

3000.x = (2000.x * 1,0) + (1000.x * 1.0)
32-bit representation = 196608000 = 0xBB80000
16-bit representation = 3000 = 0xBB8

The average value can now be calculated as follows:

n = Number of samples / sample lines
$Value_x$ = Value from sample line x → Newer value
$Value_x$ = Value from sample line x → Older value, n samples back

Average value = $(Value_x - Value_{(x-n)}) / n$

Information:

The maximum value channel 1 can take on is 32767; otherwise, an addition overflow occurs. If values greater than 32767 are possible, the value range must be limited with scaling.

Multiplication

This function can be used to calculate the current effective power P = U * I.

Calculation

Sample line = Channel 1 * Channel 2 * Scaling

Multiplication is calculated internally as a 32-bit value; the 16-bit data from the source channels is passed to the low word. When displayed as a logical 32-bit value, the entire result is visible (no multiplication overflow possible when scaling ≤1). When displayed as a 16-bit value, only the high word is used. Though there is a loss of precision, the 16-bit values allow more data points to be transferred.

Example

Channel 1 = 2000
Channel 2 = 1000
Scaling = 1

Results

2000000 = (2000 * 1000 * 1.0)
32-bit representation = 2000000 = 0x1E8480
16-bit representation = 30 = 0x1E

Information:

If more precision is needed with the 16-bit value, scaling in steps of 2^n (..., *128, *256, ...) can be employed to shift the bits. Of course, it's important again that the input values of the source channels be limited; otherwise, an overflow will occur in the multiplication operation.

Integral of multiplication

This function can be used in the application to establish the average value of the effective power. In each cycle, the channels are multiplied together first; then the result is added to the previous value and saved in the current sample line. Depending on the result data type being used (16-bit or 32-bit), eventually the continuous integration will cause the calculation to overflow after n samples. Because the result value is signed, it is important to set the number n of samples small enough so that the integration is less than half of the value range. If this is done, determining the average value can be carried out despite an overflow.

Calculation

Sample line = Integral (Channel 1 * Channel 2 * Scaling)

Multiplication is calculated internally as a 32-bit value; the 16-bit data from the source channels is passed to the low word. When displayed as a logical 32-bit value, the entire result is visible (no multiplication overflow possible when scaling ≤1). When displayed as a 16-bit value, only the high word is used. Though there is a loss of precision, the 16-bit values allow more data points to be transferred.

Example

Channel 1 = 2000
Channel 2 = 1000
Scaling = 1

Results

2000000 = (2000 * 1000 * 1.0)
32-bit representation = 2000000 = 0x1E8480
16-bit representation = 30 = 0x1E

The average value can now be calculated as follows:

n = Number of samples / sample lines
$Value_x$ = Value from sample line x → Newer value
$Value_x$ = Value from sample line x → Older value, n samples back

Average value = $(Value_x - Value_{(x-n)}) / n$

Information:

If more precision is needed with the 16-bit value, scaling in steps of 2^n (..., *128, *256, ...) can be employed to shift the bits. Of course, it's important again that the input values of the source channels be limited; otherwise, an overflow will occur in the multiplication operation.

Channel comparator

This function can be used to compare channel values. The following applies:

- Channel 1 > Channel 2 = 1
- Channel 1 < Channel 2 = 0
- Channel 1 = Channel 2 = State before values are the same

Calculation

Sample line (bit) = Comparison (channel value 1 with channel value 2)

Hysteresis comparator

This function can be used to monitor range violations by channels. The following applies:

- Channel > Upper threshold value = 1
- Channel < Lower threshold value = 0
- Channel within threshold = Value before occurrence

Calculation

Sample line (bit) = Comparison (channel value with lower threshold value) and (channel value with upper threshold value))

4.3.11.8.14.2 Operation in the bus controller function model

When used on the bus controller, there are 4 logical functions available for each of the analog input channels in addition to the physical value output. Each channel can be configured with one of the following functions:

- Output of physical values (default setting)
- Addition of two channels with scaling
- Integral addition of two channels with scaling
- Multiplication of two channels with scaling
- Integral multiplication of two channels with scaling
- Comparator function of two channels
- Hysteresis comparator of one channel

In contrast to the standard function model, oversampling and the two digital comparators are not supported. As a result, there is only one newly generated value per channel in each update cycle. Another difference is that there are only 4 logical calculation channels instead of 6.

The logical functions addition, integral of addition, multiplication and integral of multiplication do not differ from the standard function model in their configuration and function when operating on the bus controller.

Physical value display

The physical value display in the bus controller function model is initialized automatically and represents a special form of the logical function "Addition" with defined scaling factors.

Calculation

Result = Channel value
Formula used for addition: Result = (Channel value 1 * 1) + (Channel value 2 * 0)

Information:

In this function model, only the 4 physical input channels are available, and the scaling factors have defined values.

4.3.11.8.14.3 "CfO_LogChMode" register

Name:
CfO_LogCh01Mode to CfO_LogCh06Mode
"Logical configuration channel 0x / Addition" in the AS I/O configuration.
"Logical configuration channel 0x / Integral of addition" in the AS I/O configuration.
"Logical configuration channel 0x / Multiplication" in the AS I/O configuration.
"Logical configuration channel 0x / Integral of multiplication" in the AS I/O configuration.
"Logical configuration channel 0x / Channel comparator" in the AS I/O configuration.
"Logical configuration channel 0x / Hysteresis comparator" in the AS I/O configuration.
"Logical configuration channel 0x / Physical value display" in the AS I/O configuration.

The operating mode for each logical channel can be configured in this register.

The selection of the sources to be used for each logical channel is made using the register 4.3.11.8.14.4 "CfO_LogCh0NSource0x". Any additionally needed function parameters are configured in the 4.3.11.8.14.5 "CfO_LogCh0NFuncPar0x" registers. "N" stands for the logical channel to be used, while "x" stands for either the source or function 0 or 1.

The following links can be made:

- Addition: Result = (Source 0 * Function parameter 0) + (Source 1 * Function parameter 1)
- Integral of addition: Result = Σ(Source 0 * Function parameter 0) + (Source 1 * Function parameter 1)
- Multiplication: Result = Source 0 * Source 1 * Function parameter 0
- Integral of multiplication: Result = Σ(Source 0 * Source 1 * Function parameter 0)
- Channel comparator: Result = Comparison of source 0 with source 1
- Hysteresis comparator: Result = comparison of source 0 with (Lower threshold value = Function parameter 0) and (Upper threshold value = Function parameter 1)
- Physical value display: Result = (Source 0 * 1) + (Source 1 * 0)

Data type	Value	Information
UINT	0	Channel switched off (default)
	256	Addition or physical value display[1)]
	257	Integral of addition
	512	Multiplication
	513	Integral of multiplication
	768	Channel comparator
	1024	Hysteresis comparator

1) Only registers CfO_LogCh01Mode to CfO_LogCh04Mode are used for physical value display.

4.3.11.8.14.4 "CfO_LogChSource" register

Name:
CfO_LogCh01Source00 to CfO_LogCh06Source00
CfO_LogCh01Source01 to CfO_LogCh06Source01

These registers can be used to select the source registers for the operating mode of the logical channel configured in the register 4.3.11.8.14.3 "CfO_LogCh0NMode".
In the name, "Source00" stands for source register 0; "Source01" stands for source register 1.

In "Physical value display" mode, the same channel number is written to both source registers.

Data type	Value	Information
USINT	0	Physical channel 01
	1	Physical channel 02
	8	Logical channel 01[1)]
	...	...
	13	Logical channel 06

1) Logical channels cannot be used in the bus controller function model.

4.3.11.8.14.5 "CfO_LogChFuncPar" register

Name:
CfO_LogCh01FuncPar00 to CfO_LogCh06FuncPar00
CfO_LogCh01FuncPar01 to CfO_LogCh06FuncPar01

These registers can be used to configure additional function parameters for the operating mode of the logical channel configured in the register 4.3.11.8.14.3 "CfO_LogCh0NMode".

The effect of the function parameters is different depending on the operating mode.

Operating mode	Parameter 1	Parameter 2
(Integral of) addition	Scaling factor	Scaling factor
(Integral of) multiplication	Scaling factor	-
Channel comparator	-	-
Hysteresis comparator	Upper threshold value	Lower threshold value
Output of physical values	Defined scaling factor = 65,536	Defined scaling factor = 0

The value 0x10000 (65,536) corresponds to a scaling or a threshold value of 1.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Scaling factor or threshold value
	0	Default
	65,536	1

4.3.11.8.15 Error registers

The registers for displaying and acknowledging errors are transferred either cyclically or acyclically depending on the function model.

4.3.11.8.15.1 "CfO_ErrorID1017" register

Name:
CfO_ErrorID1017
Automatic enabling by the AS I/O configuration.

This register can be used to enable standard error messages. The channels' composite errors are derived from the individual extended error status, e.g. overflow/underflow of the input range for the analog value. Oversampling error statuses result from a cycle time violation of the configured sampling cycle time.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Composite errors on channel 01	0	Error generation disabled
		1	Error generation enabled
1	Composite errors on channel 02	0	Error generation disabled
		1	Error generation enabled
2 - 3	Reserved	0	
4	Physical sample error status	0	Error generation disabled
		1	Error generation enabled
5	Logical sample error status	0	Error generation disabled
		1	Error generation enabled
6 - 7	Reserved	0	

4.3.11.8.15.2 "CfO_ErrorID0x0x" register

Name:
CfO_ErrorID0007
Automatic enabling in the AS I/O configuration by selecting "Extended error status information" and channel activation.

This register can be used to enable extended error messages for analog channels 1 and 2. Meaning of individual bits:

- **Range exceeded violation (pos.):** The analog input signal is outside of the specified working range.
- **Filter error:** The configured filter theorem cannot be calculated (parameter error).
- **Underflow:** The input signal is less than the lower limit value.
- **Overflow:** The input signal is greater than the upper limit value.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1: Range exceeded violation (pos.)	0	Error generation disabled
		1	Range exceeded violation (pos.) enabled
1	Channel 1: Filter error	0	Error generation disabled
		1	Filter error enabled
2	Channel 1: Underflow	0	Error generation disabled
		1	Underflow enabled
3	Channel 1: Overrun	0	Error generation disabled
		1	Overflow enabled
4	Channel 2: Range exceeded violation (pos.)	0	Error generation disabled
		1	Range exceeded violation (pos.) enabled
5	Channel 2: Filter error	0	Error generation disabled
		1	Filter error enabled
6	Channel 2: Underflow	0	Error generation disabled
		1	Underflow enabled
7	Channel 2: Overrun	0	Error generation disabled
		1	Overflow enabled

4.3.11.8.15.3 "StandardErrors" registers

Name:
Channel01Error to Channel02Error
PhysicalError
LogicalError

Composite errors are mapped to this register.

All configured functions of the physical and logical oversampling must be able to be carried out in the configured sampling cycle time; otherwise, these error messages occur. Settings for processing priority and the prescaler can be used to additionally adjust the system for logical oversampling.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01Error	0	No error
		1	Composite errors on channel 1
1	Channel02Error	0	No error
		1	Composite errors on channel 2
2 - 3	Reserved	0	
4	PhysicalError	0	No error
		1	Physical sample error status, sampling cycle time too short
5	LogicalError	0	No error
		1	Logical sample error status, sampling cycle time too short or prescaler configured too low
6 - 7	Reserved	0	

4.3.11.8.15.4 "AcknowledgeStandardErrors" registers

Name:
AckChannel01Error to AckChannel02Error
AckPhysicalError
AckLogicalError

Error messages from the 4.3.11.8.15.3 ""StandardErrors" registers" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AckChannel01Error	0	No change
		1	Acknowledge error
1	AckChannel02Error	0	No change
		1	Acknowledge error
2 - 3	Reserved	0	
4	AckPhysicalError	0	No change
		1	Acknowledge error
5	AckLogicalError	0	No change
		1	Acknowledge error
6 - 7	Reserved	0	

4.3.11.8.15.5 "ExtendedChannelErrorMessages" registers

Name:
Channel01OutOfRange to Channel02OutOfRange
Channel01FilterError to Channel02FilterError
Channel01Underflow to Channel02Underflow
Channel01Overflow to Channel02Overflow

The error states of input channels 1 and 2 are represented in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutOfRange	0	No error
		1	Range exceeded violation (pos.) occurred
1	Channel01FilterError	0	No error
		1	Filter error occurred
2	Channel01Underflow	0	No error
		1	Underflow occurred
3	Channel01Overflow	0	No error
		1	Overflow occurred
4	Channel02OutOfRange	0	No error
		1	Range exceeded violation (pos.) occurred
5	Channel02FilterError	0	No error
		1	Filter error occurred
6	Channel02Underflow	0	No error
		1	Underflow occurred
7	Channel02Overflow	0	No error
		1	Overflow occurred

4.3.11.8.15.6 "AcknowledgeExtendedChannelErrorMessages" registers

Name:
AckChannel01OutOfRange to AckChannel02OutOfRange
AckChannel01FilterError to AckChannel02FilterError
AckChannel01Underflow to AckChannel02Underflow
AckChannel01Overflow to AckChannel02Overflow

These registers can be used to acknowledge the error messages from the 4.3.11.8.15.5 "ExtendedChannelErrorMessages" registers by setting the corresponding bit.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AckChannel01OutOfRange	0	No change
		1	Acknowledge error
1	AckChannel01FilterError	0	No change
		1	Acknowledge error
2	AckChannel01Underflow	0	No change
		1	Acknowledge error
3	AckChannel01Overflow	0	No change
		1	Acknowledge error
4	AckChannel02OutOfRange	0	No change
		1	Acknowledge error
5	AckChannel02FilterError	0	No change
		1	Acknowledge error
6	AckChannel02Underflow	0	No change
		1	Acknowledge error
7	AckChannel02Overflow	0	No change
		1	Acknowledge error

4.3.11.8.16 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.11.8.17 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.12 X20AI4222

4.3.12.1 General information

The module is equipped with 4 inputs with 13-bit (including sign) digital converter resolution. It can be used to capture voltage signals in the range from ±10 V.

- 4 analog inputs ±10 V
- 13-bit digital converter resolution

4.3.12.2 Order data

Model number	Short description	Figure
	Analog inputs

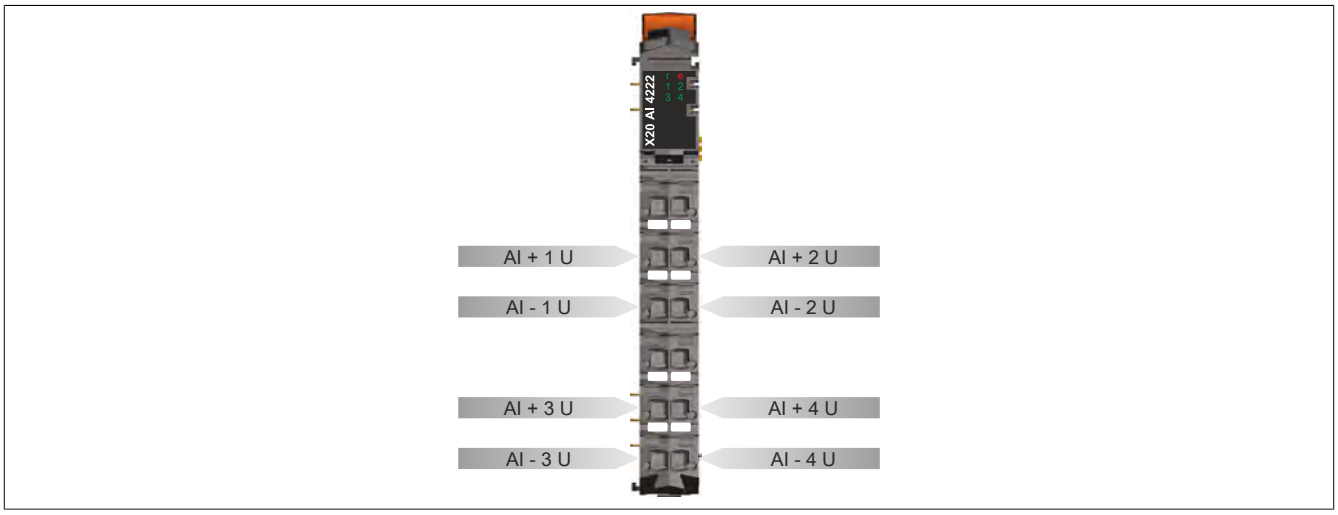
1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.

4.3.12.4 LED status indicators

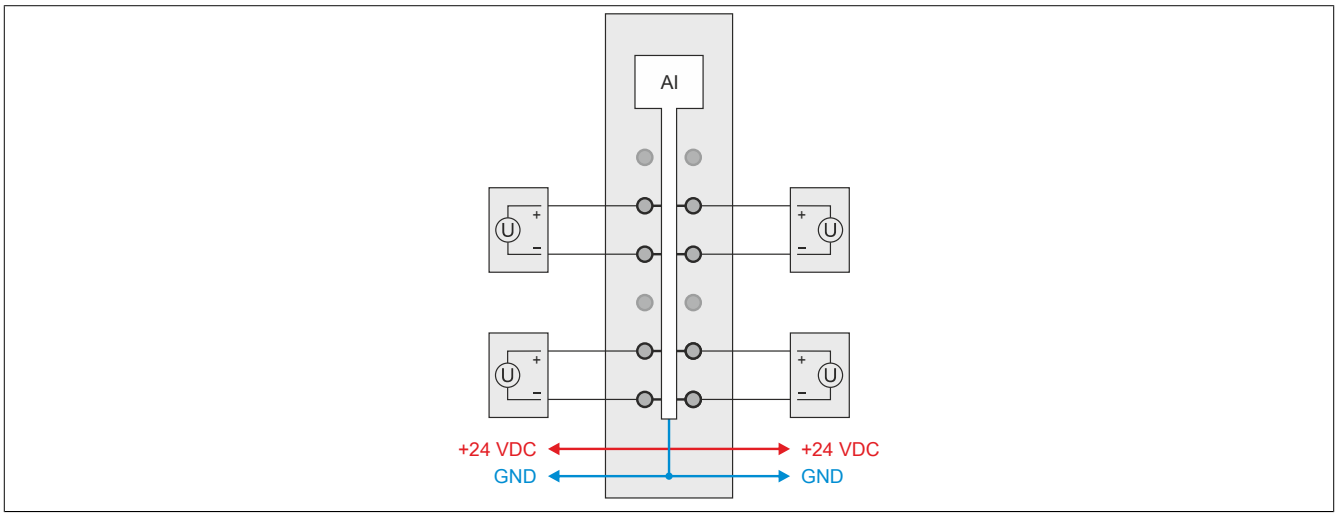
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green	Off	Open line or sensor is disconnected
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

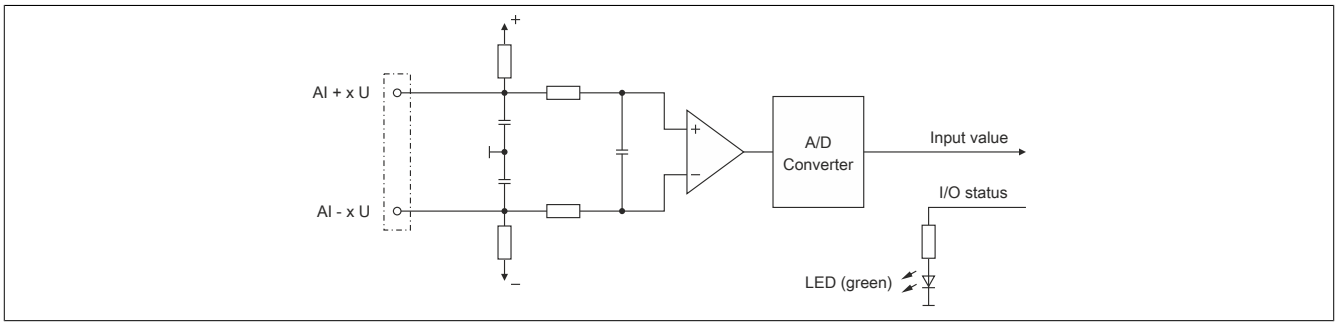
4.3.12.5 Pinout



4.3.12.6 Connection example



4.3.12.7 Input circuit diagram



4.3.12.8 Register description

4.3.12.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.12.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
16	Configuring the input filter	USINT				•
20	Lower limit value	INT				•
22	Upper limit value	INT				•
Analog signal - Communication						
Index * 2 - 2	AnalogInput0N (Index N = 1 to 4)	INT	•			
30	Input status	USINT	•			

4.3.12.8.3 Function model 254 - Bus controller

Register	Offset	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
16	-	Configuring the input filter	USINT				•
20	-	Lower limit value	INT				•
22	-	Upper limit value	INT				•
Analog signal - Communication							
Index * 2 - 2	Index * 2 - 2	AnalogInput0N (Index N = 1 to 4)	INT	•			
30	-	Input status	USINT		•		

1) The offset specifies the position of the register within the CAN object.

4.3.12.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.12.8.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.12.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput04

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal -10 to 10 VDC

4.3.12.8.6 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be >500 µs. Filtering is disabled for shorter cycle times.

If the input filter is active, then the scan rate for the channels is measured in ms. The time offset between the channels is 200 µs. The conversion takes place asynchronously to the network cycle.

4.3.12.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

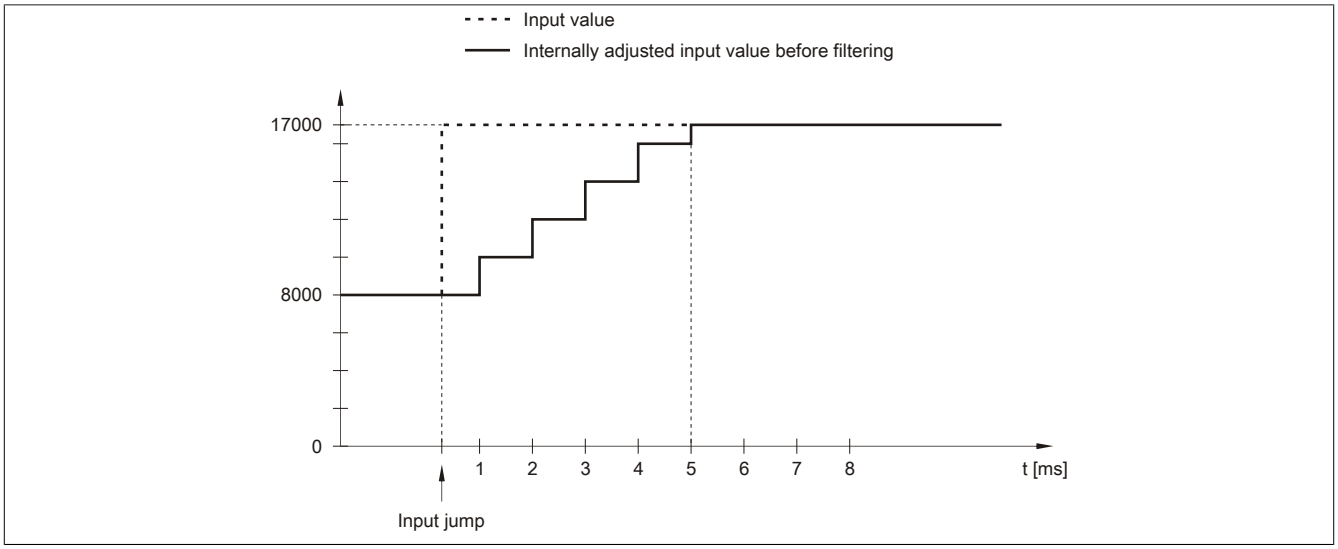


Figure 84: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

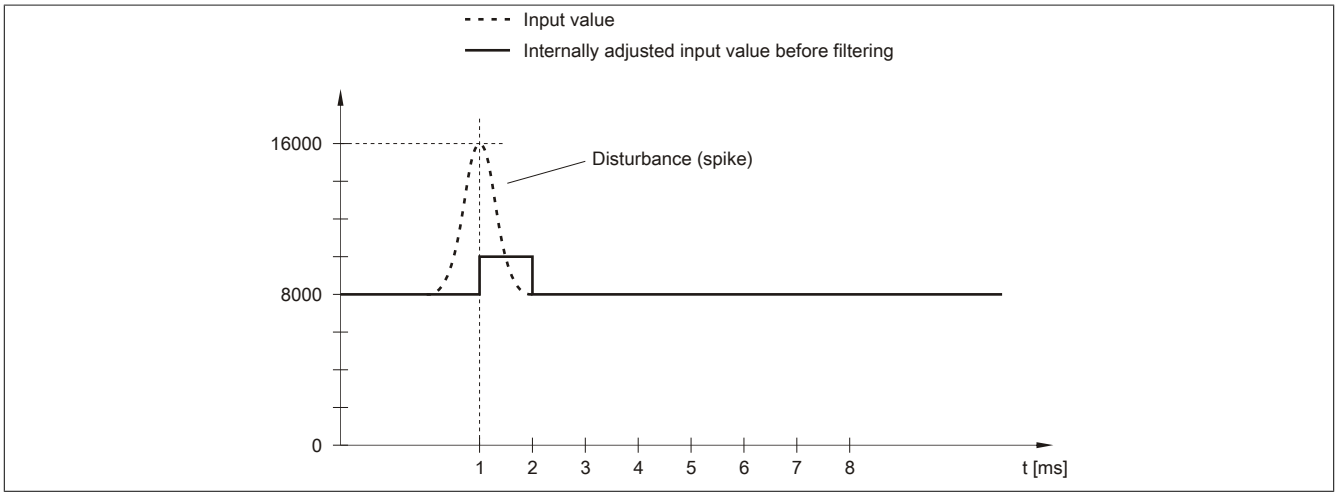

Figure 85: Adjusted input value for disturbance

4.3.12.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

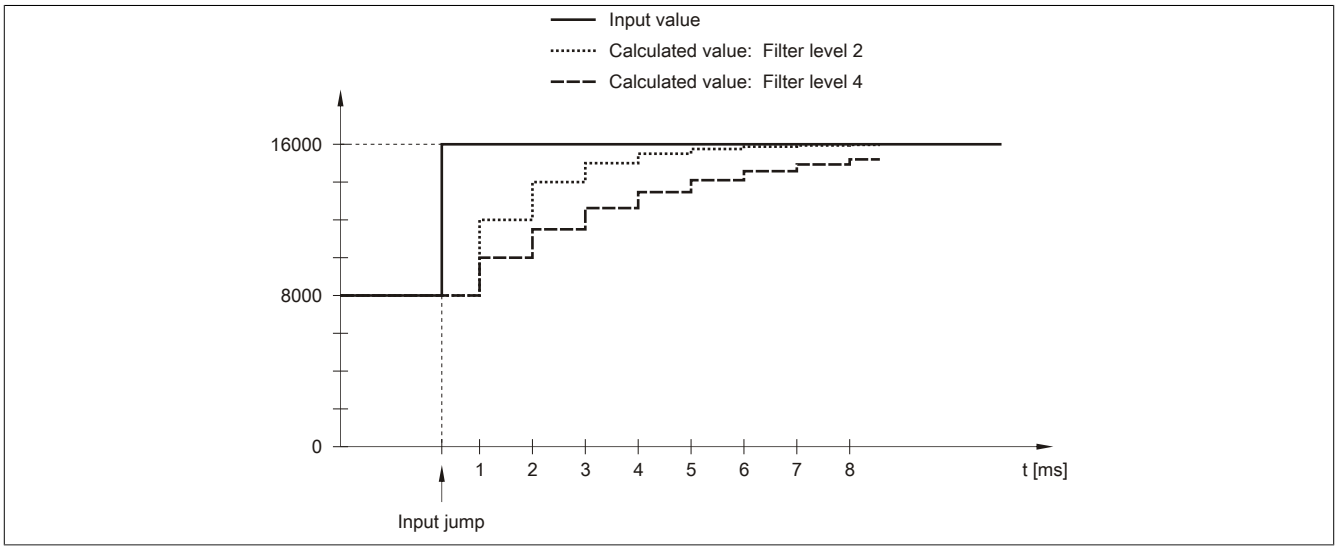

Figure 86: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

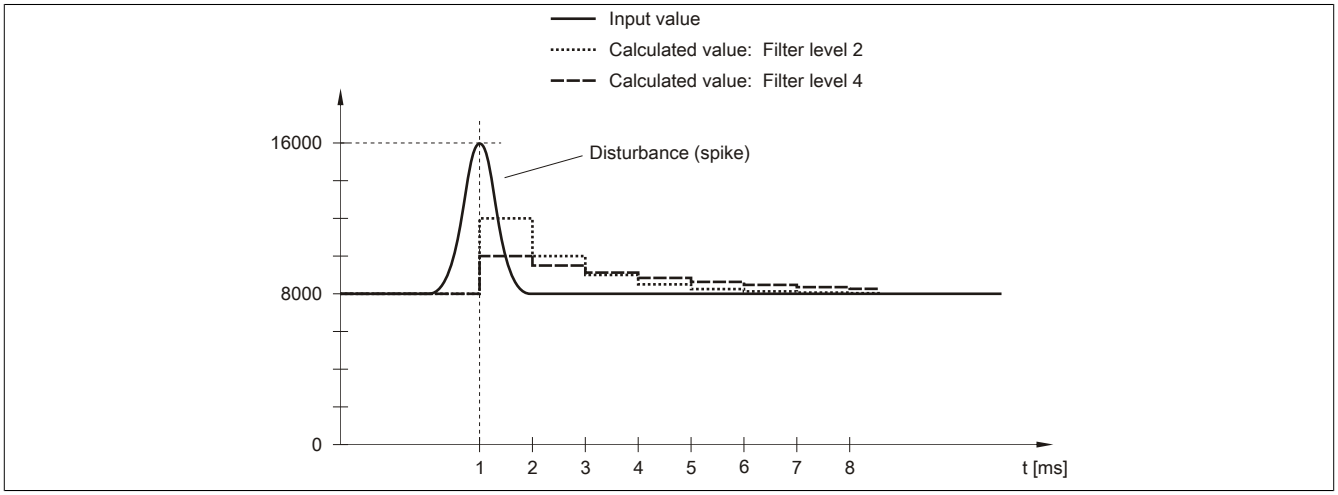

Figure 87: Calculated value during disturbance

4.3.12.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.12.8.8 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of -32768 corresponds to the minimum default value of -10 VDC.

Keep in mind that this setting applies to all channels!

4.3.12.8.9 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at +10 VDC.

Keep in mind that this setting applies to all channels!

4.3.12.8.10 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
...		...	
6 - 7	Channel 4	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

4.3.12.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.12.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Inputs without filtering	400 µs for all inputs
Inputs with filtering	1 ms

4.3.13 X20AI4322

4.3.13.1 General information

The module is equipped with 4 inputs with 12-bit digital converter resolution. It is possible to select between the two current ranges 0 to 20 mA and 4 to 20 mA.

- 4 analog inputs, 0 to 20 mA or 4 to 20 mA
- 12-bit digital converter resolution

4.3.13.2 Order data

1) The offset specifies the position of the register within the CAN object.

4.3.13.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.13.8.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.13.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput04

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	0 to 32767	Current signal 0 to 20 mA or 4 to 20 mA

4.3.13.8.6 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be >500 µs. Filtering is disabled for shorter cycle times.

If the input filter is active, then the scan rate for the channels is measured in ms. The time offset between the channels is 200 µs. The conversion takes place asynchronously to the network cycle.

4.3.13.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

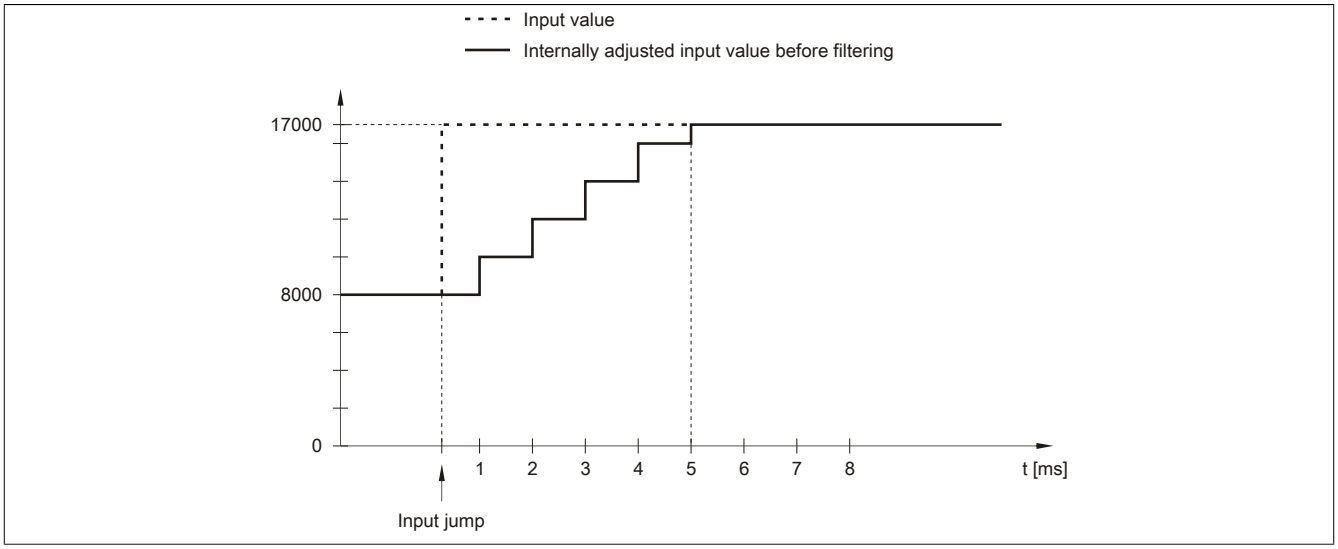

Figure 88: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

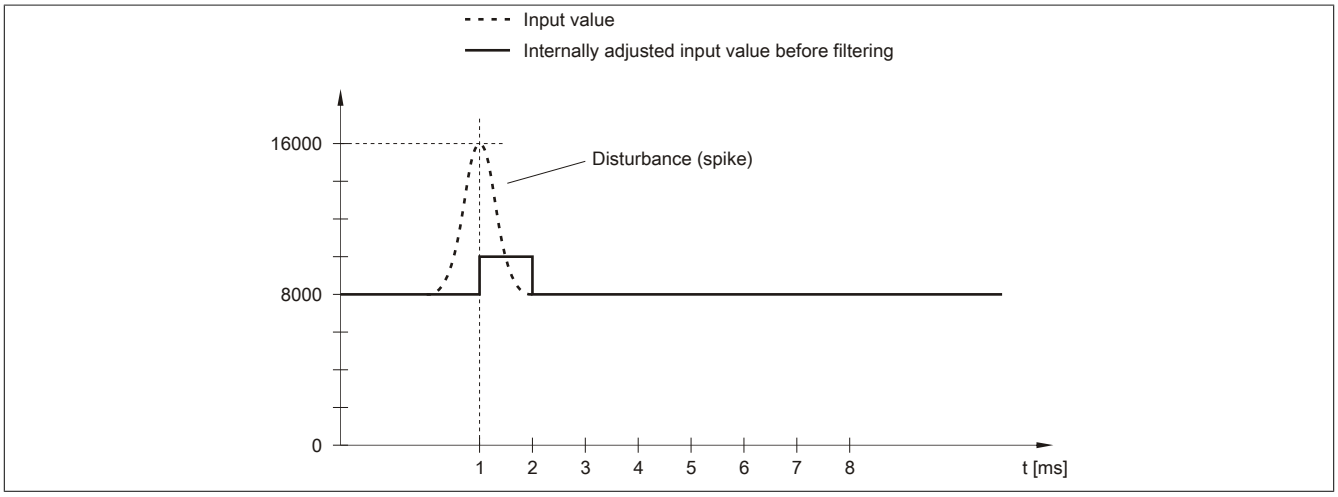

Figure 89: Adjusted input value for disturbance

4.3.13.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

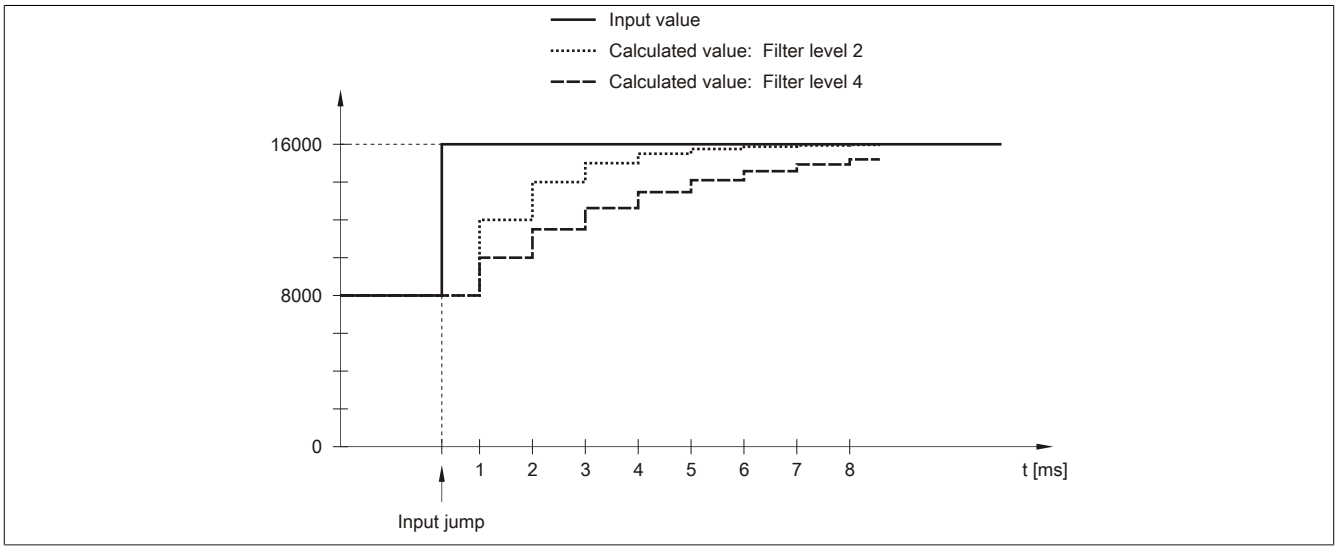

Figure 90: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

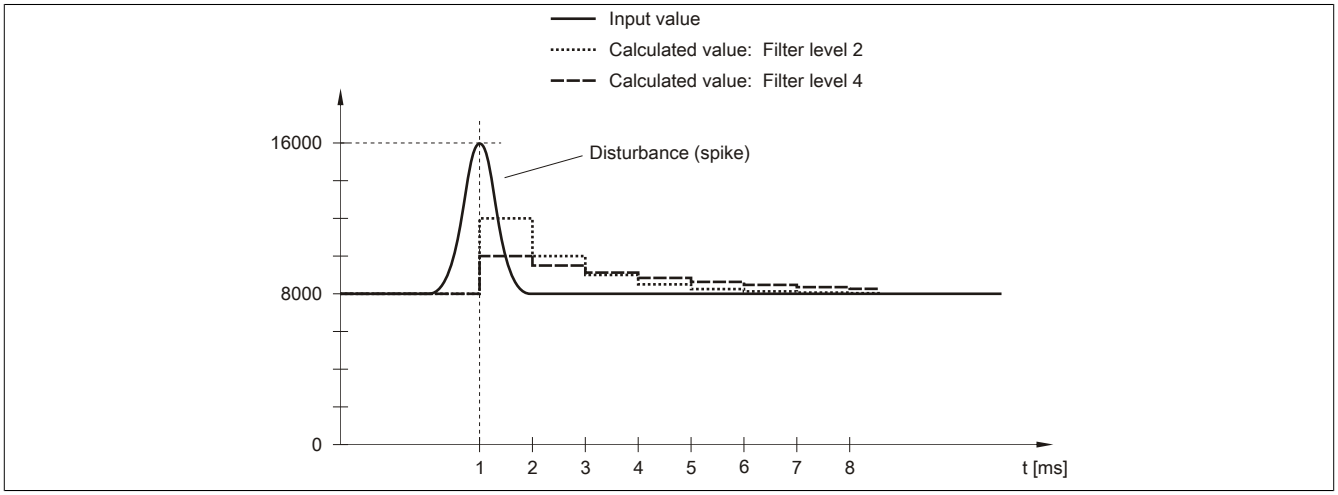

Figure 91: Calculated value during disturbance

4.3.13.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.13.8.8 Channel type

Name:
ConfigOutput02

This register can be used to set the range of the current signal. This is determined by how they are configured. The following input signals can be set:

- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	1	
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
...		...	
7	Channel 4: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal

4.3.13.8.9 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

- **When configured as 0 to 20 mA, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Keep in mind that this setting applies to all channels!

4.3.13.8.10 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at 20 mA.

Keep in mind that this setting applies to all channels!

4.3.13.8.11 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
...		...	
6 - 7	Channel 4	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)	
	0 to 20 mA	4 to 20 mA
Upper limit value exceeded	+32767 (0x7FFF)	
Lower limit value exceeded	0	-8191 (0xE001)

4.3.13.8.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.13.8.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Inputs without filtering	400 µs for all inputs
Inputs with filtering	1 ms

4.3.14 X20(c)AI4622

4.3.14.1 General information

The module is equipped with 4 inputs with 13-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

- 4 analog inputs
- Either current or voltage signal possible
- 13-bit digital converter resolution

4.3.14.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.
5) Based on the 20 mA measurement range.

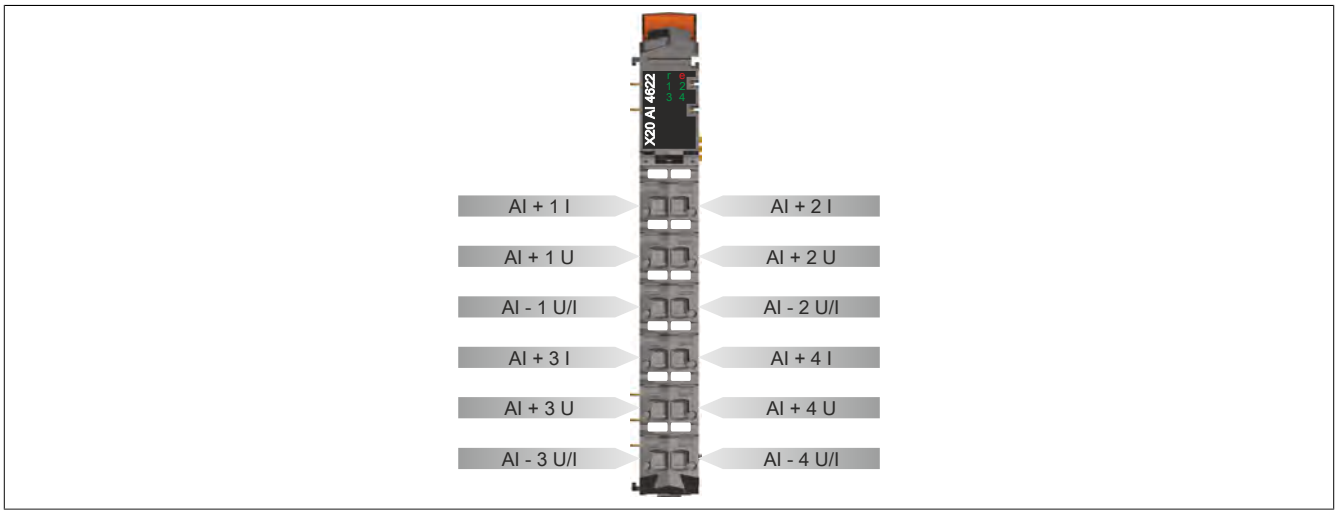
4.3.14.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

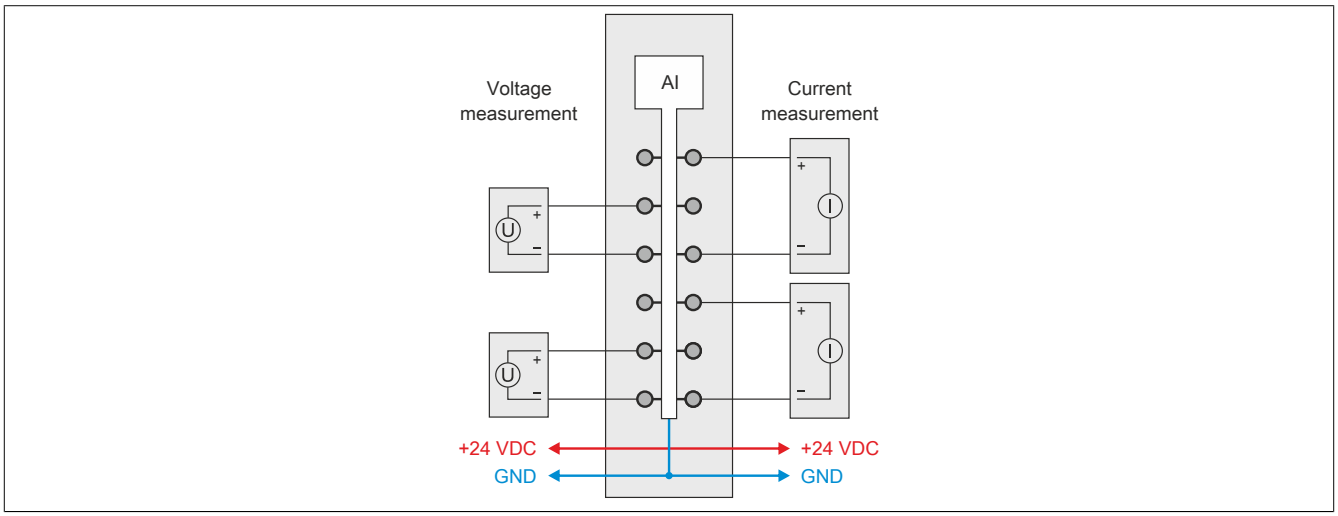
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green	Off	Open line[1)] or sensor is disconnected
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

1) Open line detection only possible when measuring voltage.

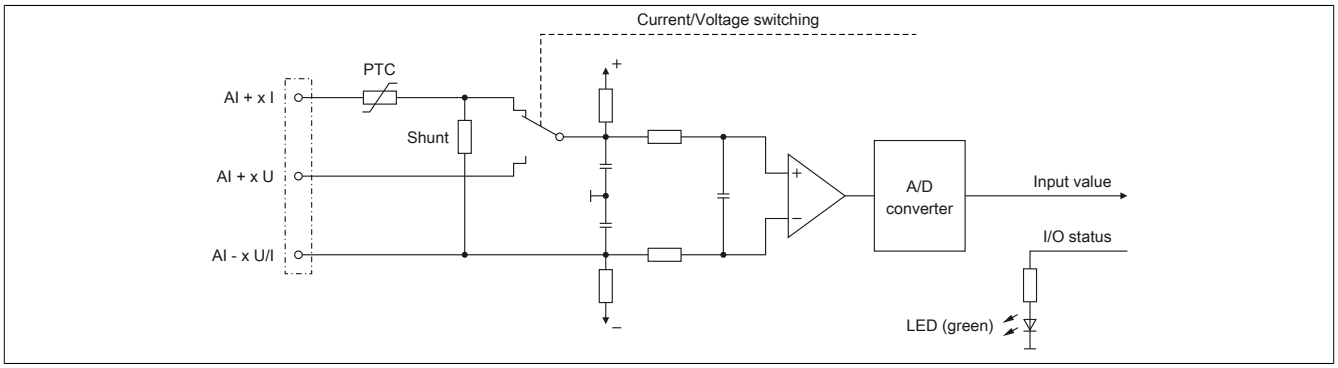
4.3.14.6 Pinout



4.3.14.7 Connection example



4.3.14.8 Input circuit diagram



4.3.14.9 Register description

4.3.14.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.14.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
16	ConfigOutput01	USINT				•
18	ConfigOutput02	USINT				•
20	ConfigOutput03	INT				•
22	ConfigOutput04	INT				•

30	-	StatusInput01	USINT		•		

1) The offset specifies the position of the register within the CAN object.

4.3.14.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.14.9.4 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.3.14.9.5 Analog input values

Name:
AnalogInput01 to AnalogInput04

The analog input value are mapped to this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA

4.3.14.9.6 Input filter

This module is equipped with a configurable input filter. The minimum X2X cycle time must be >500 µs. Filtering is disabled for shorter X2X cycle times.

If the input filter is active, then the channels are scanned in 1 ms cycles. The time offset between the channels is 200 µs. Conversion is performed acyclically to the X2X cycle.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

4.3.14.9.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

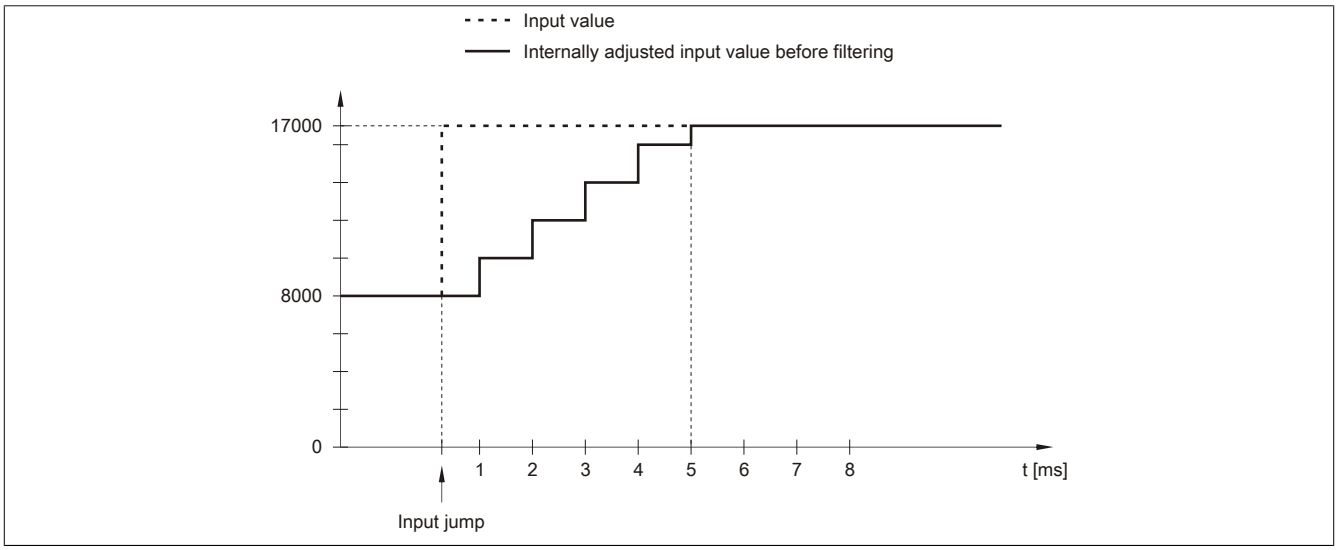

Figure 92: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

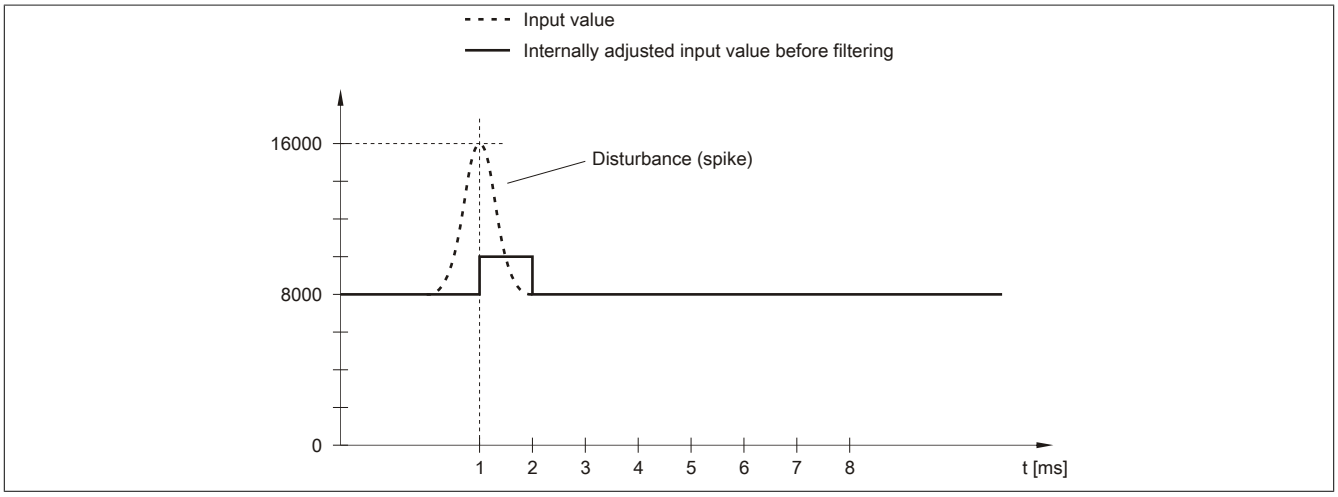

Figure 93: Adjusted input value for disturbance

4.3.14.9.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

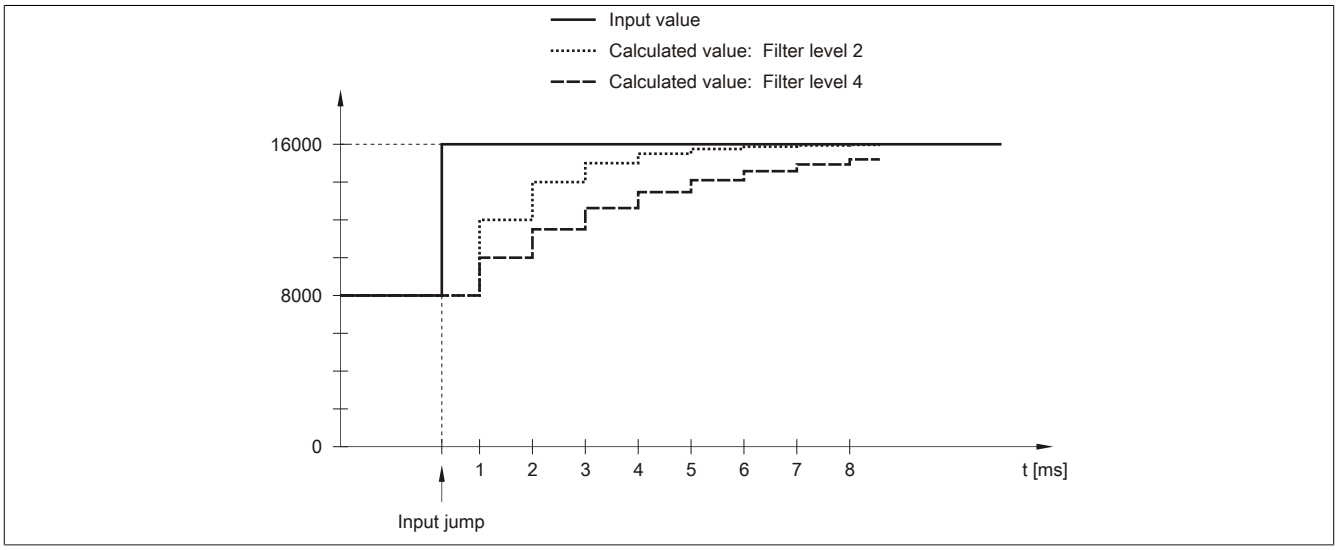

Figure 94: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

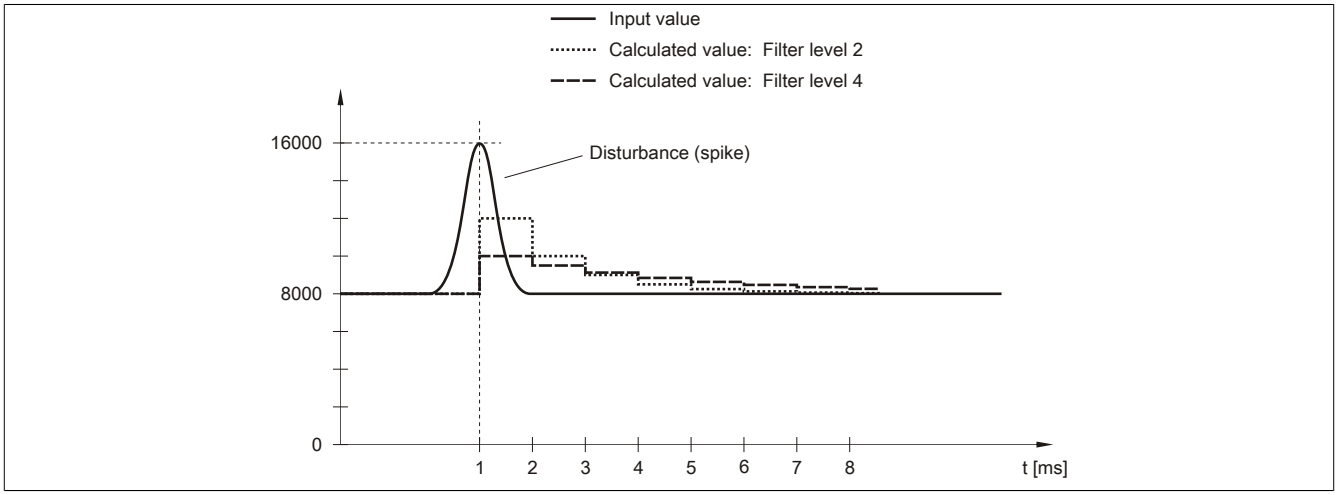

Figure 95: Calculated value during disturbance

4.3.14.9.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.3.14.9.8 Channel type

Name:
ConfigOutput02

This register can be used to define the type and range of signal measurement.

Each channel is capable of handling either current or voltage signals. This differentiation is made using multiple connection terminal points and an integrated switch in the module. The switch is automatically activated by the module depending on the specified configuration. The following input signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 4
...		...	
3	Channel 4	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 7
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
...		...	
7	Channel 4: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal

4.3.14.9.9 Limit values

The input signal is monitored at the upper and lower limit values. These must be defined according to the operating mode:

Limit value (default)	Voltage signal ±10 V		Current signal 0 to 20 mA		Current signal 4 to 20 mA	
Upper maximum limit value	+10 V	+32767 (0x7FFF)	20 mA	+32767 (0x7FFF)	20 mA	+32767 (0x7FFF)
Lower minimum limit value	-10 V	-32767 (0x8001)	0 mA	0[1)]	4 mA	0[2)]

1) The analog value is limited down to 0.
2) The analog value is limited down to 0 at currents <4 mA. The status bit for the lower limit is set.

Other limit values can be defined if necessary. Limit values are valid for all channels and activated automatically by writing to the limit value registers. From this point on, the analog values will be monitored and limited according to the new limits. The results of monitoring are displayed in the status register.

Examples of limit value settings

Application case	Limit value settings
Current signal: 4 to 20 mA	A negative limit value must be configured in order to measure values <4 mA with a current signal of 4 to 20 mA: 0 mA is equal to a value of -8192 (0xE000).
Mixed voltage and current signal	The configured limit values are valid for all channels. Mixed operation (voltage and current signal) therefore requires a compromise. The following configuration has proven effective: Upper limit = +32767, lower limit = -32767 This makes it possible to also measure negative voltage values. A lower limit value of 0 would limit the voltage value to 0.
Current signal on all channels	All channels are configured for measuring current. The limit value setting in Automation Studio is not adjusted automatically. That means that +32767 is configured as the upper limit value and -32767 as the lower limit value. The necessary changes must be made by the user, e.g. lower limit value = 0

4.3.14.9.9.1 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

- **The default value of -32768 corresponds to the minimum default value of -10 VDC.**
- **When configured as 0 to 20 mA, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Information:

Keep in mind that this setting applies to all channels!

4.3.14.9.9.2 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value of 20 mA or +10 VDC.

Information:

Keep in mind that this setting applies to all channels!

4.3.14.9.10 Input status

Name:
StatusInput01

This register is used to monitor the module inputs. A change in the monitoring status generates an error message. The following states are monitored depending on the settings:

Value	Voltage signal ±10 V	Current signal 0 to 20 mA	Current signal 4 to 20 mA
0	No error	No error	No error
1	Lower limit value exceeded	Default setting The input value has a lower limit of 0x0000. Underflow monitoring is therefore not necessary. After lower limit value change The input value is limited to the configured value. The status bit is set when the lower limit value is passed.	Lower limit value exceeded
2	Upper limit value exceeded	Upper limit value exceeded	Upper limit value exceeded
3	Open line	-	-

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
...		...	
6 - 7	Channel 4	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

4.3.14.9.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Inputs without filtering	100 µs
Inputs with filtering	500 µs

4.3.14.9.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Inputs without filtering	300 µs for all inputs
Inputs with filtering	1 ms

4.3.15 X20(c)AI4632

4.3.15.1 General information

The module is equipped with 4 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections.

- 4 analog inputs
- Either current or voltage signal possible
- 16-bit digital converter resolution
- Simultaneous input conversion
- Very fast conversion time

4.3.15.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.3.15.3 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI4632	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions	
X20cAI4632	X20 analog input module, coated, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions

Table 57: X20AI4632, X20cAI4632 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.
5) Based on the 20 mA measurement range.

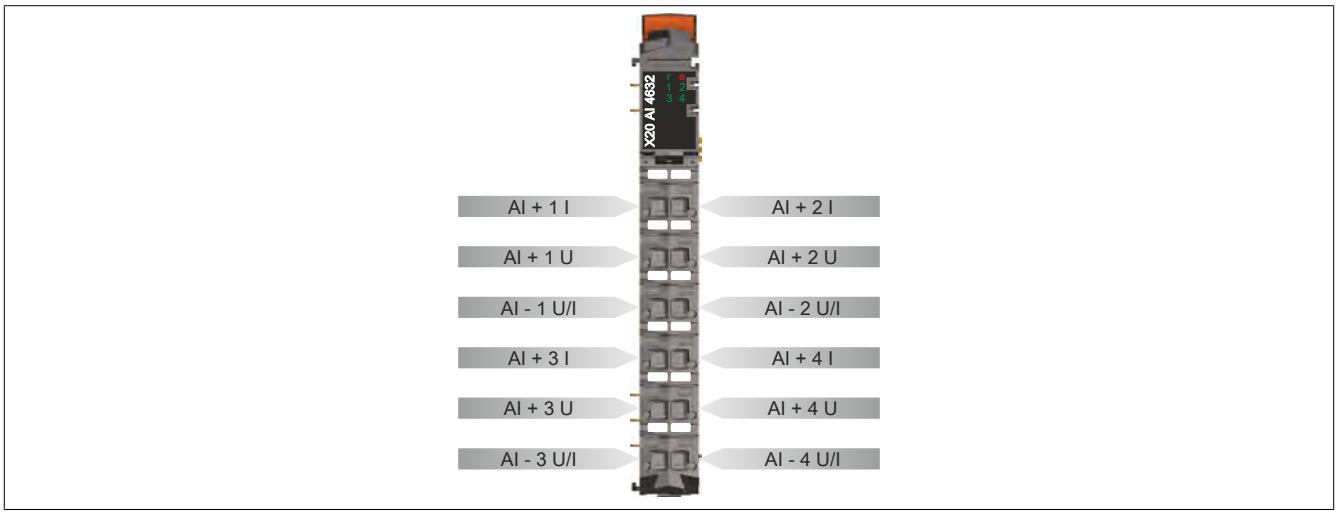
4.3.15.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	System error: • Violation of the scan time • Synchronization error
	1 - 4	Green	Off	Open line[2] or sensor is disconnected
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

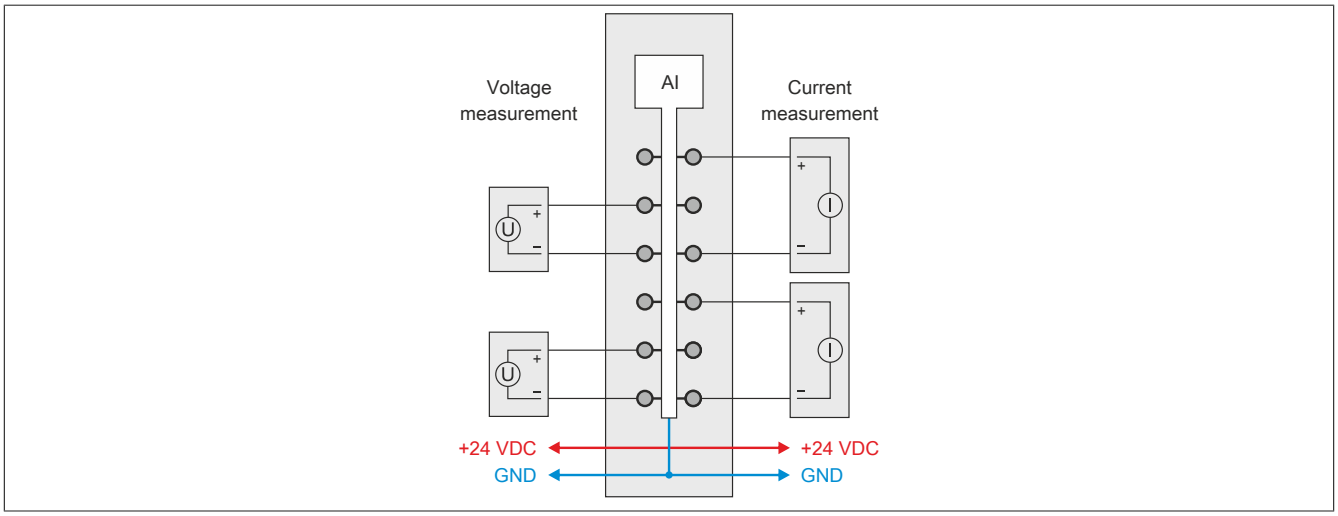
4.3.15.6 Pinout



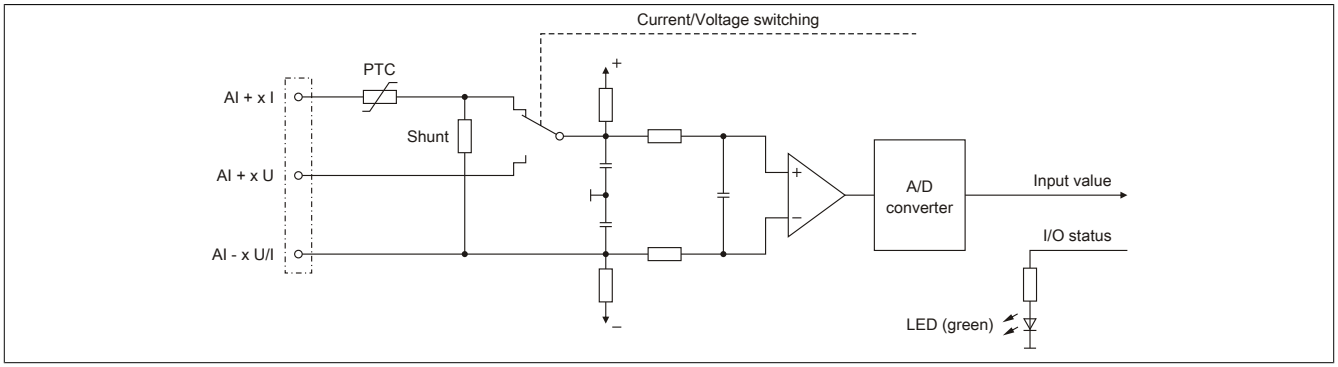
4.3.15.7 Connection example

To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules



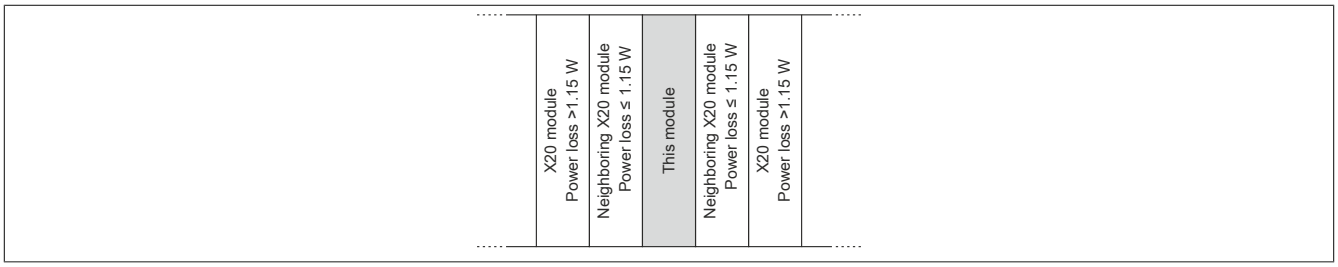
4.3.15.8 Input circuit diagram



4.3.15.9 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.3.15.10 Register description

4.3.15.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.15.10.2 Function model 0 - default

1) The offset specifies the position of the register within the CAN object.

4.3.15.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.15.10.4 Configuration

This module is equipped with analog inputs with connected 16-bit A/D converters. Each of the inputs can be configured separately from one another either on the voltage or current input for the following areas:

- Permitted voltage: ±10 V
- Permitted current: 0 to 20 mA

4.3.15.10.4.1 Channel configuration

Name:
ConfigOutput01 for channel 1
ConfigOutput06 for channel 2
ConfigOutput11 for channel 3
ConfigOutput16 for channel 4

The individual inputs for processing the current or voltage signal are configured in these registers. This configuration must be made in addition to using the correct terminal block pins.

Filtering, analysis and error monitoring (bits 4 to 6) can only be used if the channel is enabled (bit 7 = 0).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Terminal selector	0	Voltage terminal for ±10 VDC
		1	Current terminal for 0 to 20 mA
1	Gain selector	0	Voltage ±10 VDC
		1	Current 0 to 20 mA
2 - 3	Reserved	-	
4	Filtering active	0	Inactive
		1	Active
5	Minimum/Maximum analysis active	0	Inactive
		1	Active
6	Error monitoring active	0	Inactive
		1	Active
7	Enables channel	0	Channel enabled
		1	Channel disabled

4.3.15.10.4.2 Sampling and conversion

The analog signal is sampled in 2 steps.

- **Conversion task**
  The A/D converter digitalizes the inputs signals for the enabled inputs once per conversion cycle. Then the results are available internally in the module. To ensure that this process is executed without delays, the corresponding task will be handled with very high priority.
  The timespan needed for conversion results from the set sampling time.
- **Processing task**
  The converted A/D converter values are further processed according to the user settings (filtering, scaling, limit values, error statistics, min/max analysis, hysteresis comparison). The task for this process has low priority. The timespan needed for further processing depends on the configured functions and is the second portion of the sampling time.

Cycle time violation

In normal operation, further processing is triggered after each conversion. The conversion and sampling tasks run synchronous to one another. If the predefined sampling time is not sufficient to convert all enabled channels and complete the configured functions, a cycle time violation occurs.

Sampling time

Name:
ConfigOutput24

The sampling time is set to µs in this register. This makes it possible to improve the sampling cycle (resolution = 1 µs). The lowest configurable cycle time is 50 µs.

Data type	Value	Function
UINT	50 to 10,000	Default value = 100

Information:

Values that are too low for the cycle time will result in cycle time violations.

4.3.15.10.4.3 Filtering (optional)

If filtering is enabled in the 4.3.15.10.4.1 "Channel configuration" register, the basic data of the A/D converter is filtered per channel. The following registers are available to specify the filter order and respective cutoff frequency for configuring the low-pass filter:

- "Filter order"
- "Filter cutoff frequency"

Filter order

Name:
ConfigOutput26 for channel 1
ConfigOutput28 for channel 2
ConfigOutput30 for channel 3
ConfigOutput32 for channel 4

The filter order is specified in this register. The "Filter cutoff frequency" register is used to configure the respective cutoff frequency of the filter.

Data type	Value
USINT	1 to 4

Internal filter orders greater than 1 are implemented as cascaded first-order filters. Since the filter is calculated in the sampling cycle, the filter characteristics are directly related to the settings for the sampling cycle time.

Calculating the cutoff frequency of an nth-order filter:

yn = a * xn + b * y(n-1)

Approximate calculation

a = Sampling time / (Sampling time + 1/Cutoff frequency)

b = 1 - a

Filter cutoff frequency

Name:
ConfigOutput27 for channel 1
ConfigOutput29 for channel 2
ConfigOutput31 for channel 3
ConfigOutput33 for channel 4

The cutoff frequency of the respective filter is configured in these registers.

Data type	Value	Description
UINT	1 to 65,535	Cutoff frequency in hertz

Information:

The highest cutoff frequency is limited by the Nyquist Shannon sampling theorem (based on the sampling cycle time). The system does not check for violations of this sampling theorem.

4.3.15.10.4.4 Scaling (optional)

Scaling A/D converter data is an option for the user. The following registers are available for this:

- "User-defined gain" (= ku)
- "User-defined offset" (= du)

Scaling calculation:

Scaled value = k * A/C value + d

Gain k = $k_{Calibration}$ * ku

Offset d = $d_{Calibration}$ + du

The value has to be limited since it can exceed the 16-bit constraints. To provide the greatest degree of flexibility, limiting is possible using the registers "Minimum limit value" and "Maximum limit value".

User-defined gain

Name:
ConfigOutput04 for channel 1
ConfigOutput09 for channel 2
ConfigOutput14 for channel 3
ConfigOutput19 for channel 4

The user-defined gain for the A/D converter data of the respective physical channel can be specified in these registers.

The value 65,536 (0x10000) corresponds to a gain of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

User-defined offset

Name:
ConfigOutput05 for channel 1
ConfigOutput10 for channel 2
ConfigOutput15 for channel 3
ConfigOutput20 for channel 4

The user-defined offset for the A/D converter data of the respective physical channel can be specified in this register.

The value 65,536 (0x10000) corresponds to an offset of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.3.15.10.4.5 Limit values

If the application requires a limitation of the range of values, then the user can define his own limit values. These values will also be use for the module's error statistics. The following registers are available for this:

- "Minimum limit value"
- "Maximum limit value"

Information:

32-bit numbers are used inside the module. A limit value violation can therefore also be determined if the permitted range of values was defined from -32768 to 32767.

Minimum limit value

Name:
ConfigOutput02 for channel 1
ConfigOutput07 for channel 2
ConfigOutput12 for channel 3
ConfigOutput17 for channel 4

The minimum limit value is configured in this register. This limit value is also used as the lower value in the error statistics (see register "Counter for range exceeded violations (neg.)").

Data type	Value
INT	-32768 to 32767

Maximum limit value

Name:
ConfigOutput03 for channel 1
ConfigOutput08 for channel 2
ConfigOutput13 for channel 3
ConfigOutput18 for channel 4

The maximum limit value is configured in this register. This limit value is also used as the upper value in the error statistics (see register "Counter for range exceeded violations (pos.)").

Data type	Value
INT	-32768 to 32767

4.3.15.10.5 Communication - General

The module's analog inputs convert current and voltage values with 16-bit resolution. This information can be used by the application with the help of the registers listed here.

4.3.15.10.5.1 Analog input channels

Name:
AnalogInput01 to AnalogInput04

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 to 20 mA

4.3.15.10.5.2 Sampling cycle counter

Name:
SampleCycleCounter

The number of times the input signal has been sampled is provided in this register.

Data type	Value
UINT	0 to 65535

4.3.15.10.5.3 Error monitoring and counters

Channel status

Name:
Channel01OK to Channel04OK
SyncStatus
ConvertionCycle

This register collects error messages synchronously with the network cycle. Temporary error states that were registered in a conversion cycle remain active for at least 2 network cycles. In order to receive detailed error information, the corresponding error counters and X2X network events should also be observed.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OK	0	OK
		1	Errors
...		...	
3	Channel04OK	0	OK
		1	Errors
4 - 5	Reserved	-	
6	SyncStatus[1)]	0	OK
		1	Not synchronized
7	ConvertionCycle[2)]	0	OK
		1	Errors

1) Identical to bit 0 of the registers "Synchronization error counter".
2) Identical to bit 0 of the registers "Counter for faulty sampling cycles".

Synchronization error counter

Name:
SynchronizationViolationErrorCounter

This register counts how often the conversion task was triggered more than 5 µs after the next-coming X2X cycle. In this case, the module is considered being no longer synchronized with X2X Link.

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for faulty sampling cycles

Name:
SampleCycleViolationErrorCounter

This register is used to indicate the number of cycle time violations that have occurred thus far. A cycle time violation occurs if the conversion tasks initiates a sampling task before the last sampling cycle has finished. See 4.3.9.8.4.2 "Sampling and conversion".

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Range violation (neg. and pos.)

Name:
Channel01underflow to Channel04underflow
Channel01overflow to Channel04overflow

This register indicates whether a range violation (pos. and/or neg.) of the limit values defined in the registers "Minimum limit value" and "Maximum limit value" has occurred. The individual bits in this register are identical to the values of the lowest bits in the registers "Counter for range exceeded violations (neg.)" and "Counter for range exceeded violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01underflow	0	No error
		1	Range exceeded (.neg) on channel 1
...		...	
3	Channel04underflow	0	No error
		1	Range exceeded (.neg) on channel 4
4	Channel01overflow	0	No error
		1	Range exceeded (.pos) on channel 1
...		...	
7	Channel04overflow	0	No error
		1	Range exceeded (.pos) on channel 4

Working range violation (pos.)

Name:
Channel01OutofRange to Channel04OutofRange

This register indicates whether the input value exceeds the module's maximum measurement range. The individual bits in this register are identical to the values of the lowest bits in the register "Counter for work range violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutofRange	0	No error
		1	Working range violation (pos.) of channel 1
...		...	
3	Channel04OutofRange	0	No error
		1	Working range violation (pos.) of channel 4
4 - 7	Reserved	-	

Counter for work range violations (pos.)

Name:
CH01OutofRange to CH04OutofRange

Errors outside of the module's maximum possible measurement range are indicated in this register. These errors lead to full-scale deflection of the A/D converter.

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.15.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (neg.)

Name:
CH01Underflow to CH04Underflow

This register indicates range exceeded violations (neg.) of the value configured in the register "Minimum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.15.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (pos.)

Name:
CH01Overflow to CH04Overflow

This register indicates range exceeded violations (pos.) of the value configured in the register "Maximum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.15.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

4.3.15.10.6 Additional analysis functions

In addition to sampling the analog input signal, this module can also be used to perform additional analysis of the values obtained.

- **Limit value analysis**
  If limit value analysis has been enabled for a channel, the sampled minimum and maximum values are latched internally in the module. A measurement period can be triggered using the control byte. When the respective configured edge is generated by the application, the limit values from the previous measurement period are displayed and the internal latch register is reset.
- **Recording sampled values**
  If recording sampled values has been enabled for a channel, then the sampled values are additionally recorded in the module's internal FIFO memory. If the configured event occurs, the contents of the FIFO memory are transmitted to the application.

Information:

It is only possible to use the recording of sampled values if the module is operated on an X2X master that is an SG4 CPU.

4.3.15.10.6.1 Trigger condition on falling edge

Name:
ConfigOutput21

This register configures whether the falling edge is used to trigger the trace and determination of the input value in the register 4.3.15.10.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	No trigger
		1	Falling edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Falling edge determines input value of channel 1
...	...	...	
7	MinMaxStart04	0	No determination
		1	Falling edge determines input value of channel 4

4.3.15.10.6.2 Trigger condition on rising edge

Name:
ConfigOutput22

This register configures whether the rising edge is used to trigger the trace and determination of the input value in the register 4.3.15.10.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Rising edge does not initiate trigger
		1	Rising edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Rising edge determines input value of channel 1
...	...	...	
7	MinMaxStart04	0	No determination
		1	Rising edge determines input value of channel 4

4.3.15.10.6.3 Analysis control byte

Name:
TraceTrigger01
MinMaxStart01 to MinMaxStart04

The trace function and determination of the minimum/maximum input values can be started in this register.
Whether the rising and/or falling edge is used to trigger the functions can be configured using the registers 4.3.15.10.6.1 "Trigger condition on falling edge" and 4.3.15.10.6.2 "Trigger condition on rising edge".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Does not initiate trigger/trace
		1	Initiates trigger/trace
1 - 3	Reserved	-	
4	MinMaxStart01	0	Determination not initiated
		1	Initiates determination of input value of channel 1
...	...	...	
7	MinMaxStart04	0	Determination not initiated
		1	Initiates determination of input value of channel 4

Information:

To reduce the cyclic data transfer, this register combines the trace and limit value determination functions.

4.3.15.10.6.4 Analysis status byte

Name:
MinMaxStart01Readback to MinMaxStart04Readback

The currently requested module-internal analyses can be checked in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	MinMaxStart01Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
...	...	...	
7	MinMaxStart04Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel

4.3.15.10.7 Limit values

Limit value analysis must be enabled for the desired channel (see 4.3.15.10.4.1 "Channel configuration"). The sampled value of the channel is then compared to the minimum and maximum values that are stored internally in the module. If a new measurement period is initiated with the 4.3.15.10.6.3 "Analysis control byte" register, then the values determined from the previous measurement period can be taken from the respective registers intended for this.

4.3.15.10.7.1 Minimum input values

Name:
MinInput01 to MinInput04

The minimum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.15.10.7.2 Maximum input values

Name:
MaxInput01 to MaxInput04

The maximum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.15.10.7.3 Limit value trigger counter

Name:
CH01MinMaxLatchCounter to CH04MinMaxLatchCounter

The number of valid events that trigger a new measurement period for the limit value analysis is counted in this register.

Data type	Value
UINT	0 to 65535

4.3.15.10.8 Trace

If the module is operated on a SG4 CPU, the digitalized input values are recorded by the module. The module must be operated in "Supervised" mode in order to use the trace function.

Recording must be enabled for the desired channel. The enable bits can then control the recording at runtime. The sampled values are recorded in the module's internal FIFO memory.

If the previously defined state occurs on the channel, the contents of the FIFO memory are transmitted to the application. Whether the FIFO memory continued to be filled depends on how recording is configured.

Information:

The trace mechanism can only be used if the module is connected directly to the CPU, not if it is operated behind a bus controller.

4.3.15.10.8.1 Enable recording

Name:
TraceChannelEnable

The respective channel is enabled for the trace with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Channel disabled
		1	Channel enabled
...	...	...	
3	Channel 4	0	Channel disabled
		1	Channel enabled
4 - 7	Reserved	-	

4.3.15.10.8.2 Number of values to be recorded

Name:
TraceSampleDepth

16 kB are available on the module for the trace. The FIFO memory limitation means that a maximum of 8192 analog values can be recorded. This memory is divided up equally among the enabled channels. The actual number of maximum possible recordings therefore depends on the number of channels enabled for trace:

1 channel enabled: Up to 8192 recordings
2 channels enabled: Up to 4096 recordings per channel
3 channels enabled: Up to 2730 recordings per channel
4 channels enabled: Up to 2048 recordings per channel

Data type	Value	Function
UINT	2 to 8192	Default value = 1024

4.3.15.10.8.3 Recording priority

Name:
ConfigOutput25

The priority of the trace can be increased with this register.

Data type	Value	Function
USINT	3	Standard (default value)
	6	Trace priority higher than X2X Link communication

4.3.15.10.8.4 Starting a recording

Name:

TraceEnable01

This register starts the recording according to the specifications for edge control or the comparator.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceEnable01	0	Disables the trace function
		1	Enables the trace function
1 - 7	Reserved	-	

4.3.15.10.8.5 Recording status

Name:
TraceEnabled
TraceWriteActive
TraceReadActive
ReadyForTrigger
TriggerActive
TraceOk
TraceError

The status of the trace is represented in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	TraceEnabled	0	Trace inactive
		1	Trace active
1	Reserved	-	
2	TraceWriteActive	0	Data not recorded
		1	Data recorded
3	TraceReadActive	0	Data not output/read
		1	Data output/read
4	ReadyForTrigger	0	Not ready for triggering
		1	Ready for triggering
5	TriggerActive	0	No trigger active or already executed
		1	Trigger active
6	TraceOk	0	Overflow or inactive
		1	No overflow
7	TraceError	0	No error or inactive
		1	Trace buffer full

4.3.15.10.8.6 Free trace buffer

Name:
FreeBufferSize

Specifies the available FIFO memory area in bytes for the trace

Data type	Value
UINT	0 to 65535

4.3.15.10.8.7 Counter for trace triggers

Name:
TriggerCount

This register indicates the number of triggers that have occurred since "starting the trace".

Data type	Value
UINT	0 to 65535

4.3.15.10.8.8 Counter for faulty recording triggers

Name:
TriggerFailCount

Counts the trigger events for which the trace could not be performed.

Data type	Value
UINT	0 to 65535

4.3.15.10.8.9 Comparator for trigger conditions

In order to adapt the trace as closely as possible to the requirements of the application, the trace function can also be controlled using the comparator. Threshold values (hysteresis) can be defined within the permitted range of values to do so. 2 status bits are then generated for each enabled channel:

- **InRange bit**
  The InRange status is "1" if the measured value falls within the defined limits.
  The InRange status is "0" if the measured value falls outside the defined limits.
- **Threshold value bit**
  The threshold value bit is "1" if the measured value exceeds the upper threshold value.
  The threshold value bit is "0" if the measured value falls below the lower threshold value.

The InRange and threshold value bits for all channels are grouped together in the lower-value byte of the "Hysteresis status of the channels" register. In addition, the states of the previous sampling are stored in the higher-value byte.

The 4 status messages of each channel can be linked according to the following logic via a logical connective mask using AND or OR operators and used as a trace trigger:

```
delta = (Current_HysteresisStatus ^ NominalValues) // Different between current status and preset
cond = delta & Selected_HysteresisStatusBits // Eliminate irrelevant status messages
ccond = Selected_HysteresisStatusBits (Current_HysteresisStatus ^ NominalValues)
if ((0 == (cond & ~LogicalOperators)) &&
(0 != (~cond & LogicalOperators))) { => Generate trigger event}
```

	Corresponds to register:
Selected_HysteresisStatusBits	cfgComp_EnableMask
Current_HysteresisStatus	CompStateCollection
Nominal values	cfgComp_NominalState
Logical operators	cfgComp_ConditionTypeMask

Lower limit value for hysteresis

Name:
cfgComp_LowLimitCh01 to cfgComp_LowLimitCh04

The lower limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Upper limit value for hysteresis

Name:
cfgComp_HighLimitCh01 to cfgComp_HighLimitCh04

The upper limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Hysteresis status of the channels

Name:
CompStateCollection

The hysteresis status of the input channels for the current and last cycle are represented in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
7	Channel04 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
15	Channel04 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values

Comparison state of the channels

Name:
cfgComp_NominalState

The desired comparison state for the hysteresis status is indicated in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
7	Channel04 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
15	Channel04 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values

Information:

This is a "whitelist", i.e. the trace starts as soon as the current status message takes on the state predefined here.

One or more matches will be necessary depending on the selection of the relevant hysteresis status bits and logical connective operators.

Selecting the relevant hysteresis status bits

Name:
cfgComp_EnableMask

This register selects which status bits of the hysteresis comparison should be used to generate the trigger.

For more information about using this register, see 4.3.15.10.8.9 "Comparator for trigger conditions".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
1	Channel01 InRange status in the current cycle	0	Do not use
		1	Use for generation
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
7	Channel04 InRange status in the current cycle	0	Do not use
		1	Use for generation
8	Channel01 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
9	Channel01 InRange status in the last cycle	0	Do not use
		1	Use for generation
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
15	Channel04 InRange status in the last cycle	0	Do not use
		1	Use for generation

Logical connective operators for hysteresis status bits

Name:
cfgComp_ConditionTypeMask

The desired state operators with which the respective status bit is linked to others to generate a trigger are selected in this register.

At least one OR operation must be configured, but it does not necessarily have to be located on a channel configured with "1" in the "Selecting the relevant hysteresis status bits" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
1	Channel01 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
7	Channel04 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
8	Channel01 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
9	Channel01 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
15	Channel04 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation

4.3.15.10.8.10 Time-offset trace

Additional conditions for shifting the starting and stopping points can be defined if the trace should be chronologically offset to the trigger.

Starting the trace

Name:
TraceTriggerStart

The starting position is defined relative to the configured trigger condition (rising/falling edge) in this register. Positive values mean that the trace takes place x samples after the trigger condition. Negative values mean that the trace takes place x samples before the trigger condition.

The value -32768 performs the trace without regard for the configured trigger condition. If the trace memory is completely full, then the oldest recorded value is overwritten (FIFO principle).

"Trace start" in the I/O configuration or the registers 4.3.15.10.6.1 "Trigger condition on falling edge" and 4.3.15.10.6.2 "Trigger condition on rising edge" determine whether a positive, negative or any edge must be triggered.

Data type	Value
INT	-32768 to 32767

Stopping the trace

Name:
TraceTriggerStop

The stopping position is defined relative to the configured trigger condition in this register.

- When configuring an early trigger event, this value refers to the trigger event.
- When configuring a delayed trigger event, this value refers to the starting event.

Data type	Value
UINT	0 to 65535

4.3.15.10.9 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.3.15.10.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Standard priority	200 µs
High priority with trace function	300 µs

4.3.15.10.11 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.16 X20(c)AI4632-1

4.3.16.1 General information

The module is equipped with 4 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections.

- 4 analog inputs
- Either current or voltage signal possible
- Extended signal range
- 16-bit digital converter resolution
- Simultaneous input conversion
- Very fast conversion time

4.3.16.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.3.16.3 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI4632-1	X20 analog input module, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions	
X20cAI4632-1	X20 analog input module, coated, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions

Table 59: X20AI4632-1, X20cAI4632-1 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 22 V measurement range.
5) Based on the 22 mA measurement range.

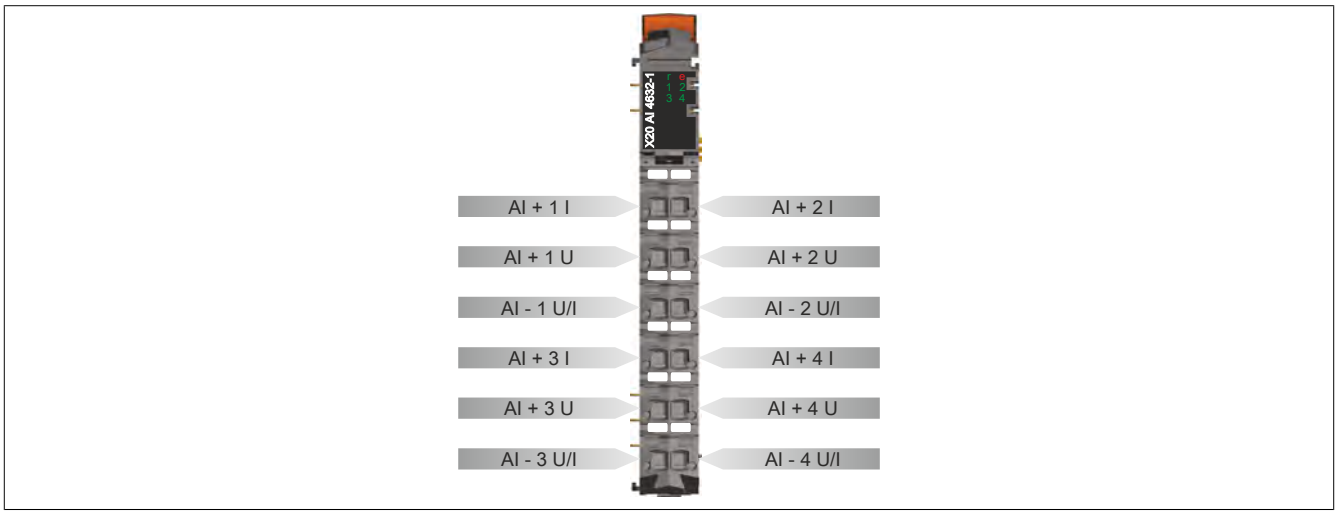
4.3.16.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	System error: • Violation of the scan time • Synchronization error
	1 - 4	Green	Off	Open line[2] or sensor is disconnected
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

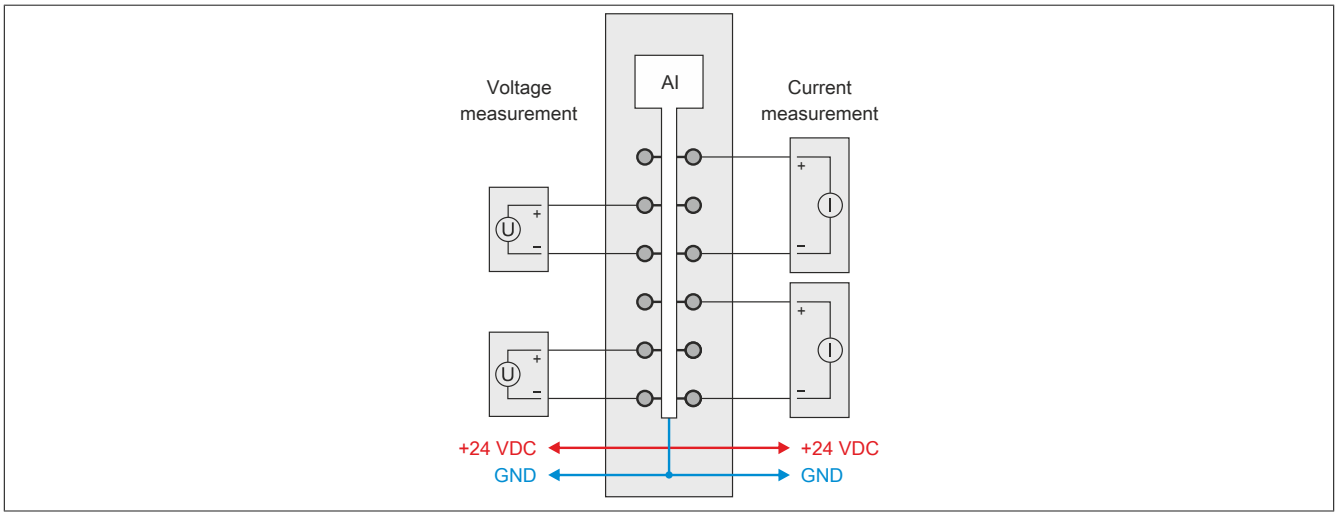
4.3.16.6 Pinout



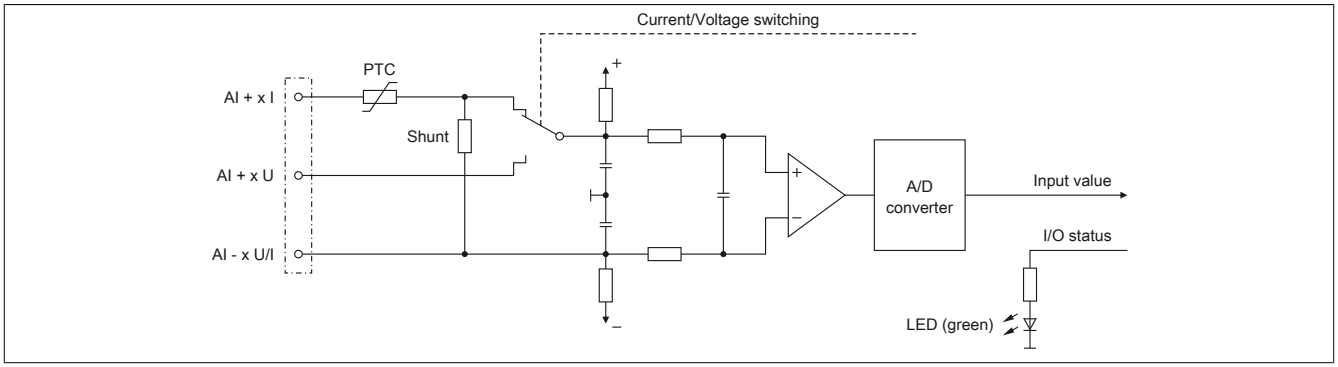
4.3.16.7 Connection example

To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules



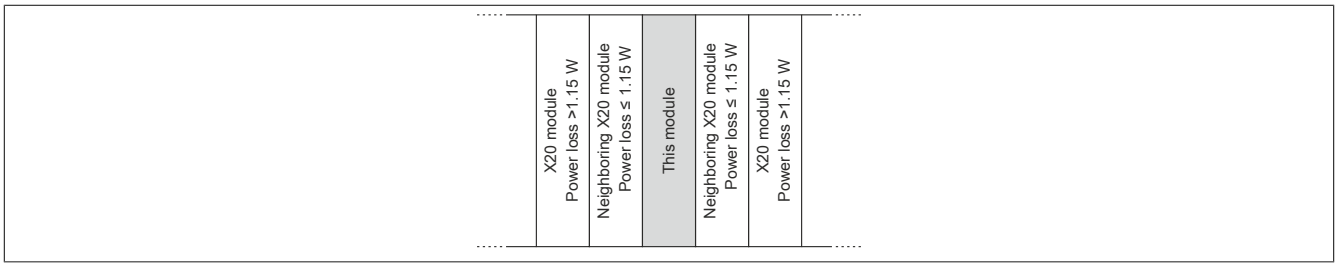
4.3.16.8 Input circuit diagram



4.3.16.9 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.3.16.10 Register description

4.3.16.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

4.3.16.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.16.10.4 Configuration

This module is equipped with analog inputs with connected 16-bit A/D converters. Each of the inputs can be configured separately from one another either on the voltage or current input for the following areas:

- Permitted voltage: ±11 V at 20 Ω
- Permitted current: 22 mA (maximum 40 mA) (<400 Ω)

4.3.16.10.4.1 Channel configuration

Name:
ConfigOutput01 for channel 01
ConfigOutput06 for channel 02
ConfigOutput11 for channel 03
ConfigOutput16 for channel 04

The individual inputs for processing the current or voltage signal are configured in these registers. This configuration must be made in addition to using the correct terminal block pins.

Filtering, analysis and error monitoring (bits 4 to 6) can only be used if the channel is enabled (bit 7 = 0).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Terminal selector	0	Voltage terminal for ±11 VDC
		1	Current terminal for 0 to 22 mA
1	Gain selector	0	Voltage ±11 VDC
		1	Current 0 to 22 mA
2 - 3	Reserved	-	
4	Filtering active (only if bit 7 = 0)	0	Inactive
		1	Active
5	Minimum/Maximum analysis active (only if bit 7 = 0)	0	Inactive
		1	Active
6	Error monitoring active (only if bit 7 = 0)	0	Inactive
		1	Active
7	Enables channel	0	Channel enabled
		1	Channel disabled

4.3.16.10.4.2 Sampling and conversion

The analog signal is sampled in 2 steps.

- **Conversion task**
  The A/D converter digitalizes the inputs signals for the enabled inputs once per conversion cycle. Then the results are available internally in the module. To ensure that this process is executed without delays, the corresponding task will be handled with very high priority.
  The timespan needed for conversion results from the set sampling time.
- **Processing task**
  The converted A/D converter values are further processed according to the user settings (filtering, scaling, limit values, error statistics, min/max analysis, hysteresis comparison). The task for this process has low priority. The timespan needed for further processing depends on the configured functions and is the second portion of the sampling time.

Cycle time violation

In normal operation, further processing is triggered after each conversion. The conversion and sampling tasks run synchronous to one another. If the predefined sampling time is not sufficient to convert all enabled channels and complete the configured functions, a cycle time violation occurs.

Sampling time

Name:
ConfigOutput24

The sampling time is set to µs in this register. This makes it possible to improve the sampling cycle (resolution = 1 µs). The lowest configurable cycle time is 50 µs.

Data type	Value	Function
UINT	50 to 10,000	Default value = 100

Information:

Values that are too low for the cycle time will result in cycle time violations.

4.3.16.10.4.3 Filtering (optional)

If filtering is enabled in the 4.3.16.10.4.1 "Channel configuration" register, the basic data of the A/D converter is filtered per channel. The following registers are available to specify the filter order and respective cutoff frequency for configuring the low-pass filter:

- "Filter order"
- "Filter cutoff frequency"

Filter order

Name:
ConfigOutput26 for channel 1
ConfigOutput28 for channel 2
ConfigOutput30 for channel 3
ConfigOutput32 for channel 4

The filter order is specified in this register. The "Filter cutoff frequency" register is used to configure the respective cutoff frequency of the filter.

Data type	Value
USINT	1 to 4

Internal filter orders greater than 1 are implemented as cascaded first-order filters. Since the filter is calculated in the sampling cycle, the filter characteristics are directly related to the settings for the sampling cycle time.

Calculating the cutoff frequency of an nth-order filter:

yn = a * xn + b * y(n-1)

Approximate calculation

a = Sampling time / (Sampling time + 1/Cutoff frequency)

b = 1 - a

Filter cutoff frequency

Name:
ConfigOutput27 for channel 1
ConfigOutput29 for channel 2
ConfigOutput31 for channel 3
ConfigOutput33 for channel 4

The cutoff frequency of the respective filter is configured in these registers.

Data type	Value	Description
UINT	1 to 65,535	Cutoff frequency in hertz

Information:

The highest cutoff frequency is limited by the Nyquist Shannon sampling theorem (based on the sampling cycle time). The system does not check for violations of this sampling theorem.

4.3.16.10.4.4 User-defined scaling

The raw and filtered A/D converter data is compared and normalized (gain = k, offset = d). In addition, user-defined normalization is available using the following registers:

- "User-defined gain" (= ku)
- "User-defined offset" (= du)

The execution time is optimized by grouping the factors together.

System scaling calculation:

nom = k * RawValue + d

k = k * ku

d = k * d + du

The value has to be limited since it can exceed the 16-bit constraints. To provide the greatest degree of flexibility, limiting is possible using the registers "Minimum limit value" and "Maximum limit value".

User-defined gain

Name:
ConfigOutput04 for channel 1
ConfigOutput09 for channel 2
ConfigOutput14 for channel 3
ConfigOutput19 for channel 4

The user-defined gain for the A/D converter data of the respective physical channel can be specified in these registers.

The value 65,536 (0x10000) corresponds to a gain of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

User-defined offset

Name:
ConfigOutput05 for channel 1
ConfigOutput10 for channel 2
ConfigOutput15 for channel 3
ConfigOutput20 for channel 4

The user-defined offset for the A/D converter data of the respective physical channel can be specified in this register.

The value 65,536 (0x10000) corresponds to an offset of 1.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.3.16.10.4.5 Limit values

If the application requires a limitation of the range of values, then the user can define his own limit values. These values will also be use for the module's error statistics. The following registers are available for this:

- "Minimum limit value"
- "Maximum limit value"

Information:

32-bit numbers are used inside the module. A limit value violation can therefore also be determined if the permitted range of values was defined from -32768 to 32767.

Minimum limit value

Name:
ConfigOutput02 for channel 1
ConfigOutput07 for channel 2
ConfigOutput12 for channel 3
ConfigOutput17 for channel 4

The minimum limit value is configured in this register. This limit value is also used as the lower value in the error statistics (see register "Counter for range exceeded violations (neg.)").

Data type	Value
INT	-32768 to 32767

Maximum limit value

Name:
ConfigOutput03 for channel 1
ConfigOutput08 for channel 2
ConfigOutput13 for channel 3
ConfigOutput18 for channel 4

The maximum limit value is configured in this register. This limit value is also used as the upper value in the error statistics (see register "Counter for range exceeded violations (pos.)").

Data type	Value
INT	-32768 to 32767

4.3.16.10.5 Communication - General

The module's analog inputs convert current and voltage values with 16-bit resolution. This information can be used by the application with the help of the registers listed here.

4.3.16.10.5.1 Analog input channels

Name:
AnalogInput01 to AnalogInput04

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal ±11 VDC
	0 to 32,767	Current signal 0 to 22 mA

4.3.16.10.5.2 Sampling cycle counter

Name:
SampleCycleCounter

The number of times the input signal has been sampled is provided in this register.

Data type	Value
UINT	0 to 65535

4.3.16.10.5.3 Error monitoring and counters

Channel status

Name:
Channel01OK to Channel04OK
SyncStatus
ConvertionCycle

This register collects error messages synchronously with the network cycle. Temporary error states that were registered in a conversion cycle remain active for at least 2 network cycles. In order to receive detailed error information, the corresponding error counters and X2X network events should also be observed.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OK	0	OK
		1	Errors
...		...	
3	Channel04OK	0	OK
		1	Errors
4 - 5	Reserved	-	
6	SyncStatus[1)]	0	OK
		1	Not synchronized
7	ConvertionCycle[2)]	0	OK
		1	Errors

1) Identical to bit 0 of the registers "Synchronization error counter".
2) Identical to bit 0 of the registers "Counter for faulty sampling cycles".

Synchronization error counter

Name:
SynchronizationViolationErrorCounter

This register counts how often the conversion task was triggered more than 5 µs after the next-coming X2X cycle. In this case, the module is considered being no longer synchronized with X2X Link.

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for faulty sampling cycles

Name:
SampleCycleViolationErrorCounter

This register is used to indicate the number of cycle time violations that have occurred thus far. A cycle time violation occurs if the conversion tasks initiates a sampling task before the last sampling cycle has finished. See 4.3.9.8.4.2 "Sampling and conversion".

The counters in this register follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Range violation (neg. and pos.)

Name:
Channel01underflow to Channel04underflow
Channel01overflow to Channel04overflow

This register indicates whether a range violation (pos. and/or neg.) of the limit values defined in the registers "Minimum limit value" and "Maximum limit value" has occurred. The individual bits in this register are identical to the values of the lowest bits in the registers "Counter for range exceeded violations (neg.)" and "Counter for range exceeded violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01underflow	0	No error
		1	Range exceeded (.neg) on channel 1
...		...	
3	Channel04underflow	0	No error
		1	Range exceeded (.neg) on channel 4
4	Channel01overflow	0	No error
		1	Range exceeded (.pos) on channel 1
...		...	
7	Channel04overflow	0	No error
		1	Range exceeded (.pos) on channel 4

Working range violation (pos.)

Name:
Channel01OutofRange to Channel04OutofRange

This register indicates whether the input value exceeds the module's maximum measurement range. The individual bits in this register are identical to the values of the lowest bits in the register "Counter for work range violations (pos.)".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutofRange	0	No error
		1	Working range violation (pos.) of channel 1
...		...	
3	Channel04OutofRange	0	No error
		1	Working range violation (pos.) of channel 4
4 - 7	Reserved	-	

Counter for work range violations (pos.)

Name:
CH01OutofRange to CH04OutofRange

Errors outside of the module's maximum possible measurement range are indicated in this register. These errors lead to full-scale deflection of the A/D converter.

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.16.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (neg.)

Name:
CH01Underflow to CH04Underflow

This register indicates range exceeded violations (neg.) of the value configured in the register "Minimum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.16.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

Counter for range exceeded violations (pos.)

Name:
CH01Overflow to CH04Overflow

This register indicates range exceeded violations (pos.) of the value configured in the register "Maximum limit value".

The counters in these registers follow the rules of the event error counter, i.e. the count increased each time an error occurs or is reset. The last bit of the counter indicates the error status:

- Last bit = 1 → Error pending
- Last bit = 0 → No error

This counter is only active if the static error counter is enabled (see register 4.3.16.10.4.1 "Channel configuration").

Data type	Value	Information
UINT	0 to 65535	Counter value
	0 to 1	Bit 0: Error status

4.3.16.10.6 Additional analysis functions

In addition to sampling the analog input signal, this module can also be used to perform additional analysis of the values obtained.

- **Limit value analysis**
  If limit value analysis has been enabled for a channel, the sampled minimum and maximum values are latched internally in the module. A measurement period can be triggered using the control byte. When the respective configured edge is generated by the application, the limit values from the previous measurement period are displayed and the internal latch register is reset.
- **Recording sampled values**
  If recording sampled values has been enabled for a channel, then the sampled values are additionally recorded in the module's internal FIFO memory. If the configured event occurs, the contents of the FIFO memory are transmitted to the application.

Information:

It is only possible to use the recording of sampled values if the module is operated on an X2X master that is an SG4 CPU.

4.3.16.10.6.1 Trigger condition on falling edge

Name:
ConfigOutput21

This register configures whether the falling edge is used to trigger the trace and determination of the input value in the register 4.3.15.10.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	No trigger
		1	Falling edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Falling edge determines input value of channel 1
...	...	...	
7	MinMaxStart04	0	No determination
		1	Falling edge determines input value of channel 4

4.3.16.10.6.2 Trigger condition on rising edge

Name:
ConfigOutput22

This register configures whether the rising edge is used to trigger the trace and determination of the input value in the register 4.3.15.10.6.3 "Analysis control byte".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Rising edge does not initiate trigger
		1	Rising edge active as trigger
1 - 3	Reserved	-	
4	MinMaxStart01	0	No determination
		1	Rising edge determines input value of channel 1
...	...	...	
7	MinMaxStart04	0	No determination
		1	Rising edge determines input value of channel 4

4.3.16.10.6.3 Analysis control byte

Name:
TraceTrigger01
MinMaxStart01 to MinMaxStart04

The trace function and determination of the minimum/maximum input values can be started in this register.
Whether the rising and/or falling edge is used to trigger the functions can be configured using the registers 4.3.15.10.6.1 "Trigger condition on falling edge" and 4.3.15.10.6.2 "Trigger condition on rising edge".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceTrigger01	0	Does not initiate trigger/trace
		1	Initiates trigger/trace
1 - 3	Reserved	-	
4	MinMaxStart01	0	Determination not initiated
		1	Initiates determination of input value of channel 1
...	...	...	
7	MinMaxStart04	0	Determination not initiated
		1	Initiates determination of input value of channel 4

Information:

To reduce the cyclic data transfer, this register combines the trace and limit value determination functions.

4.3.16.10.6.4 Analysis status byte

Name:
MinMaxStart01Readback to MinMaxStart04Readback

The currently requested module-internal analyses can be checked in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4	MinMaxStart01Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel
...	...	...	
7	MinMaxStart04Readback	0 or 1	Current state of the trigger bits for determining the limit values on the channel

4.3.16.10.7 Limit values

Limit value analysis must be enabled for the desired channel (see 4.3.16.10.4.1 "Channel configuration"). The sampled value of the channel is then compared to the minimum and maximum values that are stored internally in the module. If a new measurement period is initiated with the 4.3.15.10.6.3 "Analysis control byte" register, then the values determined from the previous measurement period can be taken from the respective registers intended for this.

4.3.16.10.7.1 Minimum input values

Name:
MinInput01 to MinInput04

The minimum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.16.10.7.2 Maximum input values

Name:
MaxInput01 to MaxInput04

The maximum value of the preceding trigger period is saved in this register based on the filtered, scaled and user-defined limit values. The register value is 0 if the channel is inactive.

Data type	Value
INT	-32,768 to 32,767

4.3.16.10.7.3 Limit value trigger counter

Name:
CH01MinMaxLatchCounter to CH04MinMaxLatchCounter

The number of valid events that trigger a new measurement period for the limit value analysis is counted in this register.

Data type	Value
UINT	0 to 65535

4.3.16.10.8 Trace

If the module is operated on a SG4 CPU, the digitalized input values are recorded by the module. The module must be operated in "Supervised" mode in order to use the trace function.

Recording must be enabled for the desired channel. The enable bits can then control the recording at runtime. The sampled values are recorded in the module's internal FIFO memory.

If the previously defined state occurs on the channel, the contents of the FIFO memory are transmitted to the application. Whether the FIFO memory continued to be filled depends on how recording is configured.

Information:

The trace mechanism can only be used if the module is connected directly to the CPU, not if it is operated behind a bus controller.

4.3.16.10.8.1 Enable recording

Name:
TraceChannelEnable

The respective channel is enabled for the trace with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Channel disabled
		1	Channel enabled
...	...	...	
3	Channel 4	0	Channel disabled
		1	Channel enabled
4 - 7	Reserved	-	

4.3.16.10.8.2 Number of values to be recorded

Name:
TraceSampleDepth

16 kB are available on the module for the trace. The FIFO memory limitation means that a maximum of 8192 analog values can be recorded. This memory is divided up equally among the enabled channels. The actual number of maximum possible recordings therefore depends on the number of channels enabled for trace:

1 channel enabled: Up to 8192 recordings
2 channels enabled: Up to 4096 recordings per channel
3 channels enabled: Up to 2730 recordings per channel
4 channels enabled: Up to 2048 recordings per channel

Data type	Value	Function
UINT	2 to 8192	Default value = 1024

4.3.16.10.8.3 Recording priority

Name:
ConfigOutput25

The priority of the trace can be increased with this register.

Data type	Value	Function
USINT	3	Standard (default value)
	6	Trace priority higher than X2X Link communication

4.3.16.10.8.4 Starting a recording

Name:

TraceEnable01

This register starts the recording according to the specifications for edge control or the comparator.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TraceEnable01	0	Disables the trace function
		1	Enables the trace function
1 - 7	Reserved	-	

4.3.16.10.8.5 Recording status

Name:
TraceEnabled
TraceWriteActive
TraceReadActive
ReadyForTrigger
TriggerActive
TraceOk
TraceError

The status of the trace is represented in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	TraceEnabled	0	Trace inactive
		1	Trace active
1	Reserved	-	
2	TraceWriteActive	0	Data not recorded
		1	Data recorded
3	TraceReadActive	0	Data not output/read
		1	Data output/read
4	ReadyForTrigger	0	Not ready for triggering
		1	Ready for triggering
5	TriggerActive	0	No trigger active or already executed
		1	Trigger active
6	TraceOk	0	Overflow or inactive
		1	No overflow
7	TraceError	0	No error or inactive
		1	Trace buffer full

4.3.16.10.8.6 Free trace buffer

Name:
FreeBufferSize

Specifies the available FIFO memory area in bytes for the trace

Data type	Value
UINT	0 to 65535

4.3.16.10.8.7 Counter for trace triggers

Name:
TriggerCount

This register indicates the number of triggers that have occurred since "starting the trace".

Data type	Value
UINT	0 to 65535

4.3.16.10.8.8 Counter for faulty recording triggers

Name:
TriggerFailCount

Counts the trigger events for which the trace could not be performed.

Data type	Value
UINT	0 to 65535

4.3.16.10.8.9 Comparator for trigger conditions

In order to adapt the trace as closely as possible to the requirements of the application, the trace function can also be controlled using the comparator. Threshold values (hysteresis) can be defined within the permitted range of values to do so. 2 status bits are then generated for each enabled channel:

- **InRange bit**
  The InRange status is "1" if the measured value falls within the defined limits.
  The InRange status is "0" if the measured value falls outside the defined limits.
- **Threshold value bit**
  The threshold value bit is "1" if the measured value exceeds the upper threshold value.
  The threshold value bit is "0" if the measured value falls below the lower threshold value.

The InRange and threshold value bits for all channels are grouped together in the lower-value byte of the "Hysteresis status of the channels" register. In addition, the states of the previous sampling are stored in the higher-value byte.

The 4 status messages of each channel can be linked according to the following logic via a logical connective mask using AND or OR operators and used as a trace trigger:

```
delta = (Current_HysteresisStatus ^ NominalValues) // Different between current status and preset
cond = delta & Selected_HysteresisStatusBits // Eliminate irrelevant status messages
ccond = Selected_HysteresisStatusBits (Current_HysteresisStatus ^ NominalValues)
if ((0 == (cond & ~LogicalOperators)) &&
(0 != (~cond & LogicalOperators))) { => Generate trigger event}
```

	Corresponds to register:
Selected_HysteresisStatusBits	cfgComp_EnableMask
Current_HysteresisStatus	CompStateCollection
Nominal values	cfgComp_NominalState
Logical operators	cfgComp_ConditionTypeMask

Lower limit value for hysteresis

Name:
cfgComp_LowLimitCh01 to cfgComp_LowLimitCh04

The lower limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Upper limit value for hysteresis

Name:
cfgComp_HighLimitCh01 to cfgComp_HighLimitCh04

The upper limit value for hysteresis is configured in this register.

Data type	Value
INT	-32768 to 32767

Hysteresis status of the channels

Name:
CompStateCollection

The hysteresis status of the input channels for the current and last cycle are represented in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
7	Channel04 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
15	Channel04 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values

Comparison state of the channels

Name:
cfgComp_NominalState

The desired comparison state for the hysteresis status is indicated in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
1	Channel01 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
7	Channel04 InRange status in the current cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
8	Channel01 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
9	Channel01 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Lower limit value exceeded
		1	Upper limit value exceeded
15	Channel04 InRange status in the last cycle	0	Value lies outside of range defined by the limit values
		1	Value between lower and upper limit values

Information:

This is a "whitelist", i.e. the trace starts as soon as the current status message takes on the state predefined here.

One or more matches will be necessary depending on the selection of the relevant hysteresis status bits and logical connective operators.

Selecting the relevant hysteresis status bits

Name:
cfgComp_EnableMask

This register selects which status bits of the hysteresis comparison should be used to generate the trigger.

For more information about using this register, see 4.3.15.10.8.9 "Comparator for trigger conditions".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
1	Channel01 InRange status in the current cycle	0	Do not use
		1	Use for generation
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Do not use
		1	Use for generation
7	Channel04 InRange status in the current cycle	0	Do not use
		1	Use for generation
8	Channel01 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
9	Channel01 InRange status in the last cycle	0	Do not use
		1	Use for generation
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Do not use
		1	Use for generation
15	Channel04 InRange status in the last cycle	0	Do not use
		1	Use for generation

Logical connective operators for hysteresis status bits

Name:
cfgComp_ConditionTypeMask

The desired state operators with which the respective status bit is linked to others to generate a trigger are selected in this register.

At least one OR operation must be configured, but it does not necessarily have to be located on a channel configured with "1" in the "Selecting the relevant hysteresis status bits" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel01 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
1	Channel01 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
...	...	...	
6	Channel04 hysteresis status in the current cycle	0	Use AND operation
		1	Use OR operation
7	Channel04 InRange status in the current cycle	0	Use AND operation
		1	Use OR operation
8	Channel01 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
9	Channel01 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation
...	...	...	
14	Channel04 hysteresis status in the last cycle	0	Use AND operation
		1	Use OR operation
15	Channel04 InRange status in the last cycle	0	Use AND operation
		1	Use OR operation

4.3.16.10.8.10 Time-offset trace

Additional conditions for shifting the starting and stopping points can be defined if the trace should be chronologically offset to the trigger.

Starting the trace

Name:
TraceTriggerStart

The starting position is defined relative to the configured trigger condition (rising/falling edge) in this register. Positive values mean that the trace takes place x samples after the trigger condition. Negative values mean that the trace takes place x samples before the trigger condition.

The value -32768 performs the trace without regard for the configured trigger condition. If the trace memory is completely full, then the oldest recorded value is overwritten (FIFO principle).

"Trace start" in the I/O configuration or the registers 4.3.15.10.6.1 "Trigger condition on falling edge" and 4.3.15.10.6.2 "Trigger condition on rising edge" determine whether a positive, negative or any edge must be triggered.

Data type	Value
INT	-32768 to 32767

Stopping the trace

Name:
TraceTriggerStop

The stopping position is defined relative to the configured trigger condition in this register.

- When configuring an early trigger event, this value refers to the trigger event.
- When configuring a delayed trigger event, this value refers to the starting event.

Data type	Value
UINT	0 to 65535

4.3.16.10.9 Acyclic frame size

Name:
AsynSize

When the stream is used, data is exchanged internally between the module and CPU. For this purpose, a defined amount of acyclic bytes is reserved for this slot.
Increasing the acyclic frame size leads to increased data throughput on this slot.

Information:

This configuration involves a driver setting that cannot be changed during runtime!

Data type	Value	Information
-	8 to 28	Acyclic frame size in bytes. Default = 24

4.3.16.10.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Standard priority	200 µs
High priority with trace function	300 µs

4.3.16.10.11 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.17 X20AI4636

4.3.17.1 General information

The module is equipped with 4 inputs with 16-bit digital converter resolution. It is possible to select between the current and voltage signal using different terminal connections. With the oversampling function, up to 16 analog values per channel can be recorded.

- 4 analog inputs
- Current or voltage signal configuration for the entire module
- 16-bit digital converter resolution
- Minimum conversion time of 40 µs for all inputs
- The conversion time for the entire module can be configured in 0.02 µs steps.
- Maximum 14 samples (16-bit) for the entire module per X2X Link cycle
- Oversampling: Up to 16 analog values per channel (internal)
- Timestamp for the last conversion of an X2X Link cycle

4.3.17.2 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI4636	X20 analog input module, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oversampling functions	
	Required accessories

Spacing	12.5$^{+0.2}$ mm

Table 61: X20AI4636 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.
5) Based on the 20 mA measurement range.

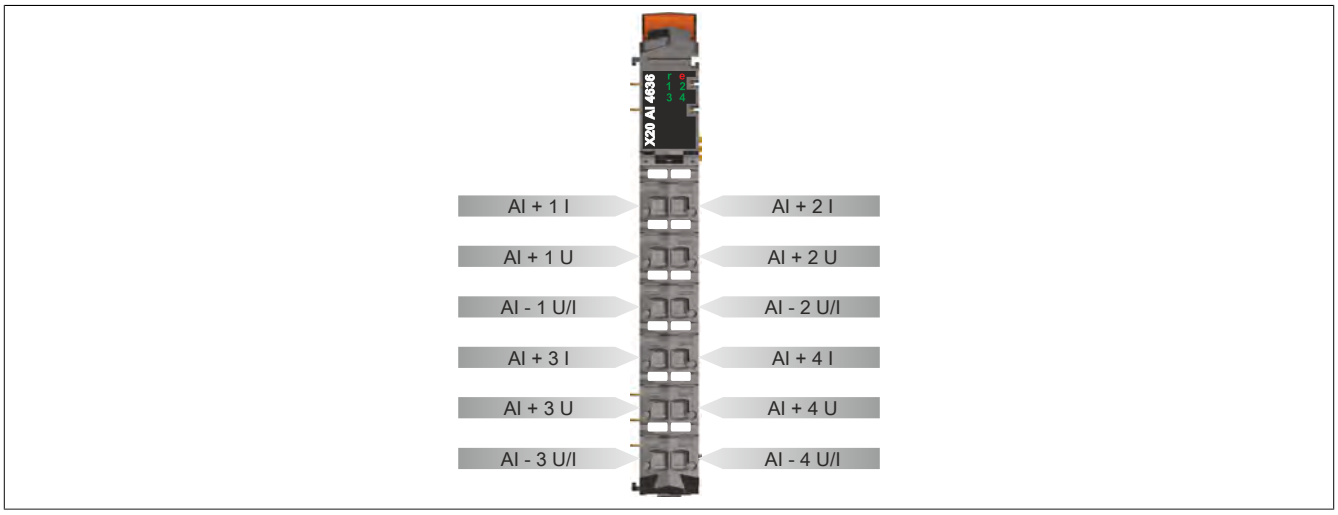
4.3.17.4 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)1)
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	System error: • Violation of the sampling cycle time • Synchronization error
		Green	Off	Open line2) or sensor is disconnected
			Blinking	Channel error: Underflow, overflow or broken connection
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Open line detection only possible when measuring voltage.

4.3.17.5 Pinout

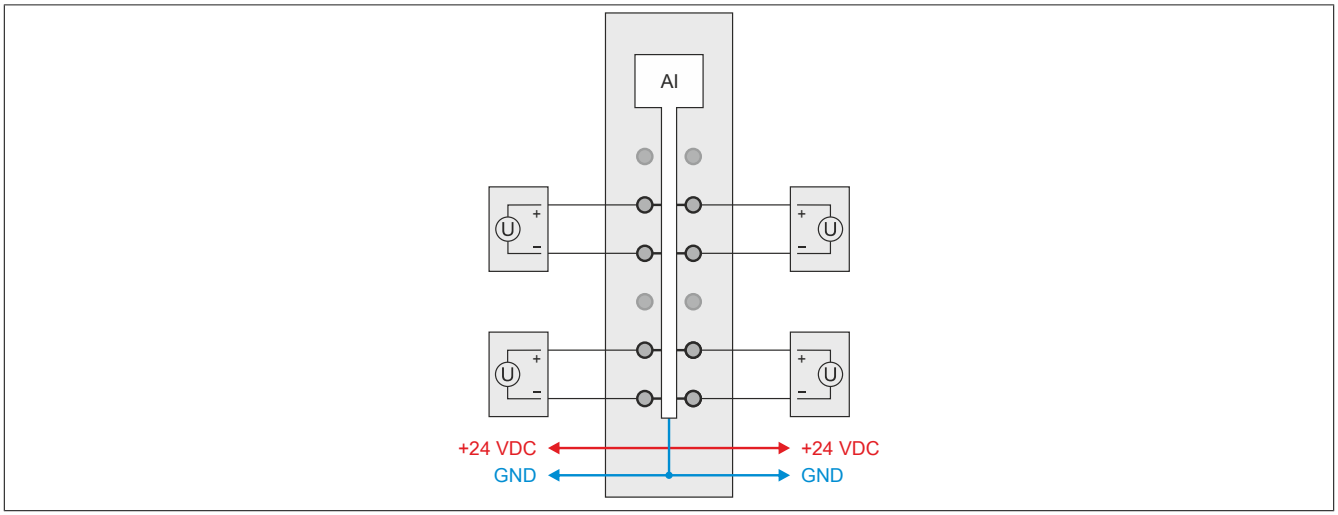


4.3.17.6 Connection example

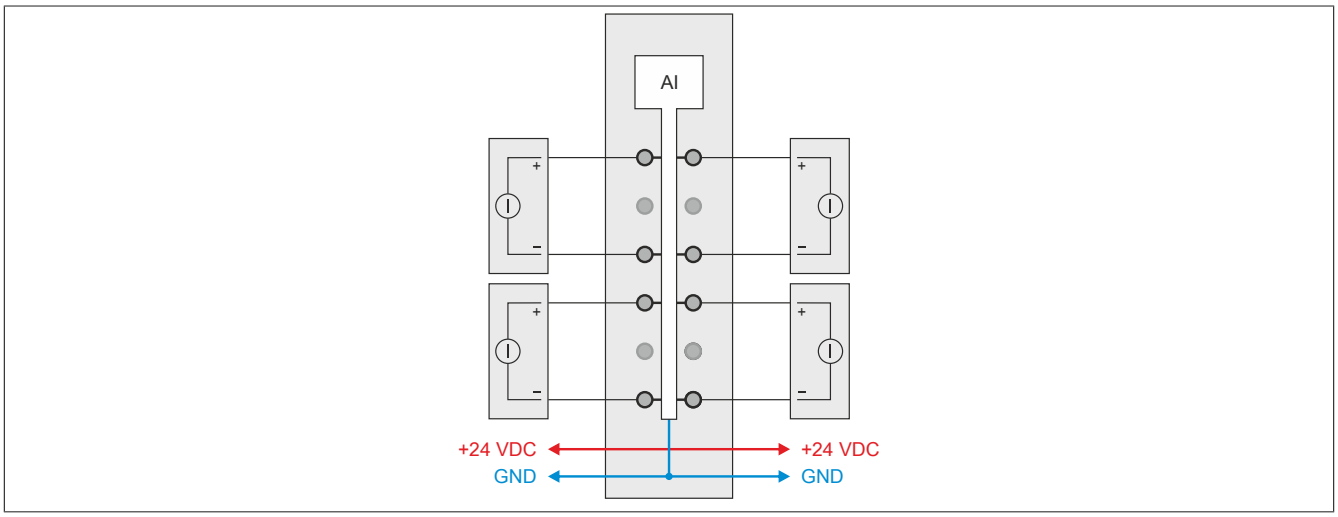
To prevent disturbances, the following modules must be separated by at least one module:

- Bus receiver X20BR9300
- Supply module X20PS3300/X20PS3310
- Supply module X20PS9400/X20PS9402
- Supply module X20PS9500/X20PS9502
- CPU modules

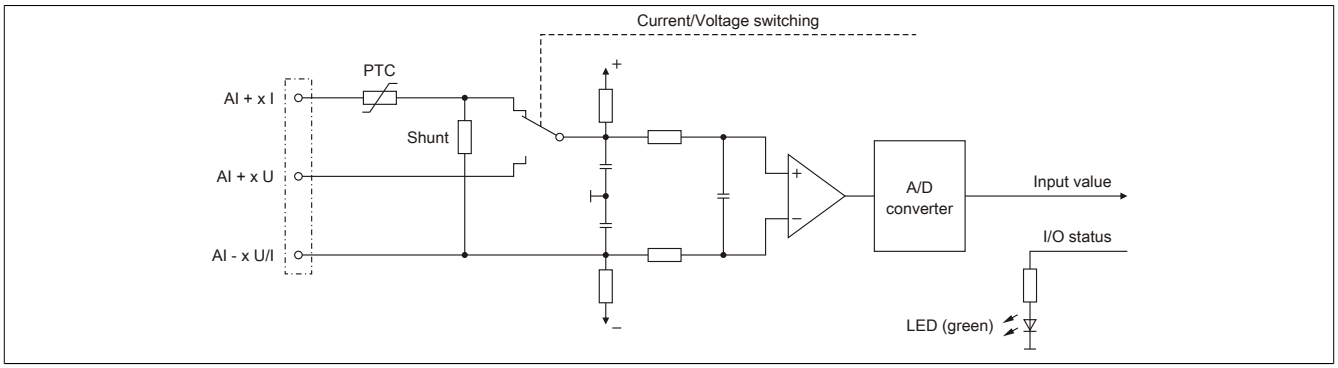
Voltage measurement



Current measurement



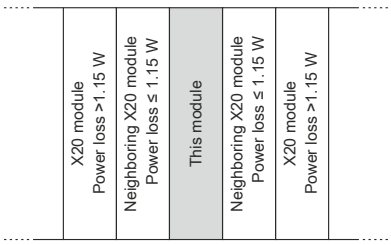
4.3.17.7 Input circuit diagram



4.3.17.8 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.3.17.9 Register description

4.3.17.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.17.9.2 Function model 0 - Standard

4.3.17.9.3 Function model 254 - Bus controller

The "Bus controller" function model has the following limitations compared to the "Standard" function model:

- No oversampling function since consistency is not possible when operating CAN-based bus controllers due to the limited data range
- The sampling cycle time is set to 100 µs.
- No timestamp function
- A range of logical functions is available for processing the physical values right on the module:
  - Output of physical values (standard)
  - Addition of two channels with scaling
  - Integral addition of two channels with scaling
  - Multiplication of two channels with scaling
  - Integral multiplication of two channels with scaling

1) The offset specifies the position of the register within the CAN object.

4.3.17.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.3.17.9.4 General information

There is a difference on the module between physical (default) and logical values:

Physical or default values
The conversion results are transferred to the higher-level system after being scaled and filtered. They are not processed further.

Logical values
The physical values can be further processed with mathematical functions and comparators. In addition, another logical channel can be used as a starting point to further process a logical function.

4.3.17.9.5 Operating mode - Oversampling

The input values are recorded with a configurable sampling cycle time and saved with timestamp to the internal physical data buffer. This data range can then be read out in the cyclic data transfer using a configurable data length.

The recording and transmission system for the logical channels is identical to that for the physical channels. The functions of the logical channels are also executed in the configured sampling cycle time and saved with timestamp to the logical data buffer. The values can also be read out from here using configurable cyclic data points.

The defined sampling cycle time may not be sufficient for the sum of all physical and logical functions if using fast X2X Link cycle times, however. If influencing the physical sampling is not permitted, then a prescaler can be used to slow down the logical processing.

Information:

The ability to adjust the sampling cycle time as needed on the module means there is basically no synchronization with X2X Link, regardless of whether standard inputs or an oversampling function is configured.

If synchronization is required, then the configured sampling cycle time must be a multiple of the X2X Link cycle time!

4.3.17.9.5.1 Analog oversampling

When using analog oversampling, the enabled channels are stored in the module within a configurable time frame independently of the X2X cycle. Space is available for 16 analog values per physical and logical channel.

These samplings are are numbered from 1 to 16 for the registers. The conversions or calculations of individual channels with the same number (i.e. sample line 1 to 16, e.g. PhysCh01Sample**10**, PhysCh02Sample**10**, etc.) are derived from the same sampling cycle or logical computing cycle and therefore have the same timestamp.

The timestamp refers to the newest data value, i.e. always to sample line 1. If a timestamp for older data points is needed, it needs to be back-calculated in the application using the sampling cycle time configured on the module. The prescaler must also be taken into account for logical channels.

Calculation example

Sample line	Calculation	
1	Timestamp	**Newest value**
2	Timestamp - Sampling cycle time	
3	Timestamp - 2 * Sampling cycle time	
4	Timestamp - 3 * Sampling cycle time	
...	...	
10	Timestamp - 9 * Sampling cycle time	
...	...	
16	Timestamp - 15 * Sampling cycle time	**Oldest value**

How the buffer is organized can be seen from this. This is not a FIFO buffer but a static buffer that the values are pushed through. Sample line 1 always contains the newest values, the next line the second newest, all the way up to sample line 16, which contains the oldest values.

The sample counter is a circular counter, with the number of new sample lines derived from the value of the last transfer cycle.

Example

A difference of 3 to the last transfer cycle means:

The data in sample line 1 and all subsequent data from the previous transfer cycle is now shifted in the current cycle beginning with sample line 4. Sample lines 1 through 3 contain the new values for further processing by the application. Sample lines 14 through 16 from the last transfer cycle are no longer in the buffer.

4.3.17.9.5.2 Comparator oversampling

When using comparator oversampling, the results of the enabled channels are stored in the module within a configurable time frame independently of the X2X cycle. 16 bits of memory space are available per logical channel.

These samplings (i.e. event bits) are consecutively numbered from 1 to 8 and 9 to 16 for the two registers. The results of individual channels with the same number (i.e. sample line 1 to 16, e.g. for channel 1 LogicCh01Sample**16_9** and LogicCh01Sample**8_1**) are derived from the same sampling cycle or logical computing cycle and therefore have the same timestamp.

The timestamp refers to the newest data value, i.e. always to sample line 1 (i.e. bit 0 in the LogicCh01Sample8_1 register). If a timestamp for older comparator results is needed, it needs to be back-calculated in the application using the sampling cycle time configured on the module. The prescaler must also be taken into account.

Calculation example

Sample line	(register name)	Calculation	
1	(LogicCh01Sample8_1 bit 0)	Timestamp	**Newest value**
2	(LogicCh01Sample8_1 bit 1)	Timestamp - Sampling cycle time	
3	(LogicCh01Sample8_1 bit 2)	Timestamp - 2 * Sampling cycle time	
4	(LogicCh01Sample8_1 bit 3)	Timestamp - 3 * Sampling cycle time	
...			
10	(LogicCh01Sample16_9 bit 1)	Timestamp - 9 * Sampling cycle time	
...			
16	(LogicCh01Sample16_9 bit 7)	Timestamp - 15 * Sampling cycle time	**Oldest value**

How the buffer is organized can be seen from this. This is not a FIFO buffer but a static buffer that the values are pushed through. Sample line 1 always contains the newest values, the next line the second newest, all the way up to sample line 16, which contains the oldest values.

The sample counter is a circular counter, with the number of new sample lines derived from the value of the last transfer cycle.

Example

A difference of 3 to the last transfer cycle means:

The comparator result in sample line 1 and all subsequent data from the previous transfer cycle is now shifted in the current cycle beginning with sample line 4. Sample lines 1 through 3 contain the new bit values for further processing by the application. Sample lines 14 through 16 from the last transfer cycle are no longer in the buffer.

Data transfer

The analog conversion rate / sampling cycle time can be considerably faster than the X2X Link cycle. Saved analog or comparator data can be transferred to the higher-level system synchronously and consistently.

In the application, it's important that the relationship between cyclic data points, the sampling cycle time on the module and the transfer time is sufficient to read all of the new data points on the higher-level system.

The sample counter can be used to check how many data values are actually new since the last transfer cycle. If the counter difference to the previous cycle is larger than the number of existing cyclic data points, then values have been overlooked and the system needs to be adjusted.

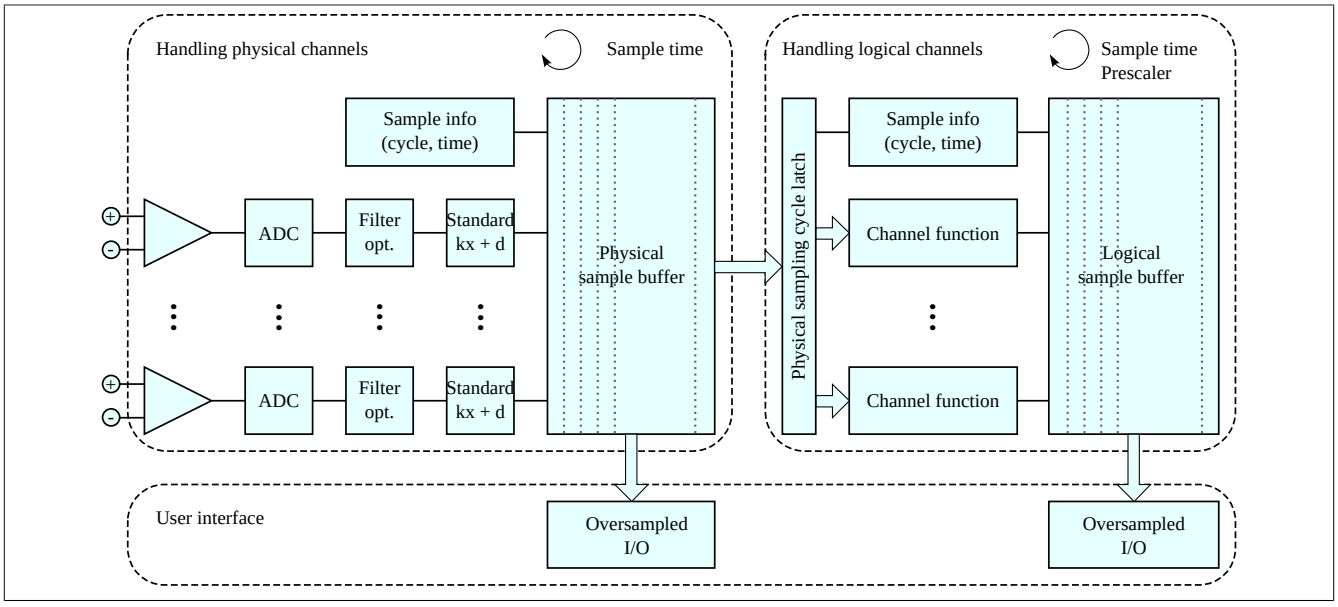
The general guideline is that a cyclic data point should be configured more than is actually required computing-wise.

Example with synchronous settings

- Sampling cycle time = 50 µs
- X2X Link cycle time = 500 µs

Samples 1 to 10 of a channel are possible to calculate in this example. Sample 11 should also be configured as a cyclic data point, however.
The reason for this is the possible jitter in the module caused by interruptions, e.g. from the X2X Link transfer. For the current cycle, this can mean that only 9 new values are available and that 11 values will have to be transferred in the next cycle.

For logical comparator functions, this problem doesn't exist since the maximum number is always transferred in the cycle data range.



4.3.17.9.6 Bus controller operating mode

The input values are recorded with a configurable sampling cycle time and saved with timestamp to the internal physical data buffer. Only the newest value will be transferred in the next possible bus cycle.

Limitations in the bus controller function model:

- No oversampling function since consistency is not possible due to the limited data range
- Sampling cycle time configured to 100 µs by default
- Range of logical functions available for processing physical values directly on the module
- Timestamp not available

4.3.17.9.7 "AnalogInput" registers

Name:
AnalogInput01 to AnalogInput04

This module can be configured and operated as a normal analog input module without logical auxiliary functions. The physical values from the last sampling cycle are used as input values in this case.

The module is operated as a normal analog input module in the bus controller function model. Nevertheless, it is still possible to connect each input channel directly to a logical function. The analog data on the bus controller is mapped using the calculation abilities of the logical channels and configured automatically (see 4.3.11.8.14.2 "Operation in the bus controller function model ").

Analog input values are displayed as signed 16-bit values depending on the configured operating mode.

Data type	Value	Information
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 mA to 20 mA

Information:

It is important to note that the oversampling function is not available in the bus controller function model due to the amount of data and lack of consistency!

4.3.17.9.8 Physical sampling

This module has a data buffer with 16 entries for each of the physical input channels. This buffer is processed according to the configured sampling cycle time.

A maximum of only 30 bytes is available for cyclic transfer on the X2X bus, however. Minus the status and sample counter, this allows only a selection of 14 samples (with a 16-bit data width) from the physical and logical buffer to be transferred.
Data loss can therefore occur with an imprecise selection and configuration.

Example

Displaying continuous sample lines.

- Sampling cycle time = 100 µs
- X2X cycle time = 500 µs

Sample line 1	PhysCh0xSample1
Sample line 2	PhysCh0xSample2
Sample line 3	PhysCh0xSample3
Sample line 4	PhysCh0xSample4
Sample line 5	PhysCh0xSample5
Sample line 6	PhysCh0xSample6
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 2	New values in sample line 1 and sample line 2
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5

Information:

It is important to note that the sample counter refers to the update of the sample lines in the data buffer and not to the number of values transferred cyclically.

Displaying each second sample line to bridge a higher recording duration:

- Sampling cycle time = 100 µs
- X2X cycle time = 1000 µs

Sample line 1	PhysCh0xSample1
Sample line 3	PhysCh0xSample3
Sample line 5	PhysCh0xSample5
Sample line 7	PhysCh0xSample7
Sample line 9	PhysCh0xSample9
Sample line 11	PhysCh0xSample11
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 3	New values in sample line 1 and sample line 3
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5
...	
Difference SampleCount = 9	New values in sample line 1 to sample line 9

4.3.17.9.8.1 "PhysChSample" registers

Name:
PhysCh01Sample1 to PhysCh01Sample16
...
PhysCh04Sample1 to PhysCh04Sample16

These registers are the physical buffer registers of the analog channels. 16 registers are available for each channel. Sample 1 is the newest value; sample 16 is the oldest.

Analog input values are displayed as signed 16-bit values.

Data type	Value	Information
INT	-32,768 to 32,767	Voltage signal ±10 VDC
	0 to 32,767	Current signal 0 mA to 20 mA

4.3.17.9.8.2 "PhysSampleCount" register

Name:
PhysSampleCount

This register is an integer counter that is increased as soon as the module has saved a new physical sample line. The number of new sample lines is calculated from the difference to the previous cycle.

Data type	Value
SINT	-128 to 127
INT	-32,768 to 32,767

4.3.17.9.8.3 "PhysTimestamp" register

Name:
PhysTimestamp

This register returns the timestamp of the values currently being determined as signed values in µs. This data point is the timestamp of the physical sample line 1.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.17.9.9 Logical sampling

The module has a data buffer with 16 entries for each of the 6 logical channels. This buffer is processed according to the configured sampling cycle time. In addition, it's also possible to adjust the logical execution cycle using a prescaler for the sampling cycle time.

A maximum of only 30 bytes is available for cyclic transfer on the X2X bus, however. Minus the status and sample counter, this allows only a selection of 14 samples (with a 16-bit data width) from the physical and logical buffer to be transferred. For the logical channels, it is also possible to configure a 32-bit data width.
Data loss can therefore occur with an imprecise selection and configuration.

Example

Displaying continuous sample lines.

- Sampling cycle time = 100 µs
- X2X cycle time = 500 µs

Sample line 1	LogicCh0xSample1
Sample line 2	LogicCh0xSample2
Sample line 3	LogicCh0xSample3
Sample line 4	LogicCh0xSample4
Sample line 5	LogicCh0xSample5
Sample line 6	LogicCh0xSample6
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 2	New values in sample line 1 and sample line 2
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5

Information:

It is important to note that the sample counter refers to the update of the sample lines in the data buffer and not to the number of values transferred cyclically.

Displaying each second sample line to bridge a higher recording duration:

- Sampling cycle time = 100 µs
- X2X cycle time = 1000 µs

Sample line 1	LogicCh0xSample1
Sample line 3	LogicCh0xSample3
Sample line 5	LogicCh0xSample5
Sample line 7	LogicCh0xSample7
Sample line 9	LogicCh0xSample9
Sample line 11	LogicCh0xSample11
Difference SampleCount = 1	New value in sample line 1
Difference SampleCount = 3	New values in sample line 1 and sample line 3
...	
Difference SampleCount = 5	New values in sample line 1 to sample line 5
...	
Difference SampleCount = 9	New values in sample line 1 to sample line 9

4.3.17.9.9.1 "LogicChSample8_1" registers

Name:
LogicCh01Sample8_1 to LogicCh06Sample8_1

These registers are used to represent the results of samples 1 to 8 of the logical digital comparator for the logical channels. Each of these bits corresponds to a sample line, with sample 1 the newest and Sample 8 the oldest comparator comparison. The results of samples 9 to 16 are represented in 4.3.11.8.9.2 ""LogicChSample16_9" registers".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator result	x	Sample 1
...	...		
7	Comparator result	x	Sample 8

4.3.17.9.9.2 "LogicChSample16_9" registers

Name:
LogicCh01Sample16_9 to LogicCh06Sample16_9

These registers are used to represent the results of samples 9 to 16 of the logical digital comparator for the logical channels. Each of these bits corresponds to a sample line, with sample 9 the newest and Sample 16 the oldest comparator comparison. The results of samples 1 to 8 are represented in 4.3.11.8.9.3 ""LogicChSample8_1" registers".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator result	x	Sample 9
...	...		
7	Comparator result	x	Sample 16

4.3.17.9.9.3 "LogicChSample" registers

Name:
LogicCh01Sample1 to LogicCh01Sample16
...
LogicCh06Sample1 to LogicCh06Sample16

These registers are the buffer registers of the logical input channels. 16 registers are available for each channel. Sample 1 is the newest value; sample 16 is the oldest.

Calculated values are displayed as signed 16- or 32-bit values depending on the register being used.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.17.9.9.4 "LogicSampleCount" register

Name:
LogicSampleCount

This register is an integer counter that is increased as soon as the module has saved a new logical sample line. The number of new sample lines is calculated from the difference to the previous cycle.

Data type	Value
SINT	-128 to 127
INT	-32,768 to 32,767

4.3.17.9.9.5 "LogicTimestamp" register

Name:
LogicTimestamp

This register returns the timestamp of the values currently being determined as signed 2 or 4-byte values in µs. This data point is the timestamp of the logical sample line 1.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.3.17.9.10 System configuration

The following registers are used to configure the module's system settings.

4.3.17.9.10.1 Register "CfO_BaseConfig"

Name:
CfO_BaseConfig

This register can be used to configure settings for handling logical oversampling and data acquisition.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	"Display configuration for logical values active/inactive" in the AS I/O configuration	0	Inactive
		1	Active
1	"Logical handling priority" in the AS I/O configuration	0	Low
		1	High
2 - 3	Reserved	-	
4	"Physical input mode" in the AS I/O configuration	0	Newest value
		1	Referenced value (reference = prescaled system timer)
5	"Logical input mode" in the AS I/O configuration	0	Newest value
		1	Referenced value (reference = prescaled system timer)
6 - 7	Reserved	-	

Priority of logical oversampling

- Low priority setting
  Logical and physical buffers are not processed in the same context. If the calculation time that results in the logical oversampling is higher than the configured sampling cycle time, this setting and a prescaler > 1 can be used to split up the logical processing over several sampling cycles. In this way, the sample lines of the physical and logical oversampling are not automatically acquired or calculated at the same point in time. If the prescaler is configured incorrectly, the logical oversampling cannot be processed successfully.
- High priority setting
  Logical and physical buffers are processed in the same context. The sample lines of the physical and logical oversampling are acquired and calculated at the same point in time. It must be possible to execute all configured functions in the configured sampling cycle time; otherwise, a cycle time violation will occur and the configuration must be changed accordingly. Configuring the logical prescaler doesn't have any effect here; only the data traffic in the logical oversampling is limited.

Current or referenced values for logical or physical oversampling

In a system being used to capacity, jitter in the sampling cycle on the module can also be caused by the necessary processing of functions (X2X Link operation, logical and physical oversampling) when the cycle time is set to synchronous. This results in a varying number of sample lines in the same time period. For this reason, more samples should also be configured in the cyclic image than are actually necessary to compute.

- Current values setting
  Passing on the sample lines to the higher-level system takes place as quickly as possible, with fewer or more sample lines possibly occurring.
- Referenced values setting
  This setting minimizes jitter and makes it possible to expect a constant number of new sample lines per cycle when configured optimally. With regard to response time, however, delays of several sampling cycles may occur.

4.3.17.9.10.2 Register "CfO_CycleTime"

Name:
CfO_CycleTime
"Physical sample time" in the AS I/O configuration.

This register configures the module's sampling cycle time. The format is a 16.16-bit unsigned 4-byte value, with the high word representing the integer part of the µs value and the low word the decimal places. The decimal places allow a closer alignment to the X2X cycle time. The absolute resolution is 1 µs.

Input value = Time in µs * 65536 data type

Data type	Value	Information
UDINT	2,621,440 to 2,147,483,647	40 µs to 32 ms sampling cycle time
	6,553,600	100 µs (default value)

4.3.17.9.10.3 Register "CfO_Prescaler"

Name:
CfO_Prescaler

This register contains the prescaler for configuring the logical channel processing time. The actual logical cycle time will be calculated from the multiple of the sampling cycle time that is defined here. If a very short sampling cycle time is required for physical samples, then the module load can be reduced using the second time base for the logical samples.

Data type	Value	Information
UINT	1 to 10	Multiple of the physical sampling cycle for logical processing
	0	Default value in the standard function model
	2	Default value in the bus controller function model

4.3.17.9.10.4 Register "CfO_SyncOffset"

Name:
CfO_SyncOffset
"Synchronization offset" in the AS I/O configuration.

The system cycle can be offset in 1 µs steps in this register.

Data type	Value	Information
UINT	-32,768 to 32,767	Synchronization offset in µs (default = 0)

4.3.17.9.11 Scaling

Analog input channels are naturally aligned and normalized when delivered (gain = k; offset = d). In addition, user-defined standardization is also available (gain = ku, offset = du). The calculation is optimized by grouping the factors together.

Normalization calculation:

nom = k * RawValue + d

k = k * ku

d = k * d + du

The values calculated here are limited to 16 bits.

4.3.17.9.11.1 "CfO_UserGainCh" registers

Name:
CfO_UserGainCh01 to CfO_UserGainCh04
"Configuration channel 0x / gain" in the AS I/O configuration

These registers are used to configure the gain for the respective channel. The format is a 16.16-bit signed 4-byte value, with the high word the integer part and the low word the decimal places.

Input value = Gain ku * 65536

The value 0x10000 corresponds to a gain of 1.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Gain
	65,535	= 1 (default value)

4.3.17.9.11.2 "CfO_UserOffsetCh" registers

Name:
CfO_UserOffsetCh01 to CfO_UserOffsetCh04
"Configuration channel 0x / offset" in the AS I/O configuration

These registers are used to configure the offset for the respective channel. The format is a 16.16-bit signed 4-byte value, with the high word the integer part and the low word the decimal places.

Input value = Offset du * 65536

The value 0x10000 corresponds to an offset of 1.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	Offset (default = 0)

4.3.17.9.12 Input filter

This module is equipped with an individually configurable input filter for each channel. The following filters can be selected:

- 1st-order low pass
- 2nd-order low pass
- 2nd-order IIR

The cutoff frequency can be configured for the 1st-order and 2nd-order low pass filters. The coefficients Alpha0, Alpha1, Alpha2, Beta1 and Beta2 must be configured for the IIR filter.

4.3.17.9.12.1 "CfO_CutOffFrequCh" register

Name:
CfO_CutOffFrequCh01 to CfO_CutOffFrequCh04

These registers are used to configure the limit frequency in hertz for a 1st- or 2nd-order low pass for the corresponding channel.

Data type	Value	Information
UINT	0 to 65535	Limit frequency for 1st- or 2nd-order low pass [Hz] (default = 0)

4.3.17.9.12.2 "CfO_AlphaCh" and "CfO_BetaCh" registers

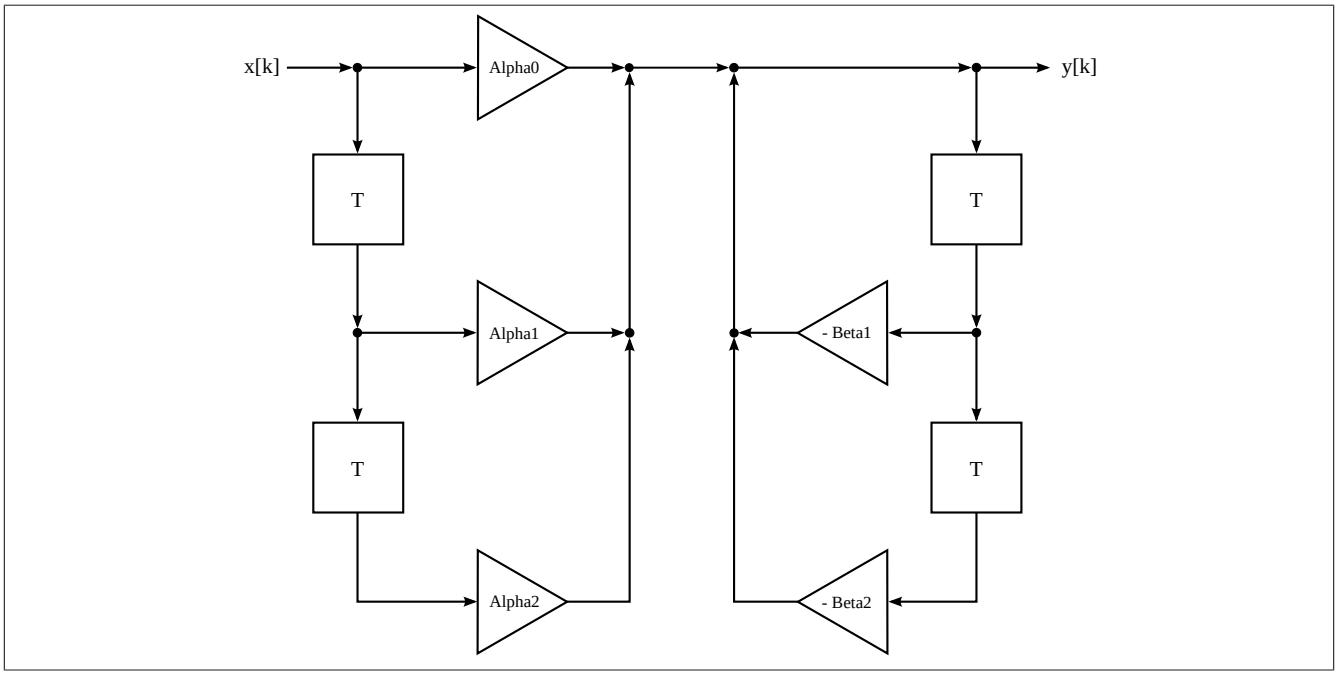
Name:
CfO_Alpha0Ch01 to CfO_Alpha0Ch04
CfO_Alpha1Ch01 to CfO_Alpha1Ch04
CfO_Alpha2Ch01 to CfO_Alpha2Ch04
CfO_Beta1Ch01 to CfO_Beta1Ch04
CfO_Beta1Ch01 to CfO_Beta1Ch04

These registers are used to configure the coefficients for the IIR filter.

Image as a z-transfer function

The 2nd-order z-transfer function is specified in coefficient form (denominator polynomial Beta1, Beta2 and numerator polynomial Alpha0, Alpha1, Alpha2). The transfer method is calculated with the sampling cycle time.

$$S(Z) = \frac{a(Z)}{b(Z)} = \frac{Alpha0 + Alpha1 * Z^{-1} + Alpha2 * Z^{-2}}{1 + Beta1 * Z^{-1} + Beta2 * Z^{-2}}$$



Data type	Value	
DINT	-2,147,483,648 to 2,147,483,647	IIR filter coefficient (default = 0)

4.3.17.9.13 Physical configuration

4.3.17.9.13.1 "CfO_ModeCh" registers

Name:
CfO_ModeCh01 to CfO_ModeCh04

The operating mode for each physical channel can be configured in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Connection configuration **This value must be set the same for each register!**	000	Voltage signal
		111	Current signal
3 - 7	Reserved	0	
8 - 10	Operating mode	000	Channel disabled
		001	No filtering
		010	2nd-order IIR (configurableAlpha and Beta coefficients)
		011	1st-order low pass (configurable limit frequency)
		100	2nd-order low pass (configurable limit frequency)
		101 to 111	Reserved
11 - 15	Reserved	0	

4.3.17.9.14 Logical configuration

4.3.17.9.14.1 Operation in the standard function model

6 logical channels are available on the module. Each channel can be configured with one of the following functions:

- Addition of two channels with scaling
- Integral addition of two channels with scaling
- Multiplication of two channels with scaling
- Integral multiplication of two channels with scaling
- Comparator function of two channels
- Hysteresis comparator of one channel

With logical oversampling, 32-bit data points are available in addition to 16-bit data points due to the possible calculated results. The AS I/O configuration or data point mapping can be opened to select which one to use.

If there is no need to use 32-bit data points, or if this would lead to too large of a limitation in the number of data points, scaling can be used to limit the range to 16 bits.

The buffer depth for the digital comparator is also able to handle 16 results. Since these are Boolean results, these 16 bits are compressed into 2-byte data points and transferred that way.

Addition

This function can be used to determine the sum or difference of two channels. To determine the difference, negative scaling needs to be configured for the channel.

Calculation

Sample line = (Channel 1 * Scaling 1) + (Channel 2 * Scaling 2)

The addition calculation is handled internally as a 32-bit value in 16.16 format; the data from the source channels is evaluated as integers (applied to the high word), with decimal places possible as a result of scaling. When displayed as a logical 32-bit result, these decimal places are visible. When displayed as a 16-bit value, only the integral high word is used.

Example

Channel 1 = 2000
Channel 2 = 1000
Both scalings = 1

Results

3000.x = (2000.x * 1,0) + (1000.x * 1.0)
32-bit representation = 196608000 = 0xBB80000
16-bit representation = 3000 = 0xBB8

Information:

The maximum value channel 1 can take on is 32767; otherwise, an addition overflow occurs. If values greater than 32767 are possible, the value range must be limited with scaling.

Integral of addition

This function can be used in the application to establish the average value of the channels or to calculate the deviation/difference between two channels over n samples. In each cycle, the channels are added together first; then the result is added to the previous value and saved in the current sample line. Depending on the result data type being used (16-bit or 32-bit), eventually the continuous integration will cause the calculation to overflow after n samples. Because the result value is signed, it is important to set the number n of samples small enough so that the integration is less than half of the value range. If this is done, determining the average value can be carried out despite an overflow.

Calculation

Sample line result = Integral ((Channel 1 * Scaling 1) + (Channel 2 * Scaling 2))

The addition calculation is handled internally as a 32-bit value in 16.16 format; the data from the source channels is evaluated as integers (applied to the high word), with decimal places possible as a result of scaling. When displayed as a logical 32-bit result, these decimal places are visible. When displayed as a 16-bit value, only the integral high word is used.

Example

Channel 1 = 2000
Channel 2 = 1000
Both scalings = 1

Results

3000.x = (2000.x * 1,0) + (1000.x * 1.0)
32-bit representation = 196608000 = 0xBB80000
16-bit representation = 3000 = 0xBB8

The average value can now be calculated as follows:

n = Number of samples / sample lines
$Value_x$ = Value from sample line x → Newer value
$Value_x$ = Value from sample line x → Older value, n samples back

Average value = $(Value_x - Value_{(x-n)}) / n$

Information:

The maximum value channel 1 can take on is 32767; otherwise, an addition overflow occurs. If values greater than 32767 are possible, the value range must be limited with scaling.

Multiplication

This function can be used to calculate the current effective power P = U * I.

Calculation

Sample line = Channel 1 * Channel 2 * Scaling

Multiplication is calculated internally as a 32-bit value; the 16-bit data from the source channels is passed to the low word. When displayed as a logical 32-bit value, the entire result is visible (no multiplication overflow possible when scaling ≤1). When displayed as a 16-bit value, only the high word is used. Though there is a loss of precision, the 16-bit values allow more data points to be transferred.

Example

Channel 1 = 2000
Channel 2 = 1000
Scaling = 1

Results

2000000 = (2000 * 1000 * 1.0)
32-bit representation = 2000000 = 0x1E8480
16-bit representation = 30 = 0x1E

Information:

If more precision is needed with the 16-bit value, scaling in steps of 2^n (..., *128, *256, ...) can be employed to shift the bits. Of course, it's important again that the input values of the source channels be limited; otherwise, an overflow will occur in the multiplication operation.

Integral of multiplication

This function can be used in the application to establish the average value of the effective power. In each cycle, the channels are multiplied together first; then the result is added to the previous value and saved in the current sample line. Depending on the result data type being used (16-bit or 32-bit), eventually the continuous integration will cause the calculation to overflow after n samples. Because the result value is signed, it is important to set the number n of samples small enough so that the integration is less than half of the value range. If this is done, determining the average value can be carried out despite an overflow.

Calculation

Sample line = Integral (Channel 1 * Channel 2 * Scaling)

Multiplication is calculated internally as a 32-bit value; the 16-bit data from the source channels is passed to the low word. When displayed as a logical 32-bit value, the entire result is visible (no multiplication overflow possible when scaling ≤1). When displayed as a 16-bit value, only the high word is used. Though there is a loss of precision, the 16-bit values allow more data points to be transferred.

Example

Channel 1 = 2000
Channel 2 = 1000
Scaling = 1

Results

2000000 = (2000 * 1000 * 1.0)
32-bit representation = 2000000 = 0x1E8480
16-bit representation = 30 = 0x1E

The average value can now be calculated as follows:

n = Number of samples / sample lines
$Value_x$ = Value from sample line x → Newer value
$Value_x$ = Value from sample line x → Older value, n samples back

Average value = $(Value_x - Value_{(x-n)}) / n$

Information:

If more precision is needed with the 16-bit value, scaling in steps of 2^n (..., *128, *256, ...) can be employed to shift the bits. Of course, it's important again that the input values of the source channels be limited; otherwise, an overflow will occur in the multiplication operation.

Channel comparator

This function can be used to compare channel values. The following applies:

- Channel 1 > Channel 2 = 1
- Channel 1 < Channel 2 = 0
- Channel 1 = Channel 2 = State before values are the same

Calculation

Sample line (bit) = Comparison (channel value 1 with channel value 2)

Hysteresis comparator

This function can be used to monitor range violations by channels. The following applies:

- Channel > Upper threshold value = 1
- Channel < Lower threshold value = 0
- Channel within threshold = Value before occurrence

Calculation

Sample line (bit) = Comparison (channel value with lower threshold value) and (channel value with upper threshold value))

4.3.17.9.14.2 Operation in the bus controller function model

When used on the bus controller, there are 4 logical functions available for each of the analog input channels in addition to the physical value output. Each channel can be configured with one of the following functions:

- Output of physical values (default setting)
- Addition of two channels with scaling
- Integral addition of two channels with scaling
- Multiplication of two channels with scaling
- Integral multiplication of two channels with scaling
- Comparator function of two channels
- Hysteresis comparator of one channel

In contrast to the standard function model, oversampling and the two digital comparators are not supported. As a result, there is only one newly generated value per channel in each update cycle. Another difference is that there are only 4 logical calculation channels instead of 6.

The logical functions addition, integral of addition, multiplication and integral of multiplication do not differ from the standard function model in their configuration and function when operating on the bus controller.

Physical value display

The physical value display in the bus controller function model is initialized automatically and represents a special form of the logical function "Addition" with defined scaling factors.

Calculation

Result = Channel value
Formula used for addition: Result = (Channel value 1 * 1) + (Channel value 2 * 0)

Information:

In this function model, only the 4 physical input channels are available, and the scaling factors have defined values.

4.3.17.9.14.3 "CfO_LogChMode" register

Name:
CfO_LogCh01Mode to CfO_LogCh06Mode
"Logical configuration channel 0x / Addition" in the AS I/O configuration.
"Logical configuration channel 0x / Integral of addition" in the AS I/O configuration.
"Logical configuration channel 0x / Multiplication" in the AS I/O configuration.
"Logical configuration channel 0x / Integral of multiplication" in the AS I/O configuration.
"Logical configuration channel 0x / Channel comparator" in the AS I/O configuration.
"Logical configuration channel 0x / Hysteresis comparator" in the AS I/O configuration.
"Logical configuration channel 0x / Physical value display" in the AS I/O configuration.

The operating mode for each logical channel can be configured in this register.

The selection of the sources to be used for each logical channel is made using the register 4.3.17.9.14.4 "CfO_LogCh0NSource0x". Any additionally needed function parameters are configured in the 4.3.17.9.14.5 "CfO_LogCh0NFuncPar0x" registers. "N" stands for the logical channel to be used, while "x" stands for either the source or function 0 or 1.

The following links can be made:

- Addition: Result = (Source 0 * Function parameter 0) + (Source 1 * Function parameter 1)
- Integral of addition: Result = Σ(Source 0 * Function parameter 0) + (Source 1 * Function parameter 1)
- Multiplication: Result = Source 0 * Source 1 * Function parameter 0
- Integral of multiplication: Result = Σ(Source 0 * Source 1 * Function parameter 0)
- Channel comparator: Result = Comparison of source 0 with source 1
- Hysteresis comparator: Result = comparison of source 0 with (Lower threshold value = Function parameter 0) and (Upper threshold value = Function parameter 1)
- Physical value display: Result = (Source 0 * 1) + (Source 1 * 0)

Data type	Value	Information
UINT	0	Channel switched off (default)
	256	Addition or physical value display[1)]
	257	Integral of addition
	512	Multiplication
	513	Integral of multiplication
	768	Channel comparator
	1024	Hysteresis comparator

1) Only registers CfO_LogCh01Mode to CfO_LogCh04Mode are used for physical value display.

4.3.17.9.14.4 "CfO_LogChSource" register

Name:
CfO_LogCh01Source00 to CfO_LogCh06Source00
CfO_LogCh01Source01 to CfO_LogCh06Source01

These registers can be used to select the source registers for the operating mode of the logical channel configured in the register 4.3.17.9.14.3 "CfO_LogCh0NMode".
In the name, "Source00" stands for source register 0; "Source01" stands for source register 1.

In "Physical value display" mode, the same channel number is written to both source registers.

Data type	Value	Information
USINT	0	Physical channel 01
	...	...
	3	Physical channel 04
	8	Logical channel 01[1)]
	...	...
	13	Logical channel 06

1) Logical channels cannot be used in the bus controller function model.

4.3.17.9.14.5 "CfO_LogChFuncPar" register

Name:
CfO_LogCh01FuncPar00 to CfO_LogCh06FuncPar00
CfO_LogCh01FuncPar01 to CfO_LogCh06FuncPar01

These registers can be used to configure additional function parameters for the operating mode of the logical channel configured in the register 4.3.17.9.14.3 "CfO_LogCh0NMode".

The effect of the function parameters is different depending on the operating mode.

Operating mode	Parameter 1	Parameter 2
(Integral of) addition	Scaling factor	Scaling factor
(Integral of) multiplication	Scaling factor	-
Channel comparator	-	-
Hysteresis comparator	Upper threshold value	Lower threshold value
Output of physical values	Defined scaling factor = 65,536	Defined scaling factor = 0

The value 0x10000 (65,536) corresponds to a scaling or a threshold value of 1.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Scaling factor or threshold value
	0	Default
	65,536	1

4.3.17.9.15 Error registers

The registers for displaying and acknowledging errors are transferred either cyclically or acyclically depending on the function model.

4.3.17.9.15.1 "CfO_ErrorID1017" register

Name:
CfO_ErrorID1017
Automatic enabling by the AS I/O configuration.

This register can be used to enable standard error messages. The channels' composite errors are derived from the individual extended error status, e.g. overflow/underflow of the input range for the analog value. Oversampling error statuses result from a cycle time violation of the configured sampling cycle time.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Composite errors on channel 01	0	Error generation disabled
		1	Error generation enabled
...		...	
3	Composite errors on channel 04	0	Error generation disabled
		1	Error generation enabled
4	Physical sample error status	0	Error generation disabled
		1	Error generation enabled
5	Logical sample error status	0	Error generation disabled
		1	Error generation enabled
6 - 7	Reserved	0	

4.3.17.9.15.2 "CfO_ErrorID0x0x" register

Name:
CfO_ErrorID0007 (for channels 1 and 2)
CfO_ErrorID080F (for channels 3 and 4)
Automatic enabling in the AS I/O configuration by selecting "Extended error status information" and channel activation.

These registers can be used to enable extended error messages for analog channels 1 and 2 as well as channels 3 and 4. Meaning of individual bits:

- **Range exceeded violation (pos.):** The analog input signal is outside of the specified working range.
- **Filter error:** The configured filter theorem cannot be calculated (parameter error).
- **Underflow:** The input signal is less than the lower limit value.
- **Overflow:** The input signal is greater than the upper limit value.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1 or 3: Range exceeded violation (pos.)	0	Error generation disabled
		1	Range exceeded violation (pos.) enabled
1	Channel 1 or 3: Filter error	0	Error generation disabled
		1	Filter error enabled
2	Channel 1 or 3: Underflow	0	Error generation disabled
		1	Underflow enabled
3	Channel 1 or 3: Overrun	0	Error generation disabled
		1	Overflow enabled
4	Channel 2 or 4: Range exceeded violation (pos.)	0	Error generation disabled
		1	Range exceeded violation (pos.) enabled
5	Channel 2 or 4: Filter error	0	Error generation disabled
		1	Filter error enabled
6	Channel 2 or 4: Underflow	0	Error generation disabled
		1	Underflow enabled
7	Channel 2 or 4: Overrun	0	Error generation disabled
		1	Overflow enabled

4.3.17.9.15.3 "StandardErrors" registers

Name:
Channel01Error to Channel04Error
PhysicalError
LogicalError

Composite errors are mapped to this register.

All configured functions of the physical and logical oversampling must be able to be carried out in the configured sampling cycle time; otherwise, these error messages occur. Settings for processing priority and the prescaler can be used to additionally adjust the system for logical oversampling.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01Error	0	No error
		1	Composite errors on channel 1
...		...	
3	Channel04Error	0	No error
		1	Composite errors on channel 4
4	PhysicalError	0	No error
		1	Physical sample error status, sampling cycle time too short
5	LogicalError	0	No error
		1	Logical sample error status, sampling cycle time too short or prescaler configured too low

4.3.17.9.15.4 "AcknowledgeStandardErrors" registers

Name:
AckChannel01Error to AckChannel04Error
AckPhysicalError
AckLogicalError

Error messages from the 4.3.17.9.15.3 "StandardErrors" register can be acknowledged by setting the corresponding bits in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AckChannel01Error	0	No change
		1	Acknowledge error
...		...	
3	AckChannel04Error	0	No change
		1	Acknowledge error
4	AckPhysicalError	0	No change
		1	Acknowledge error
5	AckLogicalError	0	No change
		1	Acknowledge error

4.3.17.9.15.5 "ExtendedChannelErrorMessages" registers

Name:
Channel01OutOfRange to Channel04OutOfRange
Channel01FilterError to Channel04FilterError
Channel01Underflow to Channel04Underflow
Channel01Overflow to Channel04Overflow

The error states of the input channels are represented in these registers. Input channels 1 and 2 as well as 3 and 4 are each grouped together in one register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel01OutOfRange or Channel03OutOfRange	0	No error
		1	Range exceeded violation (pos.) occurred
1	Channel01FilterError or Channel03FilterError	0	No error
		1	Filter error occurred
2	Channel01Underflow or Channel03underflow	0	No error
		1	Underflow occurred
3	Channel01Overflow or Channel03Overflow	0	No error
		1	Overflow occurred
4	Channel02OutOfRange or Channel04OutOfRange	0	No error
		1	Range exceeded violation (pos.) occurred
5	Channel02FilterError or Channel04FilterError	0	No error
		1	Filter error occurred
6	Channel02Underflow or Channel04Underflow	0	No error
		1	Underflow occurred
7	Channel02Overflow or Channel04Overflow	0	No error
		1	Overflow occurred

4.3.17.9.15.6 "AcknowledgeExtendedChannelErrorMessages" registers

Name:
AckChannel01OutOfRange to AckChannel04OutOfRange
AckChannel01FilterError to AckChannel04FilterError
AckChannel01Underflow to AckChannel04Underflow
AckChannel01Overflow to AckChannel04Overflow

These registers can be used to acknowledge the error messages from the 4.3.17.9.15.5 "ExtendedChannelErrorMessages" registers by setting the corresponding bit. The acknowledgment of input channels 1 and 2 as well as 3 and 4 are each grouped together in one register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	AckChannel01OutOfRange or AckChannel03OutOfRange	0	No change
		1	Acknowledge error
1	AckChannel01FilterError or AckChannel03FilterError	0	No change
		1	Acknowledge error
2	AckChannel01Underflow or AckChannel03Underflow	0	No change
		1	Acknowledge error
3	AckChannel01Overflow or AckChannel03Overflow	0	No change
		1	Acknowledge error
4	AckChannel02OutOfRange or AckChannel04OutOfRange	0	No change
		1	Acknowledge error
5	AckChannel02FilterError or AckChannel04FilterError	0	No change
		1	Acknowledge error
6	AckChannel02Underflow or AckChannel04Underflow	0	No change
		1	Acknowledge error
7	AckChannel02Overflow or AckChannel04Overflow	0	No change
		1	Acknowledge error

4.3.17.9.16 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.17.9.17 Minimum I/O update time

There is no limitation or dependency on the bus cycle time.

The I/O update time is defined using the "Sampling time" register. The fastest possible sampling time depends on the number of channels to be converted and the configuration.

4.3.18 X20AI8221

4.3.18.1 General information

The module is equipped with 8 inputs with 13-bit (including sign) digital converter resolution. It can be used to capture voltage signals in the range from ±10 V.

- 8 analog inputs ±10 V
- 13-bit digital converter resolution

4.3.18.2 Order data

Model number	Short description	Figure
	Analog inputs	
X20AI8221	X20 analog input module, 8 inputs, ±10 V, 13-bit converter resolution	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB1F	X20 terminal block, 16-pin, 24 VDC keyed	

Table 62: X20AI8221 - Order data

4.3.18.3 Technical data

Product ID	X20AI8221
Short description	
I/O module	8 analog inputs ±10 V
General information	
B&R ID code	0xD82F
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Inputs	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.04 W [1]
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [2]	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Analog inputs	
Input	±10 V
Input type	Differential input
Digital converter resolution	±12-bit
Conversion time	1 ms for all inputs
Output format	
Data type	INT
Voltage	INT 0x8001 - 0x7FFF / 1 LSB = 0x0008 = 2.441 mV
Input impedance in signal range	20 MΩ
Input protection	Protection against wiring with supply voltage
Open line detection	Yes, using software
Reverse polarity protection	Yes
Permitted input signal	Max. ±30 V
Output of the digital value during overload	Configurable

Table 63: X20AI8221 - Technical data

Product ID	X20AI8221
Conversion procedure	SAR
Input filter	3rd-order low pass / cutoff frequency 1 kHz
Max. error at 25°C	
Gain	0.08% 3)
Offset	0.015% 4)
Max. gain drift	0.006 %/°C 3)
Max. offset drift	0.002 %/°C 4)
Common-mode rejection	
DC	70 dB
50 Hz	70 dB
Common-mode range	±12 V
Crosstalk between channels	-70 dB
Nonlinearity	<0.025% 4)
Isolation voltage between channel and bus	500 VDC, 1 min
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB1F terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 63: X20AI8221 - Technical data

1) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Based on the current measured value.
4) Based on the 20 V measurement range.

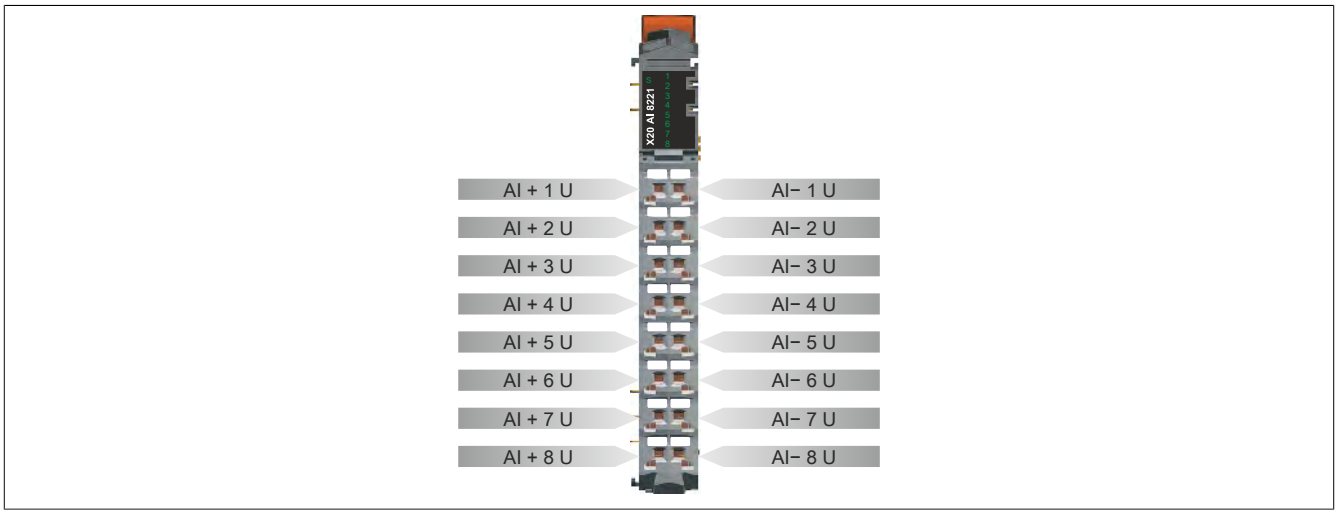
4.3.18.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

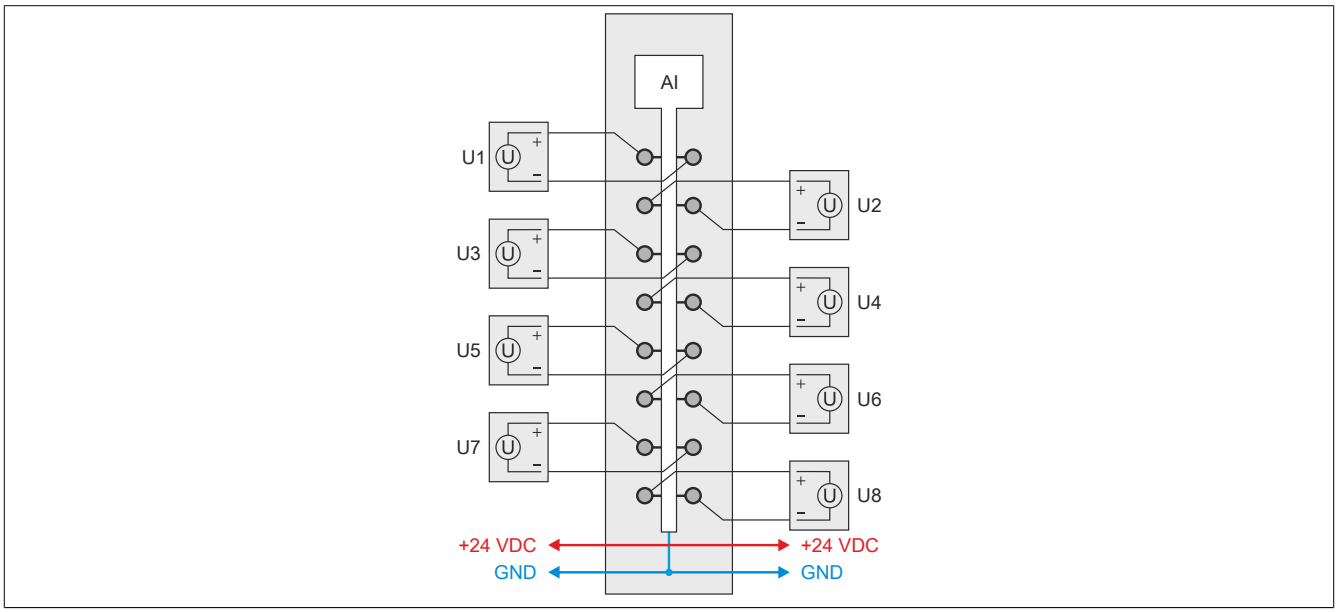
Figure	LED	Color	Status	Description
	S	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)1)
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	No power to module or everything OK
			On	Error or reset status
	1 - 8	Green	Off	Indicates one of the following cases: • No power to module • Open line
			Single flash	Input signal overflow or underflow
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

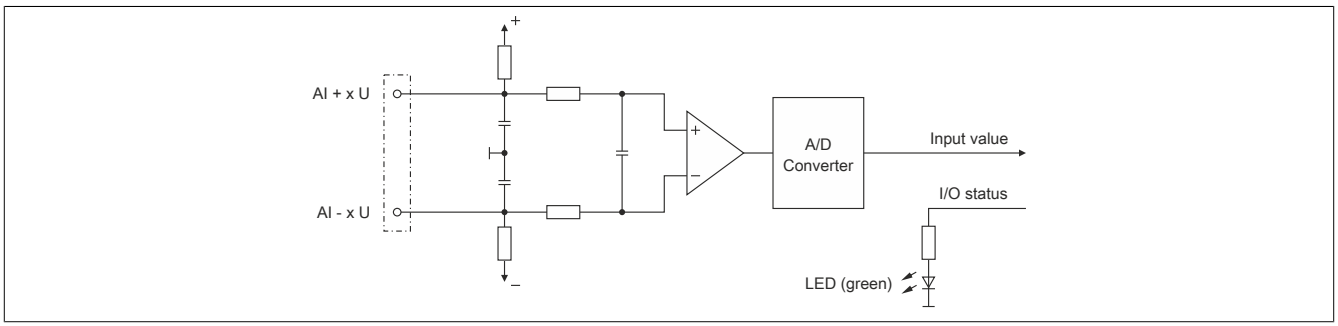
4.3.18.5 Pinout



4.3.18.6 Connection example



4.3.18.7 Input circuit diagram



4.3.18.8 Register description

4.3.18.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.18.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
16	Configuring the input filter	USINT				●
20	Lower limit value	INT				●
22	Upper limit value	INT				●
Analog signal - Communication						
Index * 2 - 2	AnalogInput0N (Index N = 1 to 8)	INT	●			
30	StatusInput01	USINT	●			
31	StatusInput02	USINT	●			

4.3.18.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
16	-	Configuring the input filter	USINT				●
20	-	Lower limit value	INT				●
22	-	Upper limit value	INT				●
Analog signal - Communication							
Index * 2 - 2	Index * 2 - 2	AnalogInput0N (Index N = 1 to 8)	INT	●			
30	-	StatusInput01	USINT		●		
31	-	StatusInput02	USINT		●		

1) The offset specifies the position of the register within the CAN object.

4.3.18.8.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.3.18.8.4 Analog inputs

Input signals are converted asynchronously in a 1 ms interval.

4.3.18.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput08

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	-32,768 to 32,767	Voltage signal -10 to 10 VDC

4.3.18.8.6 Input filter

This module is equipped with a configurable input filter.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

4.3.18.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

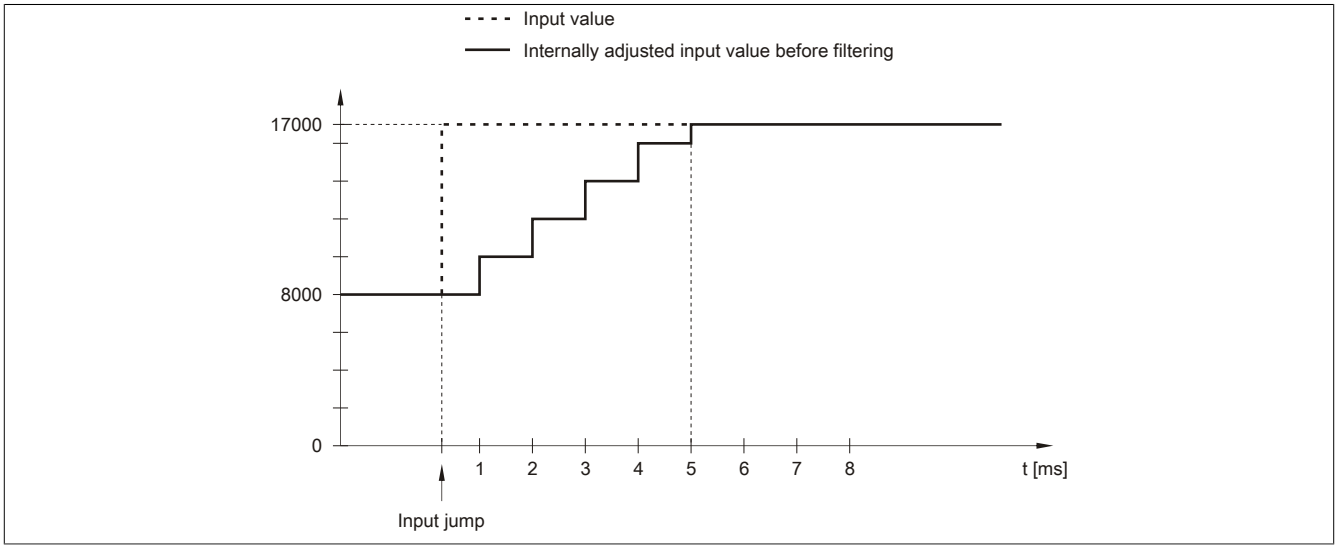


Figure 96: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

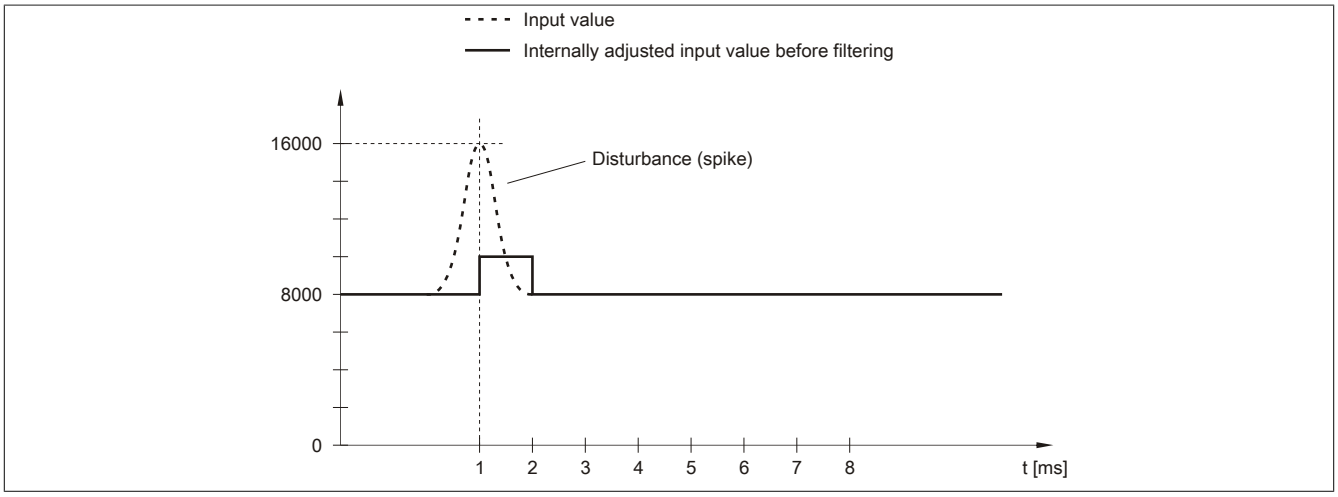

Figure 97: Adjusted input value for disturbance

4.3.18.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

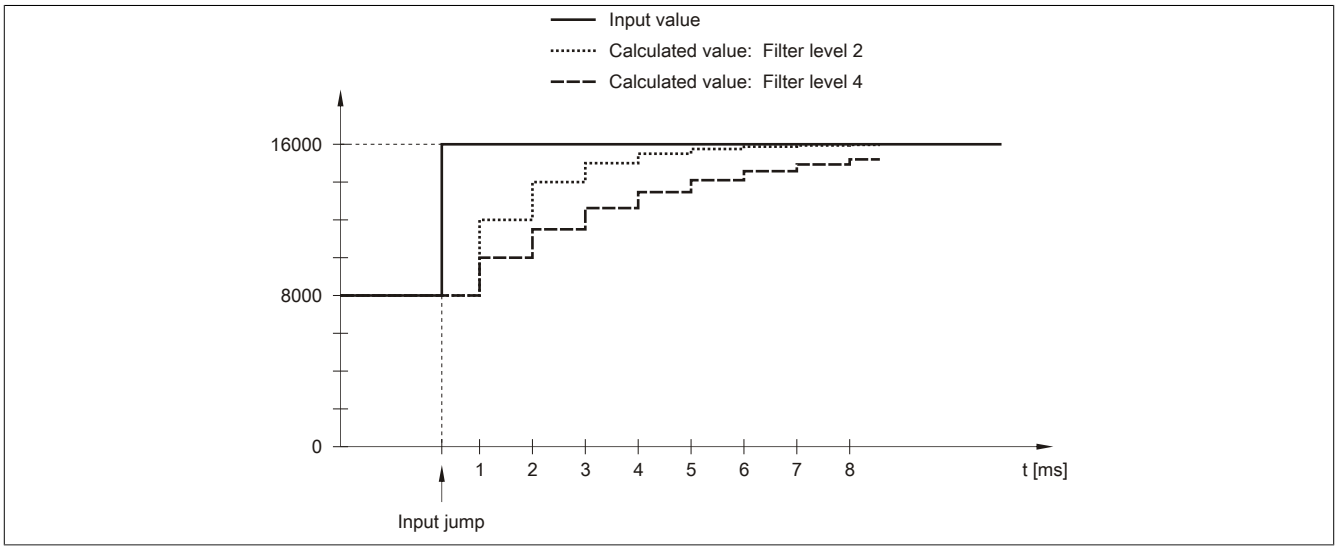

Figure 98: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

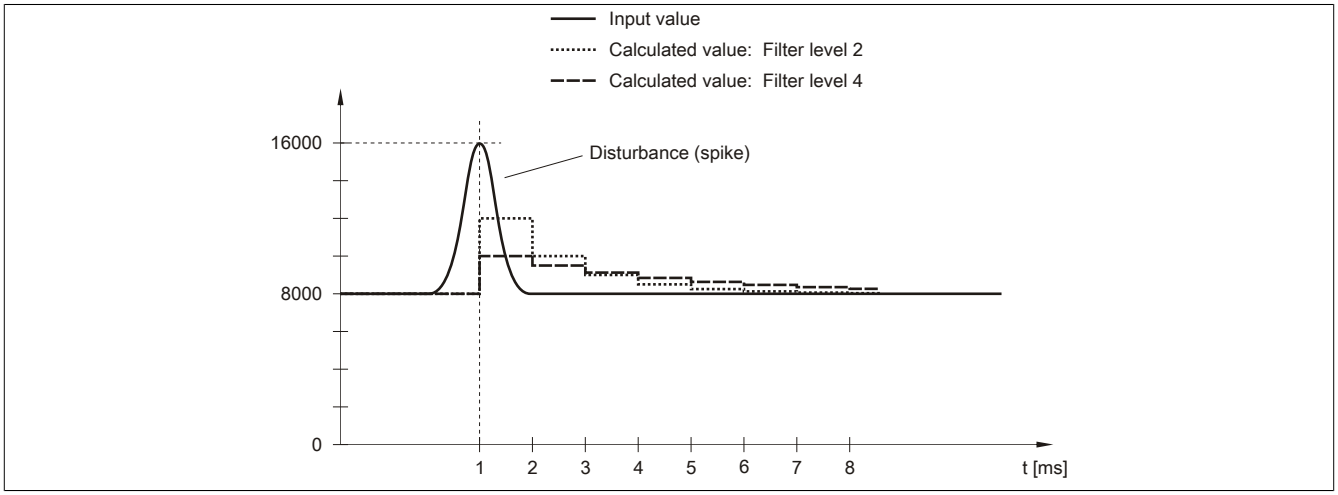

Figure 99: Calculated value during disturbance

4.3.18.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limitation	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7 - 15	Reserved	0	

4.3.18.8.8 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of -32768 corresponds to the minimum default value of -10 VDC.

Keep in mind that this setting applies to all channels!

4.3.18.8.9 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at +10 VDC.

Keep in mind that this setting applies to all channels!

4.3.18.8.10 Input status

Name:
StatusInput01 to StatusInput02

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

StatusInput01 monitors Channels 1 to 4
StatusInput02 monitors Channels 5 to 8

Bit	Description	Value	Information
0 - 1	Channel 1 or 5	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
...		...	
6 - 7	Channel 4 or 8	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

4.3.18.8.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.3.18.8.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.3.19 X20AI8321

4.3.19.1 General information

The module is equipped with 8 inputs with 12-bit digital converter resolution. It is possible to select between the two current ranges 0 to 20 mA and 4 to 20 mA.

- 8 analog inputs, 0 to 20 mA or 4 to 20 mA
- 12-bit digital converter resolution

4.3.19.2 Order data

1) The offset specifies the position of the register within the CAN object.

4.3.19.8.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.3.19.8.4 Analog inputs

Input signals are converted asynchronously in a 1 ms interval.

4.3.19.8.5 Analog input values

Name:
AnalogInput01 to AnalogInput08

The analog input values are mapped to this register.

Data type	Value	Input signal:
INT	0 to 32767	Current signal 0 to 20 mA or 4 to 20 mA

4.3.19.8.6 Input filter

This module is equipped with a configurable input filter.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

4.3.19.8.6.1 Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

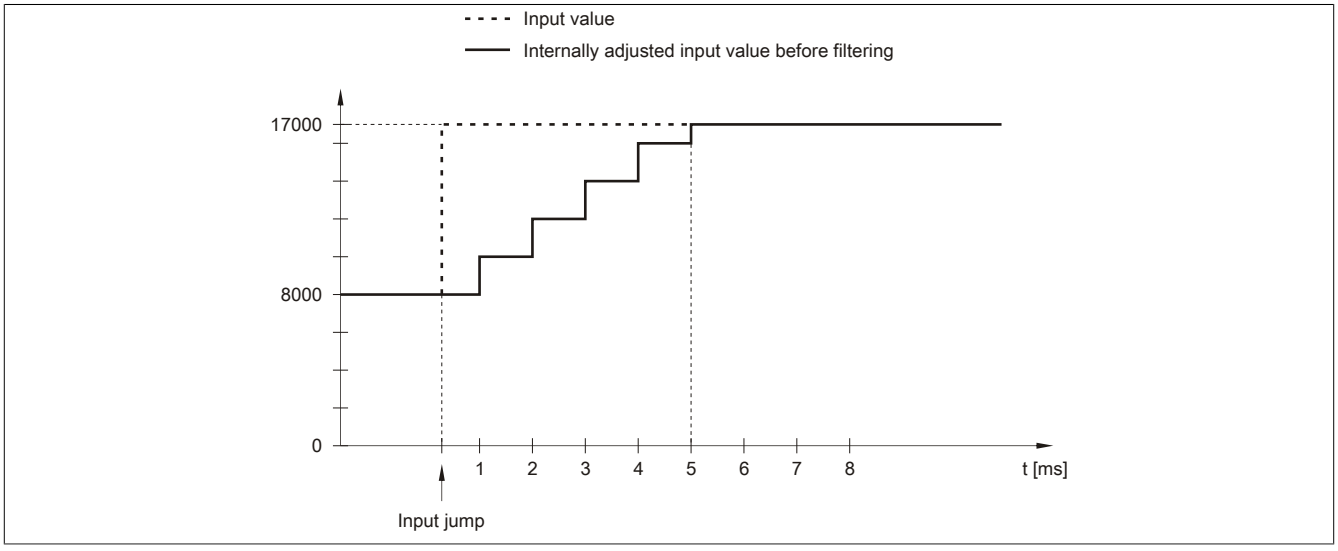

Figure 100: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

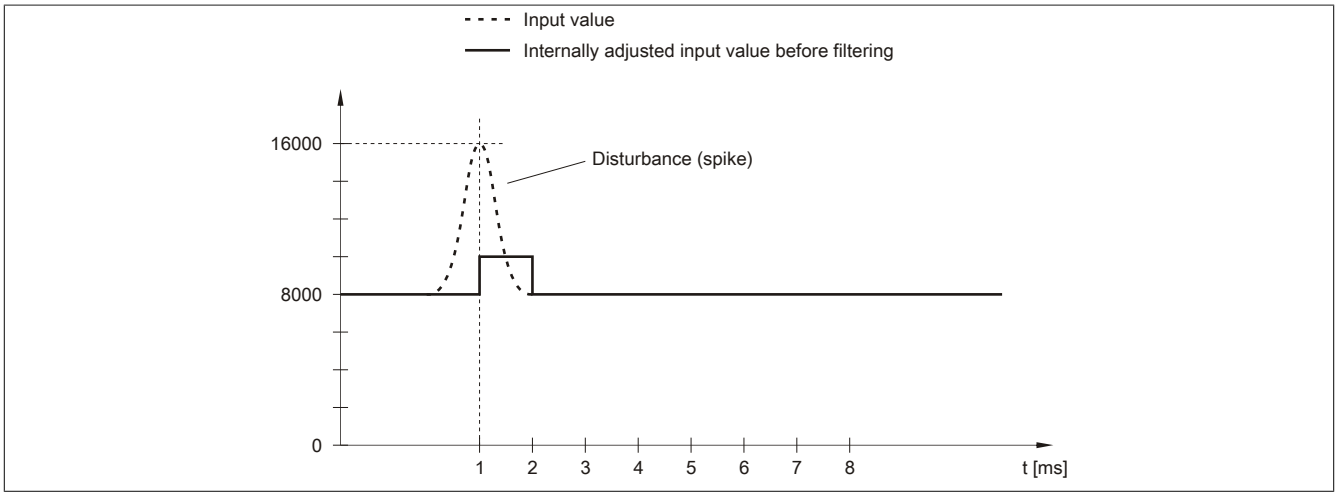

Figure 101: Adjusted input value for disturbance

4.3.19.8.6.2 Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

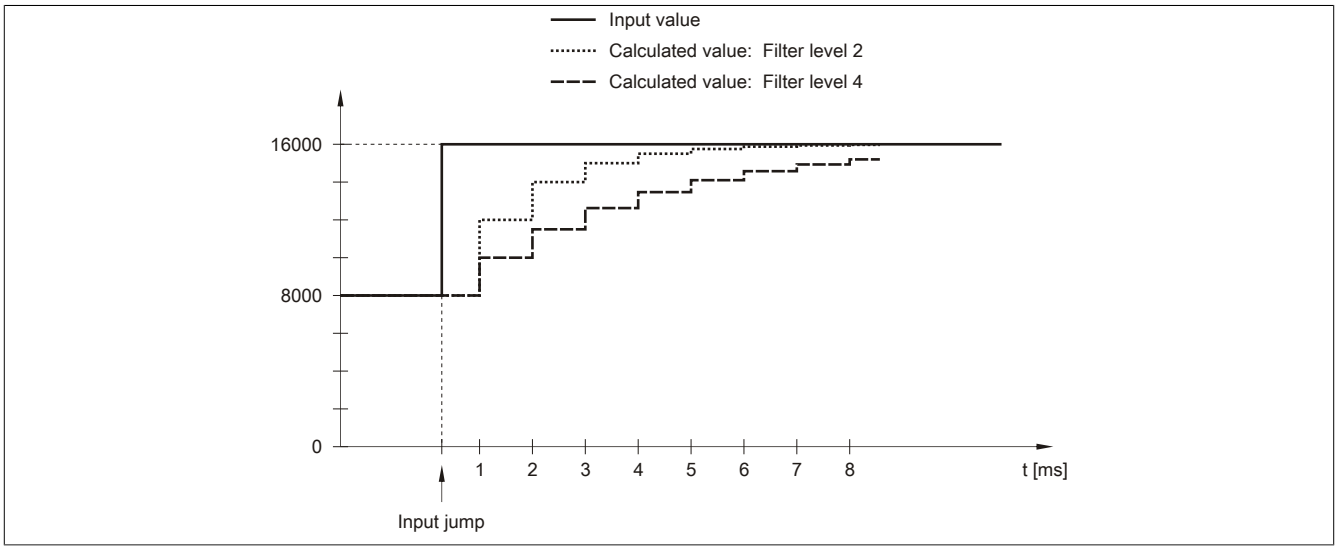

Figure 102: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

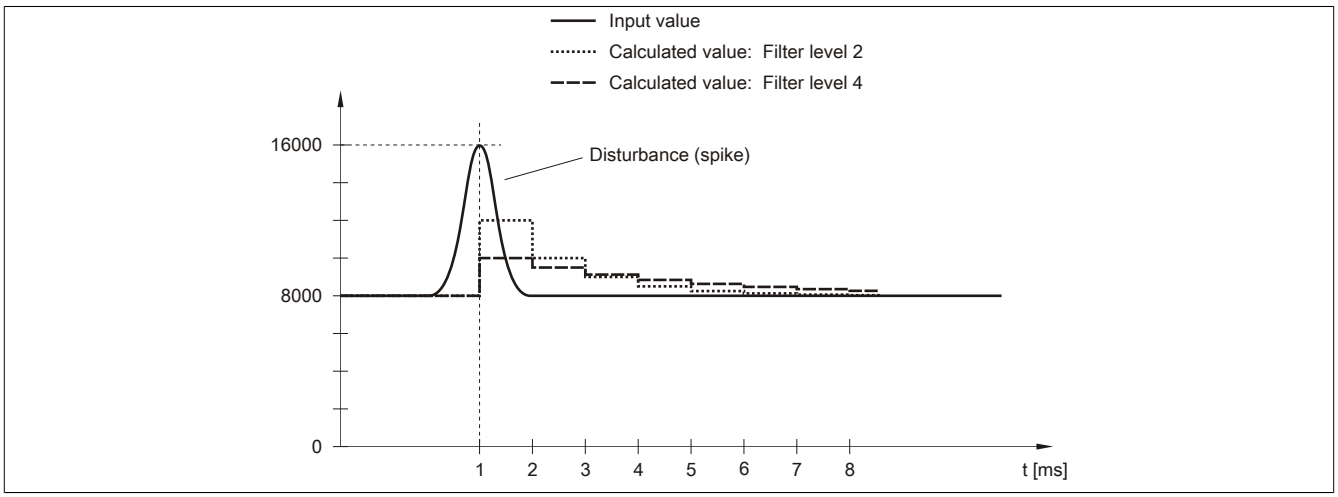

Figure 103: Calculated value during disturbance

4.3.19.8.7 Configuring the input filter

Name:
ConfigOutput01

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limitation	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7 - 15	Reserved	0	

4.3.19.8.8 Channel type

Name:
ConfigOutput02

This register can be used to set the range of the current signal. This is determined by how they are configured. The following input signals can be set:

- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
...		...	
7	Channel 8: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal

4.3.19.8.9 Lower limit value

Name:
ConfigOutput03

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

- **When configured as 0 to 20 mA, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Keep in mind that this setting applies to all channels!

4.3.19.8.10 Upper limit value

Name:
ConfigOutput04

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Data type	Value
INT	-32768 to 32767

Information:

The default value of 32767 corresponds to the maximum default value at 20 mA.

Keep in mind that this setting applies to all channels!

4.3.19.8.11 Input status

Name:
StatusInput01 to StatusInput02

This register is used to monitor the module inputs. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

StatusInput01 monitors Channels 1 to 4
StatusInput02 monitors Channels 5 to 8

Bit	Description	Value	Information
0 - 1	Channel 1 or 5	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
...		...	
6 - 7	Channel 4 or 8	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs. The analog value is limited to the new values if the limit values were changed.

Error status	Digital value for error (default values)	
	0 to 20 mA	4 to 20 mA
Upper limit value exceeded	+32767 (0x7FFF)	
Lower limit value exceeded	0	-8191 (0xE001)

4.3.19.8.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.3.19.8.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.3.20 X20AIA744

4.3.20.1 General information

This module works with 4-wire strain gauge load cells. The concept applied by the module requires compensation in the measurement system. This compensation eliminates the absolute uncertainty in the measurement circuit, such as component tolerances, effective bridge voltage or zero offset. The measurement precision refers to the absolute (compensated) value, which will only change as a result of changes in the operating temperature.

- 2 full-bridge strain gauge inputs
- 5 kHz data output rate for both channels
- Independently configurable strain gauge factor and filter level for each of the 2 channels

4.3.20.3 Technical data

Product ID	X20AIA744
Short description	
I/O module	2 full-bridge strain gauge inputs
General information	
B&R ID code	0xE50C
Status indicators	Channel status, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Open line	Yes, using status LED and software
Input	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	0.7 W
Additional power dissipation caused by the actuators (resistive) [W]	+0.72 [1)]
Electrical isolation	
Bus - Analog input	Yes
Bus - Bridge supply voltage	Yes
Channel - Channel	No
Channel - I/O supply	No
Certification	
CE	Yes
ATEX Zone 2 [2)]	Yes
GOST-R	Yes
Full-bridge strain gauge	
Strain gauge factor	2 to 256 mV/V, configurable using software
Connection	4-wire connections
Input type	Differential, used to evaluate a full-bridge strain gauge
Digital converter resolution	24-bit
Conversion time	200 µs
Data output rate	5000 samples per second and per channel (f_{DATA})
Input filter	
Cutoff frequency	2.5 kHz
Orderliness	3
Slope	60 dB

Table 67: X20AIA744 - Technical data

Product ID	X20AIA744
ADC filter characteristics	Sigma-delta, see section "Filter"
Operating range / Measurement sensor	85 to 5000 Ω
Influence of cable length	The shielded twisted pair cable should be as short as possible and run separately to the sensor (isolated from load circuit) without intermediate terminals
Input protection	RC protection
Common-mode range	0.6 to 3.8 VDC Permissible input voltage range (with regard to the potential strain gauge GND) on the inputs "Input +" and "Input -"
Isolation voltage between input and bus	500 V_{eff}
Conversion procedure	Sigma-delta
Output of the digital value	
Broken bridge supply line	Value approaches 0
Broken sensor line	Value approaches ±end value ("open circuit" status bit is set in the *Module status* register)
Valid value range	0xFF800001 to 0x007FFFFF (-8,388,607 to 8,388,607)
Strain gauge supply	
Voltage	5.5 VDC / max. 65 mA per channel
Short circuit protection, overload protection	Yes
Quantization [3]	
LSB value	
2 mV/V	1.31 nV
4 mV/V	2.62 nV
8 mV/V	5.25 nV
16 mV/V	10.49 nV
32 mV/V	20.98 nV
64 mV/V	41.96 nV
128 mV/V	83.92 nV
256 mV/V	167.85 nV
Max. gain drift	35 ppm/°C [4]
Max. offset drift	15 ppm/°C [5]
Nonlinearity	<10 ppm [5]
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations

Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB1F terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 67: X20AIA744 - Technical data

1) Depends on the full-bridge strain gauge used
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) Quantization depends on the strain gauge factor.
4) Based on the current measured value.
5) Based on the entire measurement range.

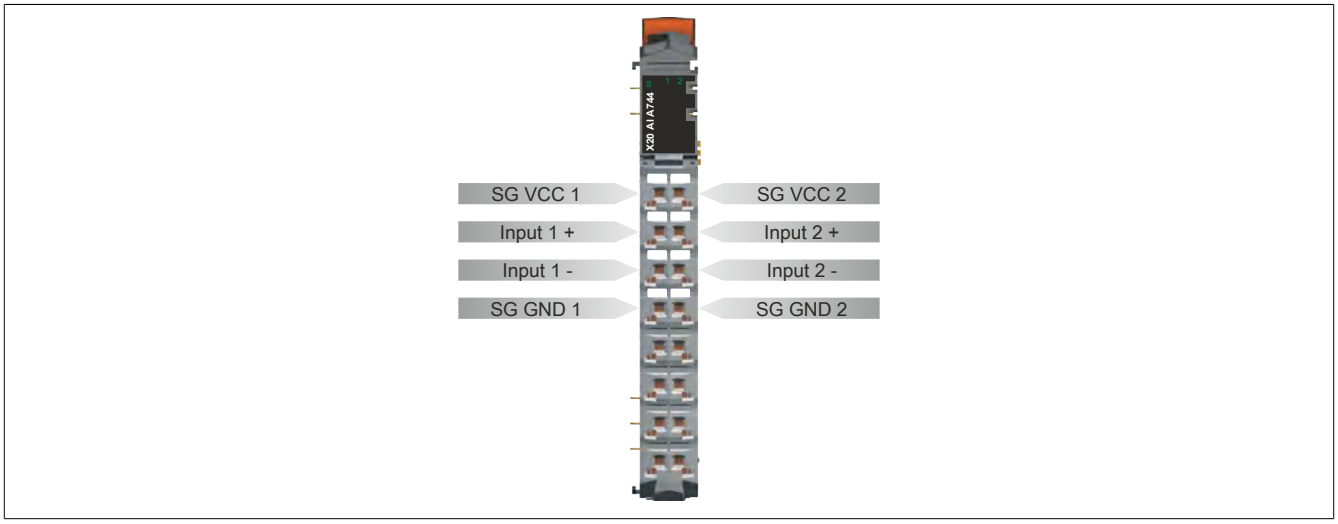
4.3.20.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

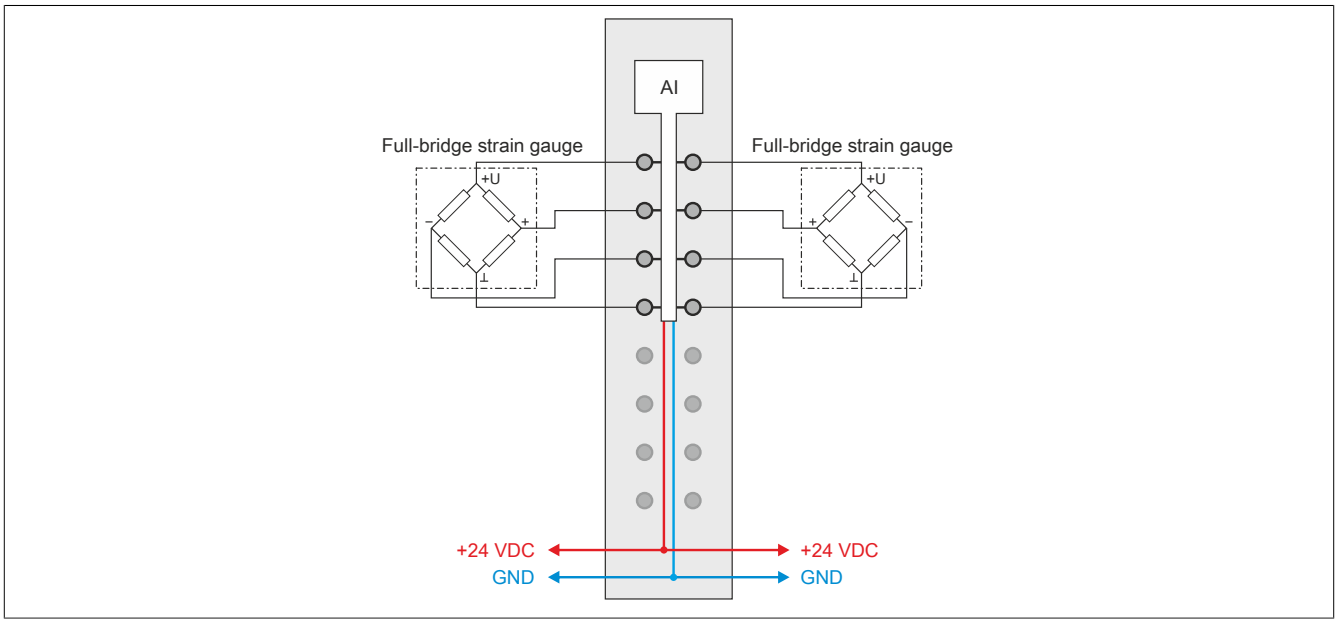
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	I/O supply outside limits
			On	Error or reset status
	1 - 2	Green	Off	Possible causes: • Supply error • Channel not yet configured
			Blinking	Possible causes: • Open line • Overvoltage • Undervoltage
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

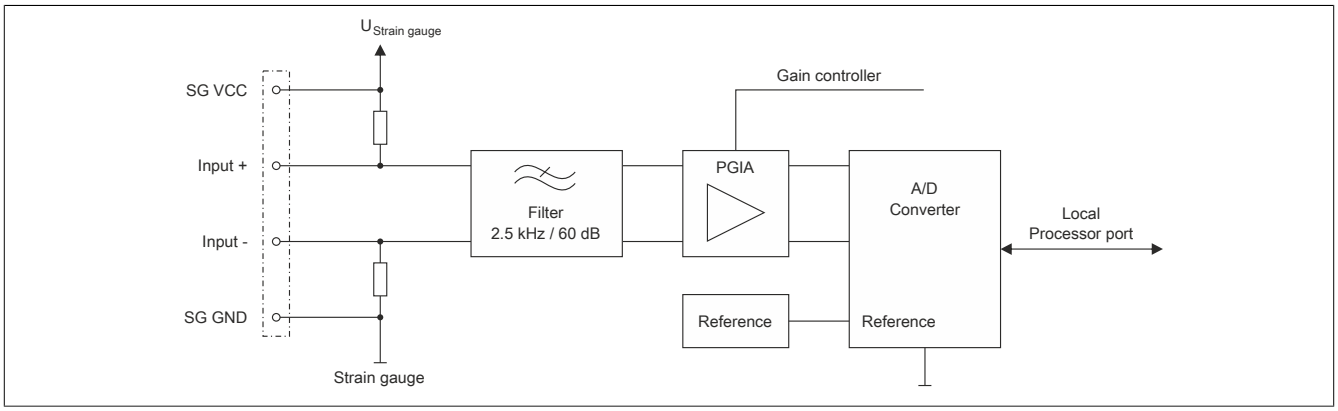
4.3.20.5 Pinout



4.3.20.6 Connection example



4.3.20.7 Input circuit diagram

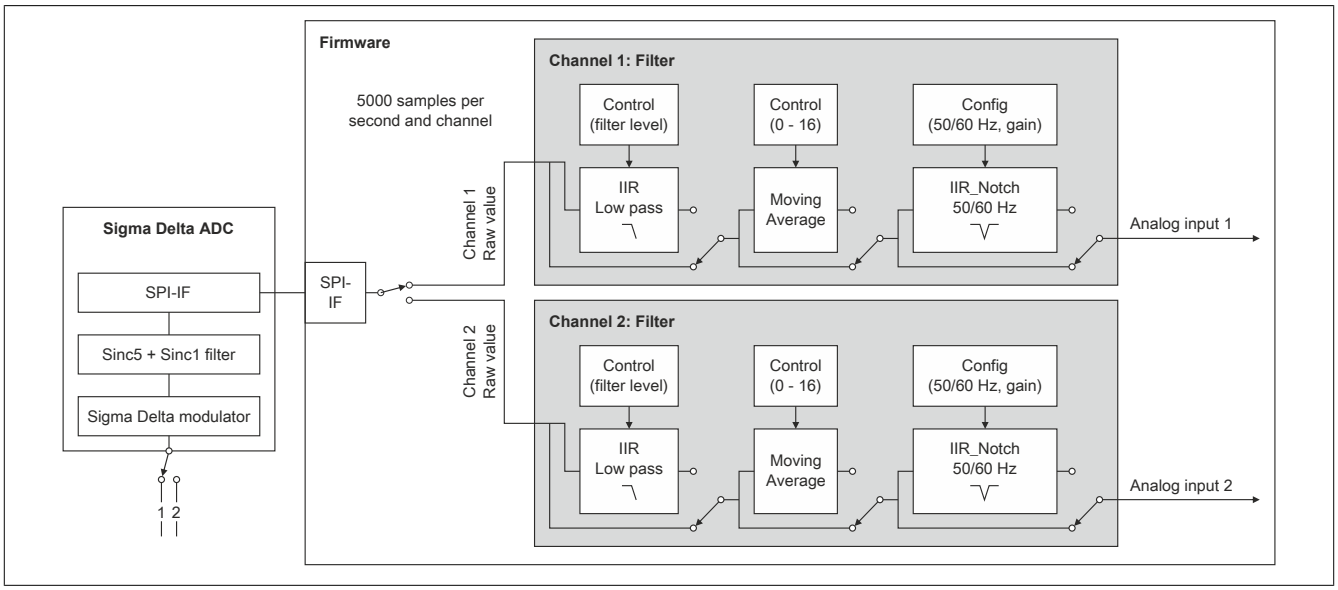


4.3.20.8 Filter

An independent cascade of filters is available for each channel. They can be individually enabled and configured at runtime. By default, all filters are disabled when the device is switched on. Filters are controlled and configured using the "ControlPacked0N" and "ConfigChannel0N" (N = 1 to 2) registers.

In order to allow the filter behavior to be adapted to the measuring situation or machine cycle (high dynamics and low precision or low dynamics and high precision), the filter characteristics of both the IIR low-pass filter as well as the moving average filter can be changed synchronously at any time.

Filter diagram



4.3.20.8.1 IIR low-pass filter

4.3.20.8.1.1 General information

The IIR low-pass filter is used to generally smooth and increase the resolution of the analog value. The filter works according to the following formula:

$$y = y_{Old} + \frac{x - y_{Old}}{2^{Filter\ level}}$$

x ... current filter input value
y_{Old} ... Old filter output value
y ... new filter output value

The "Filter level" parameter in the formula above is configured with the help of the "ControlPacked0N" register. "Filter level" = 0 if the IIR low-pass filter is disabled.

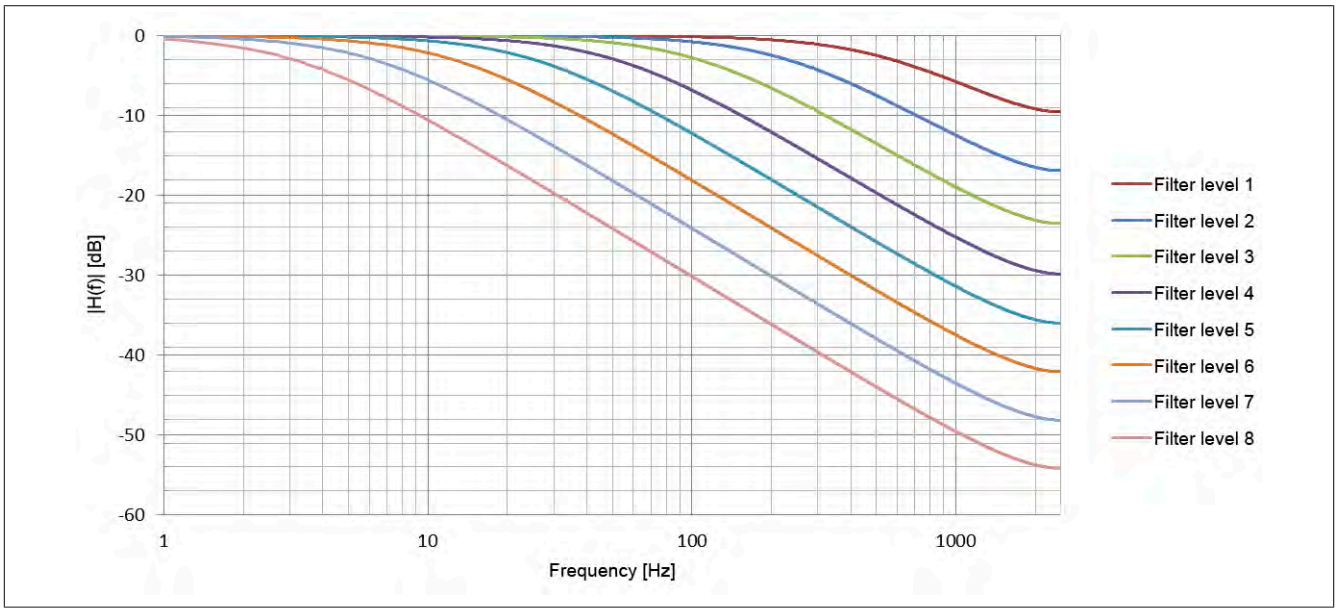
4.3.20.8.1.2 Filter characteristics of the 1st-order IIR low-pass filter

Limit frequency f_c

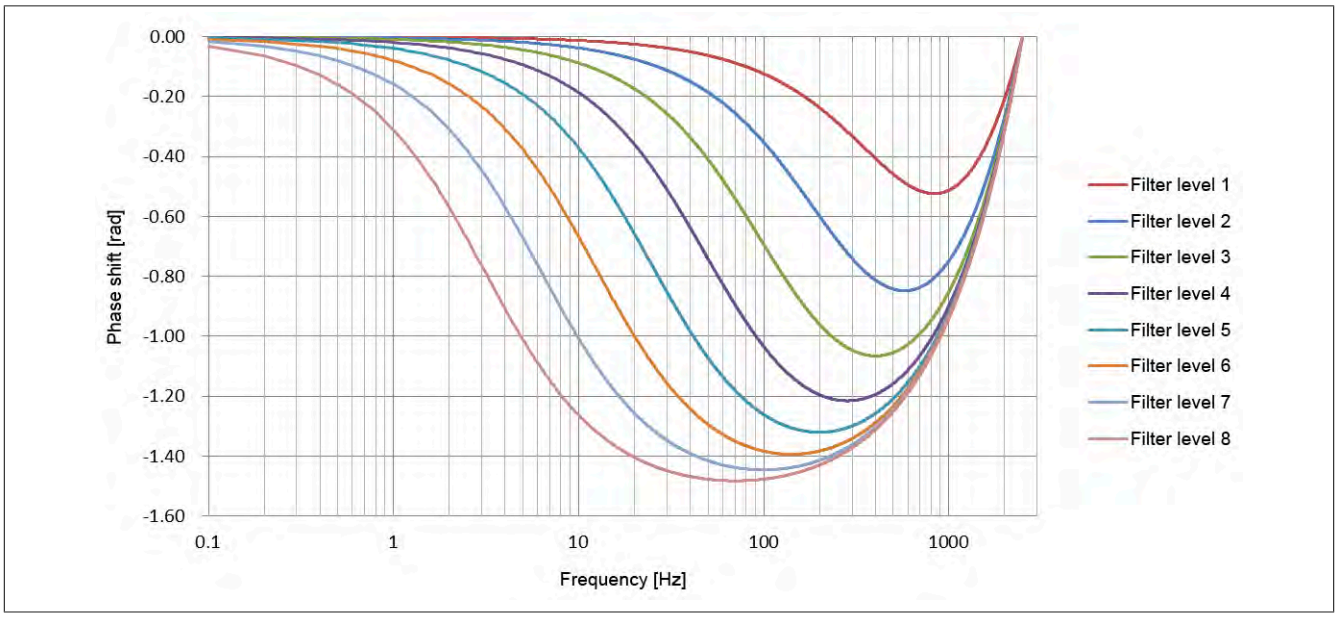
The following table provides an overview of the -3 dB limit frequency f_c depending on the configured filter level.

IIR low-pass filter level	f_c [Hz]
1	575
2	230
3	106
4	51
5	25
6	12.5
7	6.2
8	3.1

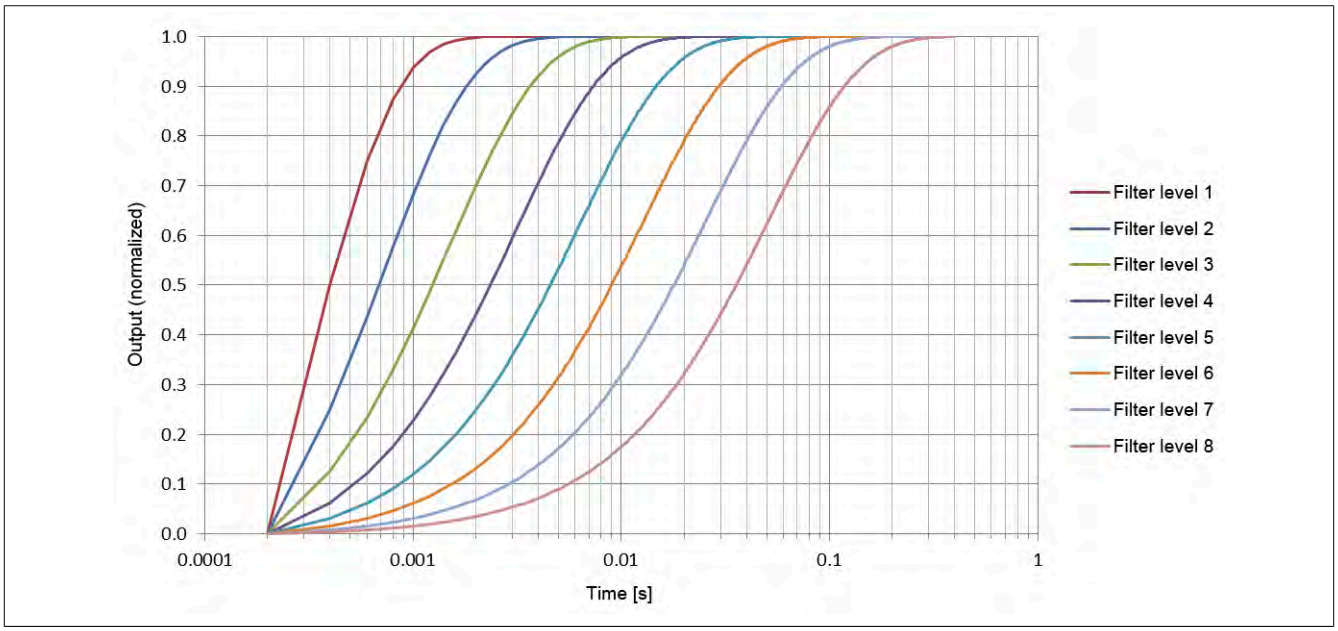
Gain of the IIR low-pass filter



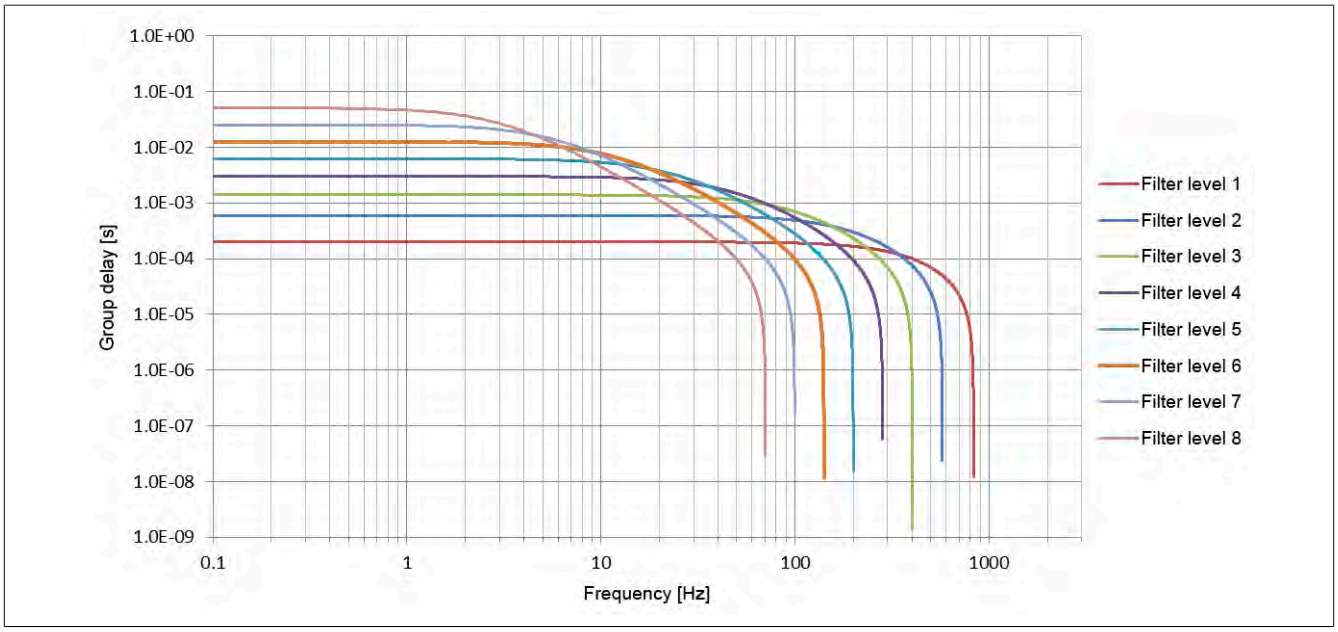
Phase shift of the IIR low-pass filter



Step response of the IIR low-pass filter



Group delay of the IIR low-pass filter



4.3.20.8.2 Sinc1 / Moving average filter

Like the low-pass filter, the moving average filter can also be used to smooth out the signal and increase its resolution. In addition, configuring the filter length accordingly makes it possible to target and efficiently filter out individual interference frequencies. The source of these interference frequencies may be mechanical or electromagnetic. Multiples of these are also filtered out (as long as they are a whole-number factor of the data output rate of 5000 samples per second and channel).

Example:
Data output rate = 5000 samples/s/channel, averaging over 4 values -> "Notch" at 1.25 kHz (and 2.5 kHz)

When reconfiguring the filter length from "n" to "m", it takes |m-n| * 200 µs until the desired filter length setpoint is reached again. As long as the filter length setpoint is not reached, this situation will be indicated by the bit 7 status bit in the "StatusPacked0N" register.

4.3.20.8.2.1 Filter characteristics of the moving average filter

Filter configuration	Filter length	f_{Notch} [Hz] 1)	f_c [Hz] 2)
0	1		
1	2	2500	1244
2	4	1250	568
3	5	1000	450
4	10	500	222
5	20	250	111
6	25	200	88.4
7	50	100	44.0
8	83	60.24	26.5
9	100	50	21.9
10	125	40	17.5
11	167	29.94	13.0
12	200	25	10.9
13	250	20	8.6
14	300	16.67	7.1
15	500	10	4.3
16	1000	5	2.0

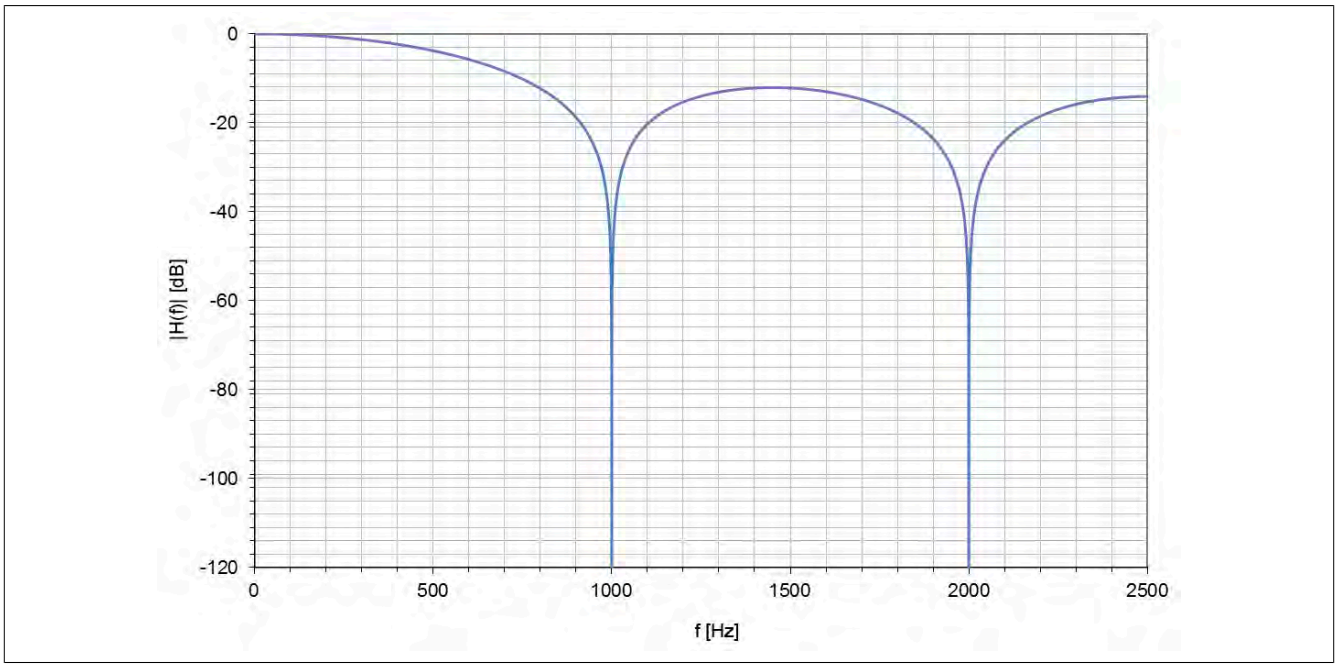
1) Mid-band frequency of the first attenuation maximum.
2) -3 dB limit frequency.

4.3.20.8.2.2 Examples for the gain of the moving average filter

Example 1

Filter setting = 3:

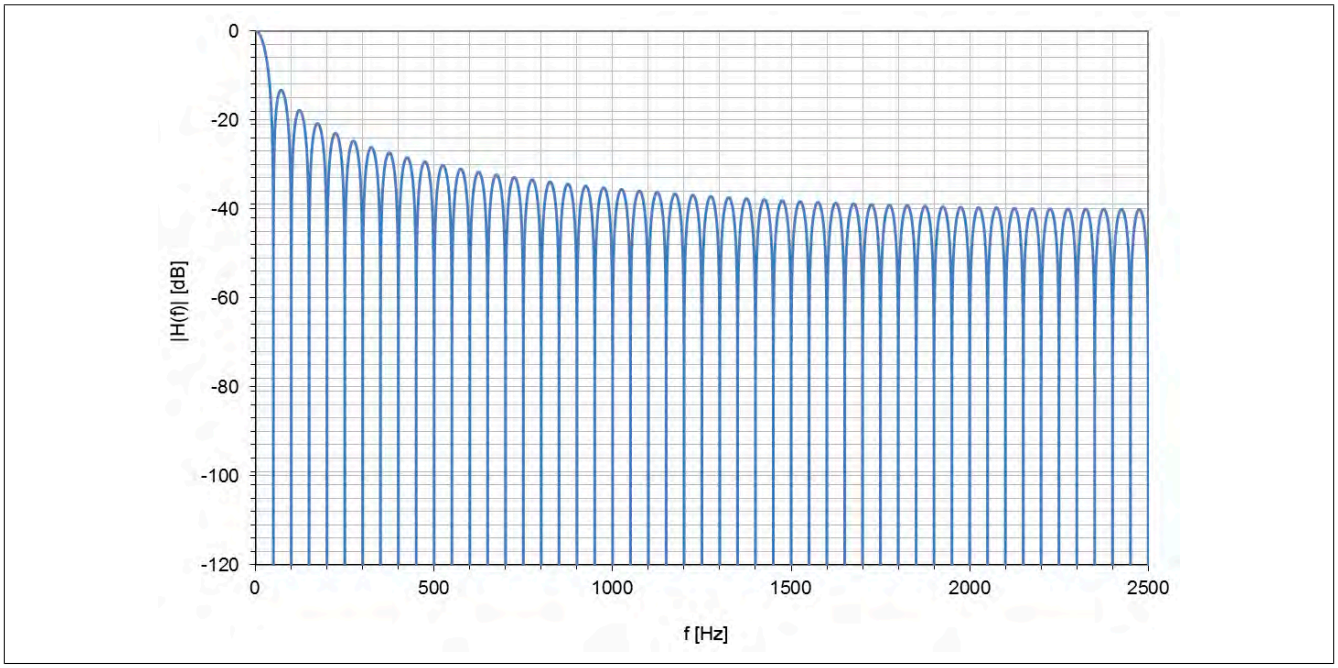
- f_{Notch} = 1000 Hz
- f_c = 449.6 Hz



Example 2

Filter setting = 9:

- f_{Notch} = 50 Hz
- f_c = 21.9 Hz



4.3.20.8.3 50/60 Hz IIR notch filter

The IIR notch filter is used for narrow-band suppression of interference caused by the mains frequency.

This is an 8th-order IIR notch filter implemented in the form of a cascade of 4 2nd-order IIR notch filters.

Information:

The IIR notch filter should only be enabled if there is actually interference being caused by the mains frequency. You should always check whether sufficiently low and sufficiently narrow band filtering at 50 Hz / 60 Hz can be implemented using a moving average filter (see section 4.3.20.8.2.1 "Filter characteristics of the moving average filter").

This is because, like every higher-order IIR notch filter, this filter also has a tendency to respond to an input step with an attenuating vibration. The higher the dynamics of the expected measurement signal, the greater the potential interfering effect of this vibration tendency. In extreme cases, the vibration can temporarily be greater than the mains interference that is supposed to be filtered out.

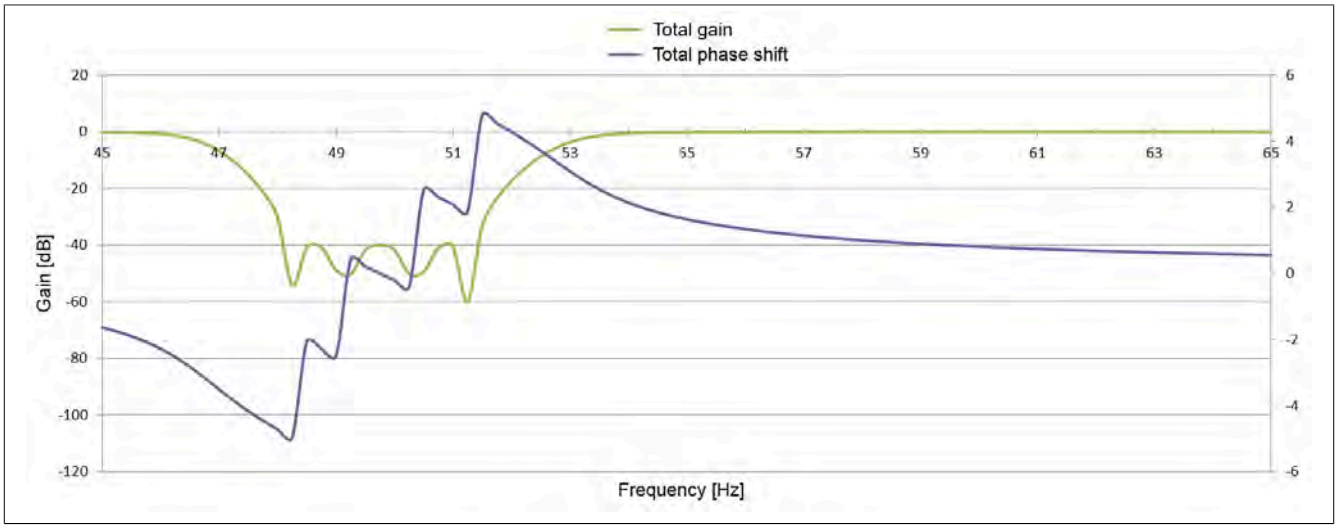
4.3.20.8.3.1 Filter characteristics of the IIR notch filter

There are three different filter characteristics that can be selected for both 50 Hz and 60 Hz (-40 dB, -60 dB and -80 dB). The higher the attenuation, the narrower the stopband.

Example 1

Filter characteristics for the following settings:

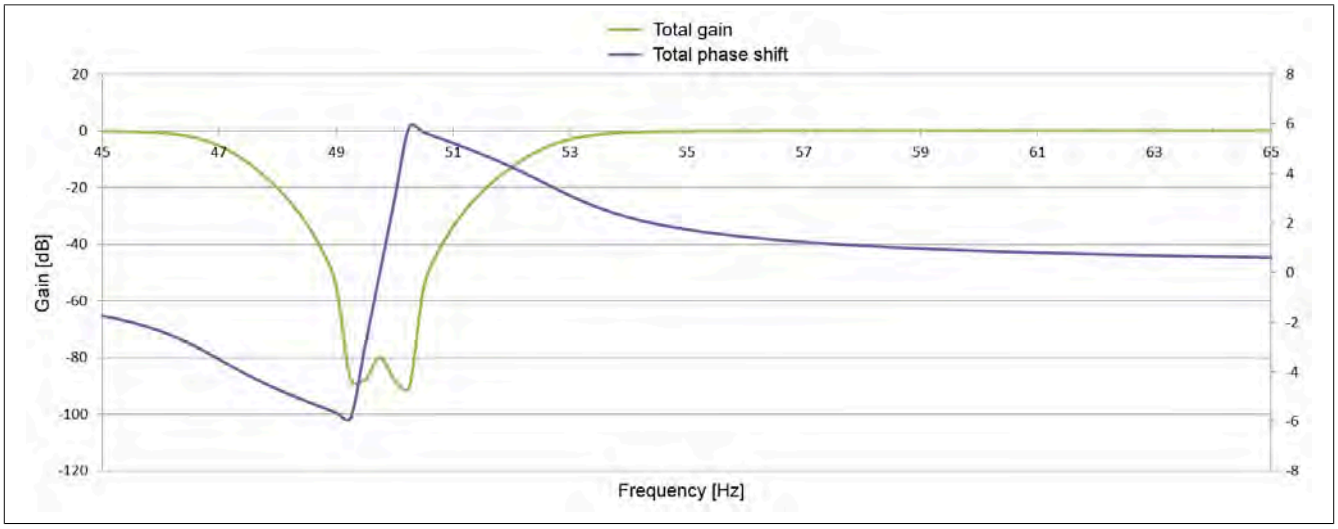
- Gain = -40 dB
- Frequency = 50 Hz
- Passband = 5 Hz
- Stopband = ±1 Hz



Example 2

Filter characteristics for the following settings:

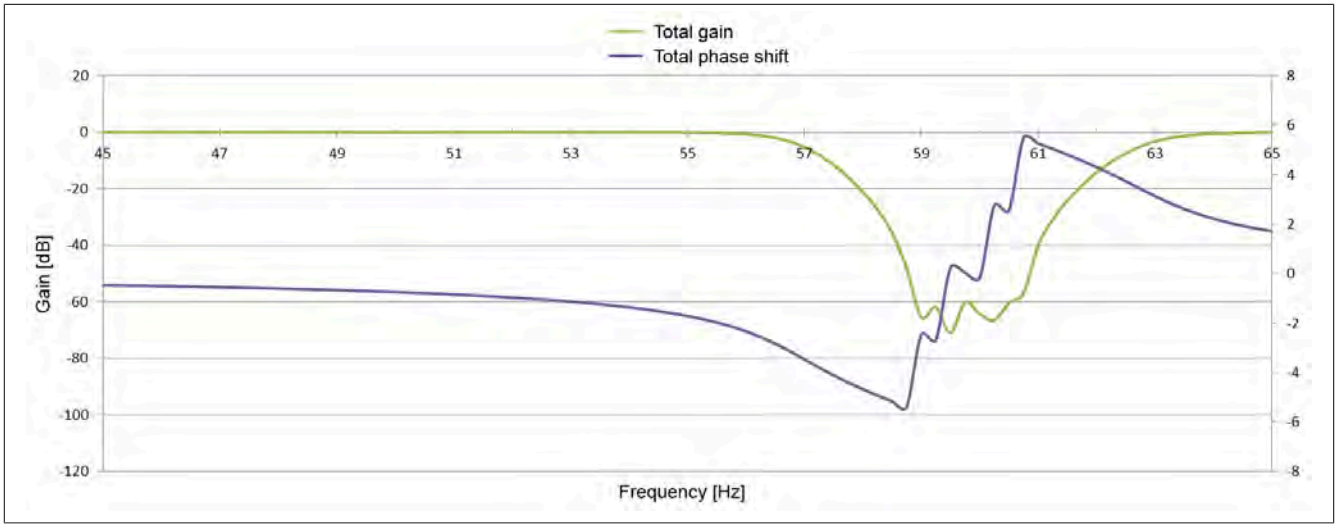
- Gain = -80 dB
- Frequency = 50 Hz
- Passband = 5 Hz
- Stopband = ±0.25 Hz



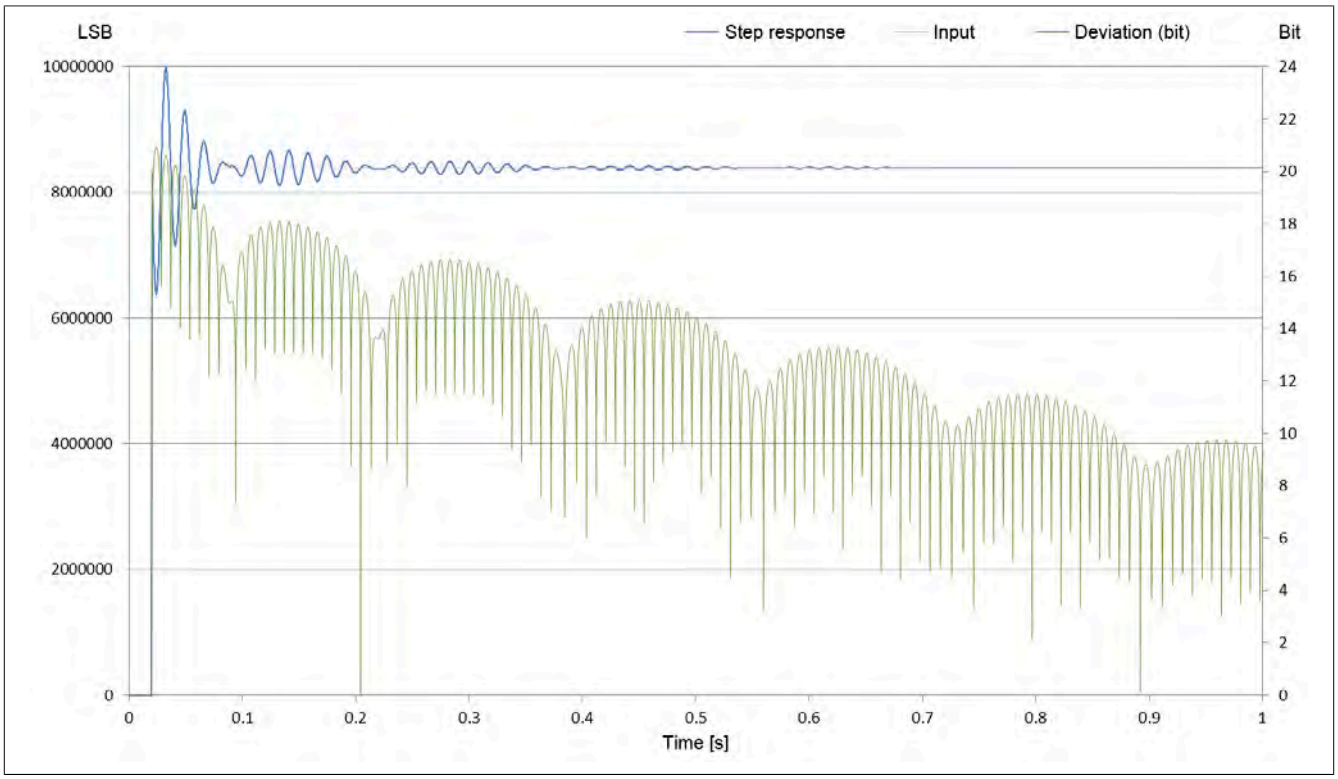
Example 3

Filter characteristics for the following settings:

- Gain = -60 dB
- Frequency = 60 Hz
- Passband = 5 Hz
- Stopband = ±0.5 Hz



Step response of an 8th-order IIR notch filter, including the deviation in bits:



4.3.20.9 Register description

4.3.20.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.20.9.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Analog signal - Configuration						
2	ControlPacked01	UINT			•	
6	ControlPacked02	UINT			•	
514	ConfigChannel01	UINT				•
578	ConfigChannel02	UINT				•
Analog signal - Communication						
4	AnalogInput01	DINT	•			
12	AnalogInput02	DINT	•			
33	StatusPacked01	USINT	•			
35	StatusPacked02	USINT	•			
257	AdcConvCtr01	SINT	•			
268	AdcConvTimeStamp01	DINT	•			

4.3.20.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Analog signal - Configuration							
2	2	ControlPacked01	UINT			•	
6	10	ControlPacked02	UINT			•	
514	514	ConfigChannel01	UINT				•
578	578	ConfigChannel02	UINT				•
Analog signal - Communication							
4	4	AnalogInput01	DINT	•			
12	12	AnalogInput02	DINT	•			
33	0	StatusPacked01	USINT	•			
35	8	StatusPacked02	USINT	•			

1) The offset specifies the position of the register within the CAN object.

4.3.20.9.3.1 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN-I/O.

4.3.20.9.4 Configuration

4.3.20.9.4.1 Configuration of strain gauge inputs

Name:
ControlPacked01 and ControlPacked02

The strain gauge inputs are configured in these registers:

- Strain gauge factor factor of strain gauge load cell
- Enabling of filters

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information	
0 - 2	Strain gauge factor	000	Default: 256 mV/V	
		001	128 mV/V	
		010	64 mV/V	
		011	32 mV/V	
		100	16 mV/V	
		101	8 mV/V	
		110	4 mV/V	
		111	2 mV/V	
			Averaging	1. Notch frequency [Hz]
3 - 7	Moving average	00000	Default: Moving average disabled (bypass)	
		00001	2	2500
		00010	4	1250
		00011	5	1000
		00100	10	500
		00101	20	250
		00110	25	200
		00111	50	100
		01000	83	60
		01001	100	50
		01010	125	40
		01011	167	30
		01100	200	25
		01101	250	20
		01110	300	16.66
		01111	500	10
		10000	1000	5
		10001 to 11111	Reserved (firmware limited to 1000)	
8	Notch filter	0	Default: IIR notch filter disabled (bypass)	
		1	IIR notch filter enabled	
9	Reserved	0		
10 - 11	Low-pass filter mode	00	IIR low-pass filter disabled (bypass)	
		01	1st-order IIR low-pass filter (see section 4.3.20.8.1 "IIR low-pass filter")	
		10 - 11	Reserved: No IIR low-pass filter active	
			Filter level	-3 db frequency [Hz]
12 - 14	Low-pass filter level	000	1	575
		001	2	230
		010	3	106
		011	4	51
		100	5	25
		101	6	12.5
		110	7	6.2
		111	8	3.1
15	Reserved	0		

4.3.20.9.4.2 Channel configuration

Name:
ConfigChannel01 and ConfigChannel02

The IIR notch filter is configured individually for each channel in these registers.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 11	Reserved	0	
12 - 13	Notch filter attenuation	00	Gain: -40 dB Pass: ±5 Hz Stop: ±1 Hz
		01	Gain: -60 dB Pass: ±5 Hz Stop: ±0.5 Hz
		10	Gain: -80 dB Pass: ±5 Hz Stop: ±0.25 Hz
		11	Reserved
14	Notch filter frequency	0	At 50 Hz
		1	At 60 Hz
15	Reserved	0	

4.3.20.9.5 Communication

4.3.20.9.5.1 Analog input values

Name:
AnalogInput01 and AnalogInput02

The analog input value is mapped in this register.

Data type	Value	Input signal:
DINT	<-8,388,607	Negative invalid range
	-8,388,607	Negative full-scale deflection / Underflow
	-8,388,606 to 8,388,606	Valid range
	8,388,607	Positive full-scale deflection / Overflow / Open line
	>8,388,607	Positive invalid range

4.3.20.9.5.2 Status of analog inputs

Name:
StatusPacked01 and StatusPacked02

The status of analog inputs is mapped in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	I/O power supply	0	No error
		1	Error in power supply
1	Bypass current	0	No error
		1	Overcurrent (sum from all sensors)
2 - 3	Reserved	0	
4	ADC configuration	0	Already configured
		1	Not yet configured
5	Analog values	0	Analog value valid
		1	Analog value invalid (analog value = 0xFF800000). Possible causes: • Internal transfer error (XOR checksum verification) • Error in strain gauge supply (bit 1) • Error in I/O voltage supply (bit 0) • ADC not (yet) configured
6	Analog value range overrun	0	Analog value valid
		1	Analog value invalid. Possible causes: • Overflow / Open line (analog value = 0x007FFFFF) • Underflow (analog value = 0xFF800001)
7	Moving average filter	0	Moving average filter engaged
		1	Moving average filter not engaged Possible causes: • After changing the filter length • Consequence of the filter being reset by another error

4.3.20.9.5.3 ADC conversion counter

Name:
AdcConvCtr01

Instead of being measured simultaneously, the strain gauge channels of the module are measured according to the multiplexing procedure. The "AdcConvTimestamp01" register contains the timestamp of the encoded last channel converted in the "AdcConvCtr01" register. The timestamp of the other channels can then be calculated later using this information.

Data type	Value
SINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Index of the last converted channel	0	Analog input 1
		1	Analog input 2
		2	Reserved
		3	Reserved
2 - 7	Rotating cycle counter	x	Incremented at the end of a conversion cycle. All channels are converted in a conversion cycle.

4.3.20.9.5.4 ADC conversion timestamp

Name:
AdcConvTimestamp01

The timestamp of the last converted channel is stored in this register (see bits 0 and 1 in the "AdcConvCtr01" register). This is always the point in time (in µs) at which the conversion of the latest ADC raw value is completed.

Data type	Value	Function
DINT	-2,147,483,648 to 2,147,483,647	Timestamp (in µs) of the last converted channel (see bits 0 and 1 in the ADC conversion counter)

The timestamp of the remaining channels can be determined in the application using the number and timestamp of the last converted channel according to the following table.

Channel	Age difference
2 - 1	47 µs
1 - 2	153 µs

Example 1:

- Latest channel (bit 0 - 1 in the "AdcConvCtr01" register) = 01 (analog input 2):
- Timestamp: "AdcConvTimestamp01" register = 0 µs

Channel	Timestamp
2	0 µs
1	-47 µs

Example 2:

- Latest channel (bit 0 - 1 in the "AdcConvCtr01" register) = 00 (analog input 1):
- Timestamp: "AdcConvTimestamp01" register = 0 µs

Channel	Timestamp
1	0 µs
2	-153 µs

4.3.20.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.20.9.7 I/O update time

I/O update time
200 µs

4.3.21 X20AIB744

4.3.21.1 General information

This module works with 4-wire strain gauge load cells. The concept applied by the module requires compensation in the measurement system. This compensation eliminates the absolute uncertainty in the measurement circuit, such as component tolerances, effective bridge voltage, or zero offset. The measurement precision refers to the absolute (compensated) value, which will only change as a result of changes in the operating temperature.

- 4 full-bridge strain gauge inputs
- 5 kHz data output rate for all 4 channels
- Independently configurable strain gauge factor and filter level for each of the 4 channels

4.3.21.2 Order data

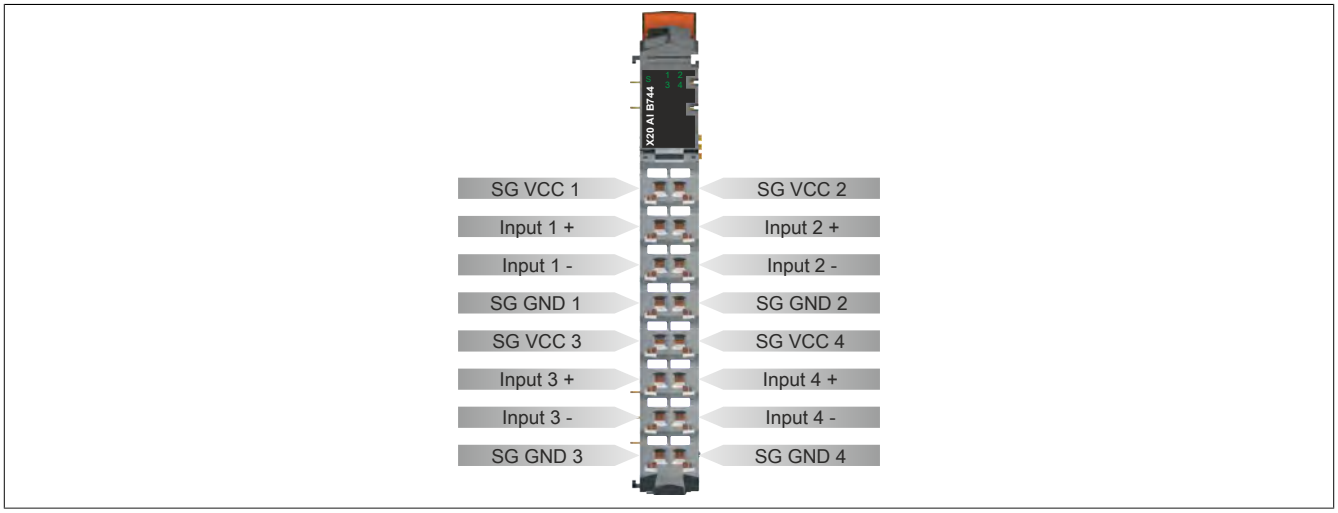
4.3.21.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

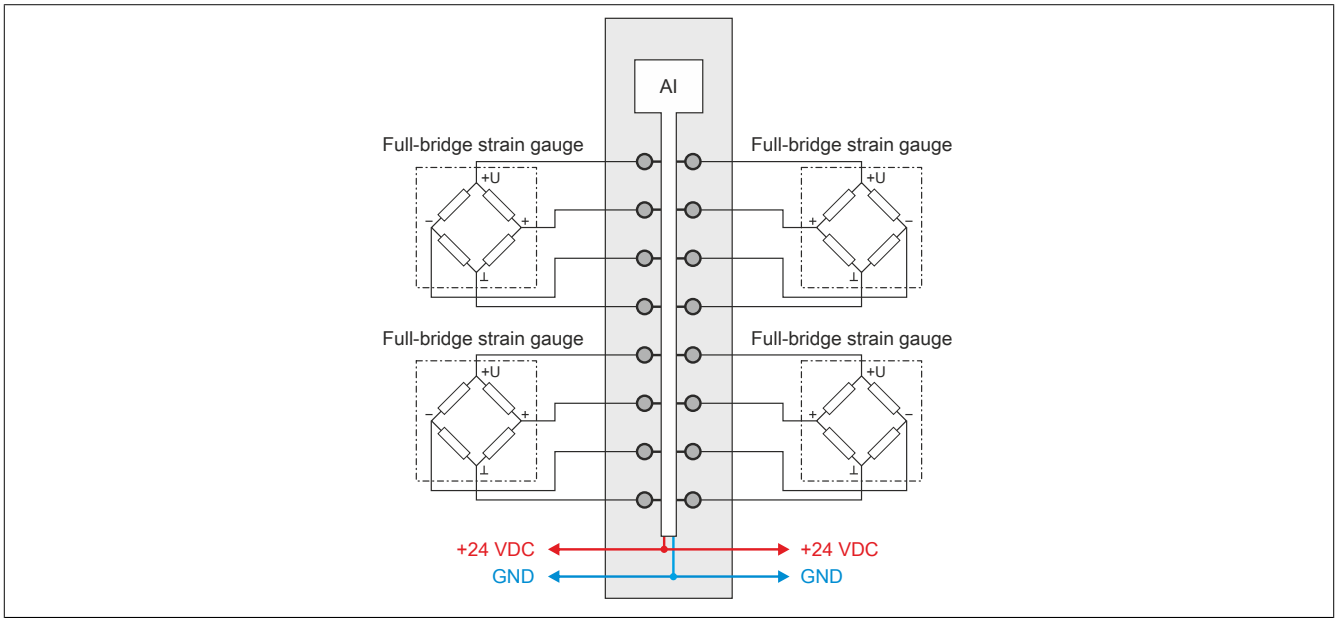
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	I/O supply outside limits
			On	Error or reset status
	1 - 4	Green	Off	Possible causes: • Supply error • Channel not yet configured
			Blinking	Possible causes: • Open line • Overvoltage • Undervoltage
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

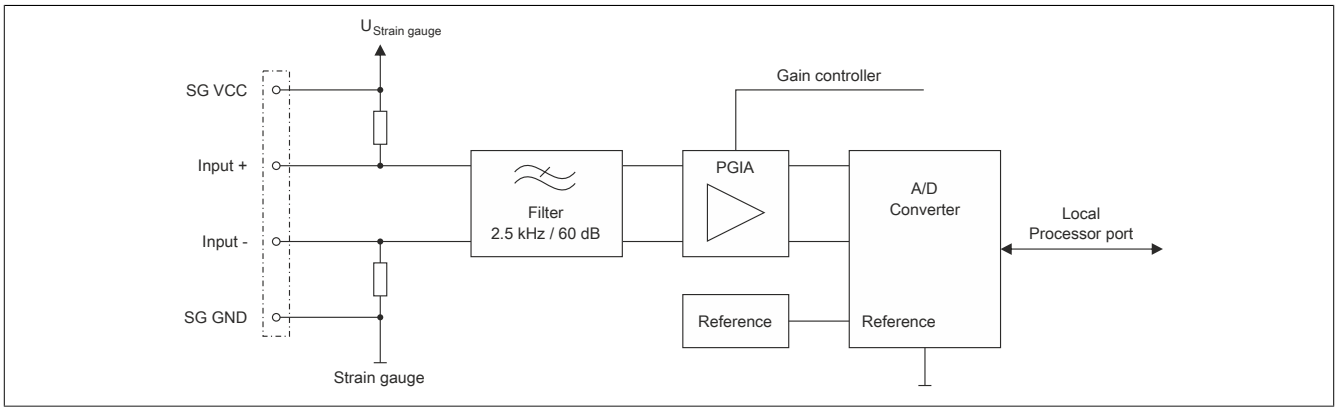
4.3.21.5 Pinout



4.3.21.6 Connection example



4.3.21.7 Input circuit diagram

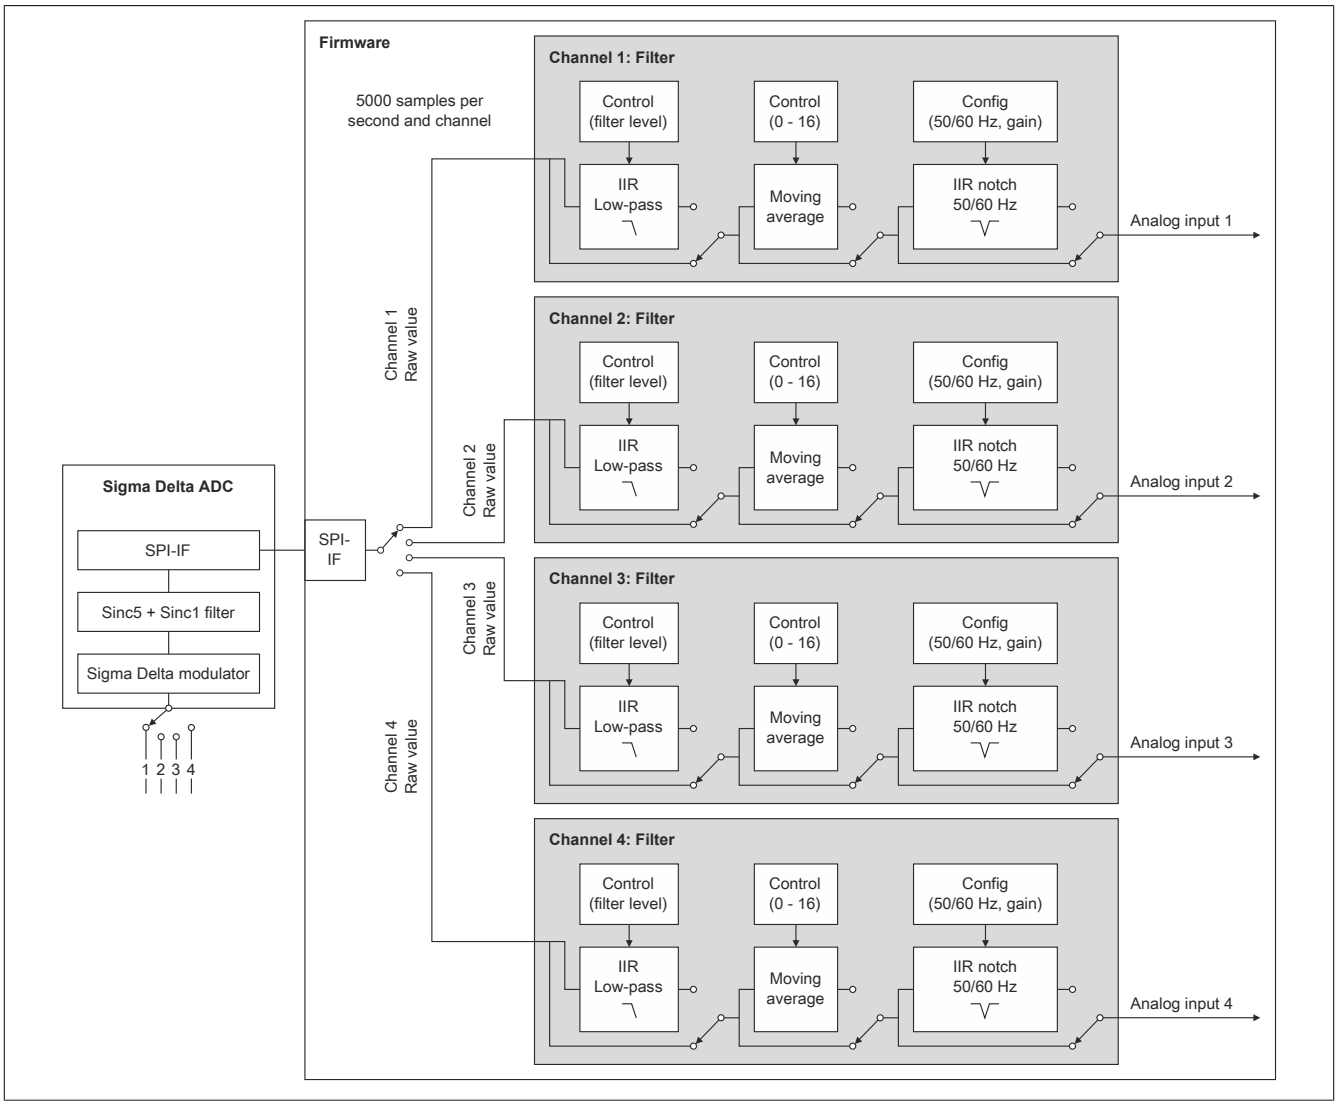


4.3.21.8 Filter

An independent cascade of filters is available for each channel. They can be individually enabled and configured at runtime. By default, all filters are disabled when the device is switched on. Filters are controlled and configured using the "ControlPacked0N" and "ConfigChannel0N" (N = 1 to 4) registers.

In order to allow the filter behavior to be adapted to the measuring situation or machine cycle (high dynamics and low precision or low dynamics and high precision), the filter characteristics of both the IIR low-pass filter as well as the moving average filter can be changed synchronously at any time.

Filter diagram



4.3.21.8.1 IIR low-pass filter

4.3.21.8.1.1 General information

The IIR low-pass filter is used to generally smooth and increase the resolution of the analog value. The filter works according to the following formula:

$$y = y_{Old} + \frac{x - y_{Old}}{2^{Filter\ level}}$$

x ... current filter input value
y_{Old} ... Old filter output value
y ... new filter output value

The "Filter level" parameter in the formula above is configured with the help of the "ControlPacked0N" register. "Filter level" = 0 if the IIR low-pass filter is disabled.

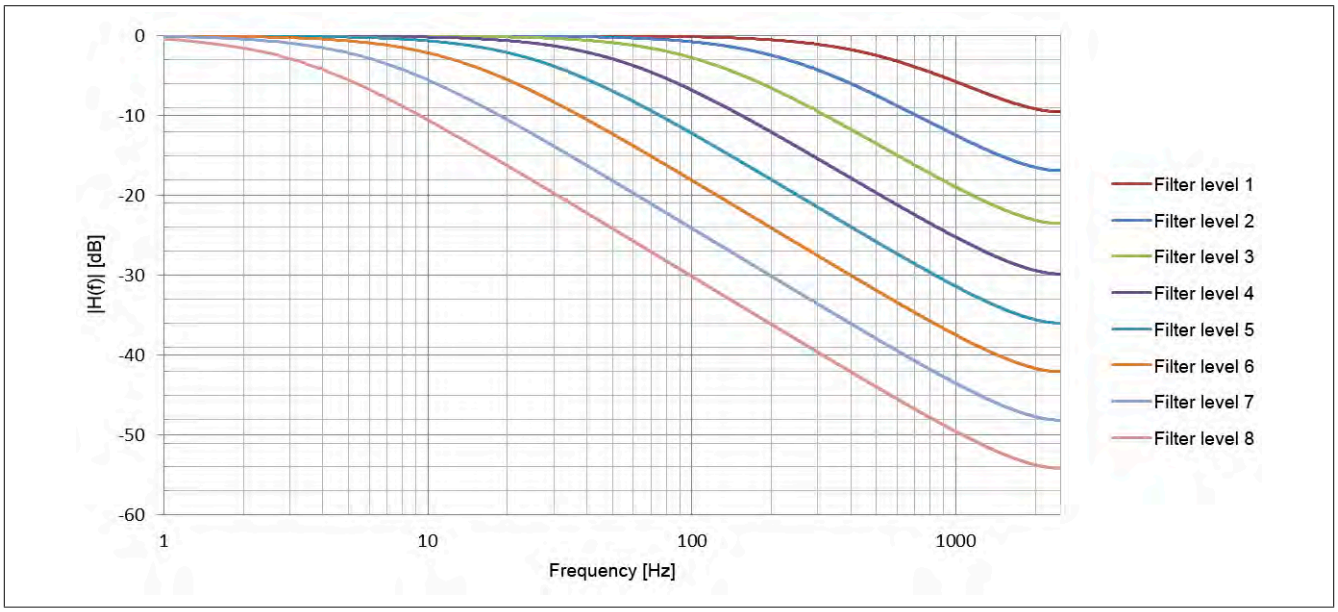
4.3.21.8.1.2 Filter characteristics of the 1st-order IIR low-pass filter

Limit frequency f_c

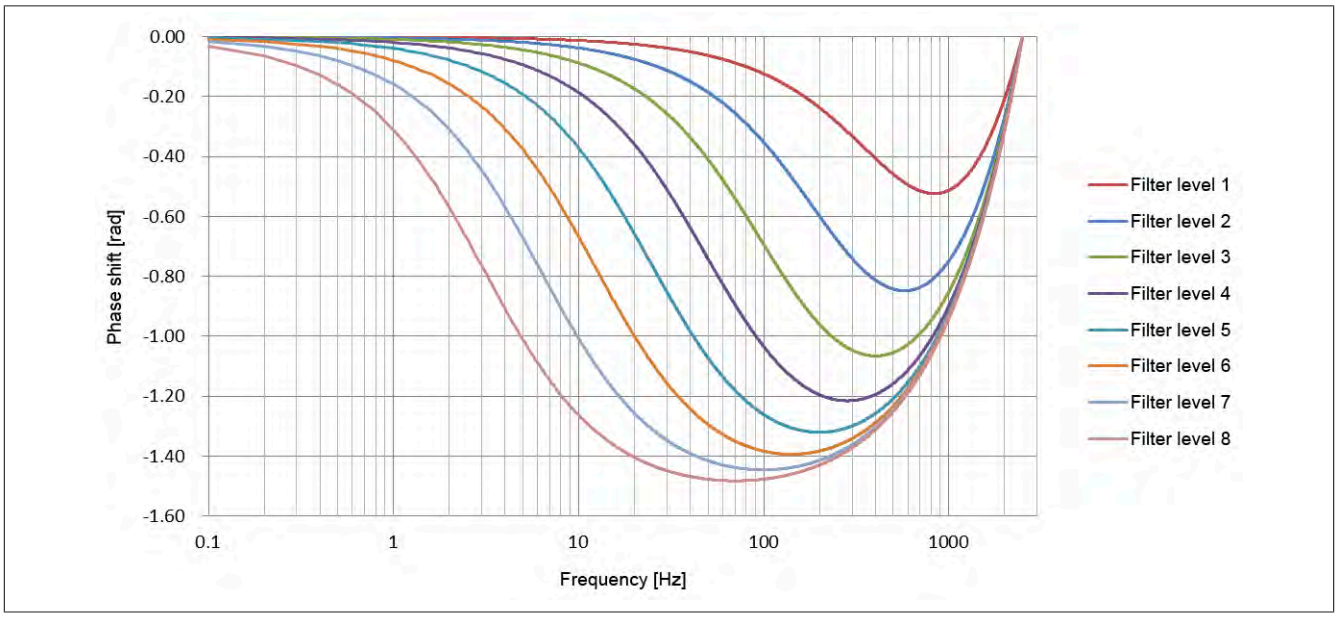
The following table provides an overview of the -3 dB limit frequency f_c depending on the configured filter level.

IIR low-pass filter level	f_c [Hz]
1	575
2	230
3	106
4	51
5	25
6	12.5
7	6.2
8	3.1

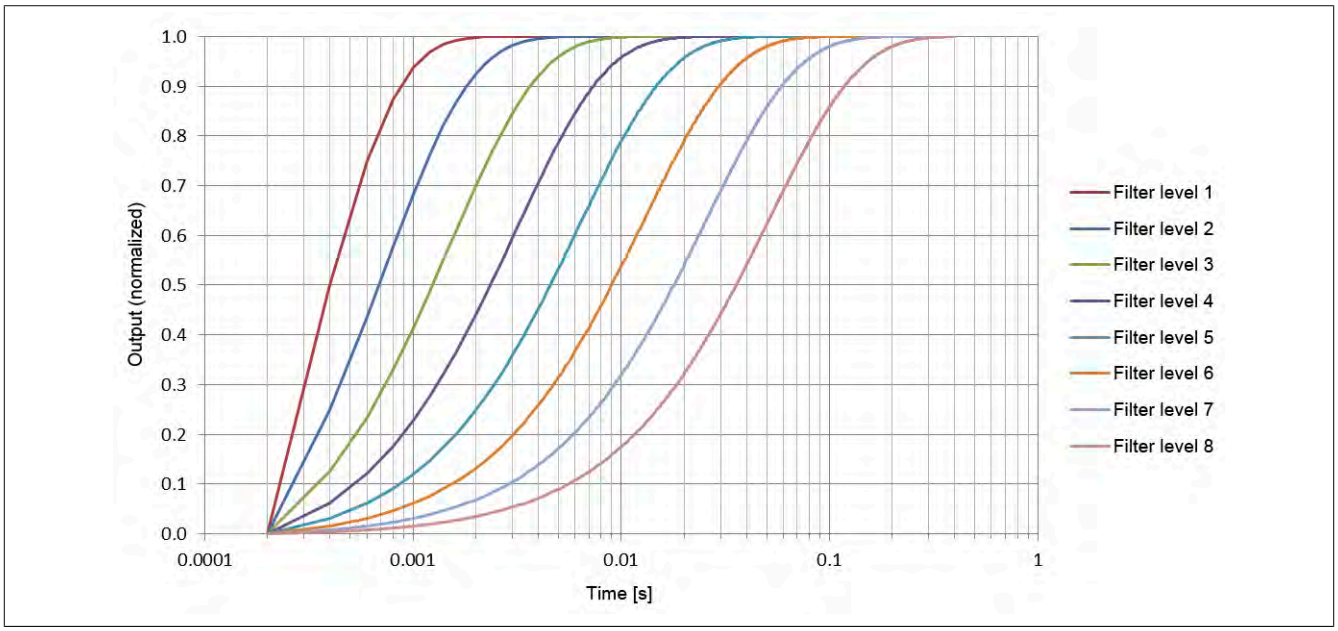
Gain of the IIR low-pass filter



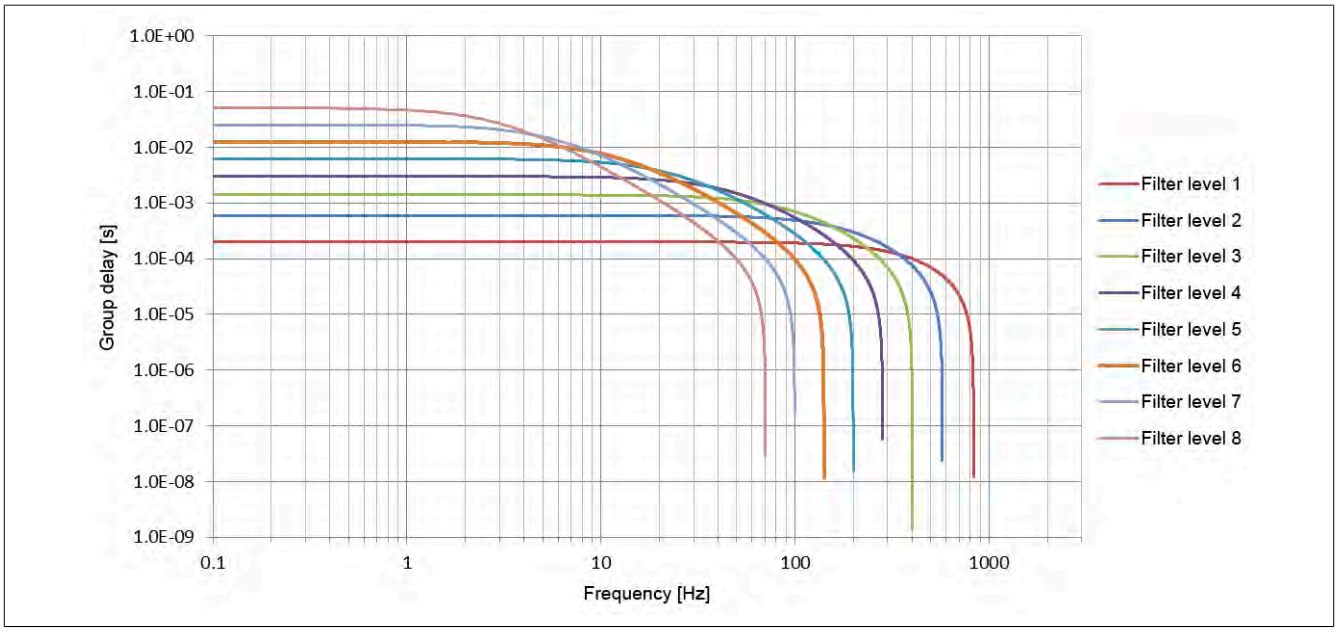
Phase shift of the IIR low-pass filter



Step response of the IIR low-pass filter



Group delay of the IIR low-pass filter



4.3.21.8.2 Sinc1 / Moving average filter

Like the low-pass filter, the moving average filter can also be used to smooth out the signal and increase its resolution. In addition, configuring the filter length accordingly makes it possible to target and efficiently filter out individual interference frequencies. The source of these interference frequencies may be mechanical or electromagnetic. Multiples of these are also filtered out (as long as they are a whole-number factor of the data output rate of 5000 samples per second and channel).

Example:
Data output rate = 5000 samples/s/channel, averaging over 4 values -> "Notch" at 1.25 kHz (and 2.5 kHz)

When reconfiguring the filter length from "n" to "m", it takes |m-n| * 200 µs until the desired filter length setpoint is reached again. As long as the filter length setpoint is not reached, this situation will be indicated by the bit 7 status bit in the "StatusPacked0N" register.

4.3.21.8.2.1 Filter characteristics of the moving average filter

Filter configuration	Filter length	f_{Notch} [Hz] 1)	f_c [Hz] 2)
0	1		
1	2	2500	1244
2	4	1250	568
3	5	1000	450
4	10	500	222
5	20	250	111
6	25	200	88.4
7	50	100	44.0
8	83	60.24	26.5
9	100	50	21.9
10	125	40	17.5
11	167	29.94	13.0
12	200	25	10.9
13	250	20	8.6
14	300	16.67	7.1
15	500	10	4.3
16	1000	5	2.0

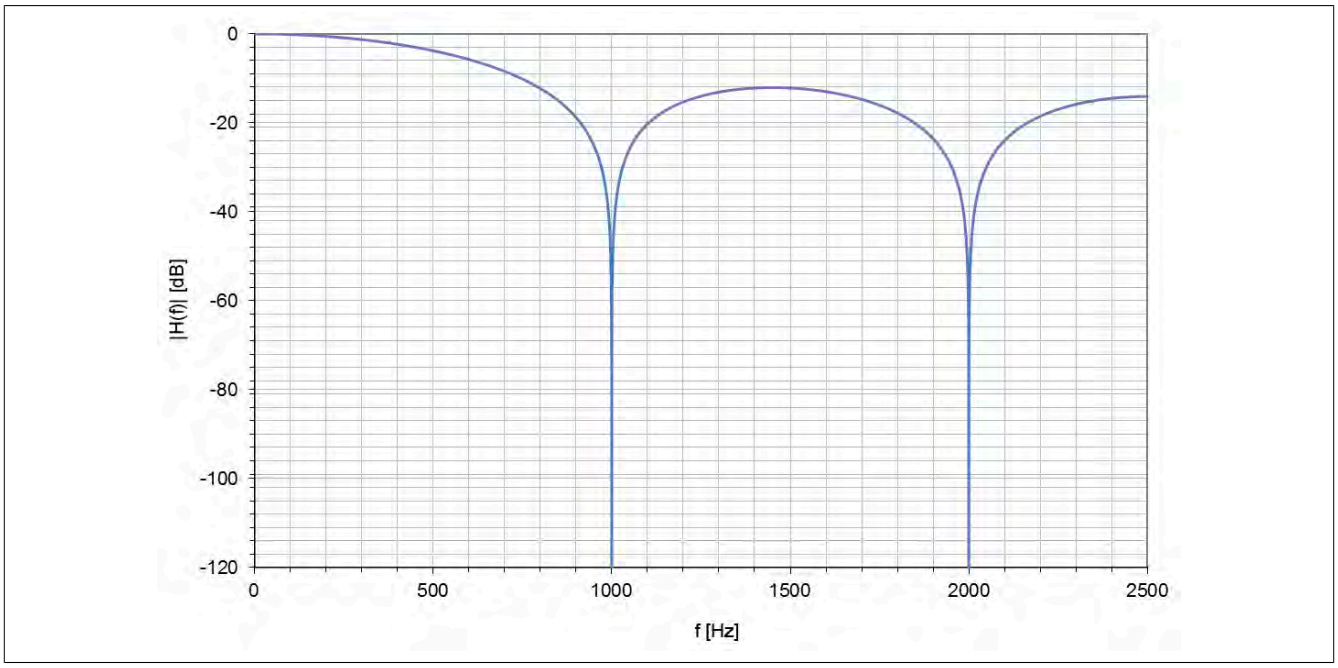
1) Mid-band frequency of the first attenuation maximum.
2) -3 dB limit frequency.

4.3.21.8.2.2 Examples for the gain of the moving average filter

Example 1

Filter setting = 3:

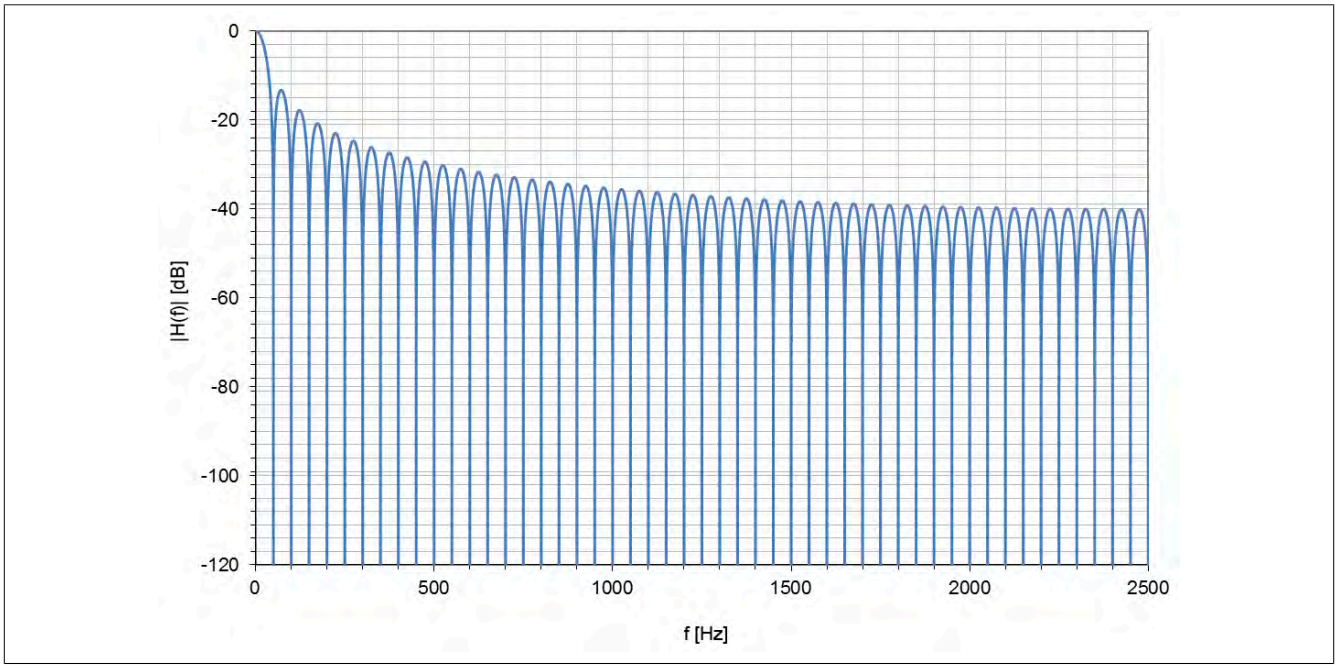
- f_{Notch} = 1000 Hz
- f_c = 449.6 Hz



Example 2

Filter setting = 9:

- f_{Notch} = 50 Hz
- f_c = 21.9 Hz



4.3.21.8.3 50/60 Hz IIR notch filter

The IIR notch filter is used for narrow-band suppression of interference caused by the mains frequency.

This is an 8th-order IIR notch filter implemented in the form of a cascade of 4 2nd-order IIR notch filters.

Information:

The IIR notch filter should only be enabled if there is actually interference being caused by the mains frequency. You should always check whether sufficiently low and sufficiently narrow band filtering at 50 Hz / 60 Hz can be implemented using a moving average filter (see section 4.3.20.8.2.1 "Filter characteristics of the moving average filter").

This is because, like every higher-order IIR notch filter, this filter also has a tendency to respond to an input step with an attenuating vibration. The higher the dynamics of the expected measurement signal, the greater the potential interfering effect of this vibration tendency. In extreme cases, the vibration can temporarily be greater than the mains interference that is supposed to be filtered out.

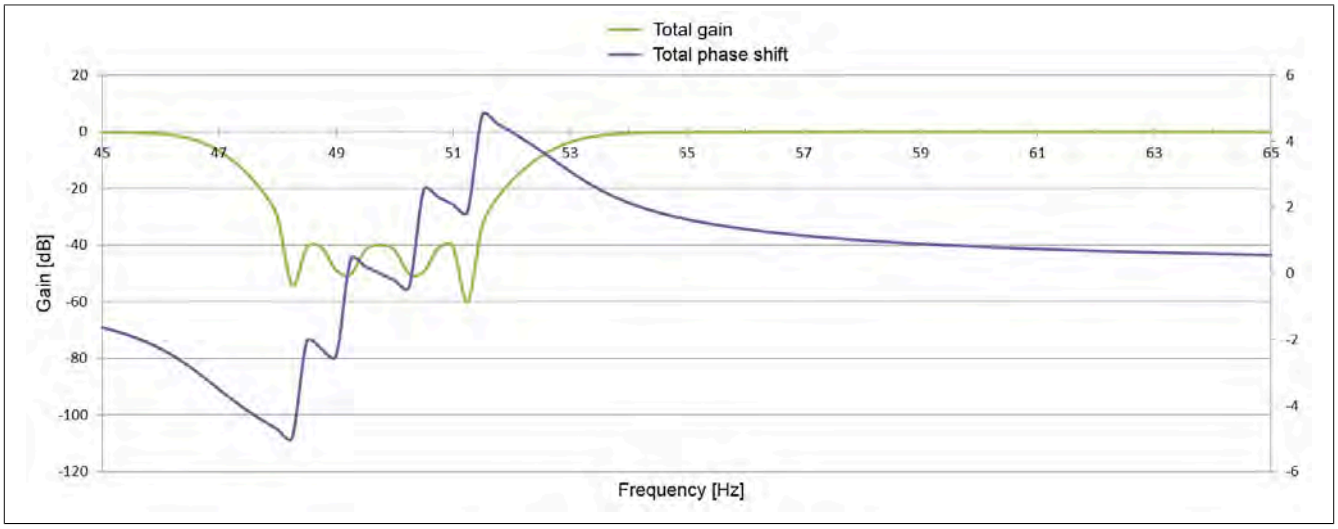
4.3.21.8.3.1 Filter characteristics of the IIR notch filter

There are three different filter characteristics that can be selected for both 50 Hz and 60 Hz (-40 dB, -60 dB and -80 dB). The higher the attenuation, the narrower the stopband.

Example 1

Filter characteristics for the following settings:

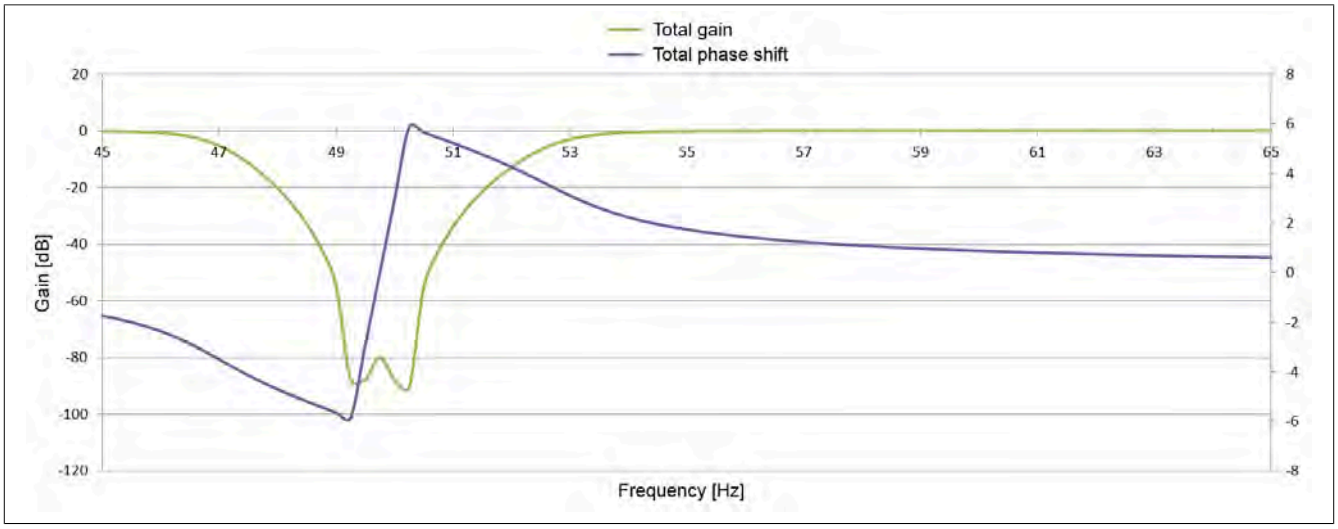
- Gain = -40 dB
- Frequency = 50 Hz
- Passband = 5 Hz
- Stopband = ±1 Hz



Example 2

Filter characteristics for the following settings:

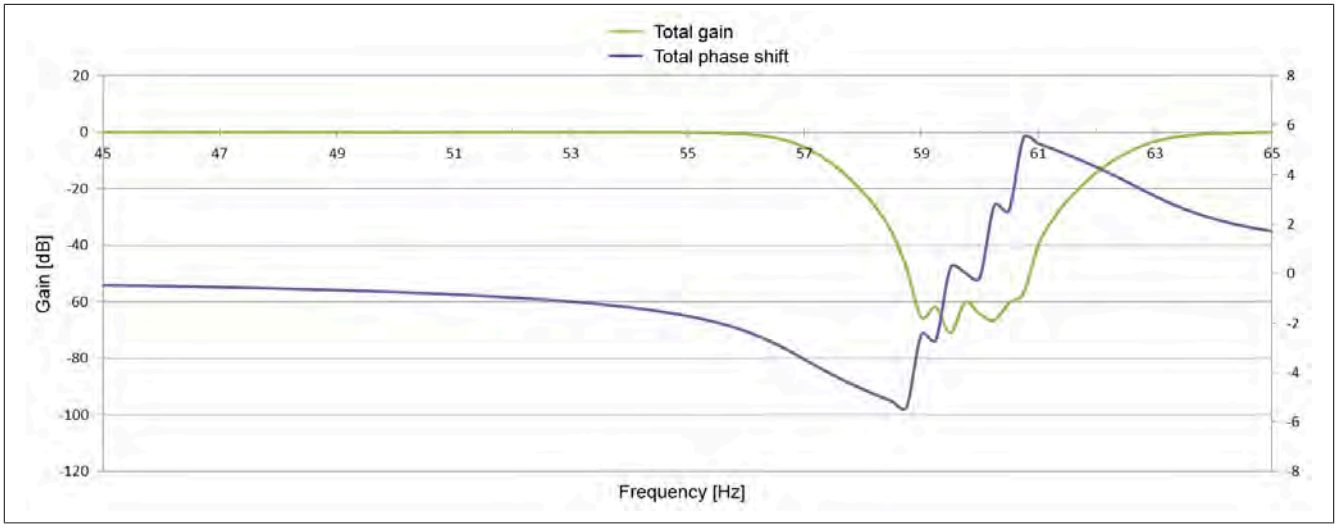
- Gain = -80 dB
- Frequency = 50 Hz
- Passband = 5 Hz
- Stopband = ±0.25 Hz



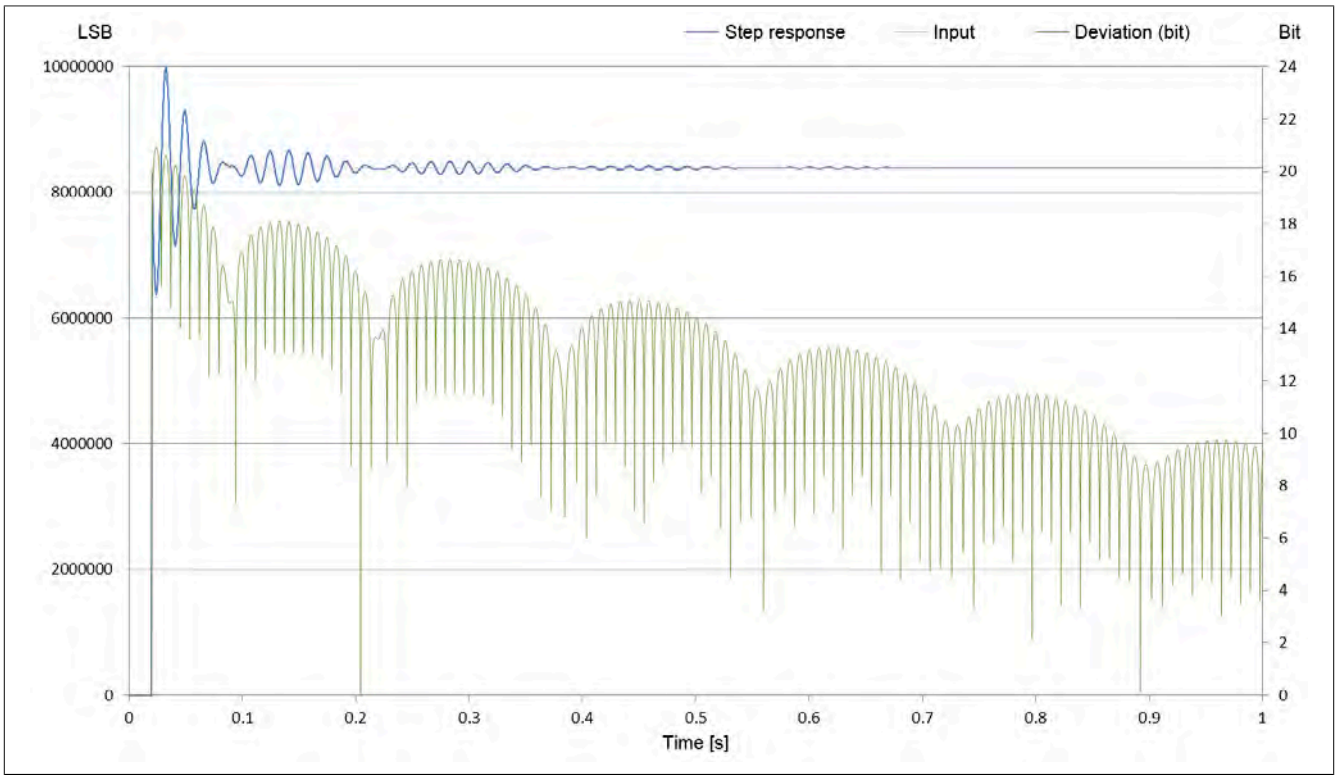
Example 3

Filter characteristics for the following settings:

- Gain = -60 dB
- Frequency = 60 Hz
- Passband = 5 Hz
- Stopband = ±0.5 Hz



Step response of an 8th-order IIR notch filter, including the deviation in bits:



4.3.21.9 Register description

4.3.21.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.3.21.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Analog signal - Configuration						
2	ControlPacked01	UINT			●	
6	ControlPacked02	UINT			●	
10	ControlPacked03	UINT			●	
14	ControlPacked04	UINT			●

39	24	StatusPacked04	USINT	●			

1) The offset specifies the position of the register within the CAN object.

4.3.21.9.3.1 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN-I/O.

4.3.21.9.4 Configuration

4.3.21.9.4.1 Configuration of strain gauge inputs

Name:
ControlPacked01 to ControlPacked04

The strain gauge inputs are configured in these registers:

- Strain gauge factor factor of strain gauge load cell
- Enabling of filters

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information	
0 - 2	Strain gauge factor	000	Default: 256 mV/V	
		001	128 mV/V	
		010	64 mV/V	
		011	32 mV/V	
		100	16 mV/V	
		101	8 mV/V	
		110	4 mV/V	
		111	2 mV/V	
			Averaging	1. Notch frequency [Hz]
3 - 7	Moving average	00000	Default: Moving average disabled (bypass)	
		00001	2	2500
		00010	4	1250
		00011	5	1000
		00100	10	500
		00101	20	250
		00110	25	200
		00111	50	100
		01000	83	60
		01001	100	50
		01010	125	40
		01011	167	30
		01100	200	25
		01101	250	20
		01110	300	16.66
		01111	500	10
		10000	1000	5
		10001 to 11111	Reserved (firmware limited to 1000)	
8	Notch filter	0	Default: IIR notch filter disabled (bypass)	
		1	IIR notch filter enabled	
9	Reserved	0		
10 - 11	Low-pass filter mode	00	IIR low-pass filter disabled (bypass)	
		01	1st-order IIR low-pass filter (see section 4.3.20.8.1 "IIR low-pass filter")	
		10 - 11	Reserved: No IIR low-pass filter active	
			Filter level	-3 db frequency [Hz]
12 - 14	Low-pass filter level	000	1	575
		001	2	230
		010	3	106
		011	4	51
		100	5	25
		101	6	12.5
		110	7	6.2
		111	8	3.1
15	Reserved	0		

4.3.21.9.4.2 Channel configuration

Name:
ConfigChannel01 to ConfigChannel04

The IIR notch filter is configured individually for each channel in these registers.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 11	Reserved	0	
12 - 13	Notch filter attenuation	00	Gain: -40 dB Pass: ±5 Hz Stop: ±1 Hz
		01	Gain: -60 dB Pass: ±5 Hz Stop: ±0.5 Hz
		10	Gain: -80 dB Pass: ±5 Hz Stop: ±0.25 Hz
		11	Reserved
14	Notch filter frequency	0	At 50 Hz
		1	At 60 Hz
15	Reserved	0	

4.3.21.9.5 Communication

4.3.21.9.5.1 Analog input values

Name:
AnalogInput01 to AnalogInput04

The analog input value is mapped in this register.

Data type	Value	Input signal:
DINT	<-8,388,607	Negative invalid range
	-8,388,607	Negative full-scale deflection / Underflow
	-8,388,606 to 8,388,606	Valid range
	8,388,607	Positive full-scale deflection / Overflow / Open line
	>8,388,607	Positive invalid range

4.3.21.9.5.2 Status of analog inputs

Name:
StatusPacked01 to StatusPacked04

The status of analog inputs is mapped in these registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	I/O power supply	0	No error
		1	Error in power supply
1	Bypass current	0	No error
		1	Overcurrent (sum from all sensors)
2 - 3	Reserved	0	
4	ADC configuration	0	Already configured
		1	Not yet configured
5	Analog values	0	Analog value valid
		1	Analog value invalid (analog value = 0xFF800000). Possible causes: • Internal transfer error (XOR checksum verification) • Error in strain gauge supply (bit 1) • Error in I/O voltage supply (bit 0) • ADC not (yet) configured
6	Analog value range overrun	0	Analog value valid
		1	Analog value invalid. Possible causes: • Overflow / Open line (analog value = 0x007FFFFF) • Underflow (analog value = 0xFF800001)
7	Moving average filter	0	Moving average filter engaged
		1	Moving average filter not engaged Possible causes: • After changing the filter length • Consequence of the filter being reset by another error

4.3.21.9.5.3 ADC conversion counter

Name:
AdcConvCtr01

Instead of being measured simultaneously, the strain gauge channels of the module are measured according to the multiplexing procedure. The "AdcConvTimestamp01" register contains the timestamp of the encoded last channel converted in the "AdcConvCtr01" register. The timestamp of the other channels can then be calculated later using this information.

Data type	Value
SINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Index of the last converted channel	0	Analog input 1
		1	Analog input 2
		2	Analog input 3
		3	Analog input 4
2 - 7	Rotating cycle counter	x	Incremented at the end of a conversion cycle. All channels are converted in a conversion cycle.

4.3.21.9.5.4 ADC conversion timestamp

Name:
AdcConvTimestamp01

The timestamp of the last converted channel is stored in this register (see bits 0 and 1 in the "AdcConvCtr01" register). This is always the point in time (in µs) at which the conversion of the latest ADC raw value is completed.

Data type	Value	Function
DINT	-2,147,483,648 to 2,147,483,647	Timestamp (in µs) of the last converted channel (see bits 0 and 1 in the ADC conversion counter)

The timestamp of the remaining channels can be determined in the application using the number and timestamp of the last converted channel according to the following table.

Channel	Age difference
4 - 3	47 µs
3 - 2	47 µs
2 - 1	47 µs
1 - 4	59 µs

Example:

- Latest channel (bit 0 - 1 in the "AdcConvCtr01" register) = 01 (analog input 2):
- Timestamp: "AdcConvTimestamp01" register = 0 µs

Channel	Timestamp
2	0 µs
1	-47 µs
4	-47-59 = -106 µs
3	-47-59-47 = -153 µs

4.3.21.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.21.9.7 I/O update time

I/O update time
200 µs

4.3.22 X20(c)AP31x1

4.3.22.1 General information

Power monitoring

These modules measure active, reactive and apparent power individually for each of the three phases and for all of them collectively. The power consumption of each phase and the total sum is also recorded. In addition, the modules provide the RMS values for voltage and current on the three phases. When measuring the current, the value of the current through the neutral line can also be detected and monitored. Measurement of the mains frequency and the phase angle of the three phases (current and voltage) complete the power measurement data.

Energy management

The integrated functions on the modules map the immediate power requirements of the machine in detail and also record its total power consumption. For the user, all relevant data is prepared and made available in the process image.

The ability to measure currents and voltages up to the 31st harmonic enables higher precision recording of RMS values. This allows the modules to easily cope with irregular sine curves, and makes them well-suited to renewable energy applications. In these types of applications, being able to accurately measure the frequency at a resolution of 0.01 Hz between 45-65 Hz is a great advantage. In general, the modules are suitable for use with 1-phase, 2-phase or 3-phase power mains.

Features

- Calculate RMS values from currents and voltages
- Calculate active, reactive and apparent power
- Calculate active, reactive and apparent energy
- Phasing detection
- Measure individual phases and calculate cumulative values
- Optionally measure current through the neutral line
- Calculate frequency and harmonics with high precision

4.3.22.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

7) From 0.126 VAC to 480 VAC

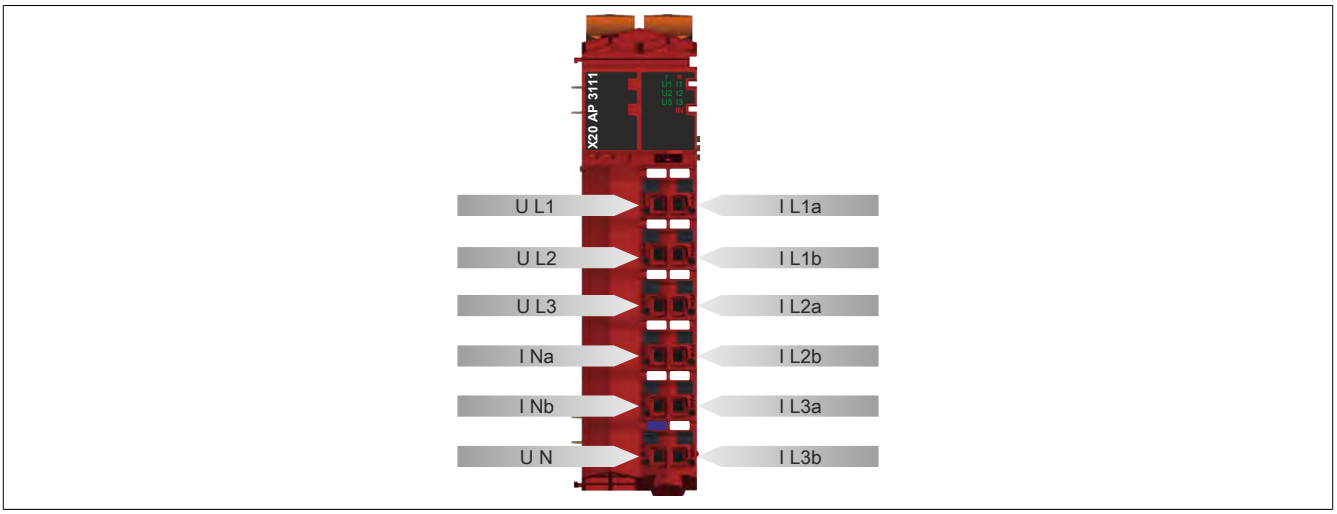
4.3.22.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	**Operating status**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
	Module status			
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	Analog input voltage			
	U1 - U3	Green / yellow	Off	Display disabled or U_{RMS} < "Fail" threshold value
		Green	Blinking	Phase sequence is correct and U_{RMS} < "Warning" threshold value
			On	Phase sequence is correct and U_{RMS} > "Warning" threshold value
		Yellow	Blinking	Phase sequence is incorrect and U_{RMS} < "Warning" threshold value
			On	Phase sequence is incorrect and U_{RMS} > "Warning" threshold value
	Analog input current			
	I1 - I3	Green / yellow	Off	Display disabled or I_{RMS} < "Display" threshold value
		Green	On	Active power positive
		Yellow	On	Active power negative
	Analog input neutral current			
	IN	Red	Off	Neutral current monitoring disabled
			On	Neutral current > threshold value

1) Depending on the configuration, a firmware update can take up to several minutes.

4.3.22.6 Pinout



Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

4.3.22.6.1 Current transformer connections

In order to be able to properly calculate values that reference all 3 phases (e.g. total active power, total reactive power, etc.), it is important for the current transformer phases to be connected correctly.

- A output on the transformer to the respective Ixa input on the module
- B output on the transformer to the respective Ixb input on the module

Converter	Input	Output
1	I L1a	
2	I L	
3		

4.3.22.7 Current transformer

Potential-free measurement of the AC current requires a current transformer. The current transformer is a transducer that delivers a secondary signal proportional to the primary current. This secondary signal is measured by the module. The maximum directly configurable primary current is 65 A. Values higher than 65 A can also be measured by implementing a transformation in the software application (see explanation and example provided below).

The maximum secondary signal depends on the module:

Module	Secondary current/voltage
X20AP3111	20 mA
X20AP3121	1 A
X20AP3131	5 A
X20AP3161	333 mV

The rated transformation ratio is calculated using the following formula:

X20AP3111 - X20AP3221 - X20AP3131	Rated transformation ratio $K_n = \frac{\text{primary nominal current}}{\text{secondary nominal current}}$
X20AP3161	No transformation; the maximum primary current corresponds to the 333 mV

A smaller transformation ratio should be defined for measuring higher primary currents. The values calculated by the module must be converted in the application according to the real rated transformation ratio that must be defined.

Example: Currents of up to 100 A are flowing on the primary side. A current transformer with a rated transformation ratio of 100/1 A is used. A rated transformation ratio of 50/1 A is defined in the module to match the current transformer. If the primary current calculated by the module is 40 A, then the actual value will be calculated as follows:

Actual primary current = 40 A * 100 / 50 = 80 A
Actual resolution = 1 mA * 100 / 50 = 2 mA

Note: **The same factor must be used for all power ratings and energy values when making the transformation.**

Caution!

To prevent damaging the module, you must ensure the current inputs are electrically isolated. This is done by connecting one transformer for each current input that is being used.

The current inputs on the module are not electrically isolated, so the secondary circuit between the transformer and the module must not be grounded. Grounding would distort the measurement and show current values that are too low!

Any other devices connected to this secondary circuit must also be electrically isolated (see also Fig. 105 "Input circuit diagram of current inputs")!

4.3.22.8 Voltage transformer

Voltage transformers are not provided in the configuration by default (e.g. by setting the transformation ratio).

They can, however, be used to measure higher voltages than the nominal voltages specified in the technical data. Similar to current value correction (see 4.3.22.7 "Current transformer") the rated transformation ratio between primary and secondary voltage should be calculated and applied.

Information:

The same factor must be used for all voltage values, power ratings and energy values when making the transformation.

4.3.22.9 Input circuit diagram

AC voltage inputs

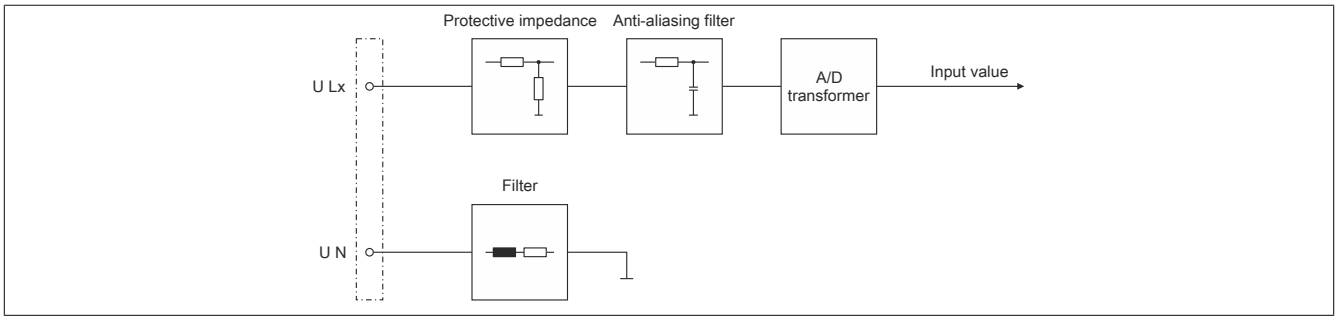


Figure 104: Input circuit diagram of voltage inputs

4.3.22.10 Typical connection examples for different mains configurations

General information

There are many different mains configurations around the world. This section will present a few typical connection examples.

Connection example 1 - Mains A

This example involves a 3-element, 3-phase, 4-line star measurement with grounded neutral conductor and optional fault current detection.

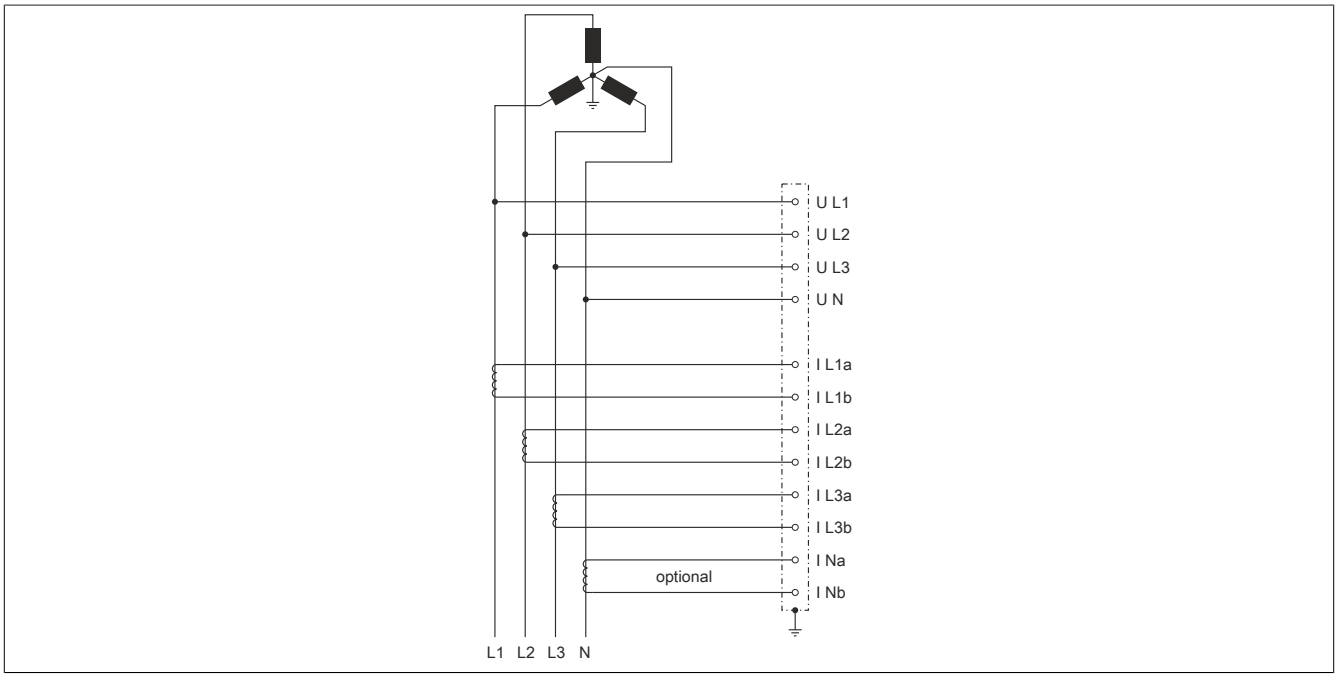

Figure 106: Supported mains configuration A

Connection example 2 - Mains B

This example involves a 3-element, 3-phase, 3-line star measurement.

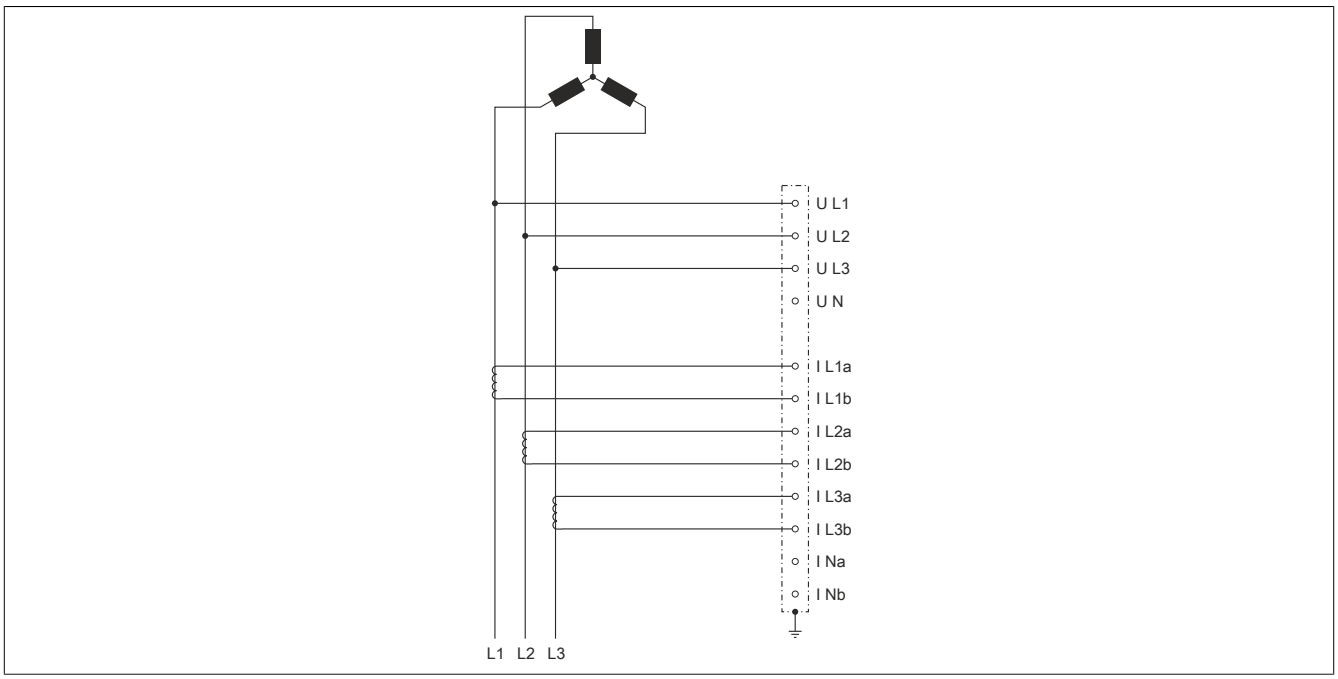

Figure 107: Supported mains configuration B

Connection example 3 - Mains C

This example involves a 3-element, 3-phase, 3-line star measurement with grounded neutral conductor and optional fault current detection.

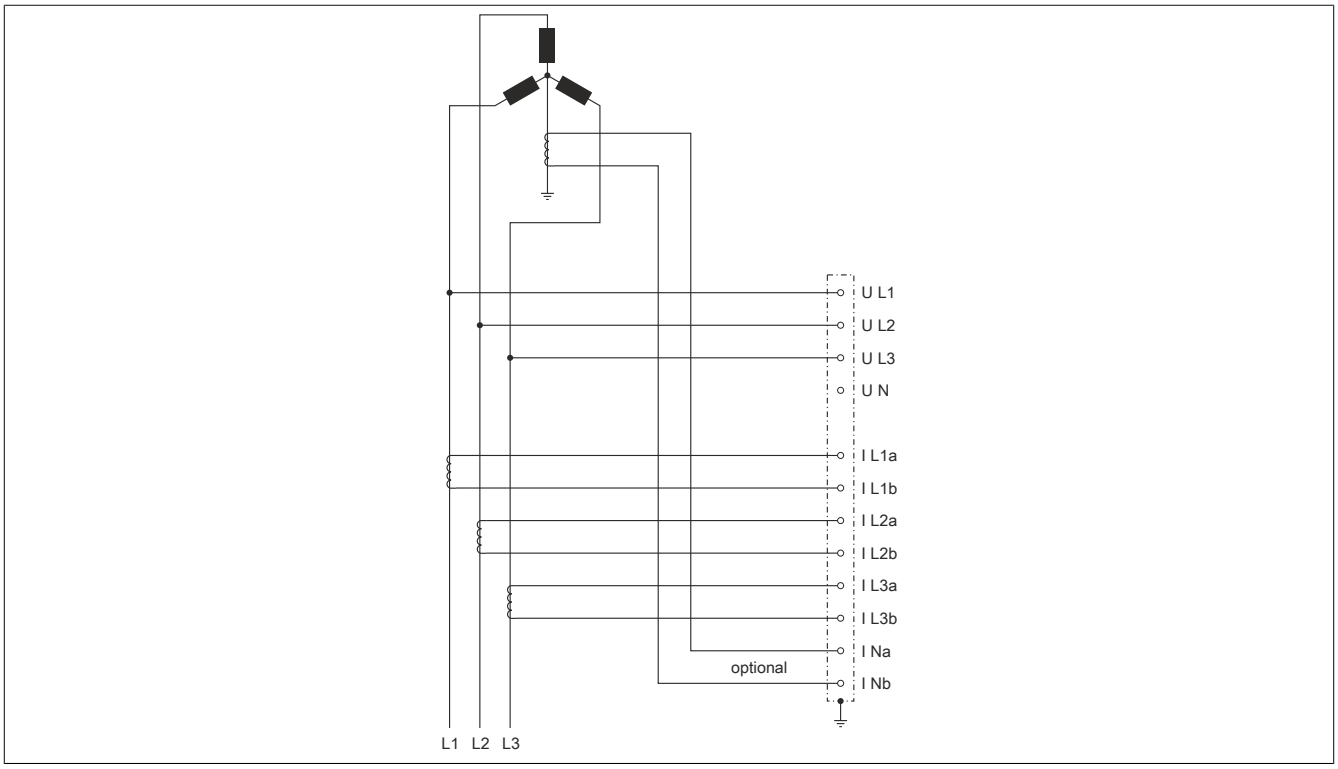

Figure 108: Supported mains configuration C

Connection example 4 - Mains D

This example involves a 3-element, 3-phase, 4-line star measurement with optional fault current detection.

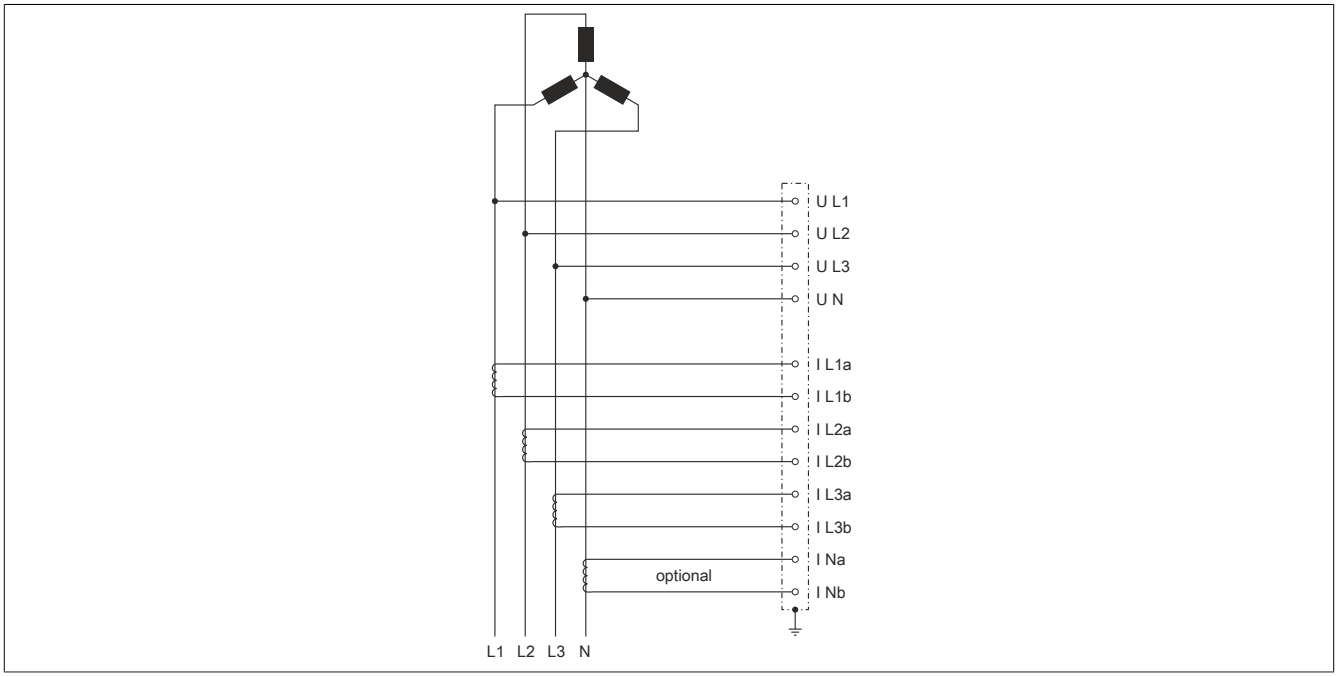

Figure 109: Supported mains configuration D

Connection example 5 - Mains E

This example involves a 2-element, 2-phase, 3-line star measurement with grounded neutral line conductor.

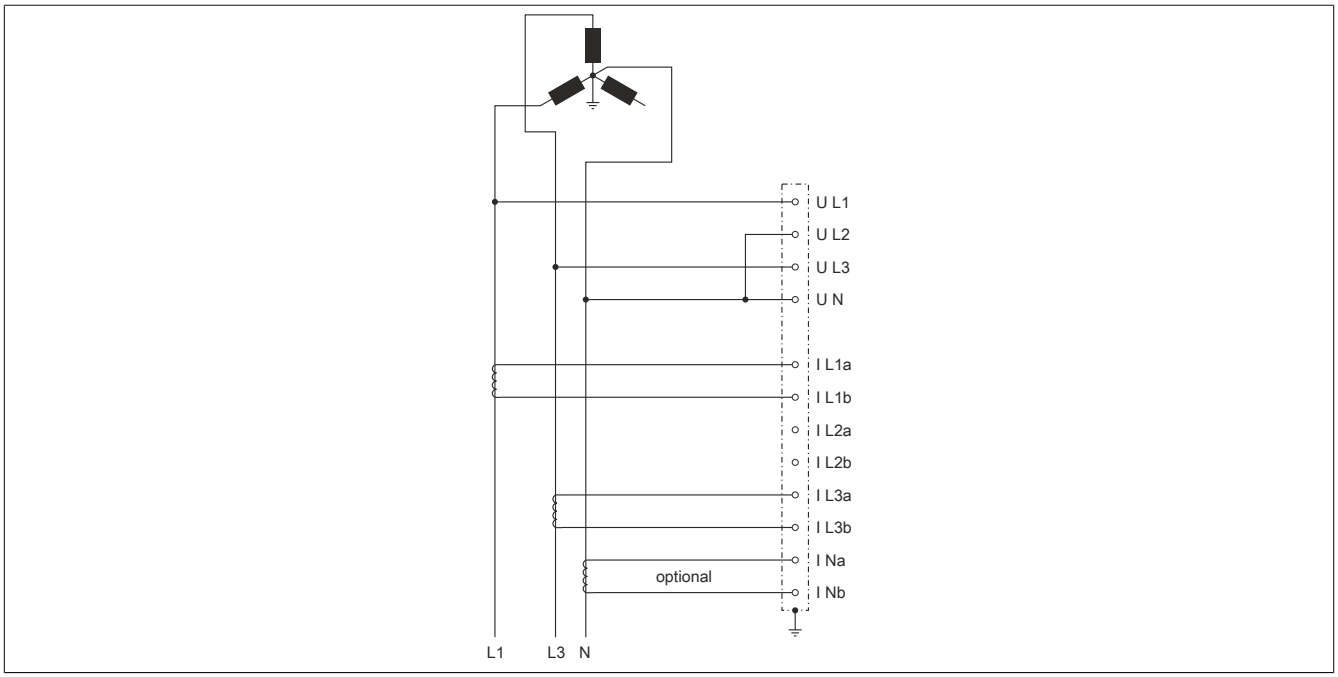

Figure 110: Supported mains configuration E

Connection example 6 - Mains F

This example involves a 3-element, 3-phase, 3-line delta measurement.

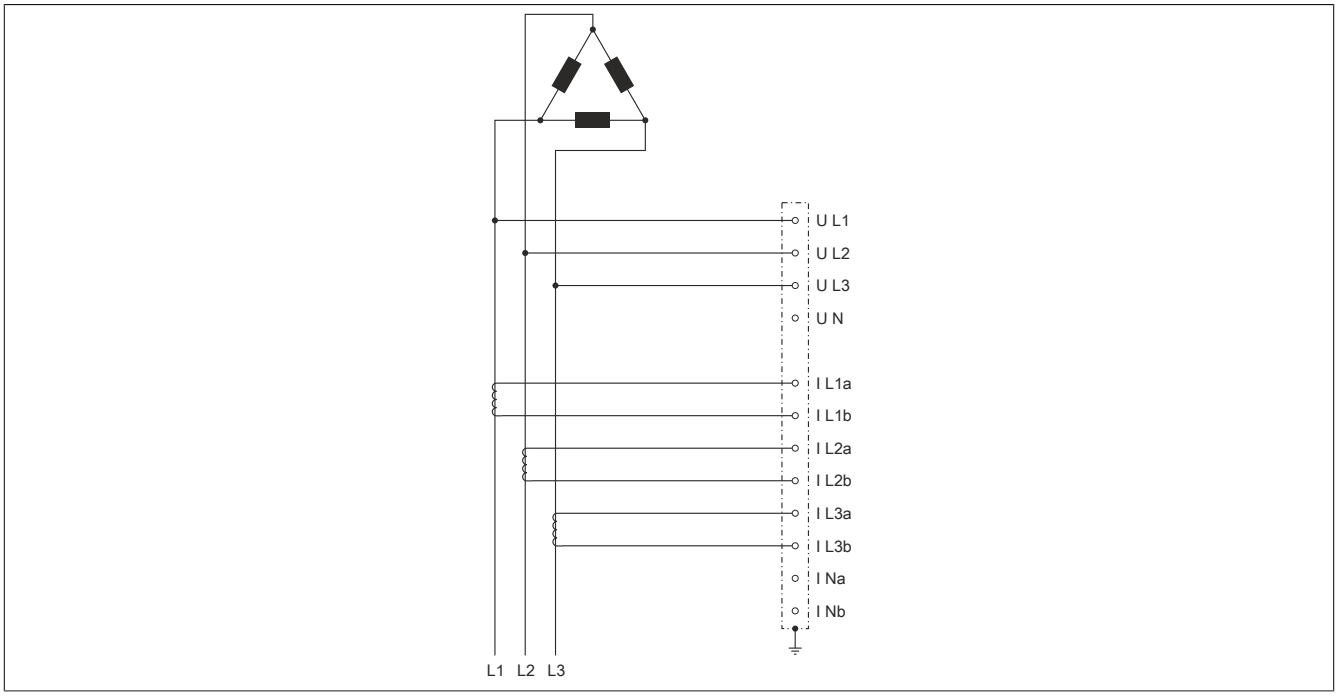

Figure 111: Supported mains configuration F

Connection example 7 - Mains G

This example involves a 3-element, 3-phase, 4-line delta measurement with grounded neutral.

Information:

The maximum voltage value specified in the data sheet must not be exceeded!

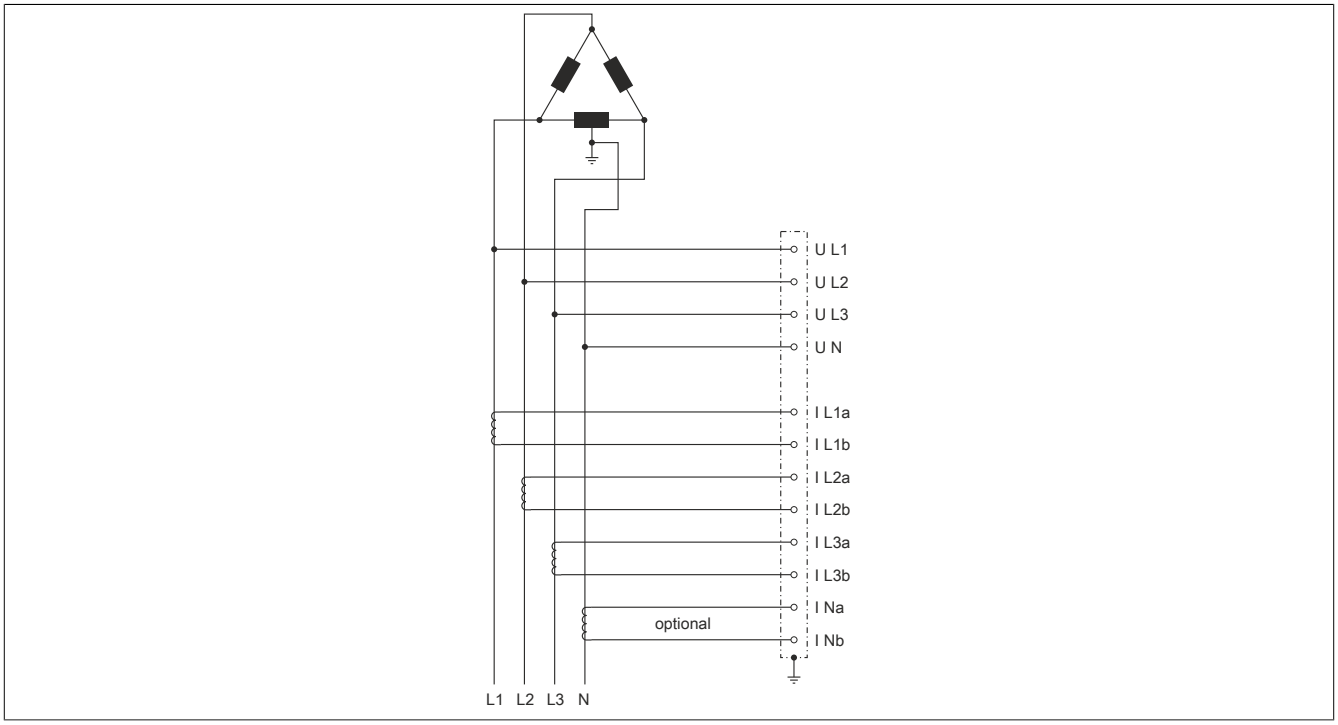

Figure 112: Supported mains configuration G

4.3.22.11 Register description

4.3.22.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

4.3.22.11.3.1 CAN I/O bus controller

The module occupies 3 analog logical slots on CAN-I/O.

4.3.22.11.4 General information

The modules are used for power monitoring and for a machine's energy management. Examples of where this would be used:

- Multi-phase energy measurement for class 0.5S or class 1 for
  - 3-phase, 4-line applications with neutral line (with/without grounding)
  - 3-phase, 3-line applications (with/without grounding)
  - 2-phase mains networks with grounded phase B connection
  - ARON connection
- Single-phase measurement by disabling inputs that are not needed
- Mains analysis according to harmonic content
- Signal trace by 8 kHz recording of the 3 voltage channels and 4 current channels with FIFO

4.3.22.11.4.1 Measured value preparation

The modules provide the following possibilities for measured value preparation:

- Precision of ±0.1% for real energy and ±0.2% for reactive energy
- Temperature coefficient of internal reference of 6 ppm/°C
- Error ≤±0.5% for voltage, current, active-, reactive-, apparent power, frequency active power factor and phase angle
- Energy registers for active, reactive and apparent energy, separated for forward and backward, fundamental waves and harmonics
- Threshold register for status signal generation and activation of power and energy measurement
- Determining the THD harmonic component
- Discrete Fourier Transformation (DFT) up to 31st harmonic component per phase for voltage and current
- Status signals for voltage dip, loss of voltage, phase sequence, energy flow, neutral current monitor, harmonic component monitor

4.3.22.11.4.2 Additional information

Information	Description
Measurement range monitoring	Due to the majority of registers consisting of 16 bit values (exception: energy registers, which are interpolated to 32 bit by the FW), the measurement ranges are subject to limitations, e.g. voltage 650.00 Vrms and current 65,000 Arms (after accounting for the transfer factor of the current transformer).
Extended measurement ranges	Extended measurement ranges can be achieved with the software application by upscaling the measured values.
Frozen values	Sample time register: A NetTime is assigned to the group of measured values when read from the power meter. This NetTime can be used to determine if the values have been frozen.
Environment variables	The values for duty cycle, boot counter, and minimum / maximum transformer temperature are recorded.

4.3.22.11.4.3 Measurement function

The values measured for RMS, power, active power factor, phase angle and frequency are mean values over 16 full waves, the update rate is ~3 Hz.

The following represents the measurement time over 16 full waves at the corresponding frequency:

50 Hz ... 320 ms
60 Hz ... 267 ms

Energy measurement

The power measurement (energy measurement) is based on the integration of the measured values with a sampling rate of 1 MHz.

The collected energy values are made available as energy pulses with an adjustable resolution of 0.1 CF or 0.01 CF values in the energy registers and with a resolution of 1 CF on the CF status flags.

The conversion can be defined using the PL constant. The default value 0x4A817C80 = 1.250.000.000 is equal to 360 CF/kWh or 0.1 CF/kWs. Increasing the value causes the CF amount to decrease per energy unit (e.g. 0x53D1AC10 = 1.406.250.000 is equal to 320 CF/kWh). When choosing to display the values as kWh, a resolution of 0.08789 CF/kWs is set internally and the register values are converted with a factor of 1/4096.

The energy threshold register (e.g. PStartTh) can be used to set the amount of energy needed to start an accumulation or to reset the "no load" signals in the status registers. The length of the CF pulse can vary according to the resulting output rate.

Automatic reading of the energy meter from the transformer must be enabled because valid values are only available after the transformer has been configured. It is possible to clear the energy register or to set it with a block of the register written in the software application.

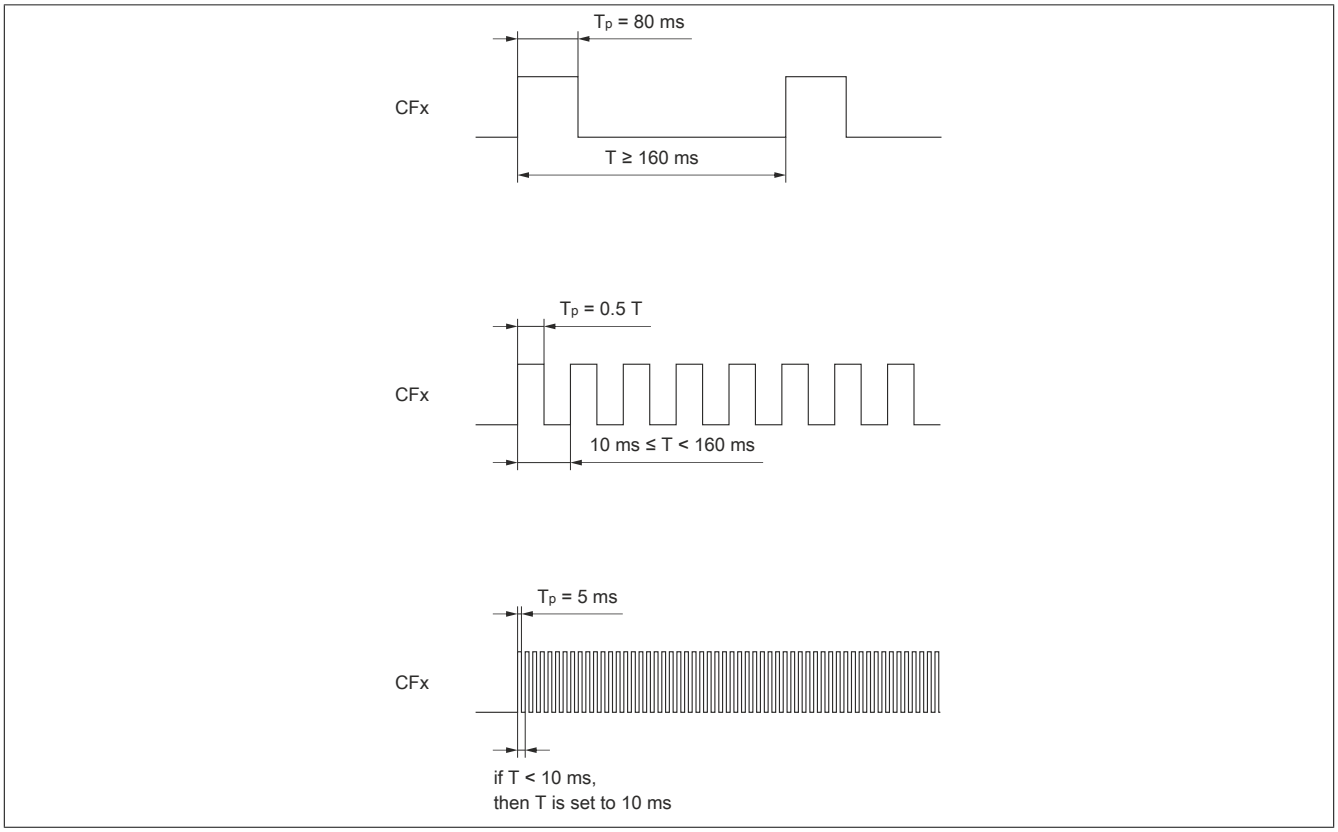

Figure 113: The length of the CF pulse can vary according to the resulting output rate

Power measurement

The phase power ratings are calculated by the module and stored in the corresponding registers.

The total power ratings are equal to the sum of the phase power ratings. To prevent the number range from being exceeded, the value in the registers is equal to a fourth of the actual power. This value must be multiplied by 4 by the application.

The vector-based total apparent power (complex total apparent power) is calculated according to IEEE1459.

Power factor

The phase power factor is calculated by dividing the phase active power by the phase apparent power.

The total power factor is calculated by dividing the total active power by the total apparent power.

Neutral current

The neutral current can be measured or calculated. Both values are available.

The user can configure which one to use for displaying the status.

Phase angle

The phase angle is calculated based on the zero-crossing detection.

Frequency

Frequency measurement is based on Phase A. If A fails, then Phase C is used. If both A and C fail, then Phase B is used.

Temperature

The Chip-Junction temperature is measured approximately every 100 ms using the sensor integrated in the transformer.

THD+N - Sum of interference power of the harmonic (THD) + interference power of the noise (N)

The THD+N measurement is used to monitor the percentage of harmonics in the network.

If this percentage falls below 10%, then an accuracy of 0.01% can no longer be guaranteed.

This is calculated as follows: (SQR (RMS_{total}^2 - $RMS_{fundamental\ wave}$^2)) / $RMS_{fundamental\ wave}$

Fourier analysis

The harmonic component from the 2nd to the 31st harmonic is calculated for voltage and current and the THD (Total Harmonic Distortion) of each phase.

The DFT period is 0.5 s. This corresponds to a resolution of 2 Hz. The input samples are recorded at a sampling rate of 8 kHz and can be optionally multiplied with a "Hann window" before being evaluated. This is initiated when requested by the application.

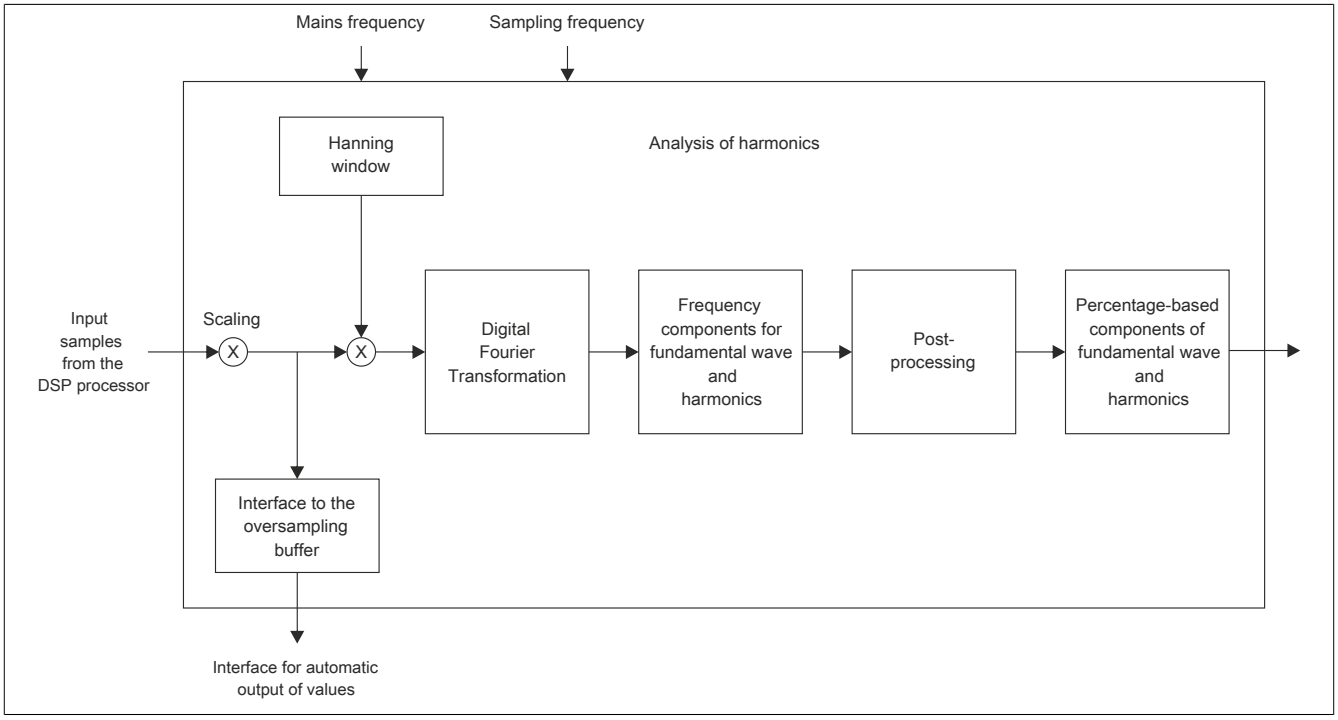

Figure 114: Diagram of Fourier analysis

4.3.22.11.4.4 Event generation

Zero-crossing detection

Zero-crossing detection can be configured for each phase for cu or voltage and edge and forms the basis for frequency and angle measurements and subsequently also for active and reactive power calculations.

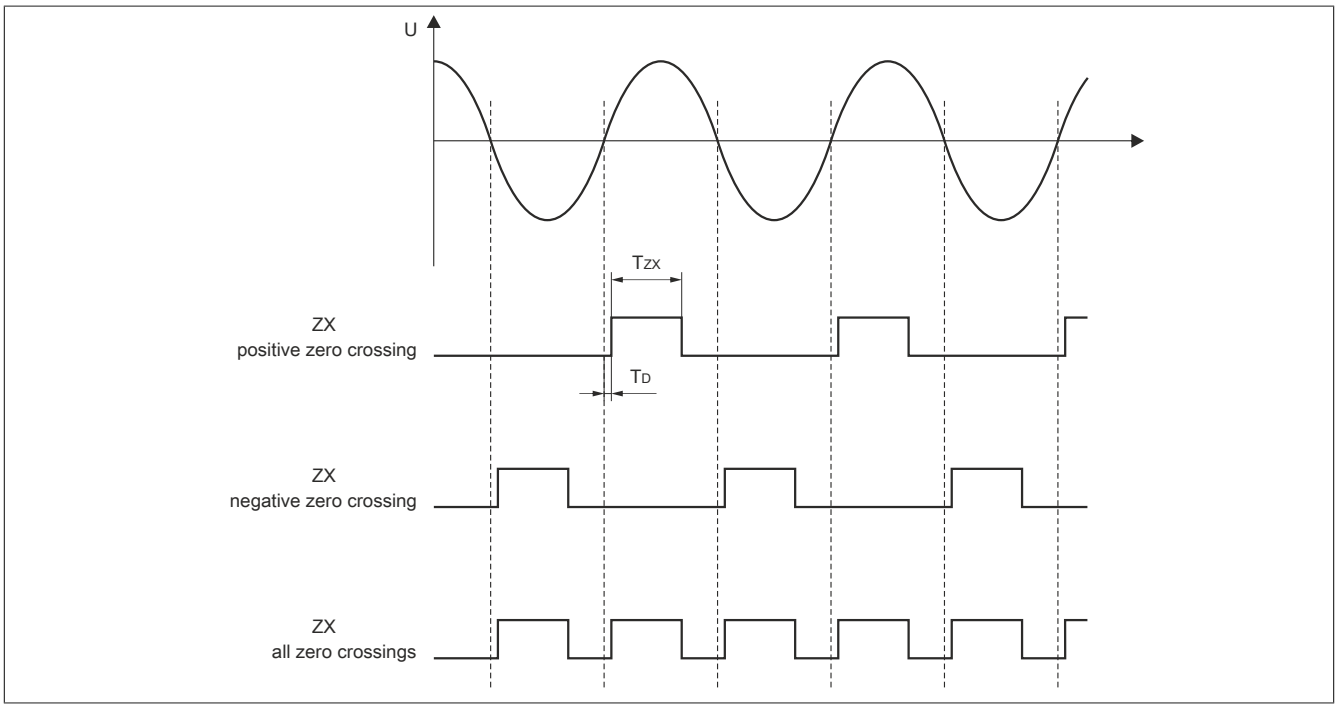

Figure 115: Time diagram of zero-crossing detection per phase

Icon	Description	Minimum	Typical	Maximum	Unit
T_{ZX}	Length of high signal		5		ms
T_D	Delay time		0.2	0.5	ms

Table 72: Specification of zero-crossing detection

Detection of voltage dip or power failure

Event	Description
Voltage dip	The threshold for voltage dips is typically set to 78% of the standard voltage (approx. 170 Vrms). The status flag is set if more than three 8 kHz samples are below the threshold value within 2 consecutive 11 ms windows.
Power failure	The threshold for voltage dips is typically set to 10% of the standard voltage (approx. 22 Vrms). The status flag is set if more than three 8 kHz samples are below the threshold value within 2 consecutive 11 ms windows. If a power failure is detected, then zero-crossing detection is disabled for voltage and current for this phase.

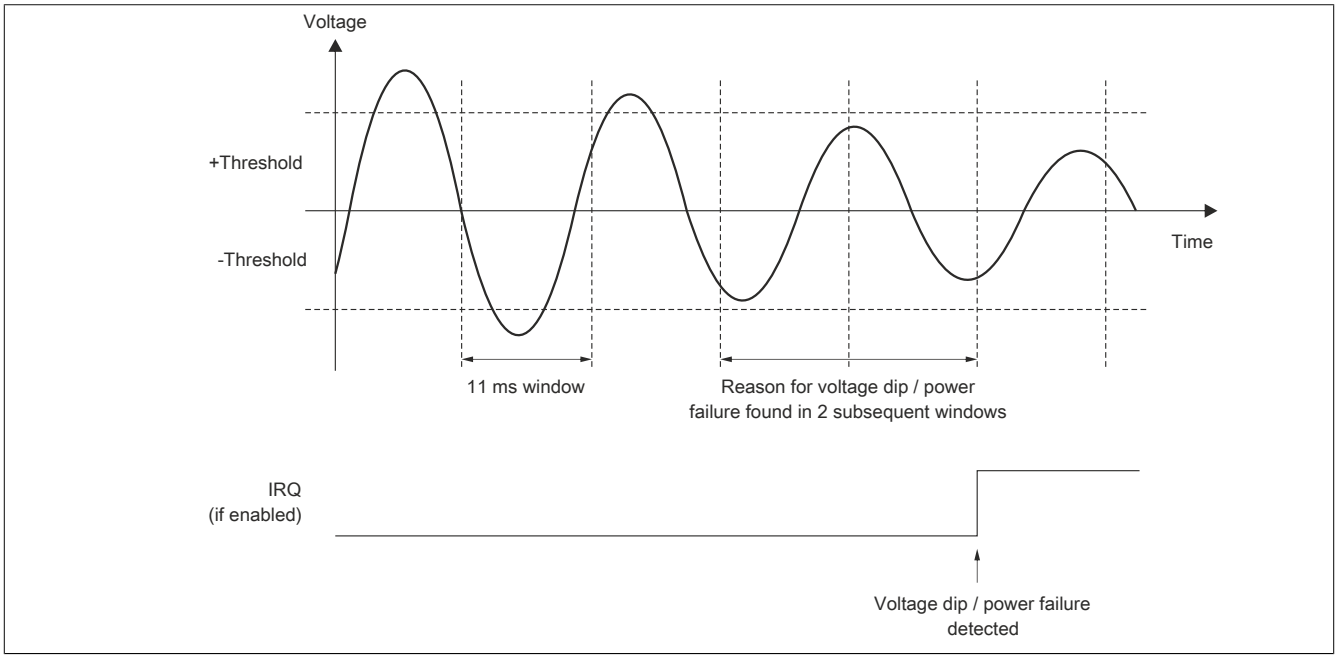

Figure 116: Time diagram for detecting a voltage dip or power failure

Neutral current monitoring

Neutral current monitoring of the measured and the calculated value is done with separate threshold value registers and status flags.

Phase sequence monitoring

3 phase and 2 phase applications are handled differently:

Application	Description
3 phases	Zero cross-overs of voltage and current must follow the sequence Phase A before Phase B before Phase C
2 phases	Zero cross-overs of voltage and current must follow the sequence Phase A at least 180° before Phase C

Table 73: Phase sequence monitoring according to the application

4.3.22.11.4.5 Configuration registers

The configuration and calibration registers are each composed of blocks and employ a checksum feature to highlight undesired changes. In order to apply this register to the transformer, the respective transfer register must be changed after the data is transferred to the module (incrementing, bit toggling, etc.). The start value of the transfer register is 0 after startup.

4.3.22.11.5 Interface for transferring process variable mapping

Due to the amount of potential cyclic input data and the limitation to 30 byte cyclic X2X data, the extended Flat Stream interface, DPS = Data Point Stream, has been defined as the mechanism for transferring the process variables. DPS is based on the Flat Streaming Interface (FSI) for serial interface modules. The FSI was expanded to include the block number as the first byte of the user data frame and implements the termination of a frame (data image of the channel) with a zero segment.

The data blocks are re-transferred if a read request is triggered after a transfer has been completed. A block number can be sent via the DPS to set a different block or transfer the entire image (default: block number 0).

It should be possible to adapt the DPS interface to the available buffer size. However, the higher-level fieldbus must be taken into account when doing so (e.g.: CAN 8 byte object, InputMTU size 7). The block number is added to the front of the actual payload data as a means to differentiate the blocks.

```
#define ADC_BLK_ALL        0   // struct ADC_REG
#define ADC_BLK_STATUS     1   // long NetTimeReg + struct ADC_REG_STATUS
#define ADC_BLK_RMS        2   // struct ADC_REG_RMS
#define ADC_BLK_POWER      3   // struct ADC_REG_POWER
#define ADC_BLK_THD_ANGLE  4   // struct THD_ANGLE
#define ADC_BLK_ENERGY     5   // long NetTimeEnergy + struct ADC_REG_ENERGY
#define ADC_BLK_DFT        6   // long NetTimeDft + struct ADC_REG_DFT
#define ADC_BLK_CFGACT     7   // struct ADC_REG_CFGACT
#define ADC_BLK_ENVREG     8   // struct ENV_STATUS
```

Information:

- **Consistency of the data is only provided for the individual variables because the data is transferred from the AD converter asynchronously to the conversion.**
- **Make sure that the byte sequence of the register is in accordance with the Little Endian model (Intel format).**

The NetTime timestamps are always updated after the blocks are generated when preparing a new alternating buffer.

4.3.22.11.5.1 Data block structure

ADC_REG

```
typedef struct ADC_REG     ADC_REG;
struct ADC_REG

4.3.22.11.6 Standard register

4.3.22.11.6.1 Total active power

Name:
PmeanT

The value in the register equals a fourth of the actual power. The calculation can be performed in either absolute or arithmetic mode (see register "MeteringMode" <Bit 3>). Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 W

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total active power = Register value * 4

4.3.22.11.6.2 Total reactive power

Name:
QmeanT

The value in the register equals a fourth of the actual power. The calculation can be performed in either absolute or arithmetic mode (see register "MeteringMode" <Bit 4>). Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 var

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total reactive power = Register value * 4

4.3.22.11.6.3 Total apparent power

Name:
SmeanT

The value in the register equals a fourth of the actual power. The power is calculated in arithmetic mode. Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	0 to 32767	Resolution 4 VA

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total apparent power = Register value * 4

4.3.22.11.6.4 Total active energy combined

Name:
AEnergyT

Total active energy in forward and backward direction.

Data type	Value	
DINT	-2,147,483,647 to 2,147,483,647	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Internal calculation formula for the total active energy:

AEnergyT = (DINT)(APenergyT - ANenergyT) ... Calculation overflows must be handled in the application

4.3.22.11.6.5 Total reactive energy combined

Name:
REnergyT

Total reactive energy in forward and backward direction.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Internal calculation formula for the total reactive energy:

REnergyT = (DINT)(RPenergyT - RNenergyT) ... Calculation overflows must be handled in the application

4.3.22.11.6.6 Status signals and responses

Name:
StatusInput

The signals are recorded in 200 µs intervals.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	CF1 energy pulse 1, total active energy	0	Not yet calculated
		1	Calculated
1	CF2 energy pulse 2, total apparent energy, configurable Standard: Arithmetic sum of apparent energy, can be reconfigured via register <MeteringMode>	0	Not yet calculated
		1	Calculated
2	CF3 energy pulse 3, total active energy, fundamental wave	0	Not yet calculated
		1	Calculated
3	CF4 energy pulse 4, total active energy, harmonics	0	Not yet calculated
		1	Calculated
4	ZX1 zero cross signal – Phase A	0	Zero cross-over not detected
		1	Standard: Pulse at positive edge of the zero cross signal of the voltage input, can be reconfigured via register "ZXConfig"
5	ZX2 zero cross signal – Phase B	0	Zero cross-over not detected
		1	Standard: Pulse at positive edge of the zero cross signal of the voltage input, can be reconfigured via register "ZXConfig"
6	ZX3 zero cross signal – Phase C	0	Zero cross-over not detected
		1	Standard: Pulse at positive edge of the zero cross signal of the voltage input, can be reconfigured via register "ZXConfig"
7	Reserved	0	
8	DFT response sent	x	If the state in the register "ControlOutput" corresponds with the response, then the action is complete
9	Energy value update response sent	0	No update
		1	Update complete
10	Energy value response deleted	x	If the state in the register "ControlOutput" corresponds with the response, then the action is complete
11	Energy value response set	x	If the state in the register "ControlOutput" corresponds with the response, then the action is complete
12 - 15	Reserved	0	

4.3.22.11.6.7 Control signals

Name:
ControlOutput

Control signals are evaluated in a ~5 ms interval.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	DFT analysis	0	Don't start
		1	Start[1)]
1	Automatically read energy values	0	Do not automatically read
		1	Automatically read
2	Clear energy values	0	Don't delete
		1	Delete[1)]
3	Set energy values	0	Don't start
		1	Start[1)]
4 - 15	Reserved	0	

1) If the state in the register "ControlOutput" corresponds with the response, then the action is complete.

4.3.22.11.7 Analog status registers

4.3.22.11.7.1 Read timestamp for I/O register (+0x0022 = 16 bit)

Name:
SampleTime01_32bit

Network timestamp for the readout of the status, RMS, power register.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Network time

4.3.22.11.7.2 ADC system status 1

Name:
SysStatus1

The register is read by the converter in a ~5 ms interval.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	
2	SumStatusPhaseLoss, voltage of one or more phases < failure threshold in the register	0	Voltage within permitted range
		1	Voltage lower than the failure threshold
3	SumStatusPhaseWarning, voltage of one or more phases < warning threshold in the register	0	Voltage within permitted range
		1	Voltage lower than the warning threshold
4 - 5	Reserved	0	
6	ErrOrderPhasecurrent, error in the order of phase currents	0	No error
		1	Error
7	ErrOrderPhaseVoltage, error in the order of phase voltages	0	No error
		1	Error
8	CS3Err, checksum error in configuration block 3	0	No error
		1	Error
9	Reserved	0	
10	CS2Err, checksum error in configuration block 2	0	No error
		1	Error
11	Reserved	0	
12	CS1Err, checksum error in configuration block 1	0	No error
		1	Error
13	Reserved	0	
14	CS0Err, checksum error in configuration block 0	0	No error
		1	Error
15	Reserved	0	

4.3.22.11.7.3 ADC system status 2

Name:
SysStatus2

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	RevPchgC, the direction of the active energy for phase C has changed	0	No change of direction
		1	Direction has changed
1	RevPchgB, the direction of the active energy for phase B has changed	0	No change of direction
		1	Direction has changed
2	RevPchgA, the direction of the active energy for phase A has changed	0	No change of direction
		1	Direction has changed
3	RevPchgT, the direction of the active energy for the total has changed	0	No change of direction
		1	Direction has changed
4	RevQchgC, the direction of the reactive energy for phase C has changed	0	No change of direction
		1	Direction has changed
5	RevQchgB, the direction of the reactive energy for phase B has changed	0	No change of direction
		1	Direction has changed
6	RevQchgA, the direction of the reactive energy for phase A has changed	0	No change of direction
		1	Direction has changed
7	RevQchgT, the direction of the reactive energy for the total has changed	0	No change of direction
		1	Direction has changed
8	Reserved	0	
9	DFTDone, DFT analysis complete (temporary bit)	0	DFT analysis not complete
		1	DFT analysis complete
10	SumStatusWarningTHDCurrent, the THDIx value of one or more phases > warning threshold in the register	0	THDIx value within permitted range
		1	THDIx value higher than warning threshold
11	SumStatusWarningTHDVoltage, the THDUx value of one or more phases > warning threshold in the register	0	THDUx value within permitted range
		1	THDUx value higher than warning threshold
12 - 13	Reserved	0	
14	ErrIrmsNCalc, the calculated value of the neutral line > warning threshold in the Register	0	Calculated value within permitted range
		1	Calculated value higher than warning threshold
15	ErrIrmsNMeas, the measured value of the neutral line > warning threshold in the Register	0	Measured value within permitted range
		1	Measured value higher than warning threshold

4.3.22.11.7.4 ADC system status 3

Name:
SysStatus3

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	CF1RevFlag, direction of CF signal	0	Forward[1)]
		1	Back[2)]
1	CF2RevFlag, direction of CF signal	0	Forward[1)]
		1	Back[2)]
2	CF3RevFlag, direction of CF signal	0	Forward[1)]
		1	Back[2)]
3	CF4RevFlag, direction of CF signal	0	Forward[1)]
		1	Back[2)]
4 - 11	Reserved	0	
12	TVSNoload, vector-based total apparent power of all phases in "No load" state	0	Status with load
		1	Status without load
13	TASNoload, total apparent power of all phases in "No load" state	0	Status with load
		1	Status without load
14	TPNoload, total active power of all phases in "No load" state	0	Status with load
		1	Status without load
15	TQNoload, total reactive power of all phases in "No load" state	0	Status with load
		1	Status without load

1) Forward direction of CF pulse (positive sign of corresponding energy register)
2) Reverse direction of CF pulse (negative sign of corresponding energy register)

4.3.22.11.7.5 ADC system status 4

Name:
SysStatus4

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	LossPhaseC, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
1	LossPhaseB, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
2	LossPhaseA, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
3	Reserved	0	
4	WarningPhaseC, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
5	WarningPhaseB, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
6	WarningPhaseA, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
7 - 15	Reserved	0	

4.3.22.11.7.6 ADC system status 1

Name:
SystemStatusSel01

The most important bits of the "SysStatus1" register are stored in this register.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	
2	SumStatusPhaseLoss, voltage of one or more phases < failure threshold in the register	0	Voltage within permitted range
		1	Voltage lower than the failure threshold
3	SumStatusPhaseWarning, voltage of one or more phases < warning threshold in the register	0	Voltage within permitted range
		1	Voltage lower than the warning threshold
4 - 5	Reserved	0	
6	ErrOrderPhasecurrent, error in the order of phase currents	0	No error
		1	Error
7	ErrOrderPhaseVoltage, error in the order of phase voltages	0	No error
		1	Error

4.3.22.11.7.7 ADC system status 2

Name:
SystemStatusSel02

The most important bits of the "SysStatus2" register are stored in this register.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	0	
2	SumStatusWarningTHDCurrent, the THDIx value of one or more phases > warning threshold in the register	0	THDIx value within permitted range
		1	THDIx value higher than warning threshold
3	SumStatusWarningTHDVoltage, the THDUx value of one or more phases > warning threshold in the register	0	THDUx value within permitted range
		1	THDUx value higher than warning threshold
4 - 5	Reserved	0	
6	ErrIrmsNCalc, the calculated value of the neutral line > warning threshold in the Register	0	Calculated value within permitted range
		1	Calculated value higher than warning threshold
7	ErrIrmsNMeas, the measured value of the neutral line > warning threshold in the Register	0	Measured value within permitted range
		1	Measured value higher than warning threshold

4.3.22.11.7.8 Phase status

Name:
PhaseStatus

This register corresponds to the SysStatus4 register. It contains the status of phases A, B und C.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	LossPhaseC, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
1	LossPhaseB, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
2	LossPhaseA, voltage lower than value in the register "PhaseLoseTh"	0	Voltage is higher
		1	Voltage is lower
3	Reserved	0	
4	WarningPhaseC, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
5	WarningPhaseB, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
6	WarningPhaseA, voltage lower than value in the register "SagTh"	0	Voltage is higher
		1	Voltage is lower
7 - 15	Reserved	0	

4.3.22.11.8 Analog RMS registers

4.3.22.11.8.1 Current RMS neutral line measured

Name:
IrmsN

Measured value of the neutral current between the P and N connections on the current terminal, multiplied with the transfer factor of the transformer.

Data type	Value	Information
UINT	0 to 65,535	Measured value 0.001 Arms

4.3.22.11.8.2 Voltage RMS phase A/B/C

Name:
UrmsA
UrmsB
UrmsC

Measured value for N-terminal or virtual zero point.

Data type	Value	Information
UINT	0 to 65,535	Measured value 0.01 Vrms

4.3.22.11.8.3 Current RMS neutral line calculated

Name:
IrmsNcalc

Calculated value of neutral current derived from the other 3 phases.

Data type	Value	Information
UINT	0 to 65,535	Measured value 0.001 Arms

4.3.22.11.8.4 Current RMS phase A/B/C

Name:
IrmsA
IrmsB
IrmsC

Measured value of the phase current between the P and N connections on the current terminal, multiplied with the transfer factor of the transformer.

Data type	Value	Information
UINT	0 to 65,535	Measured value 0.001 Arms

4.3.22.11.9 Analog THD and angle registers

4.3.22.11.9.1 THD+N value voltage phase A/B/C

Name:
THDNUA
THDNUB
THDNUC

Data type	Value	Information
UINT	0 to 10000	Resolution 0.01%

Harmonic content = (SQR(Rms_{total}^2 - $Rms_{fundamental}$^2))/$Rms_{fundamental}$

4.3.22.11.9.2 THD+N value current phase A/B/C

Name:
THDNIA
THDNIB
THDNIC

Data type	Value	Information
UINT	0 to 10000	Resolution 0.01%

Harmonic content = (SQR(Rms_{total}^2 - $Rms_{fundamental}$^2))/$Rms_{fundamental}$

4.3.22.11.9.3 Fundamental frequency measured

Name:
Freq

Measured fundamental frequency of phases A, B and C.

Data type	Value	Information
UINT	0 to 10000	Resolution 0.01 Hz

4.3.22.11.9.4 Phase angle of power on phase A/B/C

Name:
PAngleA
PAngleB
PAngleC

Middle phase angle (power angle) of the current to the voltage based on the zero-crossing detection.

Data type	Value	Information
INT	-1800 to 1800	Resolution 0.1°

4.3.22.11.9.5 Transformer temperature

Name:
Temperature

This register contains the internal temperature of the transformer component. The temperature is recorded in a 100 ms interval.

Data type	Value	Information
INT	-200 to 200	Resolution 1°C

4.3.22.11.9.6 Phase angle of voltage on phase A/B/C

Name:
UAngleA
UAngleB
UAngleC

The value for phase A is always 0. On the other phases, the angle corresponds with the offset to A. This is based on the zero-crossing detection.

Data type	Value	Information
INT	-1800 to 1800	Resolution 0.1°

4.3.22.11.10 Analog power register

4.3.22.11.10.1 Vector sum of the total apparent power LSW

Name:
SVmeanTLSB

The value in the register equals a fourth of the actual power.

Data type	Value	Information
INT	-32,767 to 32,767	Resolution of units/LSB equals 4/65536 VA

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual vector sum of the total apparent power LSW = register value * 4 (complex sum)

4.3.22.11.10.2 Vector sum of the total apparent power MSW

Name:
SVmeanT

The value in the register equals a fourth of the actual power. The calculation is made in accordance with IEEE 1459.

Data type	Value	Information
INT	0 to 32767	Resolution 4 VA

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual vector sum of the total apparent power MSW = register value * 4 (complex sum)

4.3.22.11.10.3 Total active power

Name:
PmeanT

The value in the register equals a fourth of the actual power. The calculation can be performed in either absolute or arithmetic mode (see register "MeteringMode" <Bit 3>). Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 W

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total active power = Register value * 4

4.3.22.11.10.4 Active power on phase A/B/C

Name:
PmeanA
PmeanB
PmeanC

Active power on the phase. Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 1 W

4.3.22.11.10.5 Total reactive power

Name:
QmeanT

The value in the register equals a fourth of the actual power. The calculation can be performed in either absolute or arithmetic mode (see register "MeteringMode" <Bit 4>). Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 var

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total reactive power = Register value * 4

4.3.22.11.10.6 Reactive power on phase A/B/C

Name:
QmeanA
QmeanB
QmeanC

Reactive power on the phase. Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 1 var

4.3.22.11.10.7 Total apparent power

Name:
SmeanT

The value in the register equals a fourth of the actual power. The power is calculated in arithmetic mode. Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	0 to 32767	Resolution 4 VA

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total apparent power = Register value * 4

4.3.22.11.10.8 Apparent power on phase A/B/C

Name:
SmeanA
SmeanB
SmeanC

Apparent power on the phase. Each phase can be separately enabled for the power calculation (see register "MeteringMode" <Bits 0, 1 and 2>).

Data type	Value	Information
INT	0 to 32767	Resolution 1 VA

4.3.22.11.10.9 Total power factor

Name:
PFmeanT

Data type	Value	Information
INT	-1000 to 1000	Resolution 0.001

4.3.22.11.10.10 Power factor on phase A/B/C

Name:
PFmeanA
PFmeanB
PFmeanC

Data type	Value	Information
INT	-1000 to 1000	Resolution 0.001

4.3.22.11.10.11 Total active power of fundamental wave

Name:
PmeanTF

The value in the register equals a fourth of the actual power.

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 W

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total active power of fundamental wave = Register value * 4

4.3.22.11.10.12 Fundamental wave active power on phase A/B/C

Name:
PmeanAF
PmeanBF
PmeanCF

Active power of fundamental wave on the phase.

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 1 W

4.3.22.11.10.13 Total active power of harmonics

Name:
PmeanTH

The value in the register equals a fourth of the actual power.

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 4 W

This value must be multiplied by 4 by the application. Calculation formula for actual power:

Actual total active power of harmonics = Register value * 4

4.3.22.11.10.14 Harmonics active power on phase A/B/C

Name:
PmeanAH
PmeanBH
PmeanCH

Active power of harmonics on the phase.

Data type	Value	Information
INT	-32,767 to 32,767	Resolution 1 W

4.3.22.11.11 Analog energy registers

4.3.22.11.11.1 Read timestamp for energy registers (+0x0022 = 16 bit)

Name:
SampleTime02_32bit

Network timestamp for the readout of the energy register.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Network time

4.3.22.11.11.2 Forward total active energy

Name:
APenergyT

Total active energy in forward direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.3 Forward active energy on phase A/B/C

Name:
APenergyA
APenergyB
APenergyC

Active energy in forward direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.4 Reverse total active energy

Name:
ANenergyT

Total active energy in reverse direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.5 Reverse active energy on phase A/B/C

Name:
ANenergyA
ANenergyB
ANenergyC

Active energy in reverse direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.6 Forward total reactive energy

Name:
RPenergyT

Total reactive energy in forward direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.7 Forward reactive energy on phase A/B/C

Name:
RPenergyA
RPenergyB
RPenergyC

Reactive energy in forward direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.8 Reverse total reactive energy

Name:
RNenergyT

Total reactive energy in reverse direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.9 Reverse reactive energy on phase A/B/C

Name:
RNenergyA
RNenergyB
RNenergyC

Reactive energy in reverse direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.10 Arithmetic total apparent energy

Name:
SAenergyT

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.11 Apparent energy on phase A/B/C

Name:
SenergyA
SenergyB
SenergyC

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.12 Vectorized total apparent energy

Name:
SVenergyT

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.13 Forward fundamental wave total active energy

Name:
APenergyTF

Fundamental wave of total active energy in forward direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.14 Forward fundamental wave active energy on phase A/B/C

Name:
APenergyAF
APenergyBF
APenergyCF

Fundamental wave of active energy in forward direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.15 Reverse fundamental wave total active energy

Name:
ANenergyTF

Fundamental wave of total active energy in reverse direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.16 Reverse fundamental wave active energy on phase A/B/C

Name:
ANenergyAF
ANenergyBF
ANenergyCF

Fundamental wave of active energy in reverse direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.17 Forward harmonics total active energy

Name:
APenergyTH

Harmonics of total active energy in forward direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.18 Forward harmonics active energy on phase A/B/C

Name:
APenergyAH
APenergyBH
APenergyCH

Harmonics of active energy in forward direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.19 Reverse harmonics total active energy

Name:
ANenergyTH

Harmonics of total active energy in reverse direction.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.20 Reverse harmonics active energy on phase A/B/C

Name:
ANenergyAH
ANenergyBH
ANenergyCH

Harmonics of active energy in reverse direction of the phase.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.21 Total active energy combined

Name:
AEnergyT

Total active energy in forward and backward direction.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Internal calculation formula for the total active energy:

AEnergyT = (DINT)(APenergyT - ANenergyT) ... Calculation overflows must be handled in the application

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.11.22 Total reactive energy combined

Name:
REnergyT

Total reactive energy in forward and backward direction.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Resolution 0.1 or 0.01 CF, depending on the Power Line factor (e.g. kWs)

Internal calculation formula for the total reactive energy:

REnergyT = (DINT)(RPenergyT - RNenergyT) ... Calculation overflows must be handled in the application

Comments:

- The unit CF is derived from the Power Line factor (default: 3600 Imp/kWh), see register "MeteringMode"
- The resolution can be switched between 0.1 and 0.01, see register "MeteringMode"
- The register is updated automatically after being enabled, see register "ControlOutput" <Bit 1>
- The register is cleared upon request, see register "ControlOutput"
- The register is set upon request, see register "ControlOutput" <Bit 3>

4.3.22.11.12 Analog DFT registers

4.3.22.11.12.1 Read timestamp for DFT register (+0x0022 = 16 bit)

Name:
SampleTime03_32bit

Network timestamp for the readout of the DFT register.

Data type	Value	Information
DINT	-2,147,483,647 to 2,147,483,647	Network time

4.3.22.11.12.2 HD register current I and voltage V for phases A/B/C

Name:
DftAI (0..30), DftAV (0..30)
DftBI (0..30), DftBV (0..30)
DftCI (0..30), DftCV (0..30)

Ratio of 2nd to 32nd order harmonics.

Data type	Value	Information
UINT	0 to 32767	Ratio of frequency component

Conversion from % = register value / 163.84

4.3.22.11.12.3 THD register current I and voltage V for phases A/B/C

Name:
DftAI (31), DftAV (31)
DftBI (31), DftBV (31)
DftCI (31), DftCV (31)

Ratio of total harmonic distortion.

Data type	Value	Information
UINT	0 to 32767	Total harmonic distortion on phase A current

Conversion from % = register value / 163.84

4.3.22.11.12.4 Fundamental wave current on phase A/B/C

Name:
DftAI_Fund
DftBI_Fund
DftCI_Fund

Data type	Value	Information
UINT	0 to 32767	Fundamental wave current

Conversion (%) of fundamental wave current = register value * 209 * 65.535 / 8388608

4.3.22.11.12.5 Fundamental wave voltage on phase A/B/C

Name:
DftAV_Fund
DftBV_Fund
DftCV_Fund

Data type	Value	Information
UINT	0 to 32767	Fundamental value voltage

Conversion (%) of fundamental wave voltage = register value * 418 * 655.35 / 8388608

4.3.22.11.13 Module configuration

4.3.22.11.13.1 Analog mode register

Name:
ChanControl

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	Channel status LED for phase A	0	Disabled
		1	Enabled[1)]
1	Channel status LED for phase B	0	Disabled
		1	Enabled[1)]
2	Channel status LED for phase C	0	Disabled
		1	Enabled[1)]
3	Reserved	0	
4	Neutral current monitor and status LED	0	Disabled
		1	Enabled[1)]
5	Neutral current status derived from the calculated or measured value	0	Derived from the calculated value[1)]
		1	Derived from the calculated value
6	Conversion of energy register to kWh (internal register / 4096)	0	Disabled
		1	Enabled
7	Display current values despite power failure[2)]	0	Disabled[3)], Current values = 0
		1	Enabled
8 - 15	Oversampling with prescaler	0	Disabled[1)], Current values = 0
		1 - 255	Enabled, Display current values despite power failure

1) Standard in the bus controller function model
2) When a power failure occurs, all current values are held at 0 by default.
3) According to the power failure status of the individual phases, the following values are held at 0 by default.

- Mains frequency, phase angle, power factor
- Effective voltage and current values
- Active, reactive and apparent power values

4.3.22.11.13.2 Analog minimum current for active current channel LED

Name:
IDispTh

Data type	Value	Information
UINT	100 to 65000	I RMS indicator threshold

The indicator threshold defines the RMS value of the current at which the status LED for the phase current is illuminated. The default values vary from module to module and should be adjusted to the maximum primary current. Suggestion: 1% of maximum value

Module	Indicator threshold
X20AP3111	200 mA
X20AP3121	500 mA
X20AP3131	500 mA
X20AP3161	500 mA

4.3.22.11.13.3 Current transformer rating phase A/B/C/N

Name:
I_RatioA
I_RatioB
I_RatioC
I_RatioN

Data type	Value	Information
UINT	10 to x	Current transformer rating

In the modules AP311, 21 and 31, the rated current is multiplied by the rated transformation ratio. In the module AP3161, the maximum primary current of the transformer is configured directly.

The permissible values differ from module to module (resolution 0.1):

Module	Rating
X20AP3111	Transformer ratio: 10 to 32,500 (default: 25000)
X20AP3121	Transformer ratio: 10 to 650 (default: 500)
X20AP3131	Transformer ratio: 10 to 130 (default: 100)
X20AP3161	Measurement range: 50 to 650 (default: 500)

Information:

The maximum resulting current must not exceed the value of 65000 mA.

4.3.22.11.13.4 Update request ADC Cfg register

Name:
CfgUpdate

The registers in the group CfgReg are only updated after the CfgUpdate register is changed. Setting 0xFFFF only causes this register to be reset without updating the CfgReg register.

Data type	Value	Information
UINT	0 to 65,535	Update request

4.3.22.11.13.5 Update request ADC Cs0, Cs1 and Cs3 register

Name:
Cs0Update
Cs1Update
Cs3Update

The registers in the group CsxReg are only updated after the CsxUpdate register is changed. Setting 0xFFFF only causes this register to be reset without updating the CsxReg register.

Data type	Value	Information
UINT	0 to 65,535	Update request

Name:
Cs1UpdateFB
Cs3UpdateFB

The ADC configuration registers are only transferred to the feedback buffer after transfer to the ADC is complete.

Data type	Value	Information
UINT	0 to 65,535	

4.3.22.11.14 ADC status configuration

4.3.22.11.14.1 ADC hardware signal allocation

Name:
ZXConfig

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	Zero cross signals	0	Enabled
		1	Disabled
1 - 2	ZX20Con: Trigger zero cross-over	00	Positive zero cross-over[1)]
		01	Negative zero cross-over
		10	Both zero cross-overs
		11	No zero cross-over
3 - 4	ZX1Con: Trigger zero cross-over	00	Positive zero cross-over[1)]
		01	Negative zero cross-over
		10	Both zero cross-overs
		11	No zero cross-over
5 - 6	ZX2Con: Trigger zero cross-over	00	Positive zero cross-over[1)]
		01	Negative zero cross-over
		10	Both zero cross-overs
		11	No zero cross-over
7 - 9	ZX0Src: Signal source for ZX0 hardware signal	000	A voltage[1)]
		001	B voltage
		010	C voltage
		011	Fix 0
		100	Current A
		101	Current B
		110	Current C
		111	Fix 0
10 - 12	ZX1Src: Signal source for ZX1 hardware signal	000	A voltage
		001	B voltage[1)]
		010	C voltage
		011	Fix 0
		100	Current A
		101	Current B
		110	Current C
		111	Fix 0
13 - 15	ZX2Src: Signal source for ZX2 hardware signal	000	A voltage
		001	B voltage
		010	C voltage[1)]
		011	Fix 0
		100	Current A
		101	Current B
		110	Current C
		111	Fix 0

1) Standard in the bus controller function model

4.3.22.11.14.2 Voltage warning threshold

Name:
SagTh

Data type	Value	Information
UINT	5000 to 50000	Resolution 0.01 V

This register defines an RMS voltage value for monitoring the voltage warning signal.

4.3.22.11.14.3 Power failure threshold

Name:
PhaseLoseTh

Data type	Value	Information
UINT	1000 to 6000	Resolution 0.01 V

This register defines an RMS voltage value for monitoring the power failure signal.

4.3.22.11.14.4 Warning threshold for the calculated neutral current

Name:
INWarnTh0

Current value for monitoring the calculated neutral line current.

Data type	Value	Information
UINT	0 to 65000	Resolution 0.001 A

4.3.22.11.14.5 Warning threshold for the measured neutral current.

Name:
INWarnTh1

Current value for monitoring the measured neutral line current.

Data type	Value	Information
UINT	0 to 65000	Resolution 0.001 A

4.3.22.11.14.6 Warning threshold for exceeding voltage THD

Name:
THDNUTh

Percentage value defining warning threshold for THD ratio.

Data type	Value	Information
UINT	0 to 10000	Resolution 0.01%

4.3.22.11.14.7 Warning threshold for exceeding current THD

Name:
THDNITh

Percentage value defining warning threshold for THD ratio.

Data type	Value	Information
UINT	0 to 10000	Resolution 0.01%

4.3.22.11.15 ADC measurement configuration checksum 0

4.3.22.11.15.1 High word for power line constants

Name:
PLconstH

Data type	Value
UINT	0 to 65,535

Basis value of power line constant = 0x4A817C80 = 1,250,000,000 corresponding to 360 CF pulses per kWh or 0.1 CF pulse per kWs. The result of setting the resolution in the energy registers to a decimal (see register "MeteringMode" <Bit 9>) is 1 kWs per digit. Power line constant / 10 results in a 10x resolution.

4.3.22.11.15.2 Low word for power line constants

Name:
PLconstL

Data type	Value
UINT	0 to 65,535

Basis value of power line constant = 0x4A817C80 = 1,250,000,000 corresponding to 360 CF pulses per kWh or 0.1 CF pulse per kWs. The result of setting the resolution in the energy registers to a decimal (see register "MeteringMode" <Bit 9>) is 1 kWs per digit. Power line constant / 10 results in a 10x resolution.

4.3.22.11.15.3 Analog ADC measurement setting 1

Name:
MeteringMode

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	Enables phase C for adding the power and energy values together	0	Not enabled
		1	Approved[1)]
1	Enables phase B for adding the power and energy values together	0	Not enabled
		1	Approved[1)]
2	Enables phase A for adding the power and energy values together	0	Not enabled
		1	Approved[1)]
3	Calculation method for adding active power and active energy	0	Arithmetic sum[1)]
		1	Absolute sum
4	Calculation method for adding reactive power and reactive energy	0	Arithmetic sum[1)]
		1	Absolute sum
5	Reserved	0	
6	Selects apparent energy for CF2 source	0	Arithmetic sum[1)]
		1	Vector sum
7	CF2 source	0	Apparent energy
		1	Reactive energy[1)]
8	Measuring configuration	0	3P4W[1)]
		1	3P3W
9	Resolution of energy register	0	0.1 CF[1)]
		1	0.01 CF
10	Integrator for didt current transformer	0	Disabled
		1	Enabled
11	High-pass filter	0	Enabled
		1	Disabled
12	Basis frequency	0	50 Hz[1)]
		1	60 Hz
13	Phase assignment	0	I1 to Phase A and I3 to Phase C[1)]
		1	I1 to Phase C and I3 to Phase A
14 - 15	Reserved	0	

1) Standard in the bus controller function model

Comments regarding measurement configurations:

Measuring configuration	Note
3P4W	Monitors the phasing of voltages and currents: Phase A before phase B before phase C
3P3W	Measuring configuration: Phase A and phase C, N connection bridges to phase B or open
	Measurement: e.g. the 2 phases A and C and the 2 corresponding currents are measured, phase B disabled
	Monitors the phasing of voltages and currents: Phase difference between A and C >180°

4.3.22.11.16 User calibration of current and voltage values

Use the following procedure to properly calculate gain and offset:

- Read out the predefined values:
  See section 4.3.22.11.17 "ADC RMS comparison – read"
- Calculate and set new values:
  See section 4.3.22.11.18 "ADC RMS comparison checksum 3"
- Update predefined values by setting the register "Cs3Update". The predefined values have been updated when the value in the register "Cs3UpdateFB" is equal to the value of <Cs3Update>.

4.3.22.11.17 ADC RMS comparison – read

4.3.22.11.17.1 General information

The values in the registers specified below must be read at the beginning of the calibration. This is the only way to ensure that the gain and offset will be calculated correctly.

The values contained in the registers correspond to the $value_{old}$ in the calculation formulas for gain and offset (see 4.3.22.11.18 "ADC RMS comparison checksum 3").

4.3.22.11.17.2 Voltage RMS gain phase A/B/C

Name:
UGainA_R
UGainB_R
UGainC_R

Data type	Value
UINT	0 to 65,535

4.3.22.11.17.3 Current RMS gain phase A/B/C/N

Name:
IGainA_R
IGainB_R
IGainC_R
IGainN_R

Data type	Value
UINT	0 to 65,535

4.3.22.11.17.4 Voltage RMS offset phase A/B/C

Name:
UoffsetA_R
UoffsetB_R
UoffsetC_R

Data type	Value
INT	-32,767 to 32,767

4.3.22.11.17.5 Current RMS offset phase A/B/C/N

Name:
IoffsetA_R
IoffsetB_R
IoffsetC_R
IoffsetN_R

Data type	Value
INT	-32,767 to 32,767

4.3.22.11.18 ADC RMS comparison checksum 3

4.3.22.11.18.1 Voltage RMS gain phase A/B/C

Name:
UGainA_W
UGainB_W
UGainC_W

Data type	Value	Information
UINT	0 to 65,535	Voltage RMS gain, phase-based

The resulting gain is calculated using the following formula:

$Value_{new} = Value_{old}$ * correction factor, determined when $U = U_n$

4.3.22.11.18.2 Current RMS gain phase A/B/C/N

Name:
IGainA_W
IGainB_W
IGainC_W
IGainN_W

Data type	Value	Information
UINT	0 to 65,535	Current RMS gain, phase-based

The resulting gain is calculated using the following formula:

$Value_{new} = Value_{old}$ * correction factor, determined when $I = I_n$

4.3.22.11.18.3 Voltage RMS offset phase A/B/C

Name:
UoffsetA_W
UoffsetB_W
UoffsetC_W

Corresponds to the negated value of the corresponding RMS register when U = 0.

Data type	Value	Information
INT	-32,767 to 32,767	RMS voltage offset, phase-based

4.3.22.11.18.4 Current RMS offset phase A/B/C/N

Name:
IoffsetA_W
IoffsetB_W
IoffsetC_W
IoffsetN_W

Corresponds to the negated value of the corresponding RMS register when I = 0.

Data type	Value	Information
INT	-32,767 to 32,767	RMS current offset, phase-based

4.3.22.11.19 User calibration of power values

Use the following procedure to properly calculate the power angle correction:

1 Calculate the values
2 Write the value 0xFFFF to register Cs1Update
3 Read register Cs1UpdateFB until 0xFFFF is returned
4 Write the calculated values to the registers PhiA_W, PhiB_W, PhiC_W
5 Write the value 0x0001 to register Cs1Update
6 Read register Cs1UpdateFB until 0x0001 is returned

Information:

These registers are NOT nonvolatile, and the process needs to be repeated after every PowerOn and every positive edge of the ModuleOK bit.

4.3.22.11.19.1 ADC power angle correction, Phase A/B/C

Name:
PhiA_R
PhiB_R
PhiC_R

These registers can be used to read out the configured values at runtime, but are not nonvolatile and have the value 0 after the system is started.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 9	Delay time for energy phase angle correction	x	The clock base is 2.048 MHz. Maximum 0.499 mSec.
10 - 14	Reserved	0	
15	Delay times	0	Effect on current channel
		1	Effect on voltage channel

4.3.22.11.19.2 ADC power calibration checksum 1

Name:
PhiA_W
PhiB_W
PhiC_W

These registers can be used to correct phase shifts at runtime. This can be necessary if the transformers used distort the phase shift.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 9	Delay time for energy phase angle correction	0 to 1023	See descriptions for Bits 0 to 9
10 - 14	Reserved	0	
15	Delay times	0 or 1	See description for Bit 15

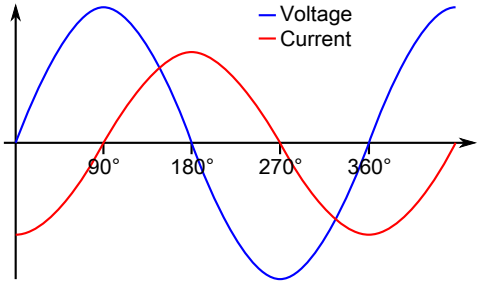
Description - Bits 0 to 9

The maximum correction 0x3FF = 1023 dec. corresponds to 0.49951 ms.

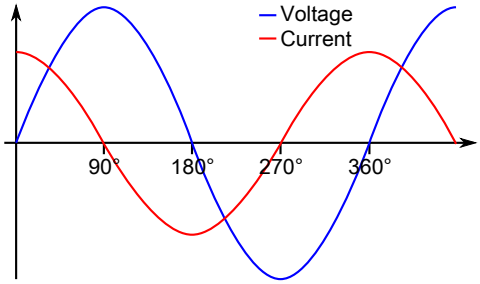
At 50 Hz mains this corresponds to a change of 8.99 degrees

At 60 Hz mains this corresponds to a change of 10.79 degrees

Schematic representation of inductive load: Voltage ahead of current



Schematic representation of capacitive load: Current ahead of voltage



Desription - Bit 15

0	Delay affects current channel	
	Effect with inductive load	Reduced angle between I and U, and therefore an increased power factor
	Effect with capacitive load	Increased angle between U and I, and therefore an reduced power factor
1	Delay affects voltage channel	
	Effect with inductive load	Reduced angle between U and I, and therefore an increased power factor
	Effect with capacitive load	Increased angle between I and U, and therefore an reduced power factor

4.3.22.11.20 FlatStream communication

4.3.22.11.20.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

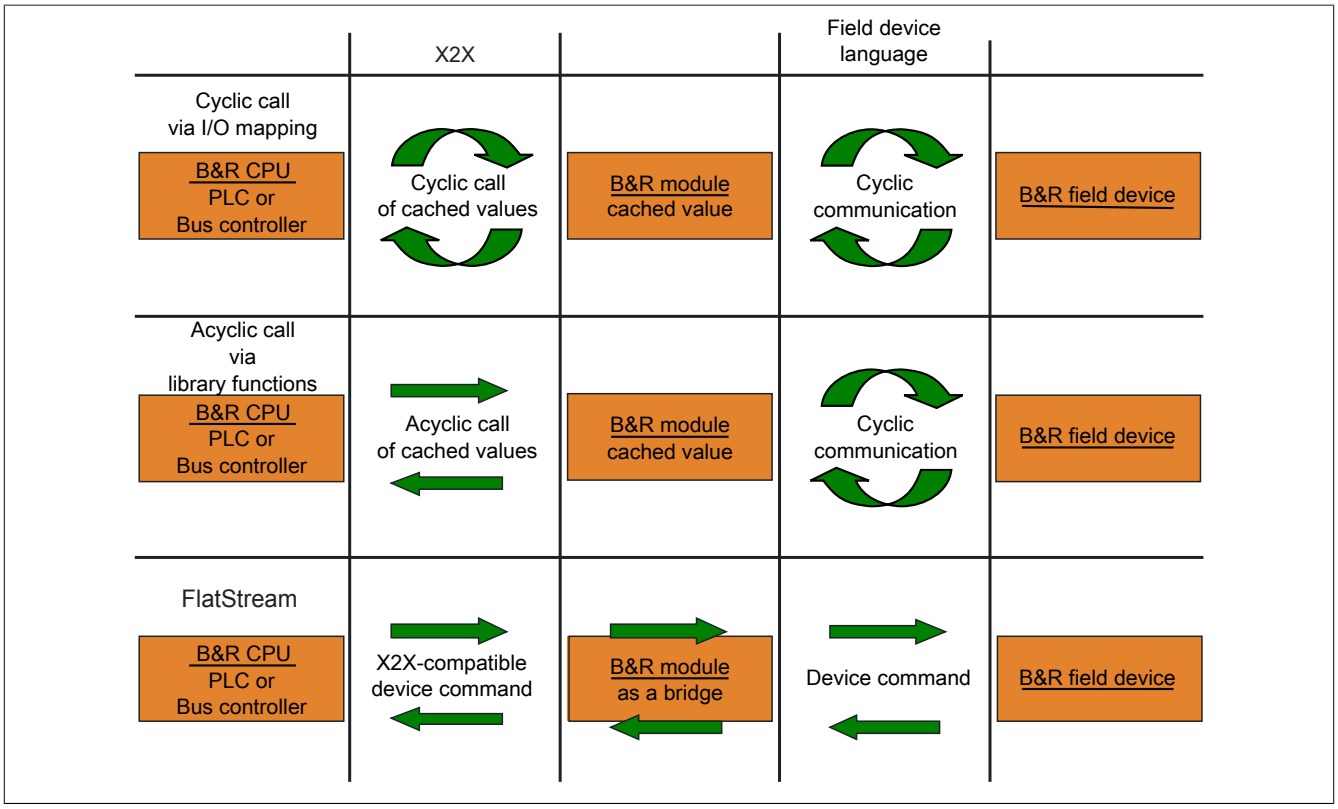


Figure 117: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.3.22.11.20.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.3.22.11.20.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

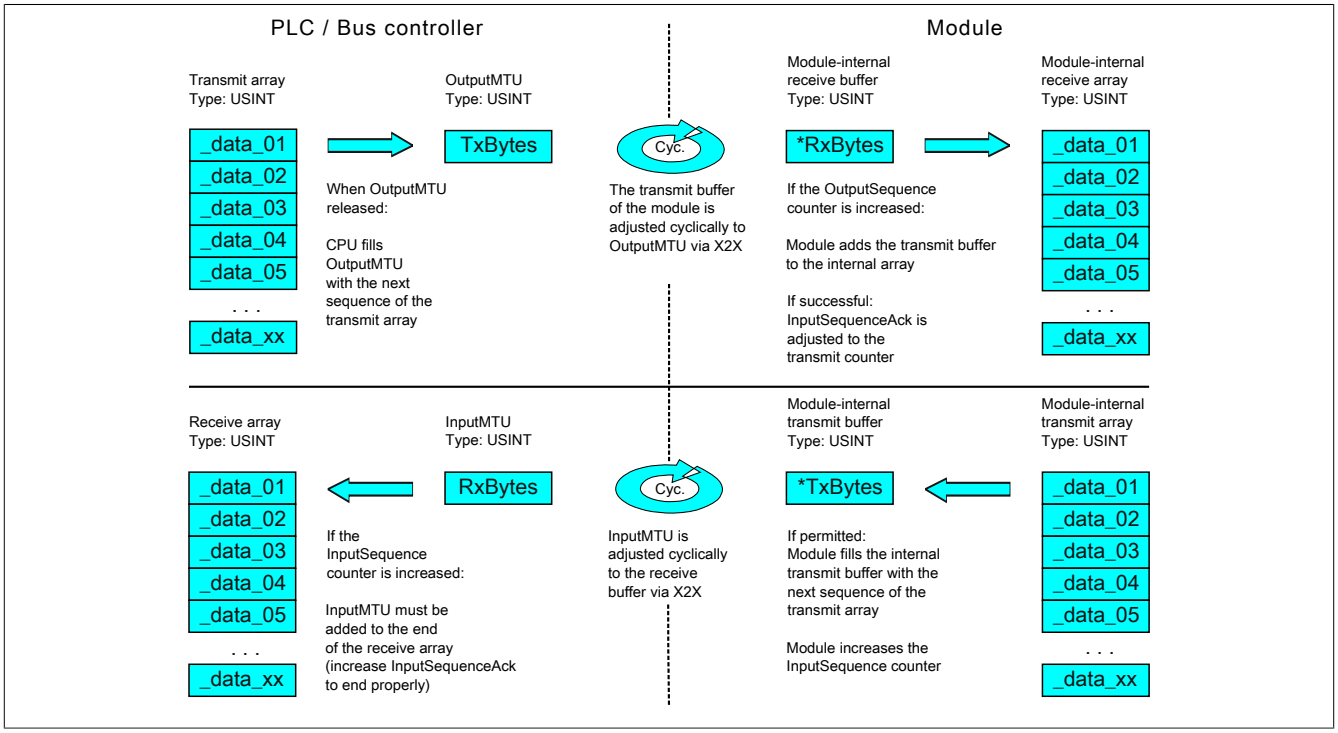

Figure 118: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.3.22.11.20.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

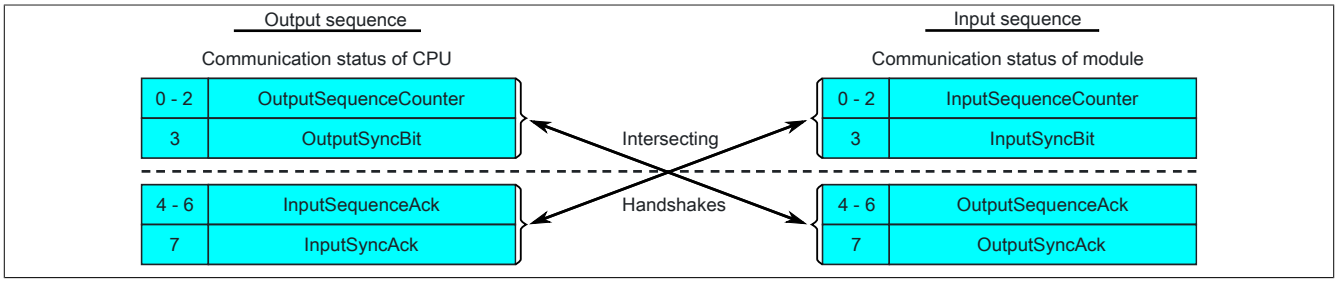

Figure 119: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

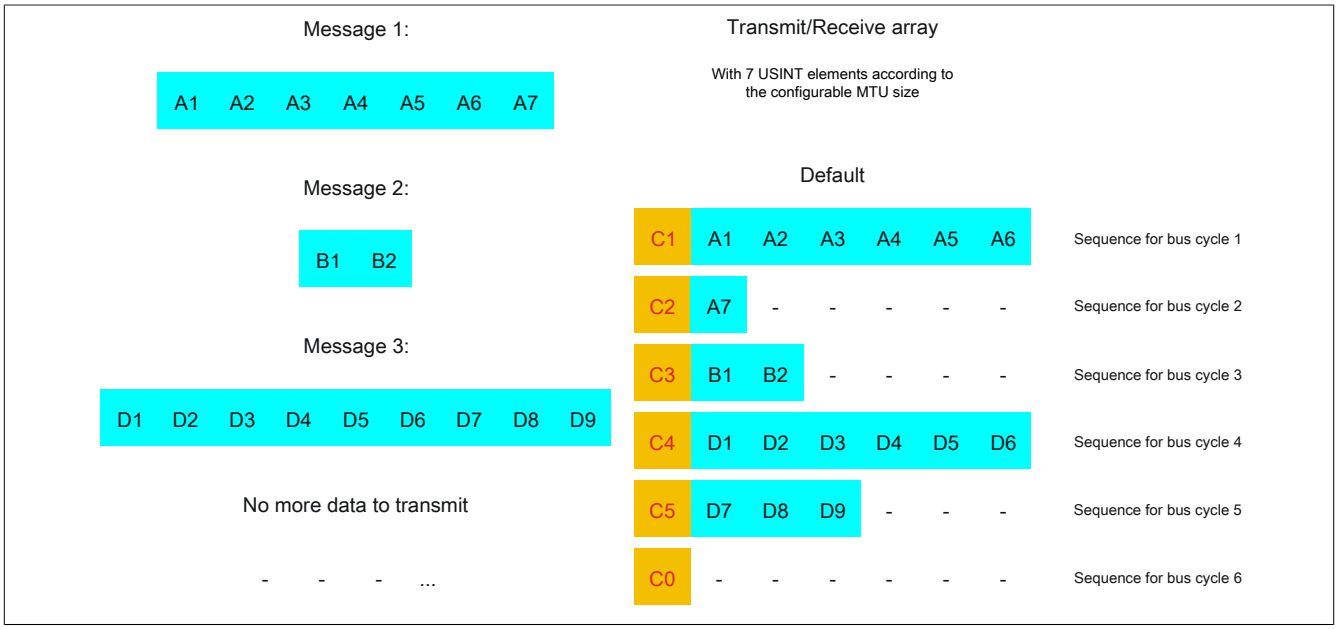

Figure 120: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 74: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 75: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

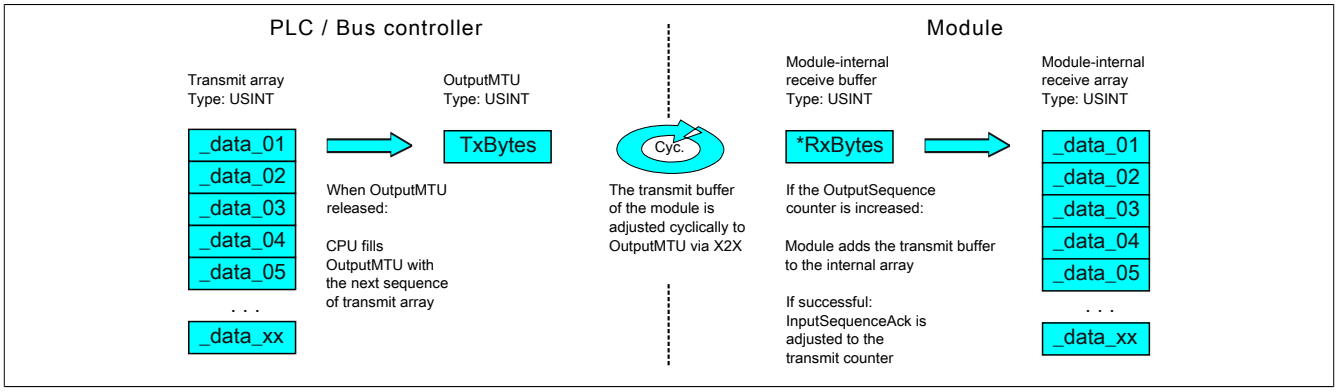

Figure 121: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

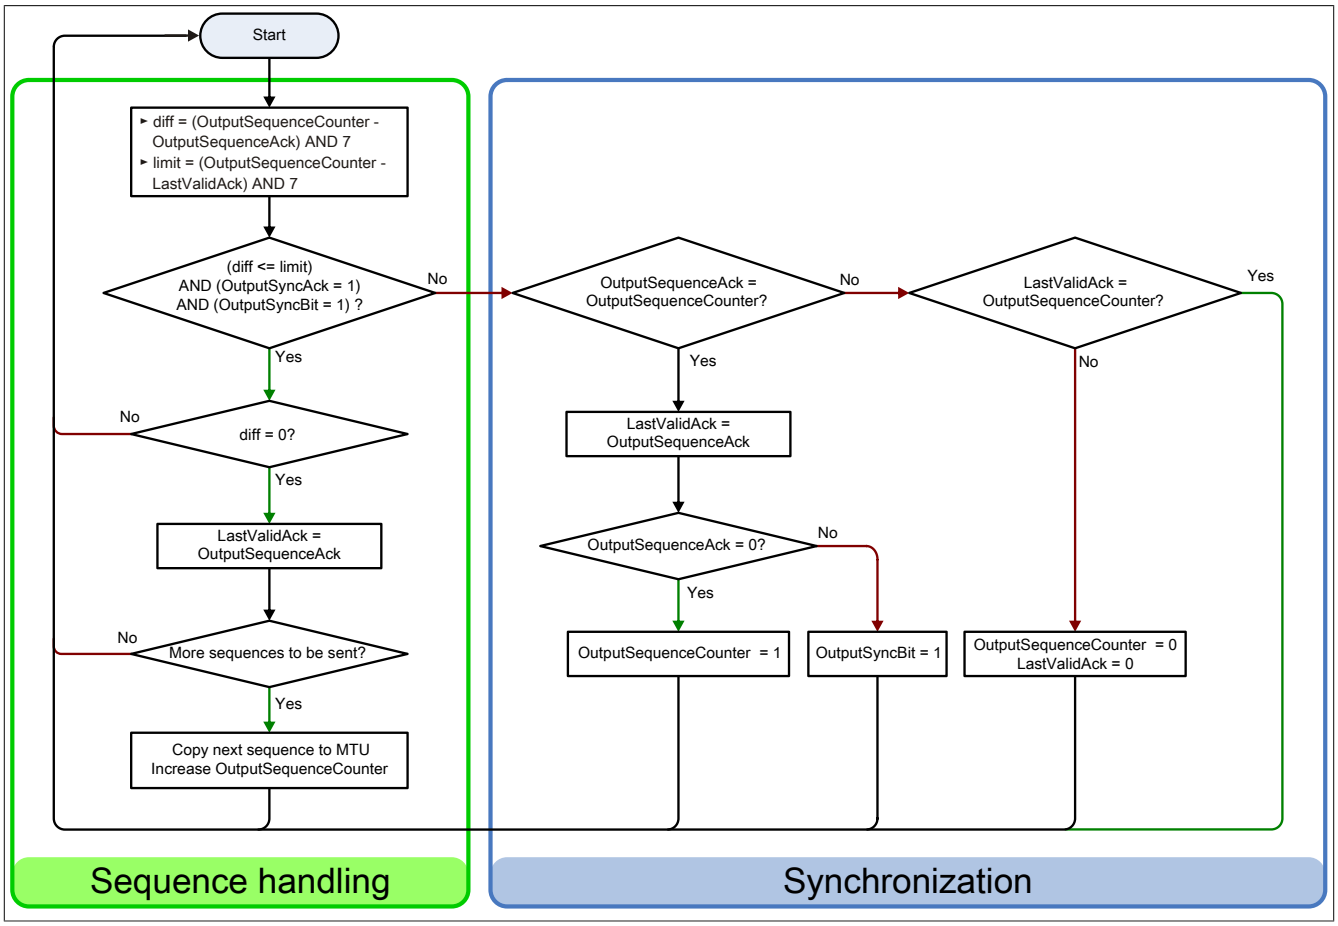

Figure 122: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

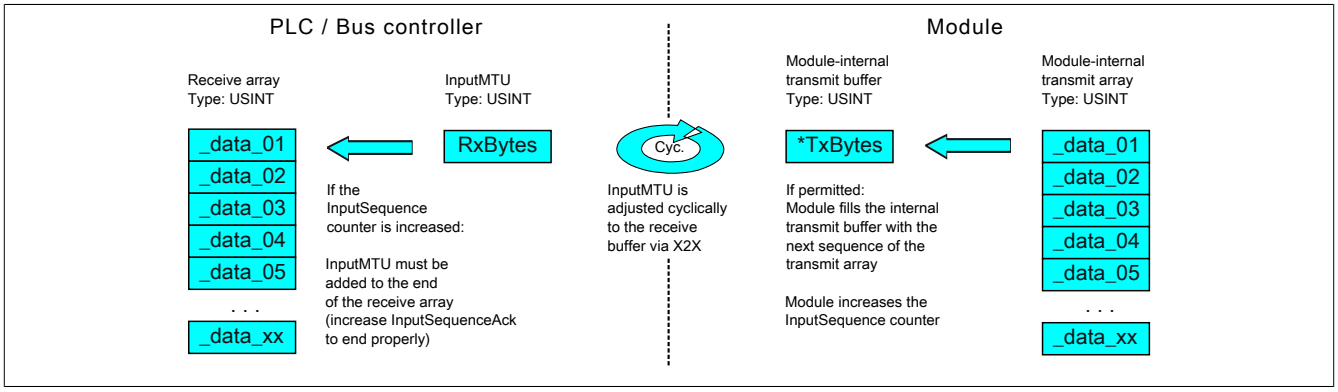

Figure 123: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

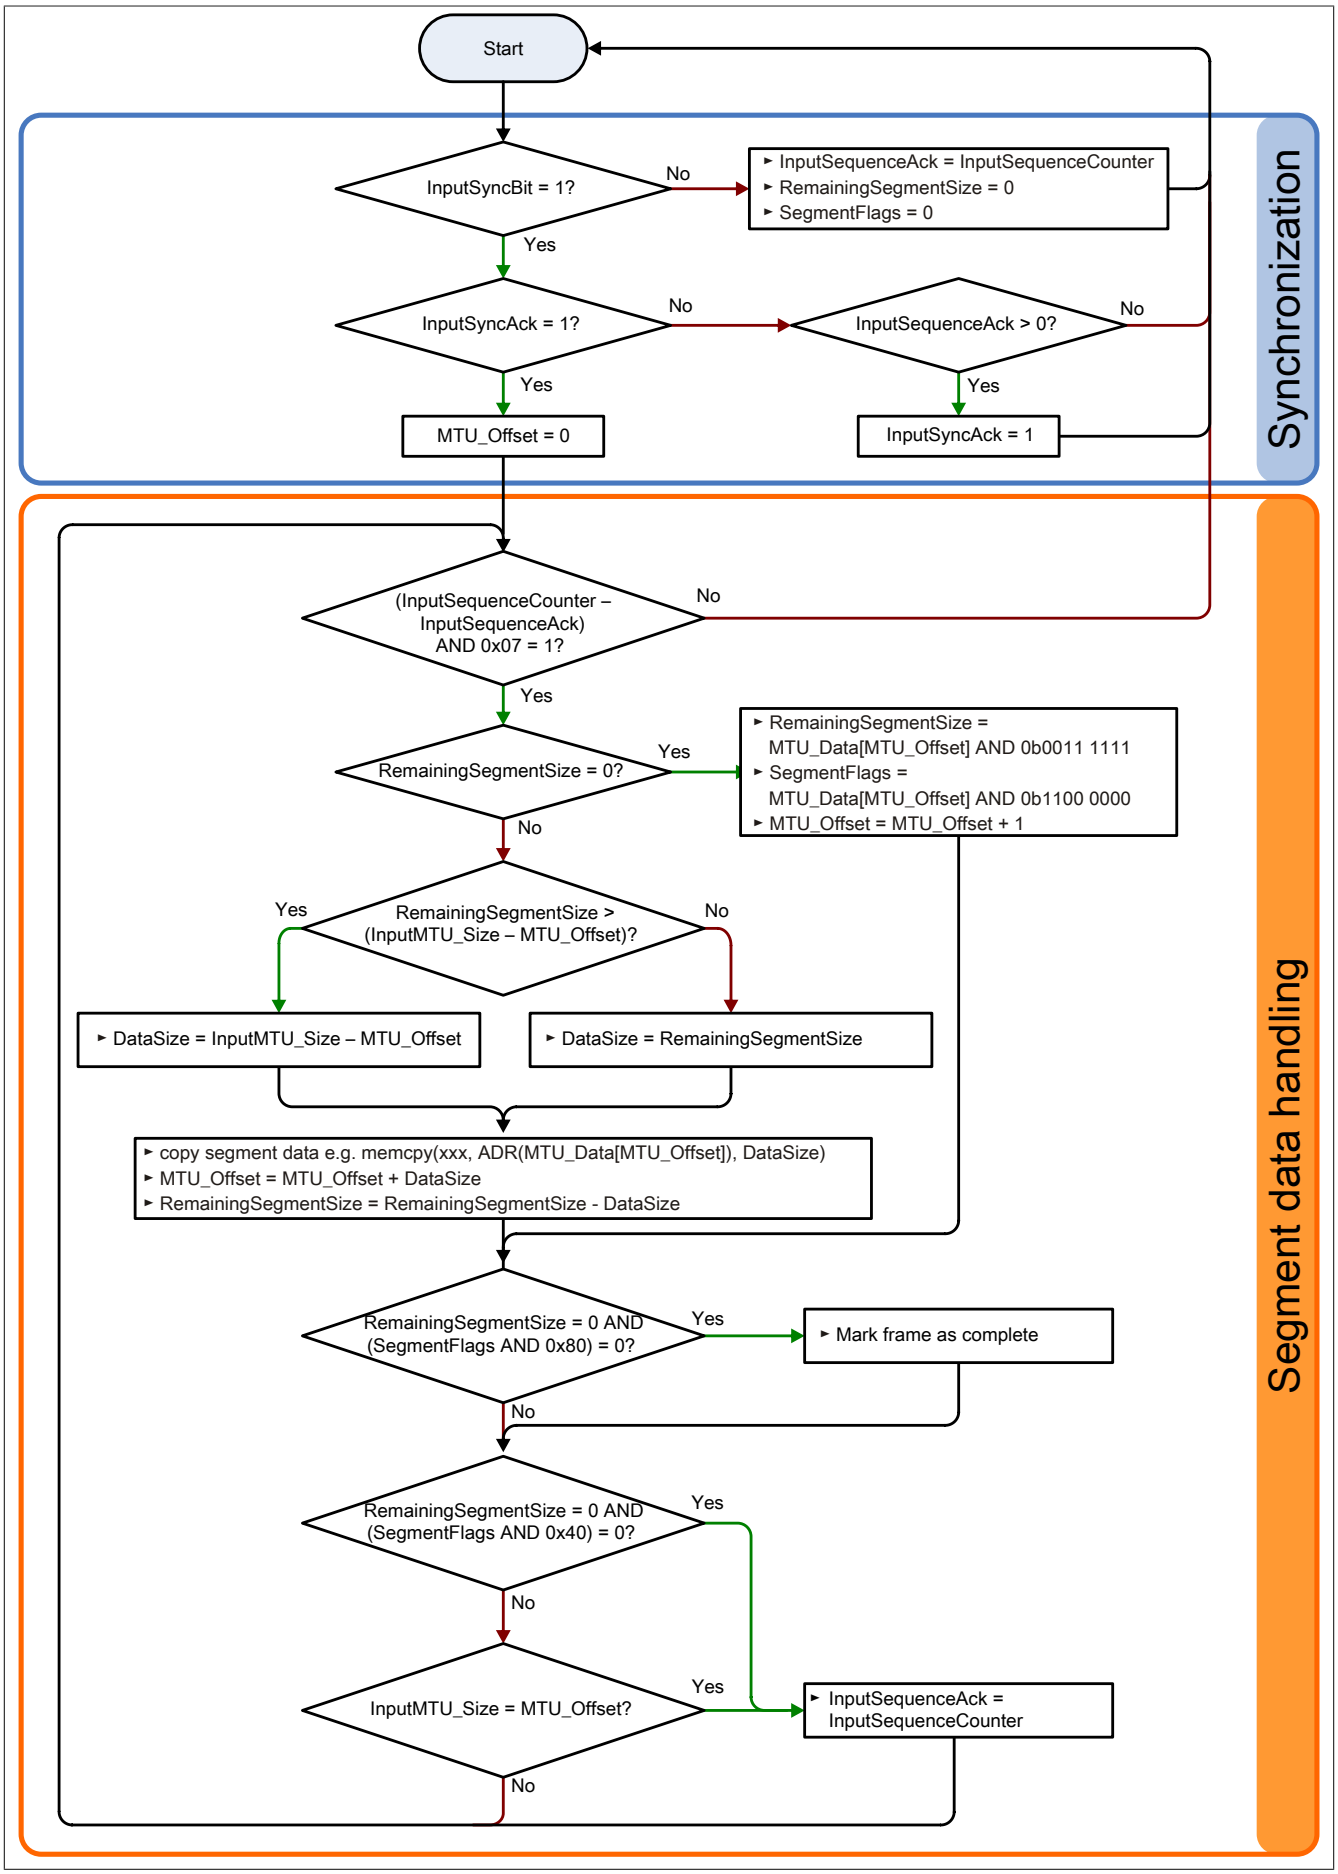

Figure 124: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

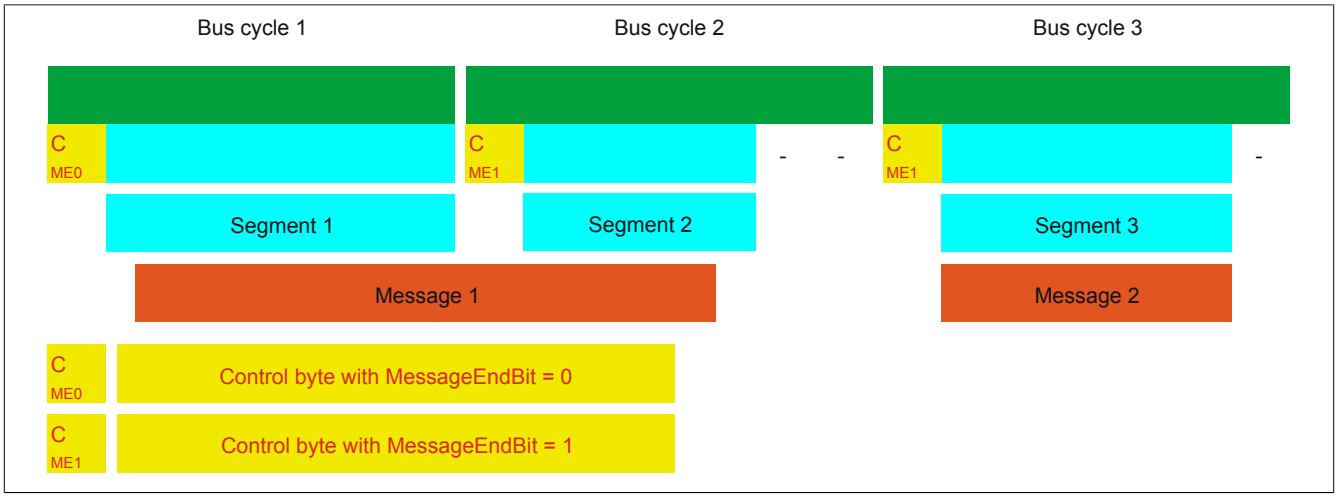

Figure 125: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

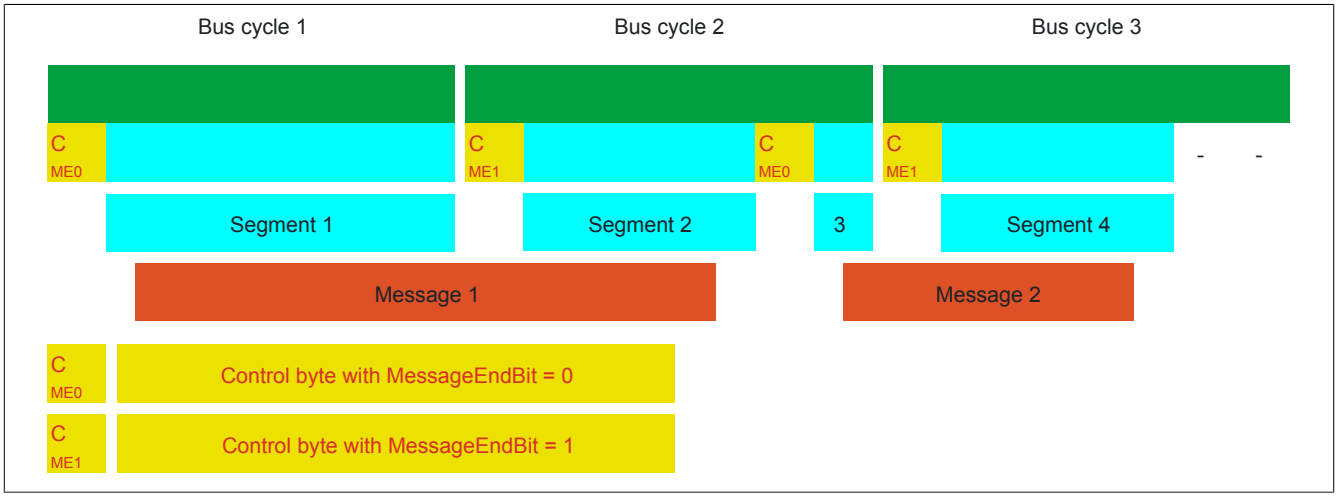

Figure 126: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

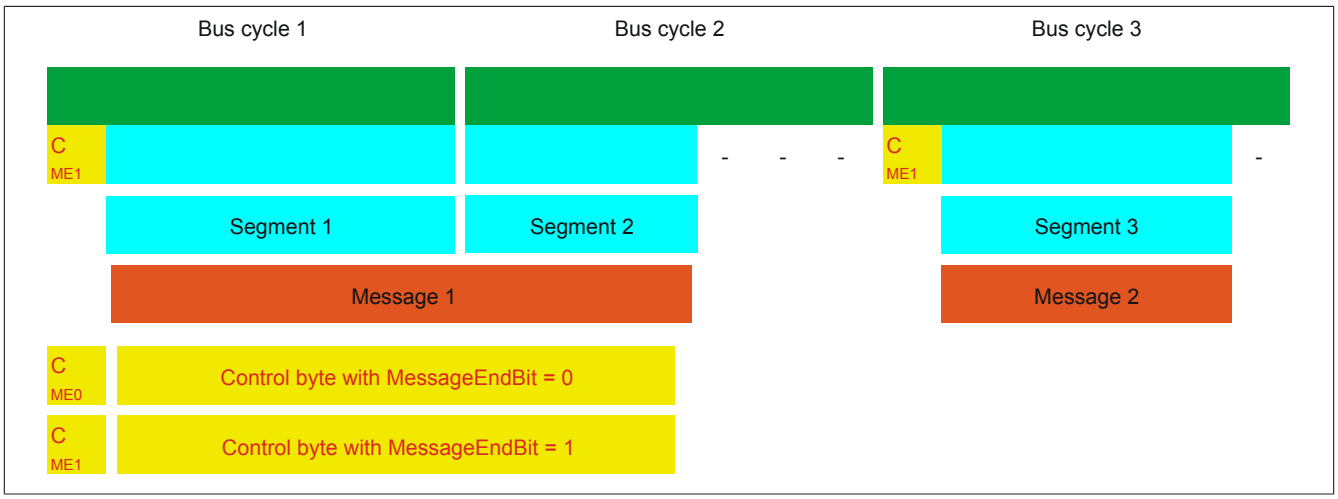

Figure 127: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

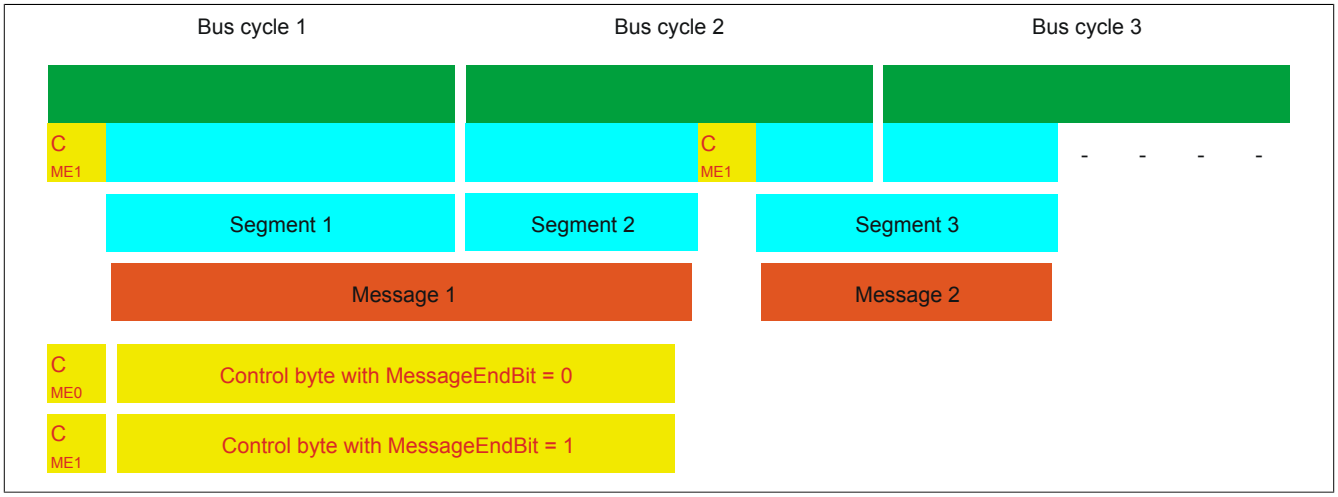

Figure 128: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

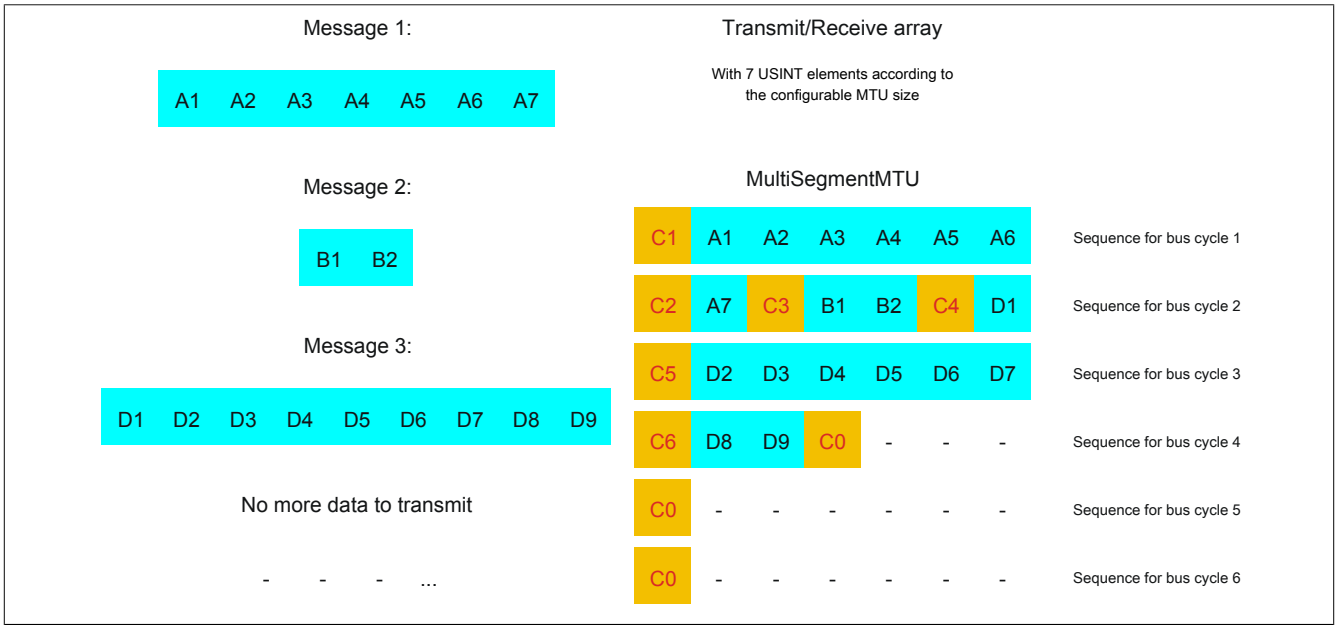

Figure 129: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 76: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 77: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

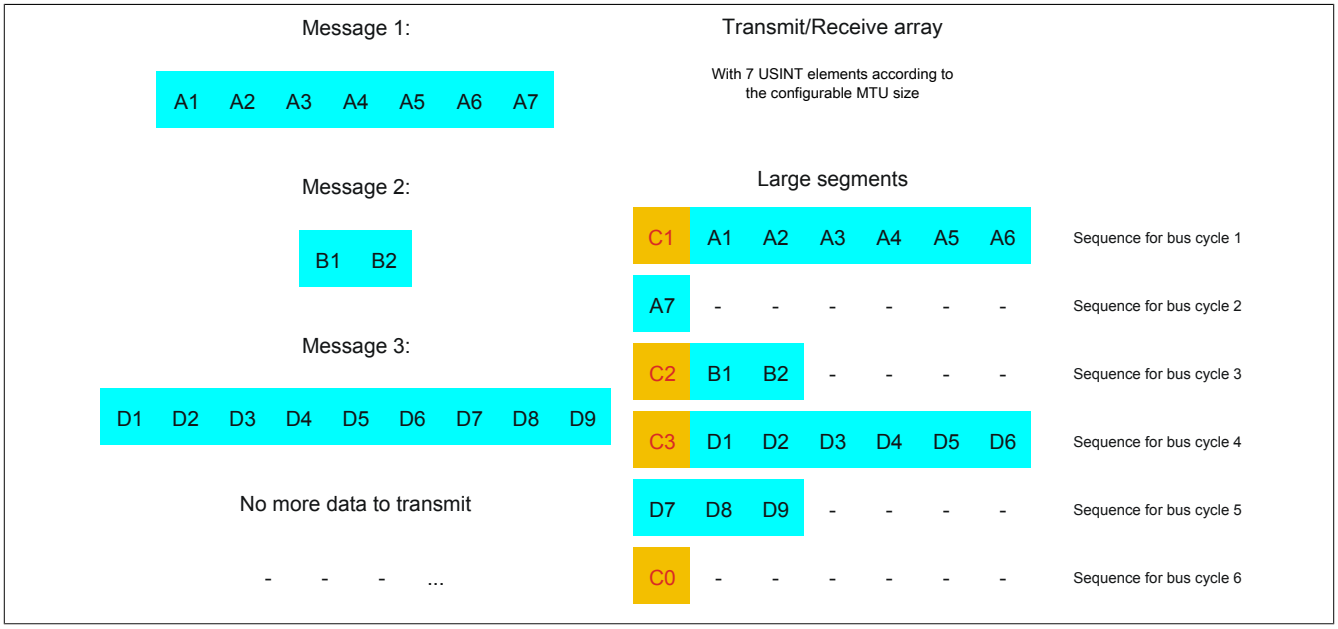

Figure 130: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 78: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

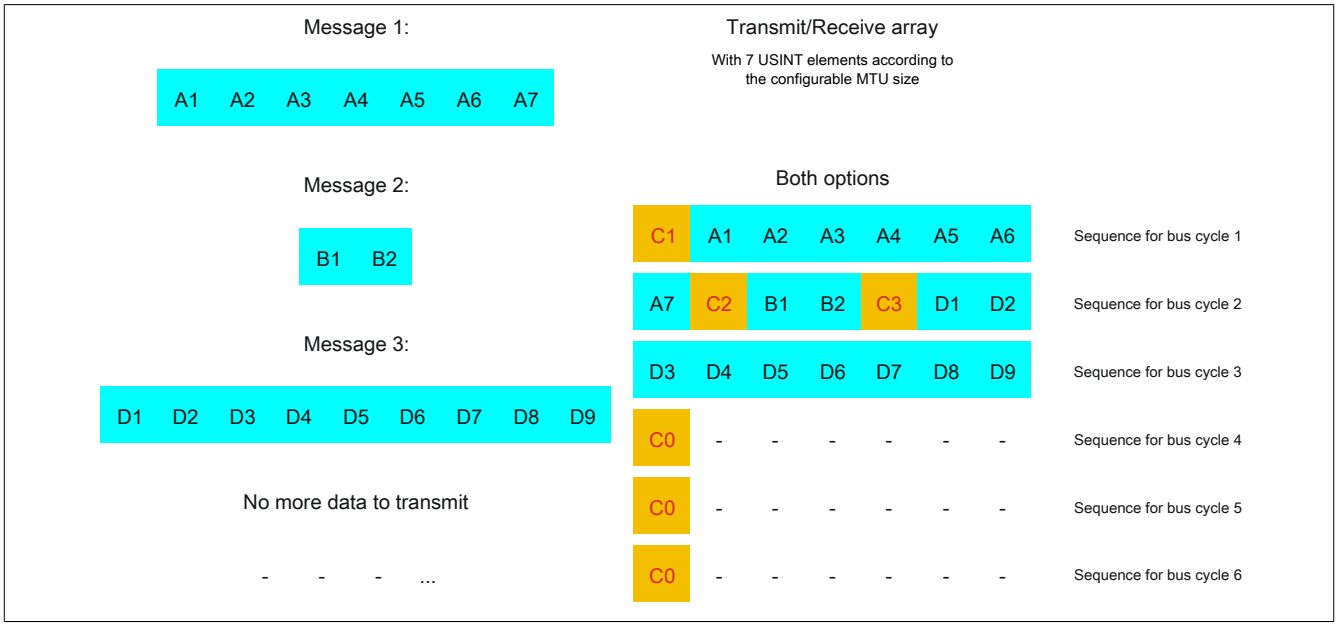

Figure 131: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 79: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.3.22.11.20.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

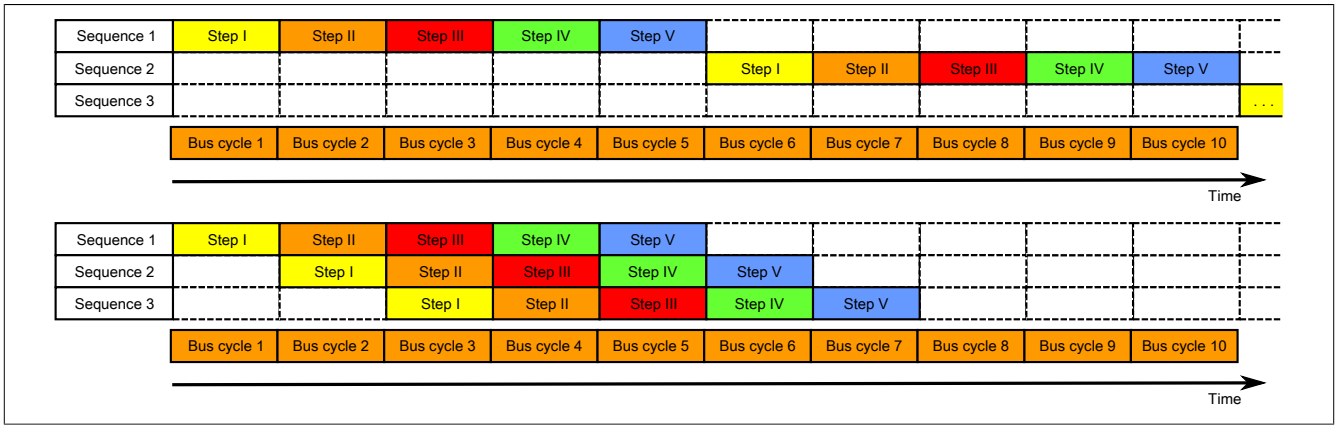

Figure 132: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

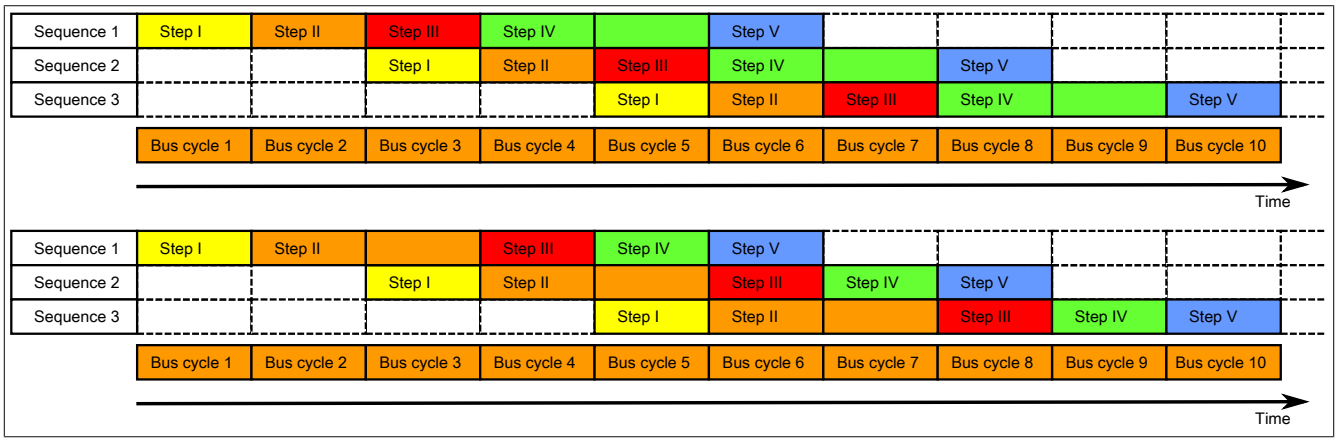

Figure 133: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

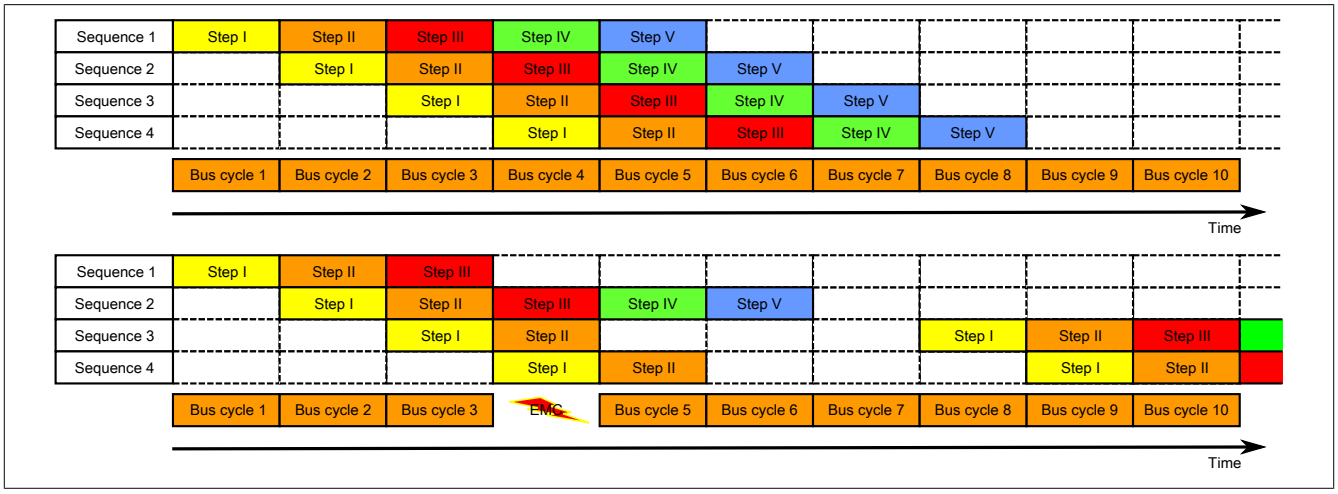

Figure 134: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.3.22.11.21 Force analog energy registers

Name:

The registers are described under 4.3.22.11.11 "Analog energy registers". Comparison:

Force registers	Read registers
Frc_APenergyT Frc_APenergyTF Frc_APenergyTH	"APenergyT"
Frc_APenergyA Frc_APenergyAF Frc_APenergyAH	"APenergyA"
Frc_APenergyB Frc_APenergyBF Frc_APenergyBH	"APenergyB"
Frc_APenergyC Frc_APenergyCF Frc_APenergyCH	"APenergyC"
Frc_ANenergyT Frc_ANenergyTF Frc_ANenergyTH	"ANenergyT"
Frc_ANenergyA Frc_ANenergyAF Frc_ANenergyAH	"ANenergyA"
Frc_ANenergyB Frc_ANenergyBF Frc_ANenergyBH	"ANenergyB"
Frc_ANenergyC Frc_ANenergyCF Frc_ANenergyCH	"ANenergyC"
Frc_RPenergyT	"RPenergyT"
Frc_RPenergyA	"RPenergyA"
Frc_RPenergyB	"RPenergyB"
Frc_RPenergyC	"RPenergyC"
Frc_RNenergyT	"RNenergyT"
Frc_RNenergyA	"RNenergyA"
Frc_RNenergyB	"RNenergyB"
Frc_RNenergyC	"RNenergyC"
Frc_SAenergyT	"SAenergyT"
Frc_SenergyA	"SenergyA"
Frc_SenergyB	"SenergyB"
Frc_SenergyC	"SenergyC"
Frc_SVenergyT	"SVenergyT"

These registers can be used to set the energy counter to a specific value after a module has been replaced.

Data type	Value
UDINT	0 to 4,294,967,295

4.3.22.11.21.1 Force forward total active energy

Name:
FrcAPenergyT

The registers are described under 4.3.22.11.11 "Analog energy registers".

These registers can be used to set the energy counter to a specific value after a module has been replaced. The register is updated to the current values when triggered by ControlOutput, Bit 3.

Data type	Value
UDINT	0 to 4,294,967,295

4.3.22.11.22 Oversampling buffer

4.3.22.11.22.1 General information

A Sample Line contains the present values for currents (4 channels) and voltages (3 channels), as well as a consecutive number and the network time when transferred from the transformer. These values are recorded in an interval of 125 µs * prescaler.

The user must then scale the values to respective physical values:

Voltage: Vrms = (INT32)Vs * 4 / Sqrt(2)
Current: Irms = (INT32)Is * 4 / Sqrt(2)

4.3.22.11.22.2 Sample - Neutral current

Name:
IactN_Sample1 to IactN_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present value of the neutral current, resolution 0,001 A

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.3 Sample - Current on phase A

Name:
IactA_Sample1 to IactA_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present current value on phase A, resolution 0.001 A

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.4 Sample - Voltage on phase A

Name:
UactA_Sample1 to UactA_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present voltage value on phase A, resolution 0.01 V

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.5 Sample - Current on phase B

Name:
IactB_Sample1 to IactB_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present current value on phase B, resolution 0.001 A

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.6 Sample - Voltage on phase B

Name:
UactB_Sample1 to UactB_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present voltage value on phase B, resolution 0.01 V

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.7 Sample - Current on phase C

Name:
IactC_Sample1 to IactC_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present current value on phase C, resolution 0.001 A

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.8 Sample - Voltage on phase C

Name:
UactC_Sample1 to UactC_Sample16

Data type	Value	Information
INT	-32,767 to 32,767	Present voltage value on phase C, resolution 0.01 V

This value must be converted by the application: See section 4.3.22.11.22.1 "General information"

4.3.22.11.22.9 Sample number

Name:
SampleCount1 to Samplecount16

Number of new Sample Lines since last readout.

Data type	Value	Information
SINT	-127 to 127	Sample Line number, ascending, cyclic
INT	-32,767 to 32,767	

4.3.22.11.22.10 Sample time

Name:
Timestamp

Older Sample Lines must each be back-calculated with 125 µs.

Data type	Value	Information
INT	-32,767 to 32,767	Network timestamp of Sample Line 1
DINT	-2,147,483,647 to 2,147,483,647	

4.3.22.11.23 Environment variables

4.3.22.11.23.1 Operating time in seconds

Name:
OnTime

The operating time since startup is saved in seconds in this register.

Data type	Value
UDINT	0 to 4,294,967,295

4.3.22.11.23.2 Startup counter

Name:
UpCounter

The number of restarts since startup is saved in this register.

Data type	Value
UDINT	0 to 4,294,967,295

4.3.22.11.23.3 Minimum operating temperature

Name:
MinTemp

The lowest transformer temperature [°C] since startup is saved in this register.

Data type	Value	Information
INT	-200 to 200	Resolution 1°C

4.3.22.11.23.4 Maximum operating temperature

Name:
MaxTemp

The highest transformer temperature [°C] since startup is saved in this register.

Data type	Value	Information
INT	-200 to 200	Resolution 1°C

4.3.22.11.24 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.3.22.11.25 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Voltage and current sampling rate for calculation of effective value, power and energy	1 MHz
Derived values: RMS, power, energy, power factor, phase angle, frequency (mean values over 16 full waves)	Approx. 3 Hz
FFT on request (SR: 8 kHz)	2 Hz

4.4 Analog output modules

Analog output modules convert PLC internal numerical values into voltages or currents. The numerical values which are to be converted must be in 16-bit 2s complement. The conversion takes place independently of the resolution of the output module used.

Every channel on an analog output module has a status LED.

4.4.1 Brief information

Product ID	Short description	on page
X20AO2437	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated	597
X20AO2438	X20 analog output module, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol	608
X20AO2622	X20 analog output module, 2 outputs, ±10 V / 0 to 20 mA / 4 to 20 mA, 13-bit resolution	661
X20AO2632	X20 analog output module, 2 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution	668
X20AO2632-1	X20 analog output module, 2 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution	675
X20AO4622	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution	682
X20AO4635	X20 analog output module, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, low temperature drift	708
X20cAO2437	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated	597
X20cAO2438	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol	608
X20cAO4622	X20 analog output module, coated, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution	682

4.4.2 X20(c)AO2437

4.4.2.1 General information

The module is equipped with 2 current outputs with 16-bit digital converter resolution. The 2 channels are electrically isolated from each other. The user can select between the 3 output ranges 4 to 20 mA, 0 to 20 mA and 0 to 24 mA.

- 2 analog current outputs
- Electrically isolated analog channels
- 16-bit digital converter resolution

4.4.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

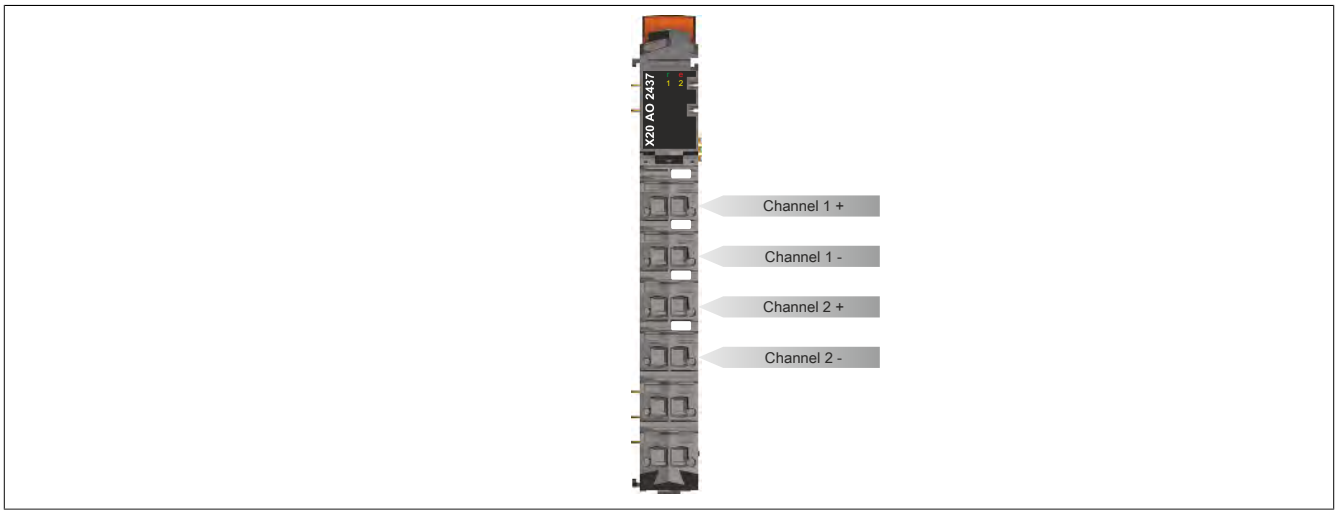
4.4.2.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

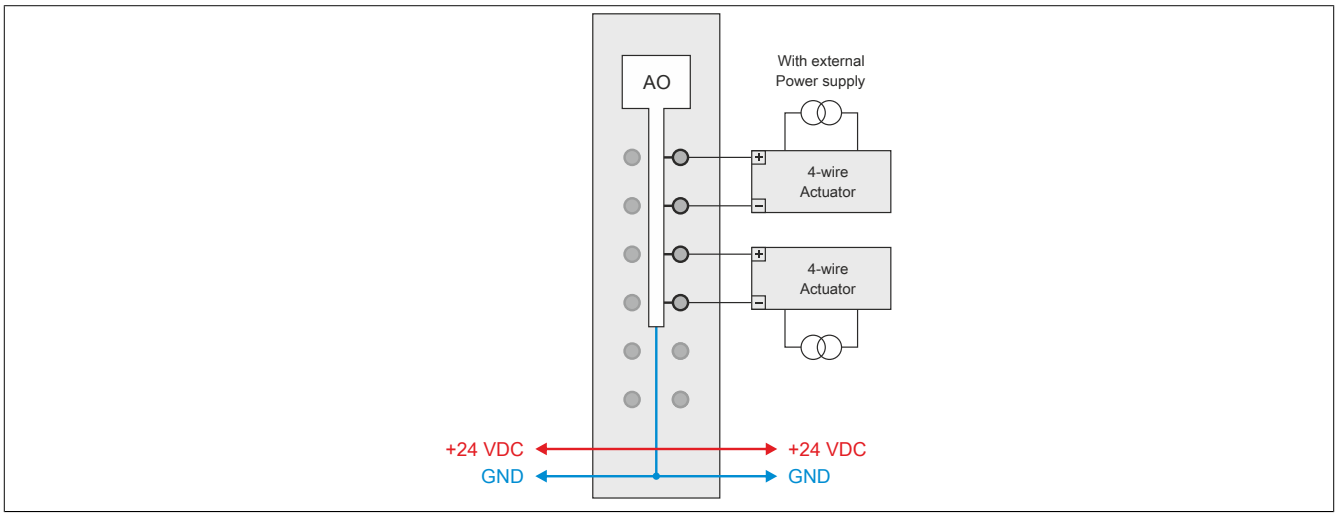
Figure	LED	Color	Status	Description
	**Operating status**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP mode
	Module status			
	e	Red	Off	No power to module or everything OK
			Single flash	A conversion error has occurred. When an error occurs, the LED of the faulty analog output channel begins to double flash and this status is output.
			On	Error or reset status
	Analog output			
	1 - 2	Orange	Off	Indicates one of the following cases: • No power to module • Channel disabled
			Single flash	Open line
			Double flash	A conversion error has occurred. A single flash is output on the red "e" module status LED.
			On	Digital/analog converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

4.4.2.6 Pinout



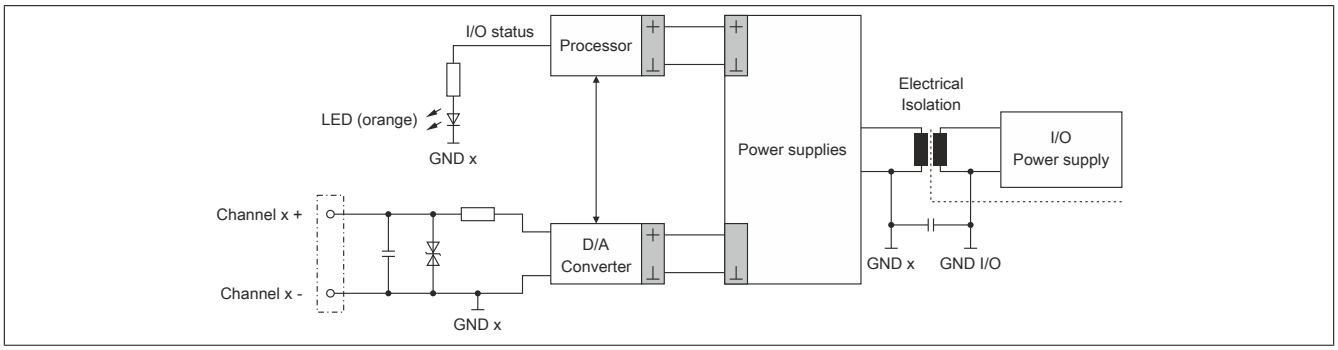
4.4.2.7 Connection example



4.4.2.8 OSP hardware requirements

In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.4.2.9 Output circuit diagram



4.4.2.10 Derating

To ensure proper operation, the derating values listed below must be adhered to:

Horizontal installation

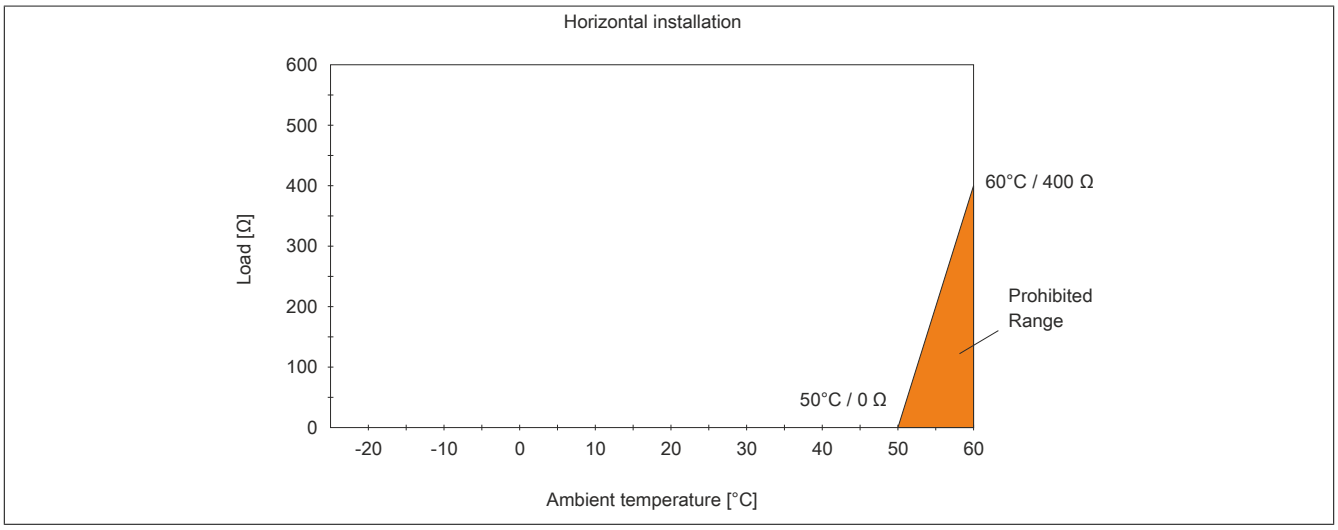


Figure 135: Derating the load with horizontal mounting

Vertical installation

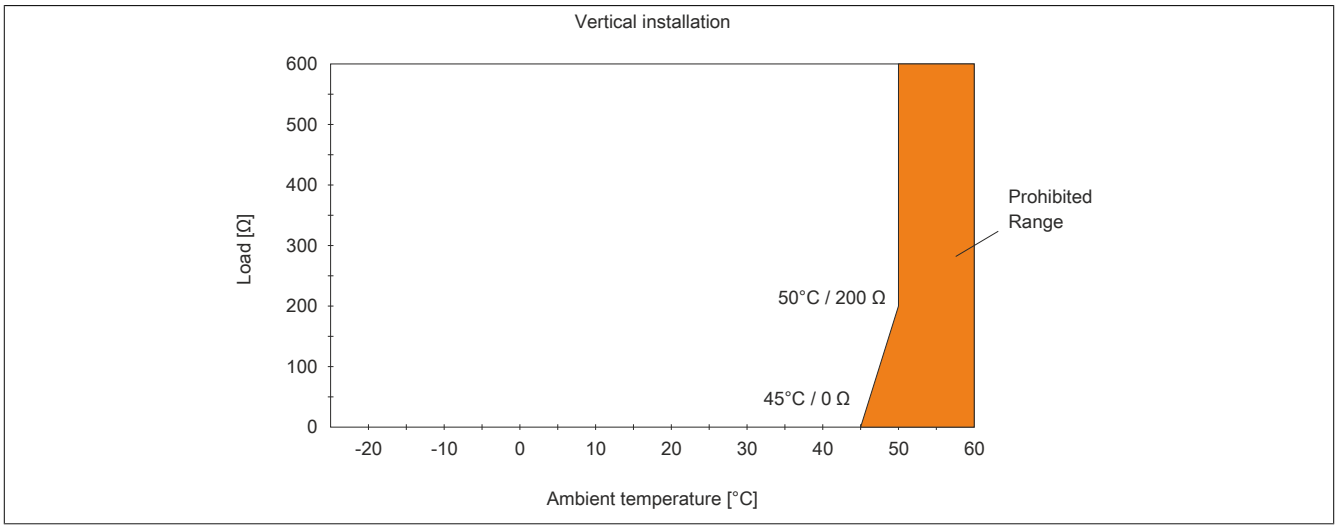

Figure 136: Derating the load with vertical mounting

4.4.2.11 Register description

4.4.2.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.2.11.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
386 394	AnalogMode01 AnalogMode02	UINT				•
390 398	DACSlewrate01 DACSlewrate02	UINT				•
Analog signal - Communication						
0 2	AnalogOutput01 AnalogOutput02	(U)INT			•	
30 31	AnalogStatus01 AnalogStatus02	USINT	•			
	OpenLineAnalogOutput01 or OpenLineAnalogOutput02	Bit 2				
	ConversionErrorAnalogOutput01 or ConversionErrorAnalogOutput02	Bit 3				
	IoSuppErrorAnalogOutput01 or IoSuppErrorAnalogOutput02	Bit 7				

4.4.2.11.3 Function model 1 - OSP

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
386 394	AnalogMode01 AnalogMode02	UINT				•
390 398	DACSlewrate01 DACSlewrate02	UINT				•
Analog signal - Communication						
0 2	AnalogOutput01 AnalogOutput02	(U)INT			•	
30 31	AnalogStatus01 AnalogStatus02	USINT	•			
	OpenLineAnalogOutput01 or OpenLineAnalogOutput02	Bit 2				
	ConversionErrorAnalogOutput01 or ConversionErrorAnalogOutput02	Bit 3				
	IoSuppErrorAnalogOutput01 or IoSuppErrorAnalogOutput02	Bit 7				
The OSP function model						
32	OSPComByte	USINT			•	
	OSPValid	Bit 0				
401 403	CfgOSPMode01 CfgOSPMode02	USINT				•
34 36	CfgOSPValue01 CfgOSPValue02	INT				•

4.4.2.11.4 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
386 394	-	AnalogMode01 AnalogMode02	UINT				•
390 398	-	DACSlewrate01 DACSlewrate02	UINT				•
Analog signal - Communication							
0 2	0 2	AnalogOutput01 AnalogOutput02	(U)INT			•	
30 31	-	AnalogStatus01 AnalogStatus02	USINT		•		
		OpenLineAnalogOutput01 or OpenLineAnalogOutput02	Bit 2				
		ConversionErrorAnalogOutput01 or ConversionErrorAnalogOutput02	Bit 3				
		IoSuppErrorAnalogOutput01 or IoSuppErrorAnalogOutput02	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.4.2.11.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.2.11.5 Analog signal - Configuration

The module has 2 electrically isolated channels. All registers have a dual design. Channels can be configured and operated independently of one another.

Specific features

- Electrical isolation by channel
- Configurable output ramp DAC slew rate (Default: 210 ms full scale)

4.4.2.11.5.1 AnalogMode

Name:
AnalogMode01 to AnalogMode02

These registers are used to predefine the operating parameters that the module will be using for the respective channel. Each channel must be activated and configured separately.

Information:

When you select the operating mode "Scaling 0 to 20 mA (Resolution 0 to 65535)", then the corresponding "AnalogOutput" registers are interpreted internally as UINT instead of INT.
The entire program must be rebuilt for the data type change to take effect. The data type cannot be changed during runtime (e.g. using a library).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel	0	Disabled
		1	Enabled (bus controller default)
1	Check - DAC configuration/status	0	Enabled (bus controller default)
		1	Disabled
2 - 3	Reserved	-	
4	Scaling 0 to 20 mA (Resolution 0 to 32767)	0	Disabled
		1	Enabled
5	Scaling 4 to 20 mA (Resolution 0 to 32767)	0	Disabled
		1	Enabled (bus controller default)
6	Scaling 0 to 24 mA (Resolution 0 to 24000)	0	Disabled
		1	Enabled
7	Scaling 0 to 20 mA (Resolution 0 to 65535)	0	Disabled
		1	Enabled
8 - 15	Reserved	-	

4.4.2.11.5.2 DACSlewrate

Name:
DACSlewrate01 to DACSlewrate02

These registers limit the rate at which the analog signal is modified. This makes it possible to define a sort of upper limit frequency.

The following formula applies: f(Analog) = f(Output rate) * Permitted change / max. Δ(standardized output value)

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 2	Permitted change per rate	000	1-bit
		001	2-bit
		010	4 bit (bus controller default)
		011	8-bit
		100	16-bit
		101	32-bit
		110	64-bit
		111	128-bit
3 - 7	Reserved	-	
8 - 11	Output rate	0000	257730 Hz
		0001	198410 Hz
		0010	152440 Hz (bus controller default)
		0011	131580 Hz
		0100	115740 Hz
		0101	69440 Hz
		0110	37590 Hz
		0111	25770 Hz
		1000	20160 Hz
		1001	16030 Hz
		1010	10290 Hz
		1011	8280 Hz
		1100	6900 Hz
		1101	5530 Hz
		1110	4240 Hz
		1111	3300 Hz
12 - 14	Reserved	-	
15	Slewrate enable (ramp functionality)	0	Disabled (undefined jump behavior)
		1	Enabled (defined transitions)

4.4.2.11.6 Analog signal - Communication

In order to output the required current signal (default: 4 to 20 mA), the module must be provided with the standardized output value (default: 0 to 32767).

4.4.2.11.6.1 AnalogOutput

Name:
AnalogOutput01 to AnalogOutput02

These registers provide the standardized output values. Depending on the scaling selected (see AnalogMode register), the value range and the data type can be adapted to the requirements of the application. Once a permitted value is determined, the module outputs the respective current.

Information:

The value "0" disables the channel status LED.

Data type	Value	Information
INT	0 to 32767	Bus controller default: 0
Optional: UINT	0 to 65535	

4.4.2.11.6.2 AnalogStatus

Name:
AnalogStatus01 to AnalogStatus02

The status register gives the user feedback about whether the respective channel is functioning properly.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	-	
2	OpenLineAnalogOutput01, 02	0	Line OK
		1	Open line
3	ConversionErrorAnalogOutput01, 02	0	Conversion temperature OK
		1	Conversion temperature too high
4 - 6	Reserved	-	
7	IoSuppErrorAnalogOutput01, 02	0	Module supply OK
		1	Module supply error

4.4.2.11.7 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.4.2.11.7.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the relevant task in the master CPU. However, an output still occurs depending on the configuration of the OSP replacement value.

4.4.2.11.7.2 Setting the OSP mode

Name:
CfgOSPMode01 to CfgOSPMode02

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.4.2.11.7.3 Define the OSP analog output value

Name:
CfgOSPValue01 to CfgOSPValue02

This register contains the analog output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
Corresponds to AnalogOutput0x	Corresponds to AnalogOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.4.2.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.2.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.4.3 X20(c)AO2438

4.4.3.1 General information

The module is equipped with 2 current outputs with 16-bit digital converter resolution. It supports the HART communication standard for data transfer, parameter configuration and diagnostics.

The 2 channels are electrically isolated from each other. The user can select between the 3 output ranges 4 to 20 mA, 0 to 20 mA and 0 to 24 mA.

- 2 analog current outputs
- HART protocol integration
- Support for HART variables
- Electrically isolated analog channels
- 16-bit digital converter resolution

4.4.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.4.3.3 Order data

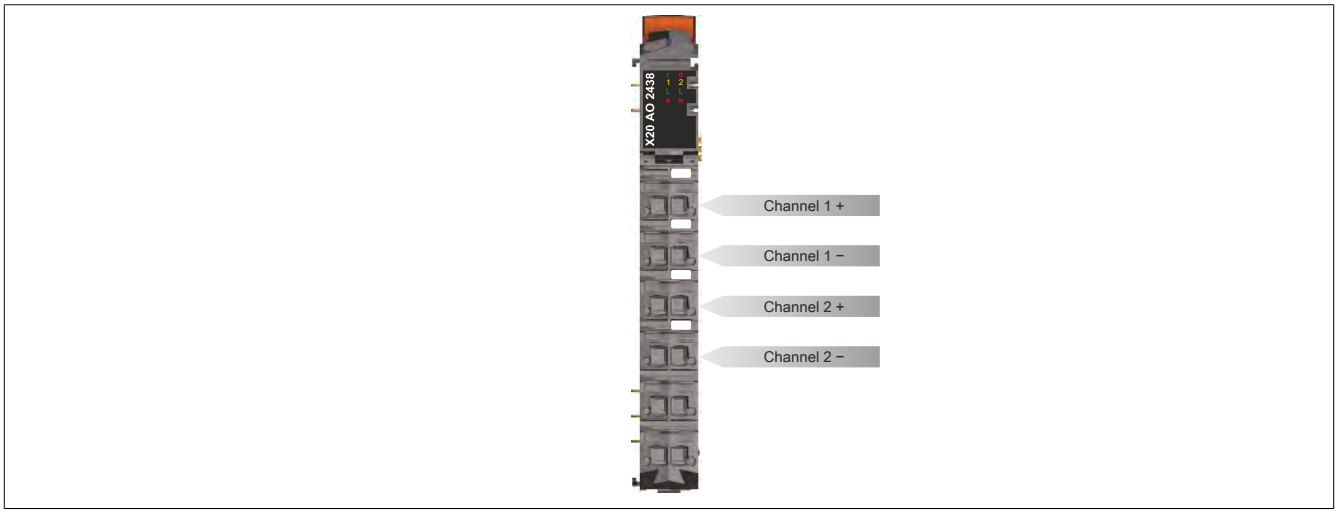
4.4.3.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

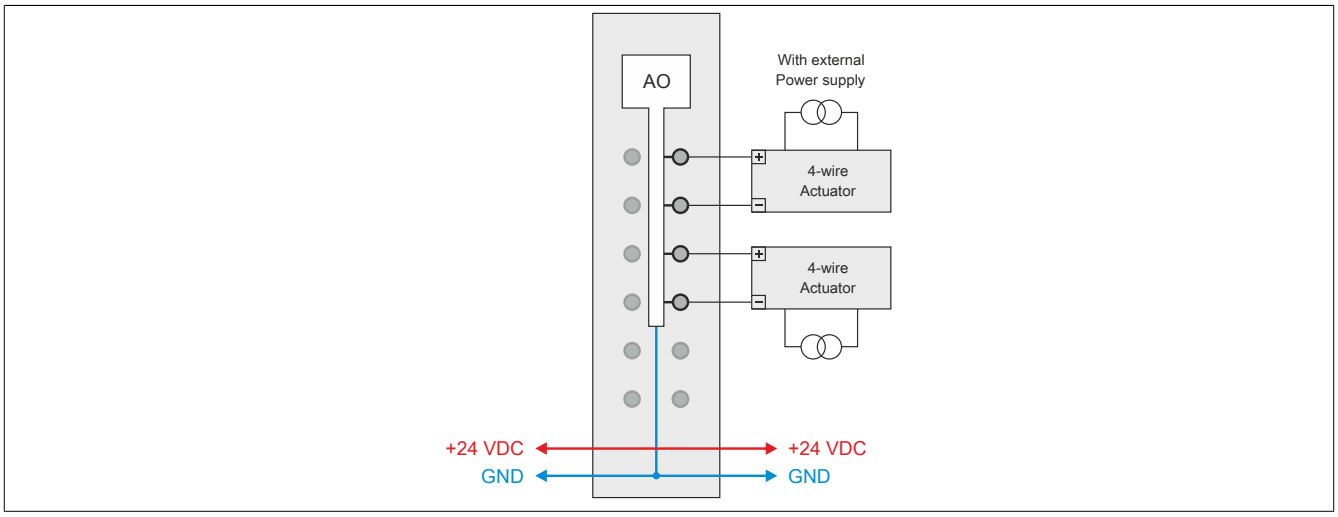
Figure	LED	Color	Status	Description
	**Operating status**			
	r	Green	Off	No power to module
			Single flash	UNLINK mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking quickly	SYNC mode
			Blinking slowly	PREOPERATIONAL mode
			On	RUN mode
			Flickering (approx. 10 Hz)	Module is in OSP mode
	Module status			
	e	Red	Off	No power to module or everything OK
			Single flash	A conversion error has occurred. When an error occurs, the LED of the faulty analog output channel begins to double flash and this status is output.
			On	Error or reset status
	Analog output			
	1 - 2	Orange	Off	Indicates one of the following cases: • No power to module • Channel disabled
			Single flash	Open line
			Double flash	A conversion error has occurred. A single flash is output on the red "e" module status LED.
			On	Digital/analog converter running, value OK
	HART link			
	L	Green	Off	Indicates one of the following cases: • No power to module • HART disabled for the respective channel
			Flickering	Carrier signal active (DCD or RTS)
	HART error			
	e	Red	Off	Indicates one of the following cases: • Communication taking place without errors • No power to module • HART disabled for the respective channel
			On	Communication error

1) Depending on the configuration, a firmware update can take up to several minutes.

4.4.3.6 Pinout



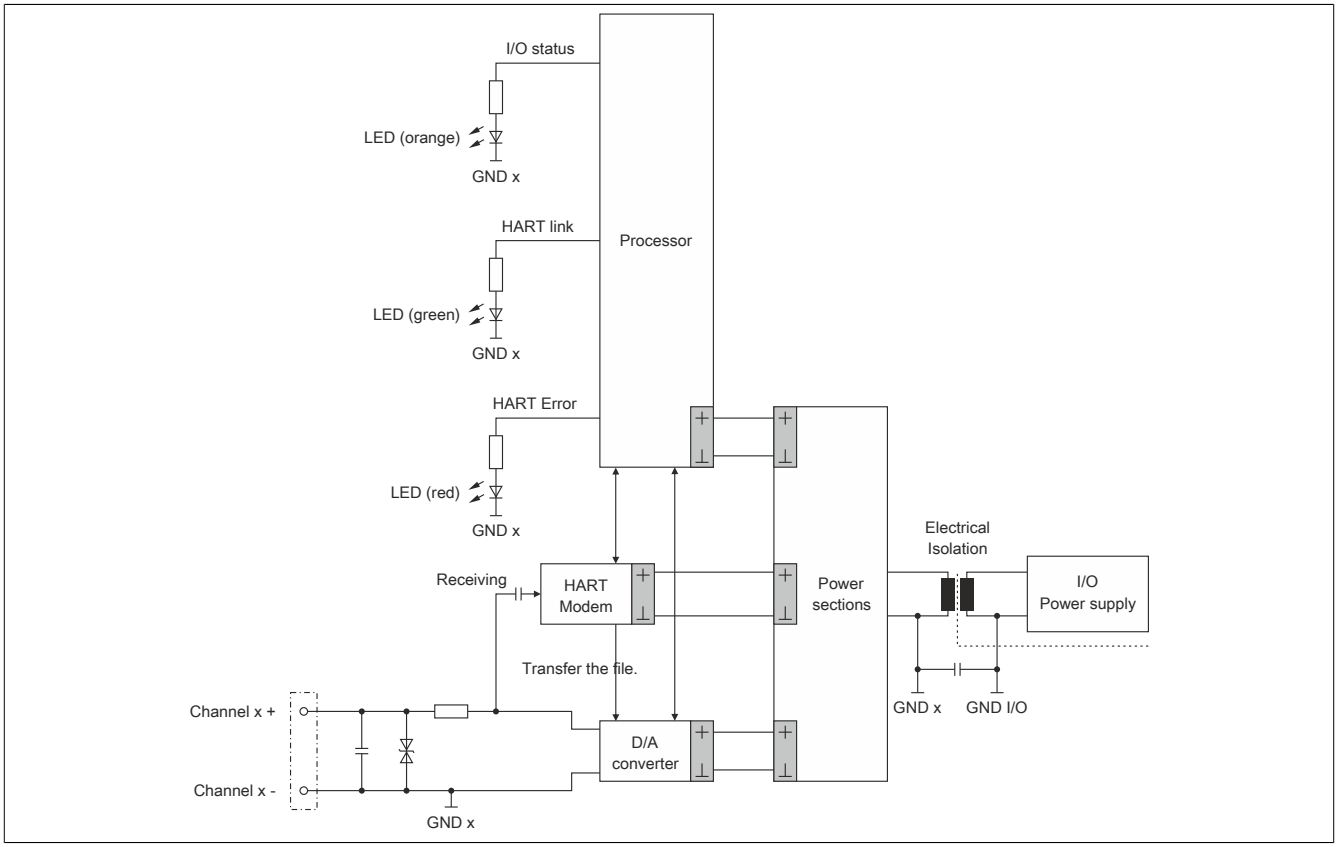
4.4.3.7 Connection example



4.4.3.8 OSP hardware requirements

In order to best use OSP mode, make sure when creating the application that the output module and CPU have separate power supplies.

4.4.3.9 Output circuit diagram



4.4.3.10 Operation

4.4.3.10.1 Derating

To ensure proper operation, the derating values listed below must be adhered to:

Horizontal installation

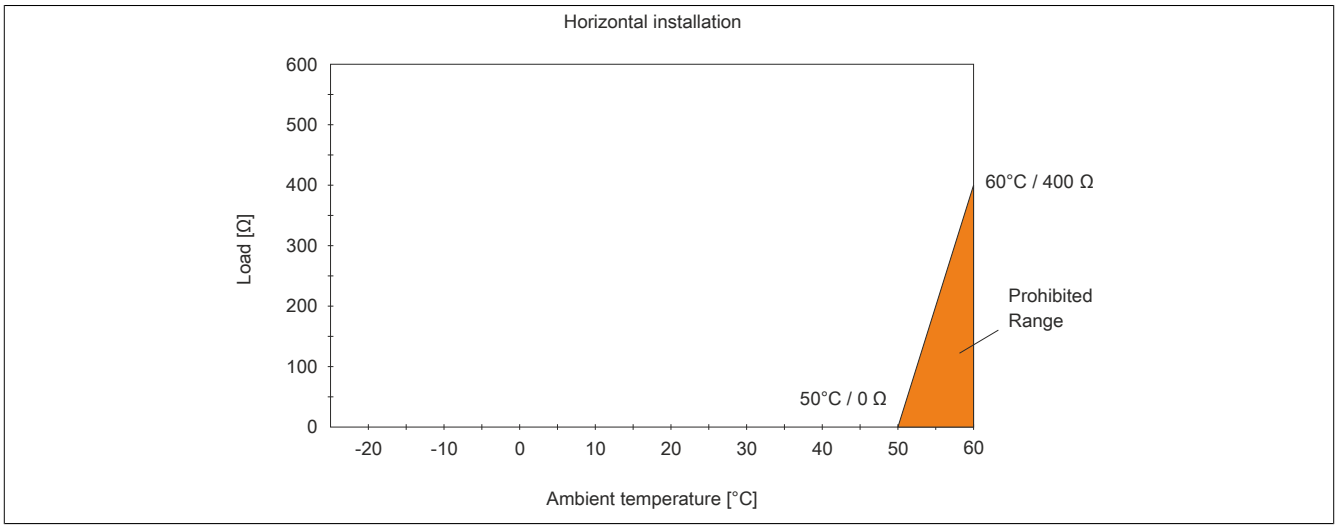


Figure 137: Derating the load with horizontal mounting

Vertical installation

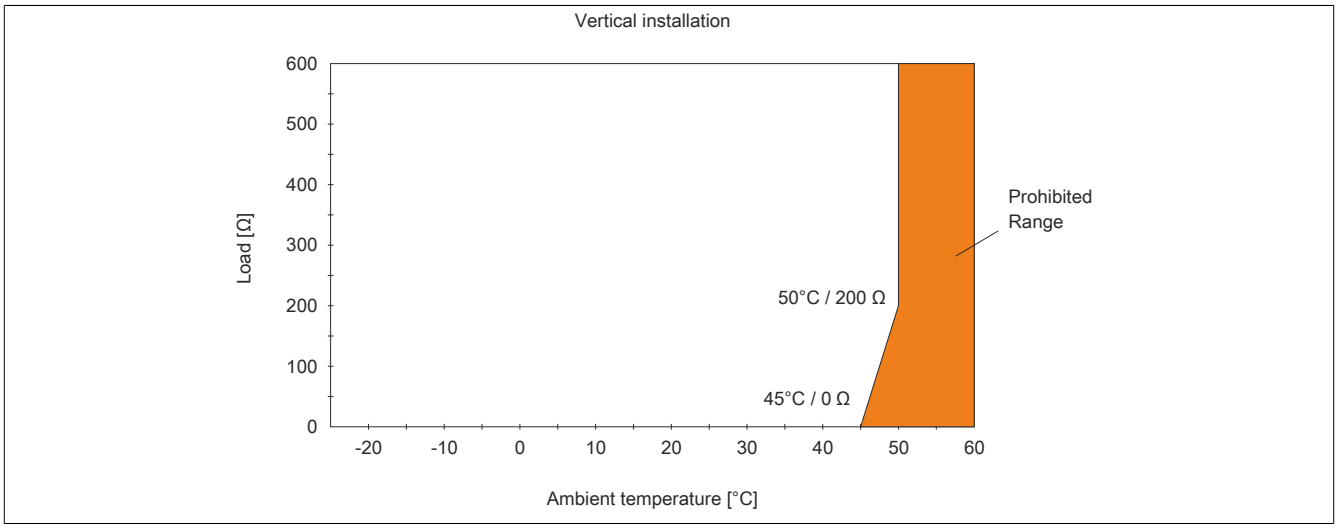

Figure 138: Derating the load with vertical mounting

4.4.3.10.2 HART communication standard

This module supports the HART communication standard for data transfer, parameter configuration and diagnostics. The HART standard is used for the current range 4 to 20 mA. Be aware that the load is not permitted to fall below 230 Ω .

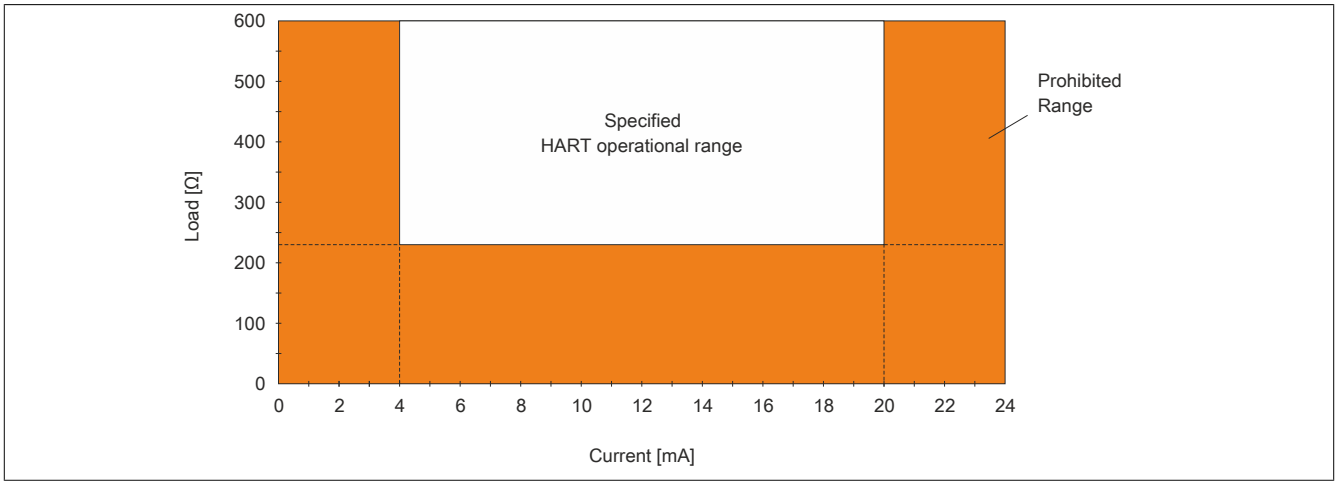

Figure 139: Specified HART operational range

Both current ranges 0 to 20 mA and 0 to 24 mA are supported by this module. HART communication can also be used in these ranges as well. It is important to make sure, however, that the output current lies within the specified HART operational range.

4.4.3.11 Register description

4.4.3.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

4.4.3.11.4.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.4.3.11.5 Analog signal - Configuration

The module has 2 independent electrically isolated channels with integrated HART modems. Both channels can be used to output an analog signal and handle HART communication. Two registers need to be configured for one analog signal. The two channels operate independently, so two registers must be configured per channel to be used.

The current outputs (default: 4 to 20 mA) can be used as conventional analog signals. The integrated HART modems retrieve digital information from the memory on the HART slave using the same physical lines that modulate the HART signals.

Each channel can use one of the following connection variants:

- Point-to-point (connection of one HART node on the channel):
  → Evaluation of the analog signal
  and
  → Recording of up to 4 HART values
- Multidrop (connection of up to 15 HART nodes on the channel):
  → Recording of one HART value per connected node

Specific features

- Electrical isolation by channel
- Up to 4 or 15 HART input variables per channel
- Configurable output rate (DAC slew rate) to transfer HART and analog signal without interference (default: 210 ms full scale)
- Selectable error strategy (static replacement value or retention of the last permitted value)
- Cyclic "HART status" polling (HART command 0), the status information received is made available for channel diagnostics
- Compatible with an additional secondary master in the HART network (module acts as the primary master)
- "HART communication error bit" (shows loss of HART connection if a connection had already been established successfully)
- Optional: BURST mode for one node per channel
- Optional: Cyclic polling of "HART variables" (HART command 3 or 9)
- Optional: FlatStream functionality (module acts as bridge for HART packets)

4.4.3.11.5.1 AnalogMode

Name:
AnalogMode01 to AnalogMode02

These registers are used to predefine the operating parameters that the module will be using for the respective channel. Each channel must be activated and configured separately.

Information:

When you select the operating mode "Scaling 0 to 20 mA (Resolution 0 to 65535)", then the corresponding "AnalogOutput" registers are interpreted internally as UINT instead of INT.
The entire program must be rebuilt for the data type change to take effect. The data type cannot be changed during runtime (e.g. using a library).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel	0	Disabled
		1	Enabled (bus controller default)
1	Check - DAC configuration/status	0	Enabled (bus controller default)
		1	Disabled
2 - 3	Reserved	-	
4	Scaling 0 to 20 mA (Resolution 0 to 32767)	0	Disabled
		1	Enabled
5	Scaling 4 to 20 mA (Resolution 0 to 32767)	0	Disabled
		1	Enabled (bus controller default)
6	Scaling 0 to 24 mA (Resolution 0 to 24000)	0	Disabled
		1	Enabled
7	Scaling 0 to 20 mA (Resolution 0 to 65535)	0	Disabled
		1	Enabled
8 - 15	Reserved	-	

Information:

The "AnalogMode" registers provide the option of avoiding the cyclic check of the DAC configuration. To manage communication reliably, this option should only be used if no HART communication is taking place on the channel.

4.4.3.11.5.2 DACSlewrate

Name:
DACSlewrate01 to DACSlewrate02

These registers limit the rate at which the analog signal is modified. This makes it possible to define a sort of upper limit frequency.

The following formula applies: f(Analog) = f(Output rate) * Permitted change / max. ∆(standardized output value)

Data type	Value
UINT	See bit structure

To ensure communication takes place without errors, it's important that the frequency range of the digital HART signal is not influenced by the analog output. HART communication takes place in the frequency range 950 to 2500 Hz.

Example (default): f(Analog) = 152440 Hz * 4 / (32767 - 0)
Conclusion: f(Analog) = ~**20 Hz << 950 Hz** = f(HART)

Bit structure:

Bit	Name	Value	Information
0 - 2	Permitted change per rate	000	1-bit
		001	2-bit
		010	4 bit (bus controller default)
		011	8-bit
		100	16-bit
		101	32-bit
		110	64-bit
		111	128-bit
3 - 7	Reserved	-	
8 - 11	Output rate	0000	257730 Hz
		0001	198410 Hz
		0010	152440 Hz (bus controller default)
		0011	131580 Hz
		0100	115740 Hz
		0101	69440 Hz
		0110	37590 Hz
		0111	25770 Hz
		1000	20160 Hz
		1001	16030 Hz
		1010	10290 Hz
		1011	8280 Hz
		1100	6900 Hz
		1101	5530 Hz
		1110	4240 Hz
		1111	3300 Hz
12 - 14	Reserved	-	
15	Slewrate enable (ramp functionality)	0	Disabled (undefined jump behavior)
		1	Enabled (defined transitions)

4.4.3.11.6 Analog signal - Communication

In order to output the required current signal (default: 4 bis 20 mA), the module must be assigned the default output value (default: 0 to 32767). In this way, the X20AO2438 can be used as a conventional output module. The integrated HART modem uses the same physical line. Using signals with a higher frequency allows the module to communicate with and also retrieve information from the HART slave.

4.4.3.11.6.1 AnalogOutput

Name:
AnalogOutput01 to AnalogOutput02

These registers provide the standardized output values. Depending on the scaling selected (see AnalogMode register), the value range and the data type can be adapted to the requirements of the application. Once a permitted value is determined, the module outputs the respective current.

Information:

The value "0" disables the channel status LED.

Data type	Value	Information
INT	0 to 32767	Bus controller default: 0
Optional: UINT	0 to 65535	

4.4.3.11.6.2 AnalogStatus

Name:
AnalogStatus01 to AnalogStatus02

The status register gives the user feedback about whether the respective channel is functioning properly.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0 - 1	Reserved	-	
2	OpenLineAnalogOutput01, 02	0	Line OK
		1	Open line
3	ConversionErrorAnalogOutput01, 02	0	Conversion temperature OK
		1	Conversion temperature too high
4 - 6	Reserved	-	
7	IoSuppErrorAnalogOutput01, 02	0	Module supply OK
		1	Module supply error

4.4.3.11.7 HART

HART (Highway Addressable Remote Transducer) is a protocol for communicating with intelligent field devices. It was developed in order to more efficiently use the infrastructure for transferring analog signals. The digital HART notifications are modulated to the analog signal using Frequency Shift Keying (FSK). HART can thus use the same physical line as the analog signal without influencing the original function.
HART slaves are able to determine different process data independently and prepare HART concordantly. This protocol supports polling of the value of a process variable as well as its unit and status. Field devices usually supply their information after the master requests it. In newer revisions, it is also possible to transfer configuration data.

There are two different types of HART networks. In a *point-to-point* network, only one slave is connected to a HART master. Here, the analog signal and the HART signal can be transferred over the same line. Managing several slaves with HART requires what is known as a *multidrop* network. Here, each HART slave is assigned and identified by a unique address. Classic analog signals cannot be clearly traced in bus systems. As a result, the HART protocol does not support analog information transfers in multidrop networks up to and including HART Revision 5.

Information:

Split range operation with HART AO modules

Beginning with HART revision 6, bus stations that use an analog signal according to the split range method are written to separately. The HART protocol supports multidrop addressing as well as the use of analog signals for these applications.

The module was designed based on HART-Revision 5. Only single-channel FSK scheme is available for transmitting the signals.

Since all HART frames are generated and evaluated in the application when using the FlatStream interface, information that isn't specified until later revisions can also be read.

4.4.3.11.7.1 HART - Configuration

HART modules are analog modules equipped with a HART modem. For each channel, a separate HART network can be managed by the module, which acts as a primary master. Once configured successfully, the HART information is stored in the module where it can then be used by the PLC.

The number of HART slaves must be specified in the configuration.
If only one slave is connected to the HART channel, then it is part of a point-to-point network. The module can then prepare up to four process variables from the connected slave.
Multidrop mode allows up to 15 HART slaves to be connected. The primary process variable from each slave is then retrieved.

HartNodeCnt

Name:
HartCodeCnt_1 to HartCodeCnt_2

These registers tell the module how many HART slaves are connected to a channel.

Information:

If a slave is not connected to one of the HART channels, the value "0" should be defined in this register. This shortens the I/O update time and avoids superfluous error messages.

Data type	Value	Information	
USINT	0	HART communication disabled for this channel	
	1	Point-to-point	Standard HART communication (bus controller default)
	2 to 15	Multidrop	Number of HART slave nodes

HartBurstNode

Name:
HartBurstNode_1 to HartBurstNode_2

In addition to the type of network, the user can also choose from two different types of communication behavior. Conventional HART communication relies on polling. The module requests the data from the individual HART slaves and receives the corresponding information from each slave as a response. If a HART node should be queried in short time intervals, the user can configure burst mode for channels on one node. In this case, the slave transmits the node's information cyclically without constant prompting from the master.
The "HartBurstNode" registers are therefore used to enter the node numbers (short address) for the channels whose information should be retrieved using burst mode. Burst mode itself is enabled with the "HartMode" register.

Data type	Value	Information	
USINT	0 to 15	Point-to-point	0 (bus controller default)

HartMode

Name:
HartMode_1 to HartMode_2

The user can use these registers to configure the communication behavior of each of the HART channels. Generally, the HART nodes are polled individually. This register can still be used to start or stop burst mode when needed. In burst mode, a node transmits its information cyclically instead of continuously. As a result, the HART standard allows the simultaneous usage of both burst mode and polling.

Information:

To retrieve information with burst mode, theHartBurstNode register must be configured correctly.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Slave polling mode	0	Polling mode enabled (Bus Controller Default)
		1	Polling mode disabled
1	Start slave burst mode	0	No response to burst (bus controller default)
		1	Enables burst mode in the HartBurstNode node
2	Stop slave burst mode	0	No response to burst (bus controller default)
		1	Disables burst mode, if enabled
3 - 7	Reserved	-	

4.4.3.11.7.2 HART - Communication

Once the configuration has been completed, the information is retrieved automatically and transferred to the module's registers. A separate register in the module is implemented for each piece of information. HART modules are designed to retrieve up to 15 pieces of information per channel. The module reads in the data, stores it in temporary memory and prepares it for retrieval. When the X2X master accesses the module registers, it is irrelevant whether the HART data originates from a point-to-point network or a multidrop network.

Overview of internal module mapping

	Point-to-point network (1 HART slave)	*Multidrop network (2 to 15 HART slaves)*
(Pv)Input_01	Primary piece of information from HART node 1	Primary piece of information from HART node 1
(Pv)Input_02	Secondary piece of information from HART node 1	Primary piece of information from HART node 2
...	...	...
(Pv)Input_04	Quaternary piece of information from HART node 1	Primary piece of information from HART node 4
(Pv)Input_05	Reserved	Primary piece of information from HART node 5
...	...	...
(Pv)Input_15	Reserved	Primary piece of information from HART node 15

The HART specifications stipulates that information from a HART node be split into various pieces. The value of a process variable is stored to the respective "PvInput" register and has a size of 4 bytes (REAL) in accordance with the HART specification. Due to the length limitation of 30 bytes on the X2X link, there are restrictions to the number of possible cyclic variables. It is recommended to only transfer a maximum of 2 "PvInput" registers cyclically to the X2X master. All other information should be transferred in a different way. To access HART information, the user can choose from among the following methods:

- Data points that are configured to be transferred cyclically are read once per bus cycle. This method allows information to be exchanged between the module and the X2X master in real time. Nevertheless, the length limitation may prevent all data from being retrieved within one cycle.
- If the AsIOAcc library is used, information is retrieved acyclically only when it is needed, i.e. communication can be adapted to the application running on the X2X master. In this way, all of the necessary module registers on the X2X link can be polled despite the length limitation.
  This method of information exchange is not real-time capable.
- HART modules are equipped with a FlatStream interface. When using FlatStream communication, the module acts a bridge between the X2X master and the HART slave, i.e. the X2X master communicates directly with the HART slave (see section "FlatStream communication""FlatStream communication").
  FlatStream communication is also not real-time capable. It allows unrestricted access to the HART slave. The user must have sufficient knowledge of the HART protocol command set as well as the capabilities of the HART slave device.

PvInput

Name:
PvInput_01 to PvInput_15
PvInput_01_01 to PvInput_01_15
PvInput_02_01 to PvInput_02_15

These registers return the current value of the process variable that has been read.

Information:

These registers are of data type REAL, which means that the available bytes on the X2X Link are filled more quickly when operated cyclically. If information from several slave nodes is needed, it must be retrieved acyclically or using Flatstream .

Data type	Value	Information
REAL	IEEE745 SPF	32-bit data type with valid value
	0x7FA00000	Not a number (NaN) with invalid value

PvUnit

Name:
PvUnit_01 to PvUnit_15
PvUnit_01_01 to PvUnit_01_15
PvUnit_02_01 to PvUnit_02_15

These registers return a HART-specific code that specifies the unit for the measured value. The coding for this is established in the HART specification.

Data type	Value
USINT	See description of the HART slave See HART specification

PvSampleTime

Name:
PvSampleTime01 to PvSampleTime02
PvSampleTime01_01 to PvSampleTime01_15
PvSampleTime02_01 to PvSampleTime02_15

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

This refers to the point in time when the HART master receives the slave's response. This is a way to check whether new HART information has been read since the last X2X cycle.

Information:

The cycle times of a HART network are relatively long so that it is not possible to reliably determine when the measured value is retrieved with just this information.

PvNodeComStatus

Name:
PvNodeComStatus01 to PvNodeComStatus02
PvNodeComStatus01_01 to PvNodeComStatus01_15
PvNodeComStatus02_01 to PvNodeComStatus02_15

These registers return information about whether a value that has been read is valid. According to the HART specification, this type of status register consists of two parts. The high byte stores the "response code" and the low byte the "field device status". This makes it possible to check the current status of a read process variable.

These registers can be checked before further processing information in temporary storage. If the current value is 0x0000, an error was not detected during the HART transfer and the information from the checked node can be used. If a different value is present, the situation in the HART network should be checked. This can be done using an extension register, for example.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Quality - Node information 2 to n	0	Digital measured value okay
		1	Measured value outside the permitted range
1	Quality - Node information 1	0	Digital measured value okay
		1	Measured value outside the permitted range
2	Limit violation	0	Parameter okay
		1	Invalid measured value(s) or encoder supply value
3	Static analog signal	0	Normal value change/fluctuation
		1	Constant analog value of Node 1 slave
4	Additional status information (only supported by a few slaves)	0	Not available
		1	Available (only using Flatstream command #48)
5	Restart	0	Normal operation
		1	Field device restarts
6	Device ID	0	Unchanged
		1	Changed
7	Device error	0	Measured value okay
		1	Questionable measured value information
8 - 14	Response code, if relevant	x	See **HART-specific response code**
15	Error - Communication	0	Error-free communication (response code irrelevant)
		1	Faulty communication (response code relevant)

HART-specific response code (excerpt):

0x82 … Receive buffer overflow 0x88 … Checksum incorrect 0x90 … Faulty protocol structure 0xA0 … Overrun 0xC0 … Parity not allowed 0xFF … Timeout	If a HART communication error occurs, the response code is written. Bit 15 is always set.

Retrieving information that has been read

After the node data has been transferred to the module registers, the information can be retrieved from the module. A separate register in the module is implemented for each piece of information.

PvCountHartRequest

Name:
PvCountHartRequest01 to PvCountHartRequest02

These registers are increased once the module is ready to transmit a message to the corresponding channel.

Data type	Value
UDINT	0 to 4,294,967,295

PvCountHartTimeout

Name:
PvCountHartTimeout01 to PvCountHartTimeout02

These registers are increased if the slave exceeds the maximum permitted time before responding to the module's request.

Data type	Value
UDINT	0 to 4,294,967,295

PvCountHartRxError

Name:
PvCountHartRxError01 to PvCountHartRxError02

These registers are increased if communication errors occur on Layer 1 of the OSI model (e.g. transmission error as per parity bit).

Data type	Value
UDINT	0 to 4,294,967,295

PvCountHartFrameError

Name:
PvCountHartFrameError01 to PvCountHartFrameError02

These registers are increased if communication errors occur on Layer 2 of the OSI model (e.g. faulty telegram structure).

Data type	Value
UDINT	0 to 4,294,967,295

PvNodeFound

Name:
PvNodeFound01 to PvNodeFound02

These registers provide information about which nodes were detected on which channel (slave identified successfully).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
1	Node 2 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
...		...	
13	Node 14 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
14	Node 15 (multidrop mode)	0	Not detected as valid
		1	Detected as valid
15	Reserved	-	

PvNodeError

Name:
PvNodeError01 to PvNodeError02

These registers contain the HART communications error bits. These bits are set if the connection to a node was established successfully but the node at some point no longer responds as it should (e.g. the HART slave exceeds the configured timeout / number of retries).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
1	Node 2 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
...		...	
13	Node 14 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
14	Node 15 (multidrop mode)	0	Detected as having no errors
		1	Detected as having errors
15	Reserved	-	

4.4.3.11.7.3 Extended configuration

The additional configuration registers are specified values when the module is started. In most systems, the user does not need to make any adjustments here. Register values should only be changed if HART network communication is not taking place satisfactorily.

HartNodeDisable

Name:
HartNodeDisable_1 to HartNodeDisable_2

These registers are intended for things like maintenance. They make it possible to cut off configured HART nodes to suppress error messages for a certain period of time. During normal operation, the configured nodes must be switched active to guarantee that the procedure runs smoothly.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Node 0 (default mode) Node 1 (multidrop mode)	0	Enabled (bus controller default setting)
		1	Disabled
1	Node 2 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
...		...	
13	Node 14 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
14	Node 15 (multidrop mode)	0	Enabled
		1	Disabled (bus controller default)
15	Reserved	-	

HartProtTimeOut

Name:
HartProtTimeOut_1 to HartProtTimeOut_2

These registers specify the time span within which the slave must respond for the response to be valid.

Data type	Values [ms]	Information
UINT	0 to 65535	Bus controller default: 256 [ms]

HartProtRetry

Name:
HartProtRetry_1 to HartProtRetry_2

These registers determine how many times the master retries a request if it receives an invalid response or no response at all.

Data type	Value	Information
UINT	0 to 65535	Bus controller default: 3 attempts

HartPreamble

Name:
HartPreamble_1 to HartPreamble_2

The length of the preamble can be set in these registers. The preamble is used to synchronize the receiver to the transmitter. The longer the declared preamble, the less chance that a communication error will occur. Nevertheless, a useful signal is not transmitted during synchronization so the preamble should be kept as short as possible.

Data type	Value	Information
UINT	5 to 20	Bus controller default: 20

4.4.3.11.8 FlatStream communication

4.4.3.11.8.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

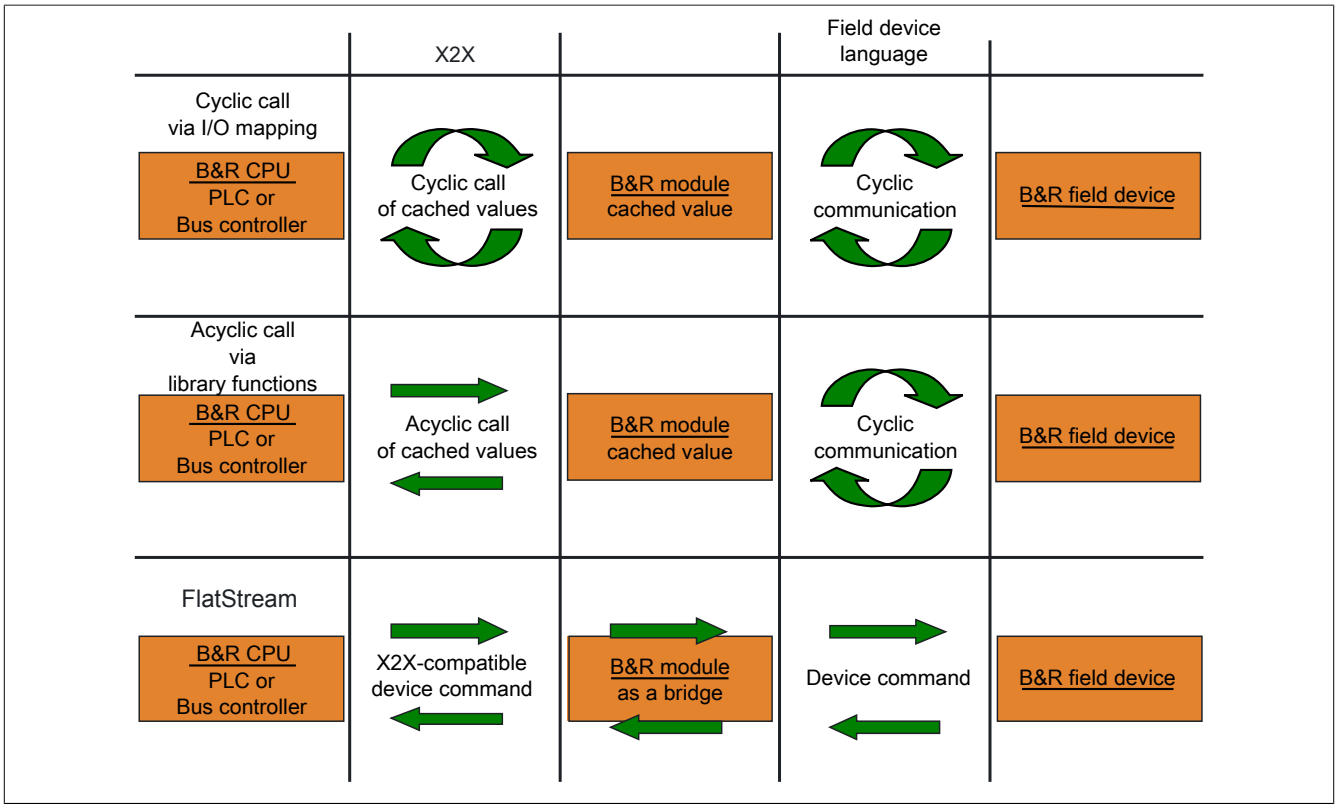

Figure 140: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.4.3.11.8.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.4.3.11.8.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

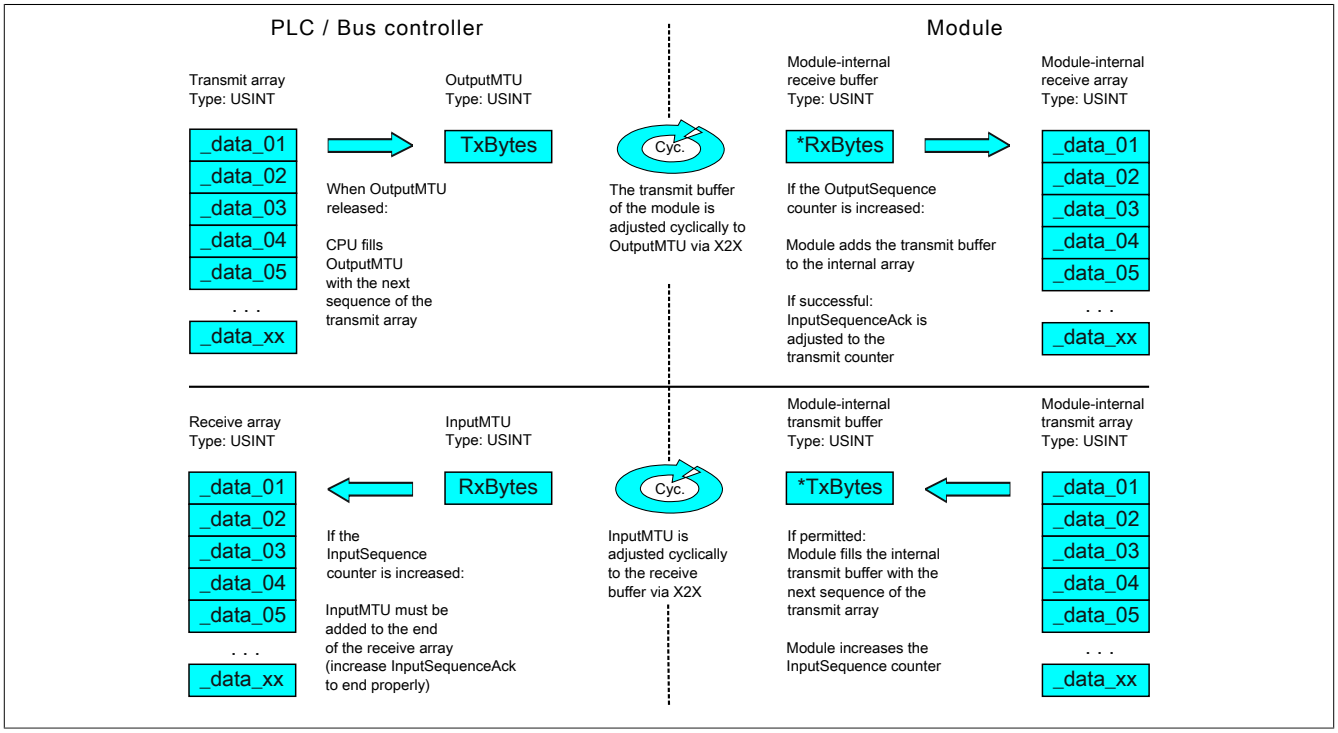

Figure 141: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.4.3.11.8.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

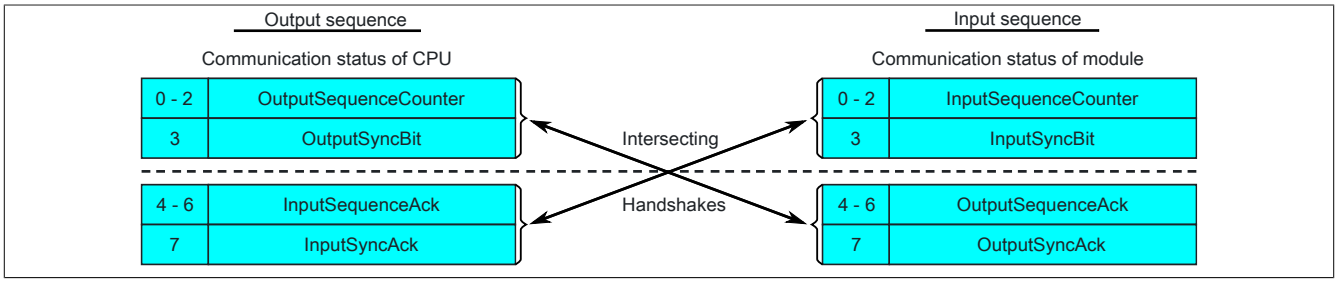

Figure 142: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

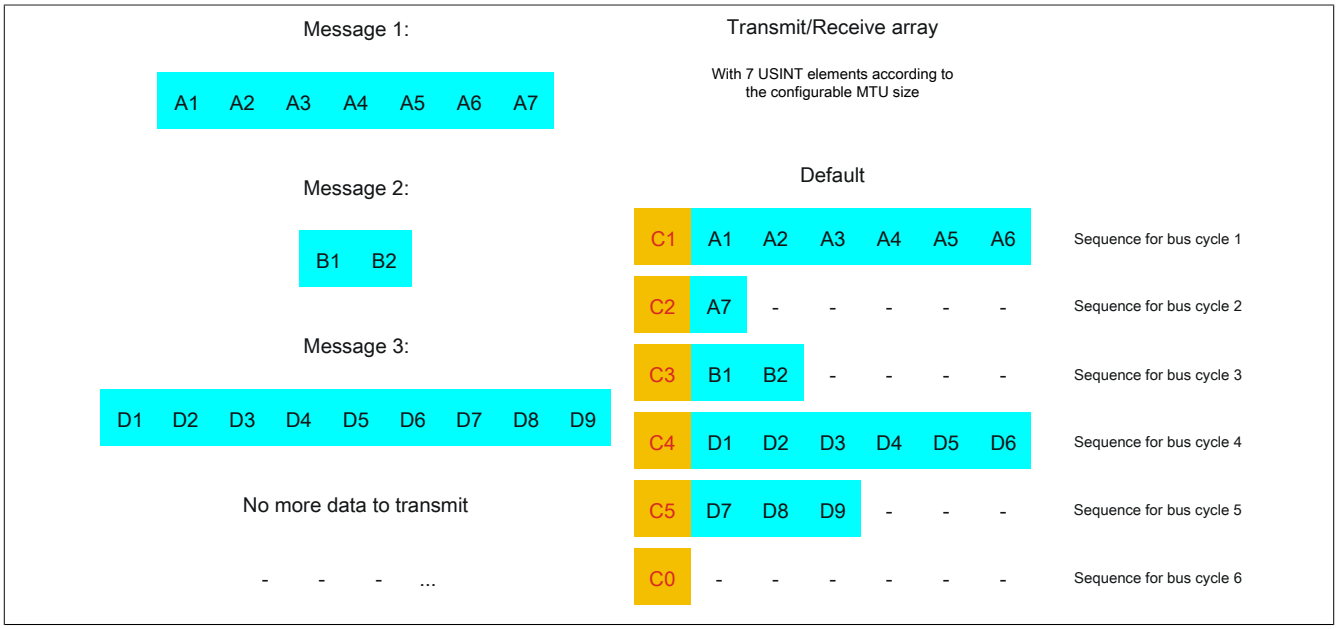

Figure 143: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 84: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 85: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

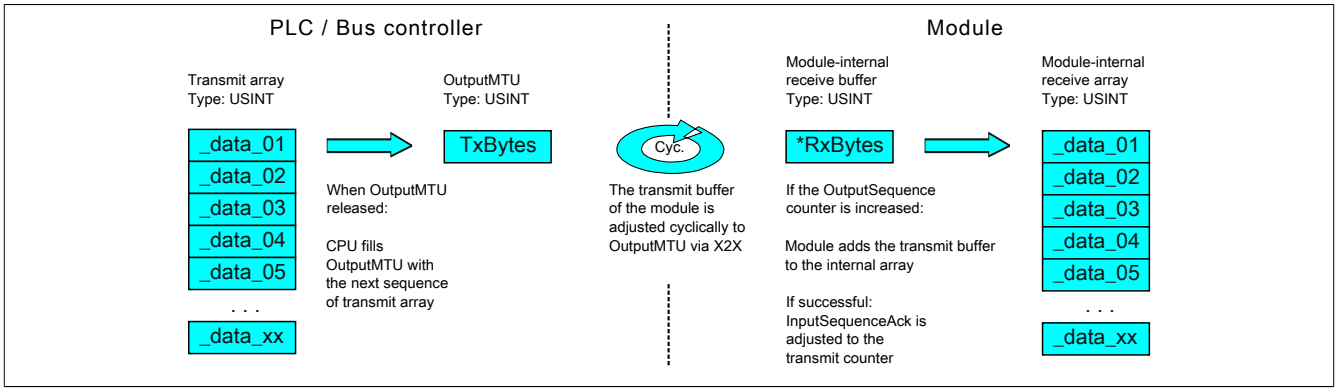

Figure 144: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

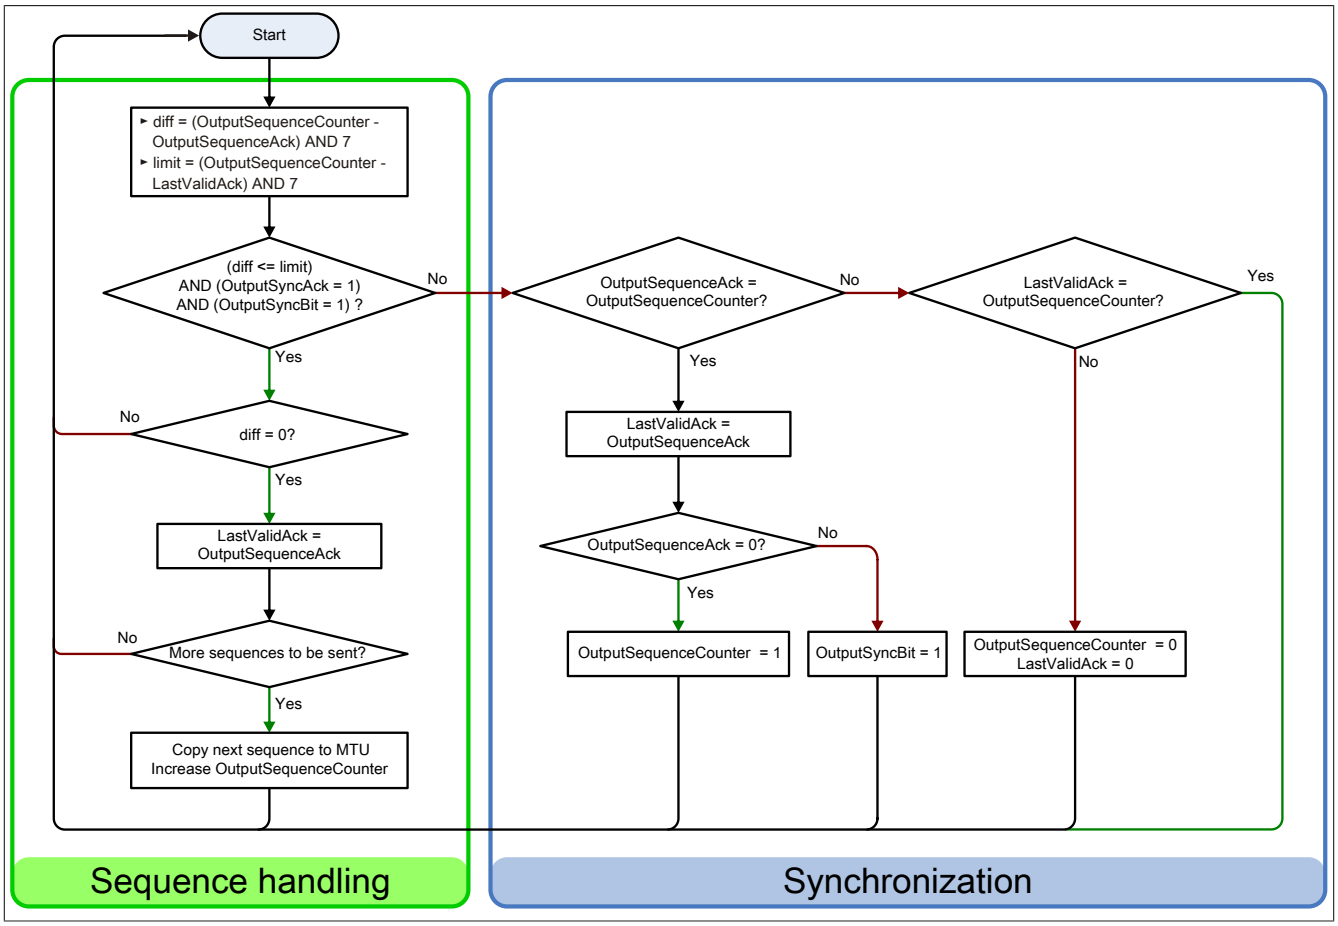

Figure 145: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

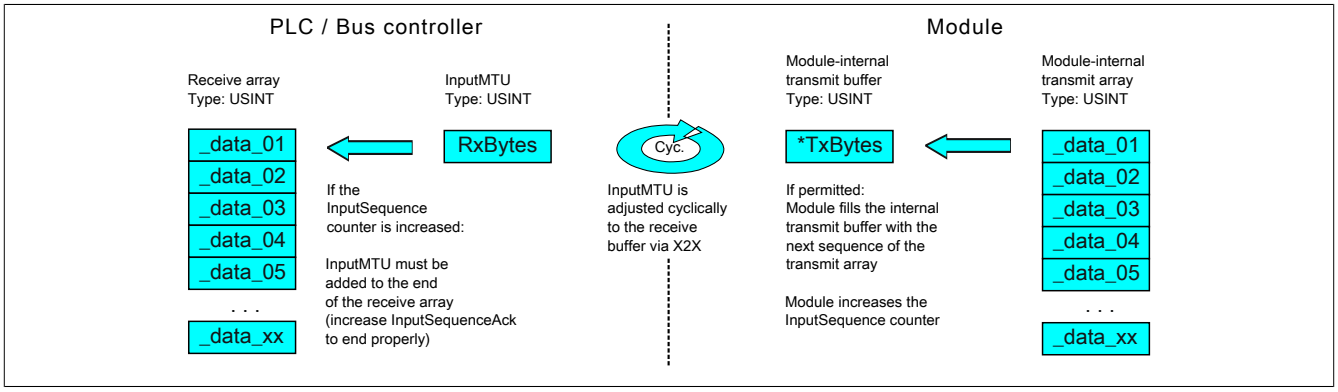

Figure 146: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

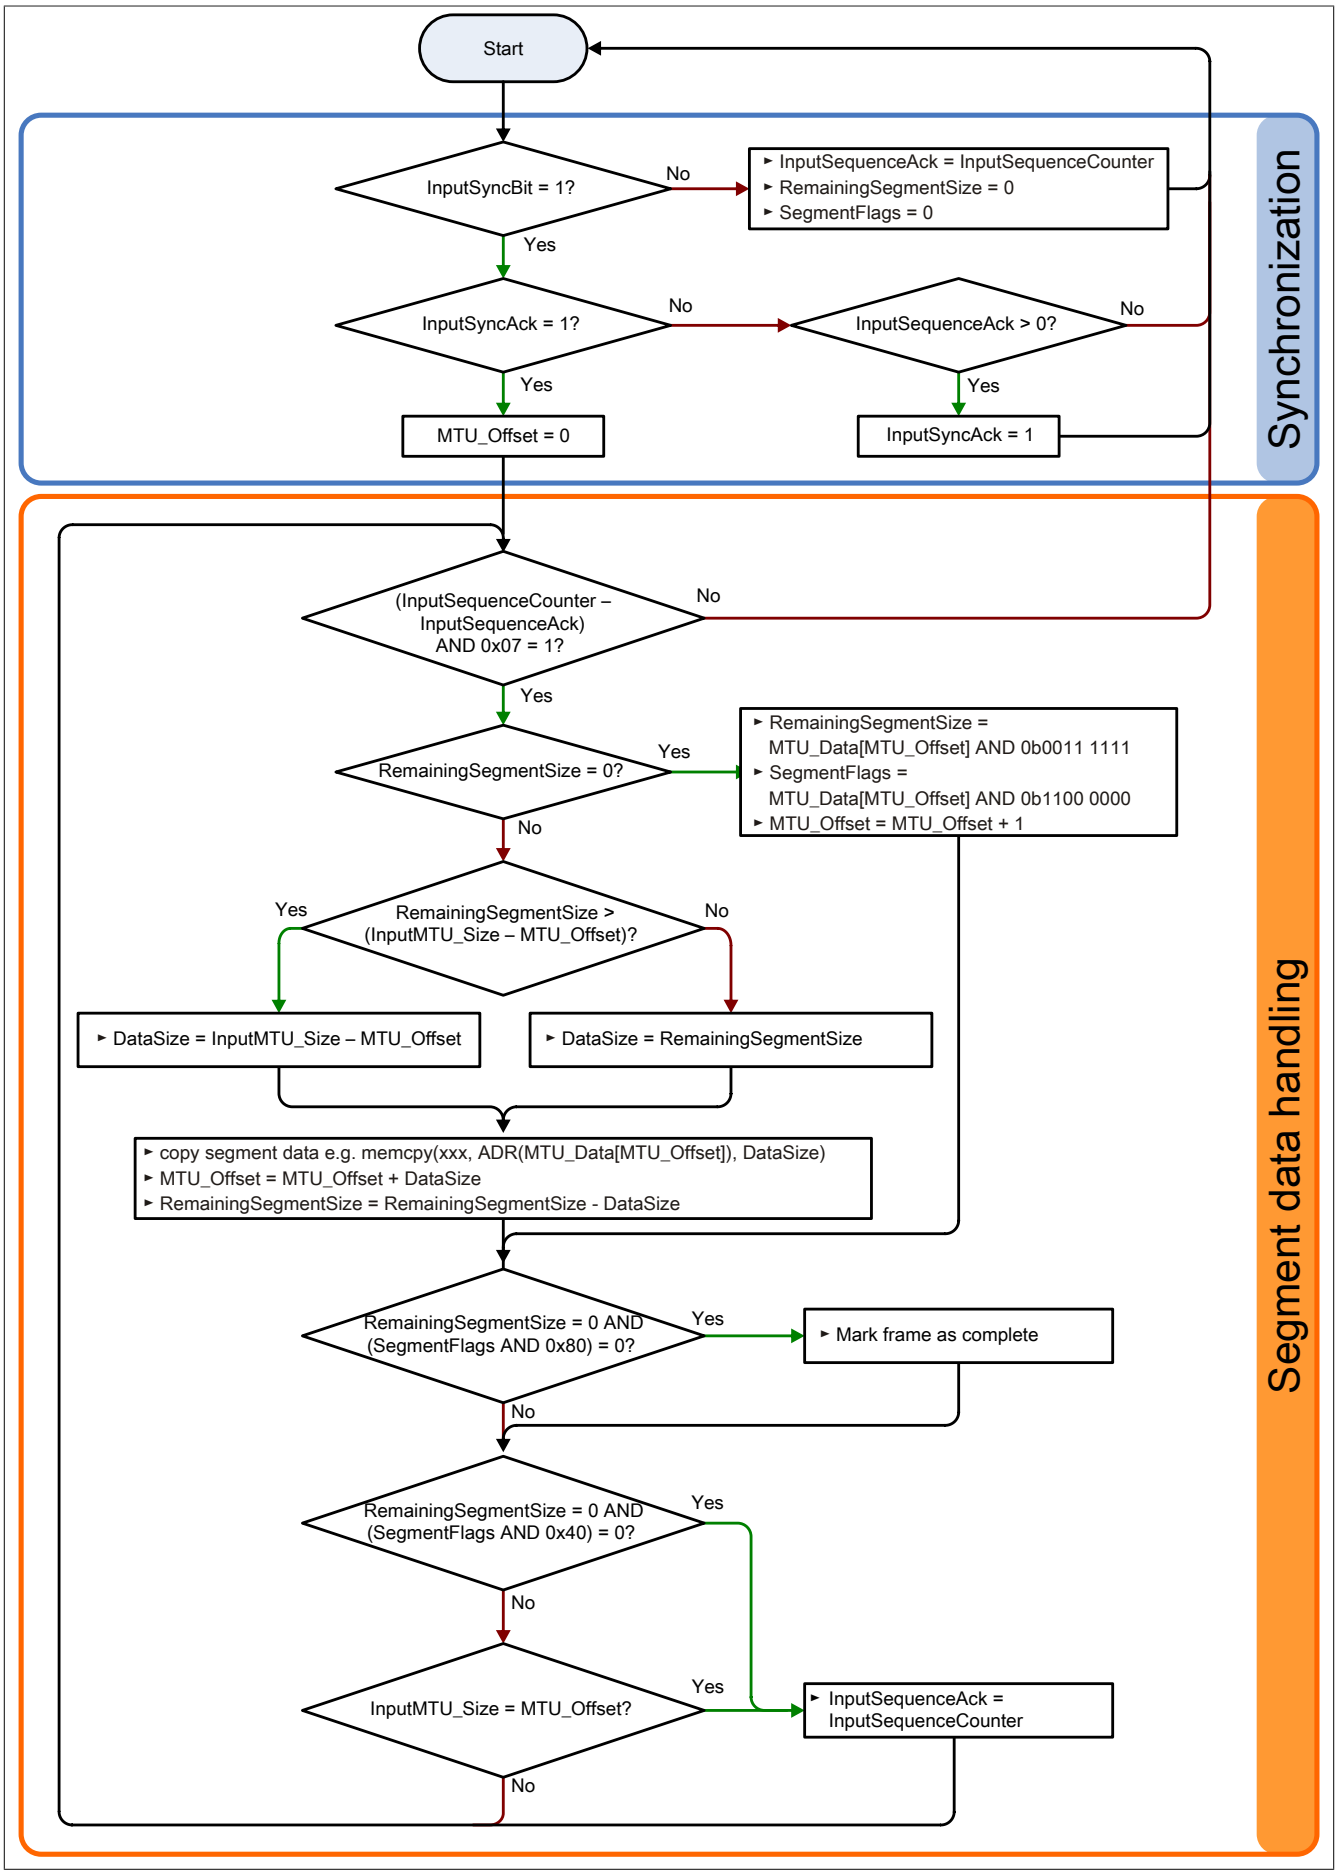

Figure 147: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

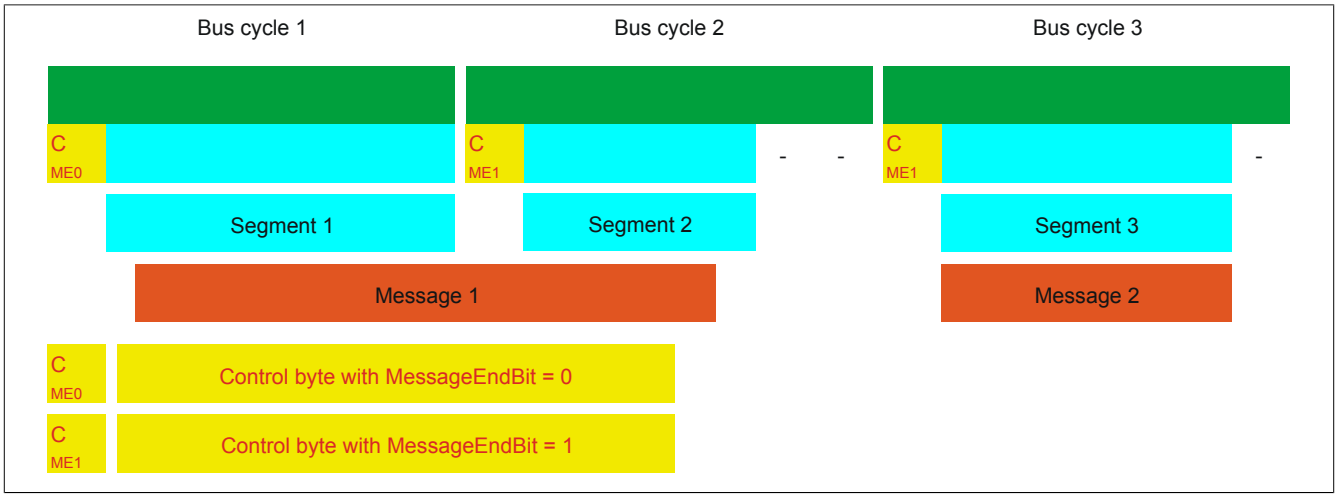

Figure 148: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

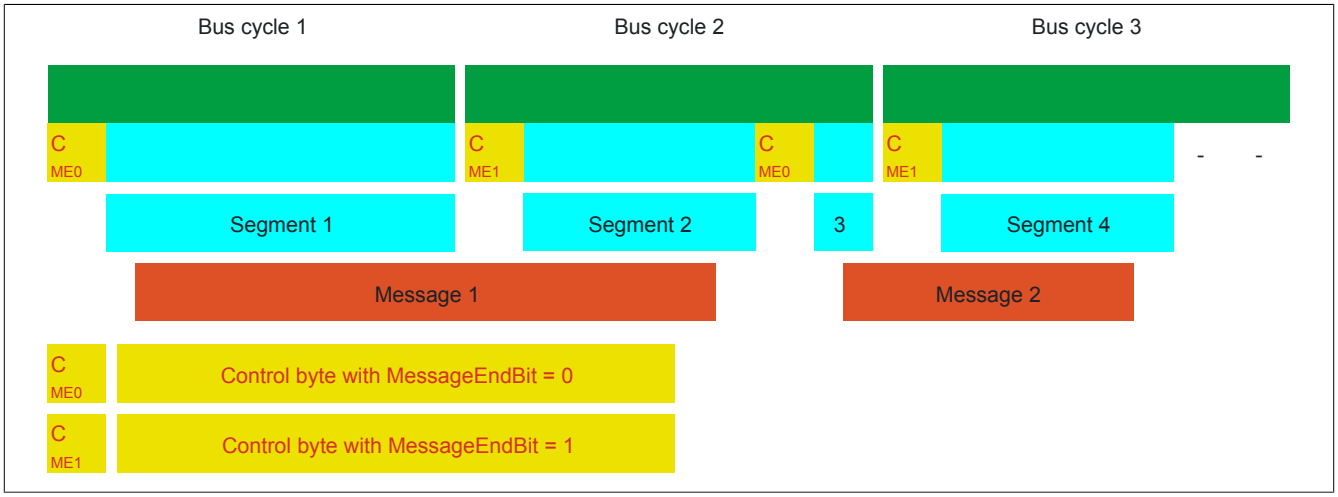

Figure 149: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

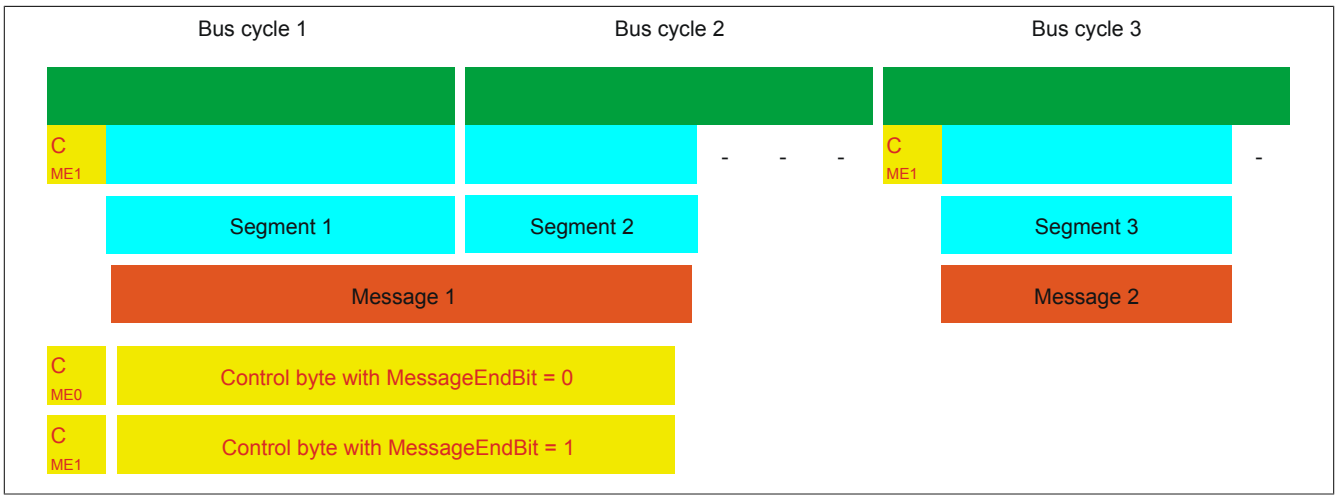

Figure 150: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

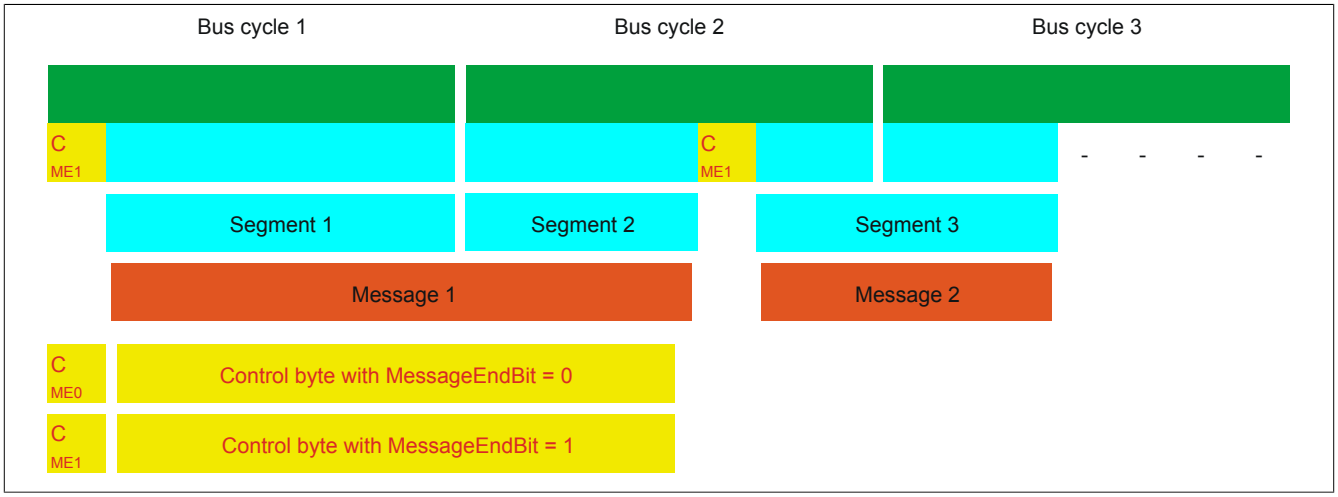

Figure 151: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

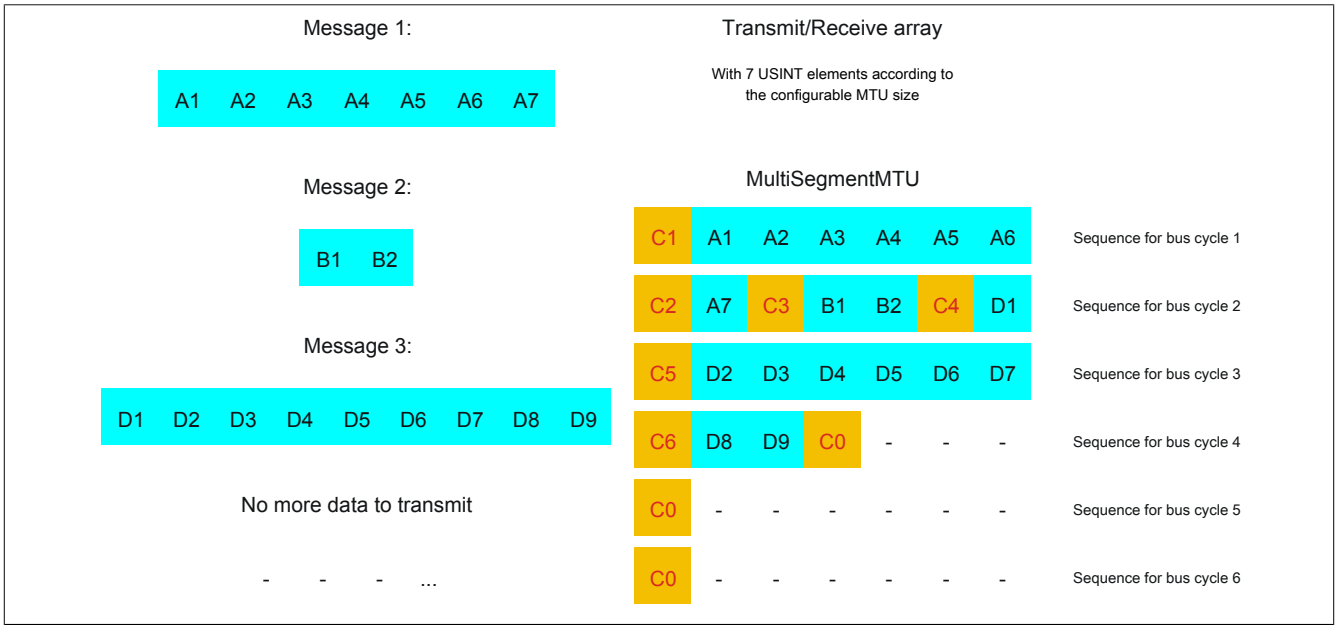

Figure 152: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 86: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 87: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

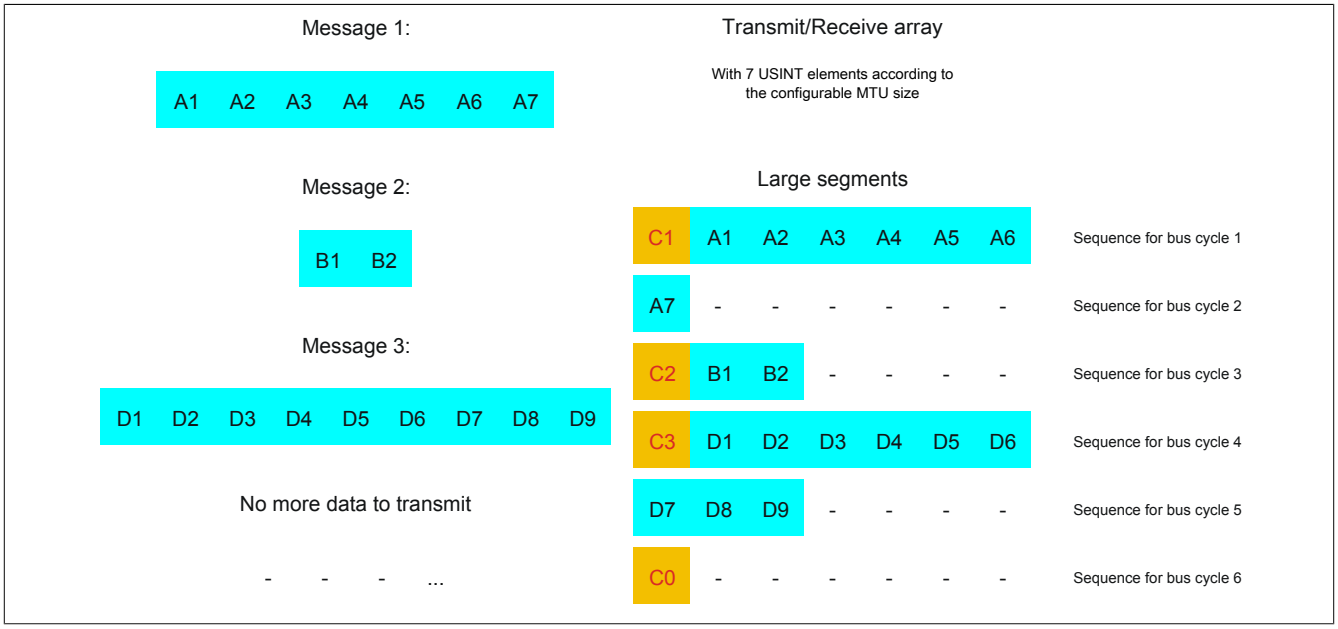

Figure 153: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 88: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

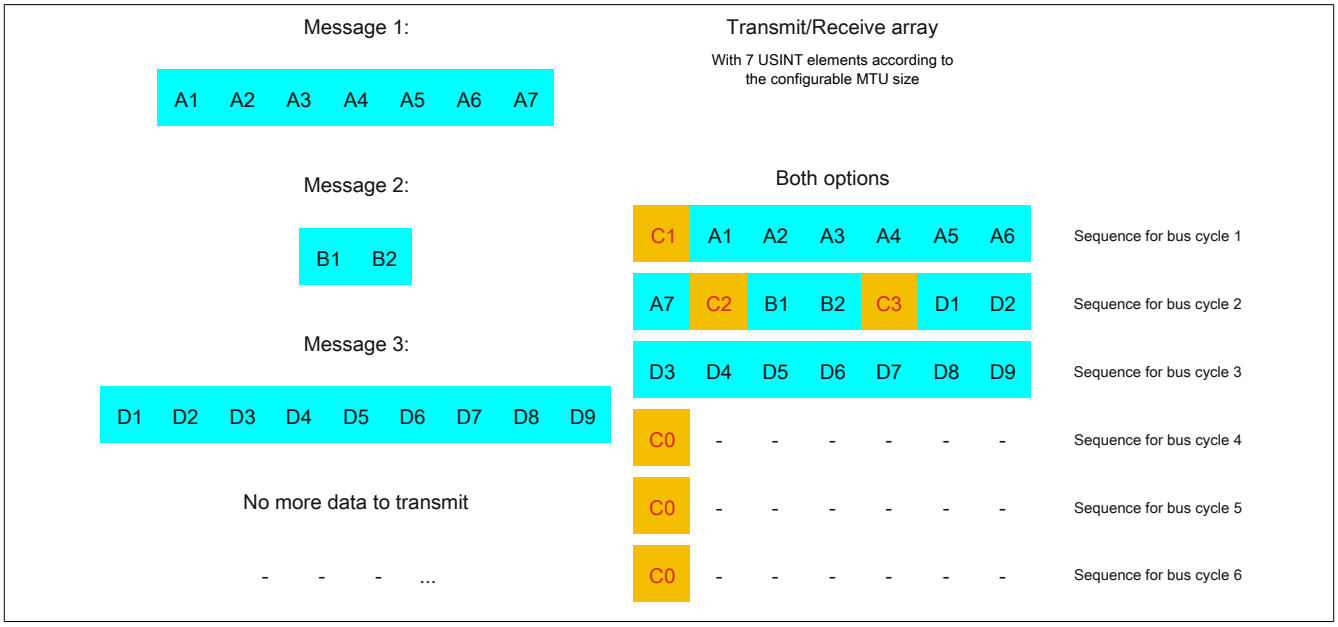

Figure 154: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 89: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.4.3.11.8.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

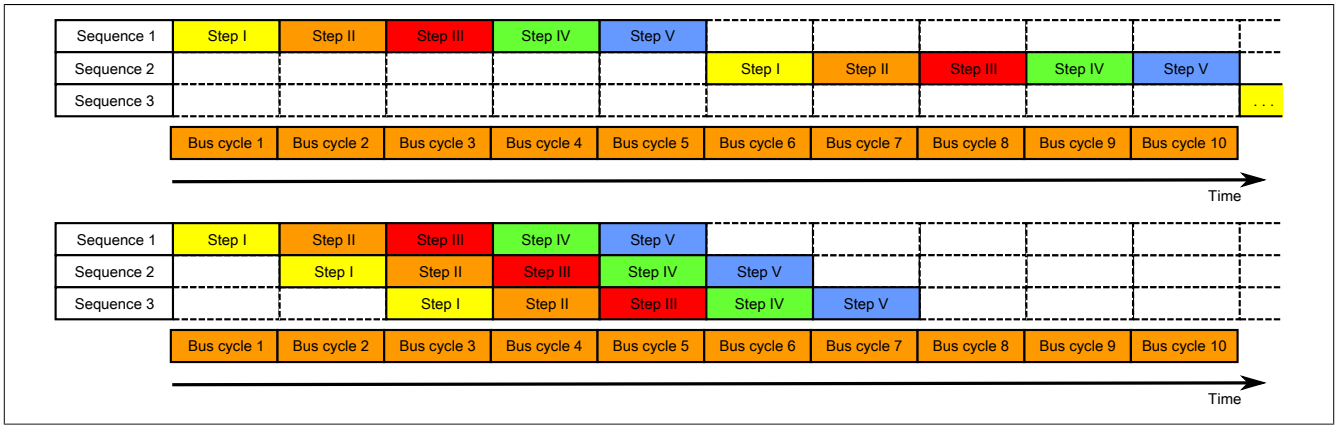

Figure 155: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

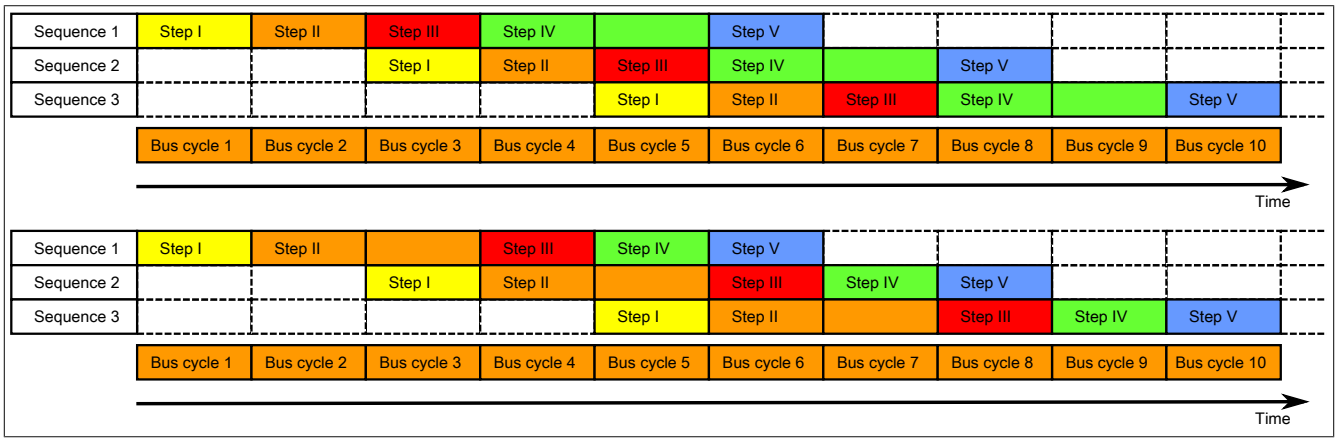

Figure 156: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

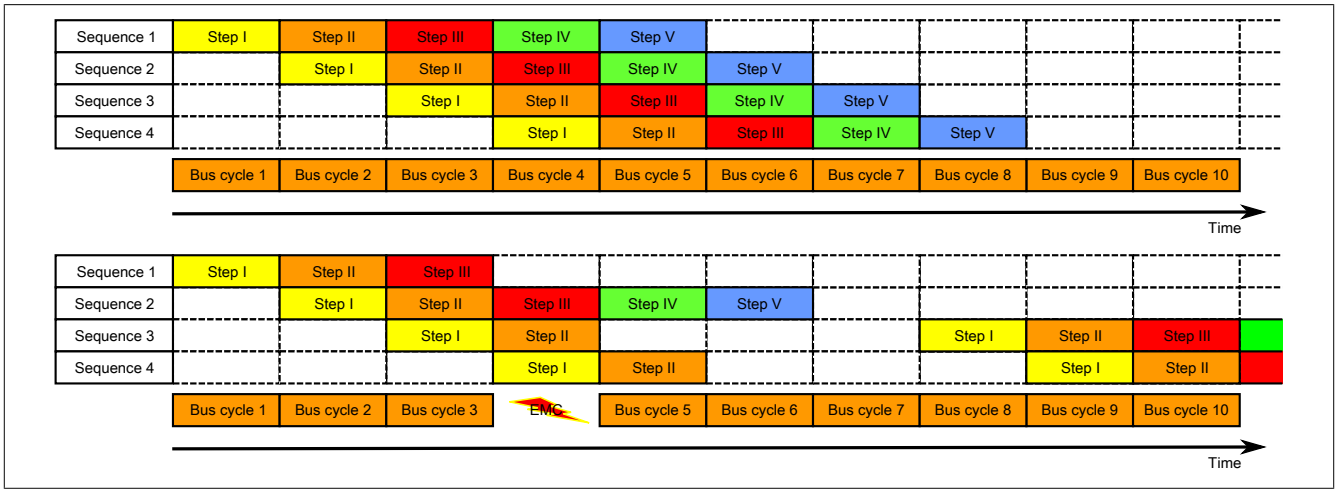

Figure 157: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.4.3.11.9 HART with Flatstream

When using Flatstream communication, the module acts as a bridge between the X2X master and an intelligent field device connected to the module. Flatstream mode can be used for either point-to-point connections as well as for multidrop systems. Specific algorithms such as timeout and checksum monitoring are usually managed automatically. During normal operation, the user does not have access to these details.

HART is considered a master-slave network where half-duplex communication takes place asynchronously. Various features have been included to ensure that signals are transmitted without errors.
For example, the user can increase the length of the preamble, thus making the transmission more secure. However, this also has an effect on the percentage of payload data and overhead.

Additional information about HART can be found at www.HARTcomm.org.

How it works

The module has two independent channels. When using Flatstream , the channel number must therefore be specified. The general structure of a Flatstream frame is extended as follows.

Input/Output sequence	Tx/Rx bytes		
(unchanged)	Control byte (unchanged)	Channel number	HART frame (without preamble and checksum)

HART frame with Flatstream					
Startup	ADDR	CMD	BCNT	(STS)	(DATA)

Startup	Start identification
ADDR	Address within the HART network
CMD	HART command
BCNT	Byte counters (number of remaining bytes)
*STS	Status of the last command received. Information about the working mode of the HART Slave and communication errors (if supported, return data from the HART Slave)
*DATA	Data (if necessary for the command)

Examples of HART commands

Command	Function
0x00	Read slave ID
0x03	Read current value and up to four variables
0x09	Read up to four variables including status
0x21	Read variables

4.4.3.11.10 "OSP" function model

In the "OSP" function model (Operator Set Predefined), the user defines an analog value or digital pattern. This OSP value is output as soon as communication between the module and master is interrupted.

Functionality

The user can choose between two OSP modes:

- Retain last valid value
- Replace with static value

In the first case, the module retains the last value as validly recognized output state.

When selecting the mode, "Replace with static value" a plausible output value must be entered in the corresponding value register. If an OSP event occurs, this value will be output instead of the value currently requested by the task.

4.4.3.11.10.1 Activating the OSP output in the module

Name:
OSPValid

This data point offers the possibility to start module output and request OSP operation during running operation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	OSPValid	0	Request OSP operation (after initial start or module in Standby)
		1	Request normal operation
1 - 7	Reserved	0	

There is one OSPValid bit on the module, which is managed by the user task. It must be set when the enabled channels are started. As long as the OSPValid bit remains set in the module, the module behaves the same as the "Standard" function model.

If an OSP event occurs (e.g. communication between the module and master CPU interrupted) then the OSPValid bit will be reset on the module. The module enters OSP mode and the output occurs in the "OSPMode" register according to the configuration.

The following applies:

The OSP replacement value remains even after the communication channel has recovered. OSP mode is only exited when a set OSPValid bit is transferred.

When the master CPU is restarted, the OSPValid bit is re-initialized on the master CPU. It must once more be set by the application and transferred via the bus.
When temporary communication errors occur between the module and master CPU (e.g. due to EMC), a few bus cycles will pass without refreshing the cyclic registers. The OSPValid bit is reset internally in the module - the bit in the CPU however remains set. Upon the next successful transfer, the OSPValid bit in the module is set again and the module returns to normal operation.

The ModulOK bit can be evaluated if the task in the master CPU needs to know which output mode the module is currently in.

Warning!

If the OSPValid bit is reset to "0" on the module, then the output state no longer depends on the relevant task in the master CPU. However, an output still occurs depending on the configuration of the OSP replacement value.

4.4.3.11.10.2 Setting the OSP mode

Name:
CfgOSPMode01 to CfgOSPMode02

This register essentially controls a channel's behavior when OSP is being used.

Data type	Value	Description
USINT	0	Replace with static value
	1	Retain last valid value

4.4.3.11.10.3 Define the OSP analog output value

Name:
CfgOSPValue01 to CfgOSPValue02

This register contains the analog output value, which is output in "Replace with static value" mode during OSP operation.

Data type	Value
Corresponds to AnalogOutput0x	Corresponds to AnalogOutput0x

Warning!

The "OSPValue" is not accepted by the module until the "OSPValid" bit has been set in the module.

4.4.3.11.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.3.11.12 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Analog outputs	1 ms

Minimum I/O update time Hart Communication	
Point-to-point	500 ms
Multidrop	Number of stations * 1000 ms

4.4.4 X20AO2622

4.4.4.1 General information

The module is equipped with two outputs with 13-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog outputs
- Either current or voltage signal possible
- 13-bit digital converter resolution

4.4.4.2 Order data

Model number	Short description	Figure

4.4.4.4 LED status indicators

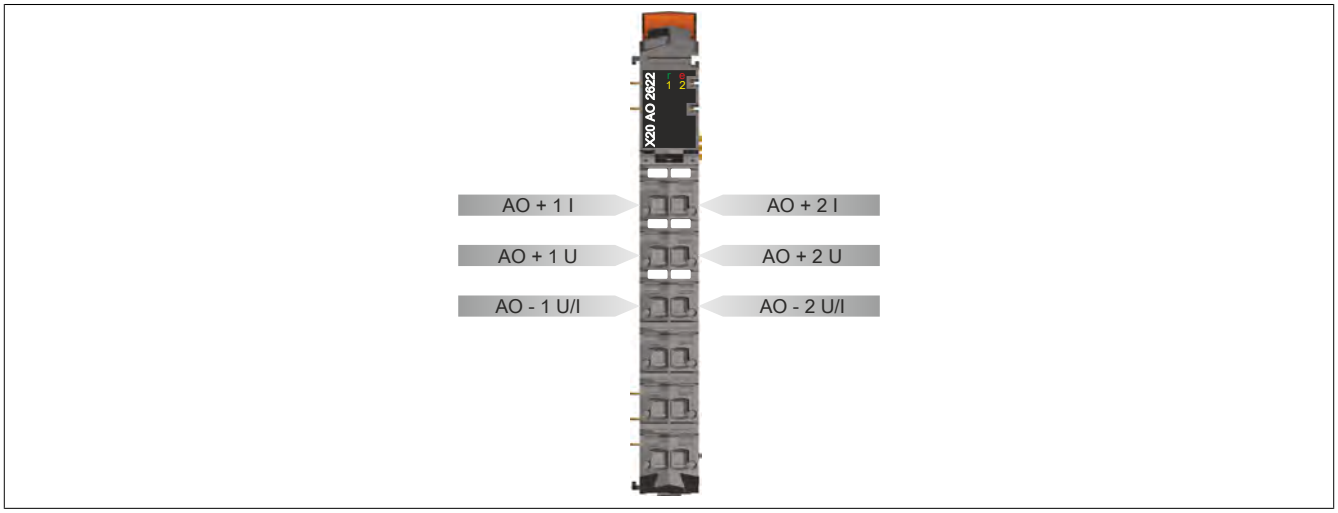
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Orange	Off	Value = 0
			On	Value ≠ 0

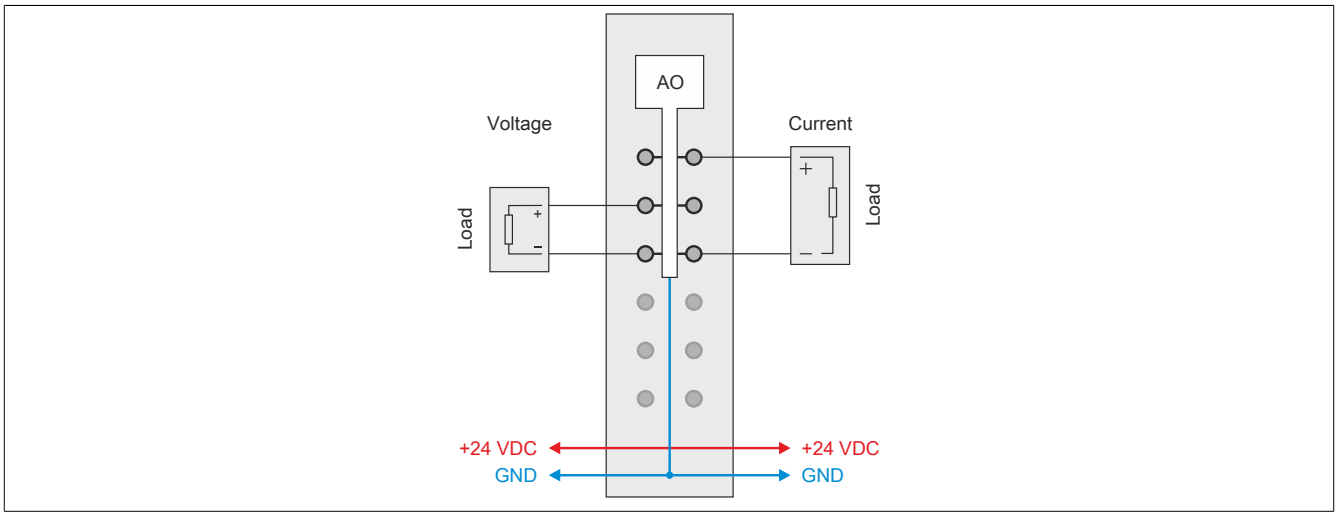
1) Depending on the configuration, a firmware update can take up to several minutes.

4.4.4.5 Pinout

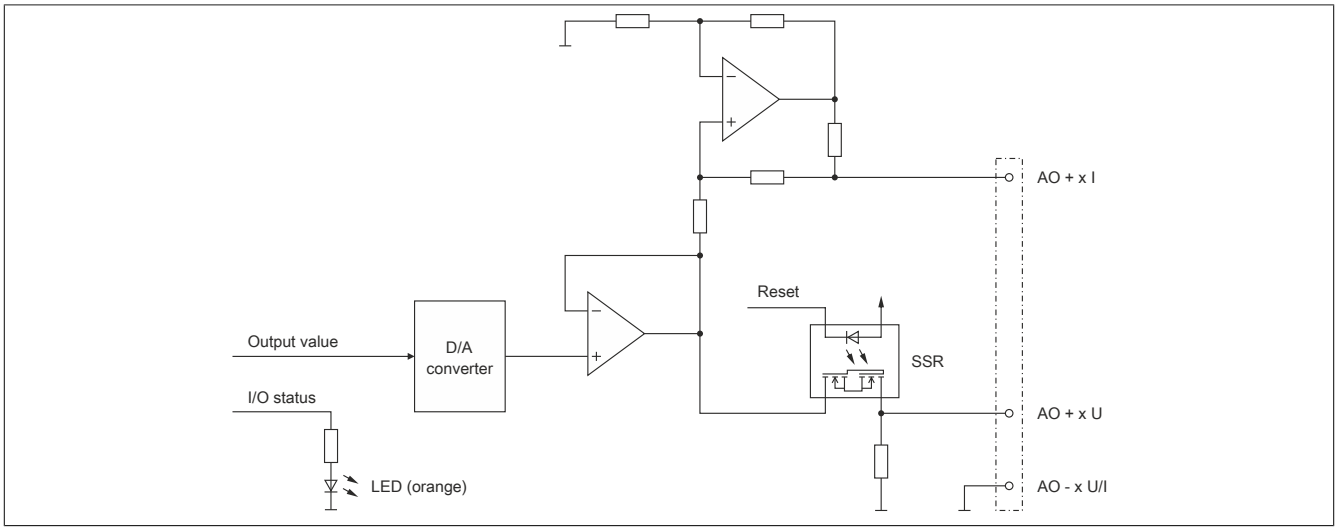
Each channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.



4.4.4.6 Connection example



4.4.4.7 Output circuit diagram



4.4.4.8 Register description

4.4.4.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.4.8.2 Function model 0 - Standard and function model 1 - I/O with fast reaction

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration						
18	ConfigOutput01	USINT				•
Communication						
0	AnalogOutput01	INT			•	
2	AnalogOutput02	INT			•	

4.4.4.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration							
18	-	ConfigOutput01	USINT				•
Communication							
0	0	AnalogOutput01	INT			•	
2	2	AnalogOutput02	INT			•	

1) The offset specifies the position of the register within the CAN object.

4.4.4.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.4.8.4 Function model comparison

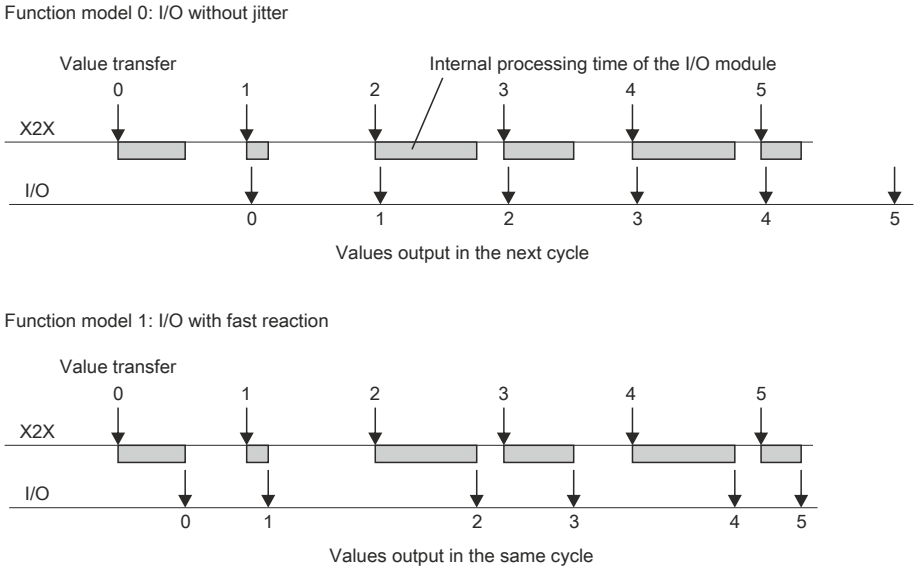
Function model 0: I/O without jitter (standard)

Corrected values are output in the next cycle if the minimum cycle is ≥300 µs in order to reduce jitter to a minimum.

Function model 1: I/O with fast reaction

Corrected values are output in the same cycle if the minimum cycle is ≥300 µs (optimized reactions).

Comparison of the two function models



4.4.4.8.5 Analog outputs

Each channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.

4.4.4.8.5.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput02

These registers provide the standardized output values. Once a permitted value is received the module outputs the respective current or voltage.

Data type	Value	Information
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA
	0 to 32767	Current signal 4 to 20 mA[1)]

1) From upgrade version 1.0.2.0 or hardware revision "I0"

4.4.4.8.5.2 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Channel 1	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 4
1	Channel 2	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 5
2 - 3	Reserved	0	
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
5	Channel 2: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
6 - 7	Reserved	0	

4.4.4.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.4.4.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
300 µs

4.4.5 X20AO2632

4.4.5.1 General information

The module is equipped with two outputs with 16-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog outputs
- Either current or voltage signal possible
- 16-bit digital converter resolution

4.4.5.2 Order data

4.4.5.8 Register description

4.4.5.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.5.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog output - Configuration						
0	ConfigOutput01	UINT				•
594 598	Cfo_Channel01TimeMode Cfo_Channel02TimeMode	UINT				•
Analog output - Communication						
2 4	AnalogOutput01 AnalogOutput02	INT			•	
457	SDCLifeCount	SINT	•			
802 810	ValidationTimer01 ValidationTimer02	INT			•	
804 812	ValidationTimer01 ValidationTimer02	DINT			•	
833	Enabling/disabling the output channels	USINT	•		•	
	AnalogOutput01Enable, ~Readback	Bit 0				
	AnalogOutput02Enable, ~Readback	Bit 1				
835	Checking the output values	USINT	•			
	AnalogOutput01OK	Bit 0				
	AnalogOutput02OK	Bit 1				

4.4.5.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog output - Configuration							
0	-	ConfigOutput01	UINT				•
Analog output - Communication							
2 4	0 2	AnalogOutput01 AnalogOutput02	INT			•	

1) The offset specifies the position of the register within the CAN object.

4.4.5.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.5.8.4 General information

The module provides two analog outputs. Each channel can output a voltage range of ±10 V or a current range of 0 to 20 mA.

The module also has a time-based watchdog monitor. The user can activate this feature channel-by-channel as needed.

4.4.5.8.5 Analog output - Configuration

Each channel is configured independently. The user can also define an optional time-based monitor. To make this possible, two watchdog timers were implemented, which can be assigned to the outputs.

4.4.5.8.5.1 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 7	Reserved	0	
8	Channel 1	0	Voltage signal
		1	Current signal
9	Channel 2	0	Voltage signal
		1	Current signal
10 - 15	Reserved	0	

4.4.5.8.5.2 Configuring the time-based watchdog monitor

Name:
Cfo_Channel01TimeMode to Cfo_Channel02TimeMode

This register is used to activate or configure the time-based watchdog monitor for the analog output channels.

Possibilities per channel:

- Validation timer data type: General choice 16 or 32 bit
- Validation window: The maximum value can be further limited within the data type.
- Timer allocation: A separate timer is available for each channel. However, all channels can be configured with the same validation timer, whereby the same settings must be made for the data type and window in the TimeMode registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 4	Max. validation time	00000	Disabled
		00001	2 µs
		00010	4 µs
		00011	8 µs
		...	...
		11111	2,147,483,648 µs (~35 min)
5 - 7	Reserved	0	
8	Timer allocation	0	ValidationTimer01 (default for channel 1)
		1	ValidationTimer02 (default for channel 2)
9 - 14	Reserved	0	
15	Time format	0	16-bit
		1	32-bit

4.4.5.8.6 Analog output - Communication

In standard mode, the module's outputs are enabled. Based on the configuration and AnalogOutput value, they output the corresponding current or voltage.

If the application requires time-based monitoring of the outputs, then a validation timer can be assigned to each channel. The validation timer register assigns a validity duration to the current output value. When validation is enabled, the module compares the validation time with the Nettime of the X2X Link. If the transferred validity duration is exceeded, the module disables the channel and resets the output. The "safety shutdown" state will not be reset until a new and valid validation time has been transferred. If enabled, the module reports which state it is currently in via the channel's error status bit.

If the value of the validation timer is incremented in each task cycle, the valid validation time will be calculated as follows:

Nettime of the X2X Link master (which the module is connected to)	
+	Timespan for transferring data from the X2X Link master to the CPU (higher-level system)
+	Cycle time of task class (including tolerance)
+	Timespan for transferring the data from the CPU to the module
+	Timespan allowed by the application (e.g. for tolerating failure of an X2X Link cycle)
=	Valid validation time

The AnalogOutputEnableByte is enabled during time-based monitoring. If the timer expires prematurely, the corresponding bit in the AnalogOutputOkayByte is reset and the output drops out. This provides an easy way to achieve a defined state.

4.4.5.8.6.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput02

These registers provide the standardized output values. Once a permitted value is received, the module outputs the respective current or voltage.

Information:

The value "0" disables the channel status LED.

Data type	Value	
INT	-32767 to 32767	Voltage; Bus controller default setting: 0
	0 to 32767	Current

4.4.5.8.6.2 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.4.5.8.6.3 Transfer of the timestamp

Name:
ValidationTimer01 to ValidationTimer02

When an output is being monitored, these registers must provide the timestamp which, when reached, will cause the output to shut down automatically. The values must be provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	
INT	-32768 to 32767	Nettime timestamp of the current output value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current output value

4.4.5.8.6.4 Enabling/disabling the output channels

Name:
AnalogOutput01Enable to AnalogOutput02Enable
AnalogOutput01EnableReadback to AnalogOutput02EnableReadback

The "OutputEnable" byte is only needed for the channels with activated time-based monitoring. The individual bits are used to enable/disable the respective channels. To receive reliable feedback about the current state of the module, the byte was also implemented so that it can be read cyclically.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01Enable AnalogOutput01EnableReadback	0	Output deactivated
		1	Output activated
1	AnalogOutput02Enable AnalogOutput02EnableReadback	0	Output deactivated
		1	Output activated
2 - 7	Reserved	0	

4.4.5.8.6.5 Checking the output values

Name:
AnalogOutput01OK to AnalogOutput02OK

These registers are only needed for channels with activated time-based monitoring. The individual bits report whether the respective channel is actually generating the required voltage or current.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01OK	0	Electrical signal deactivated
		1	Electrical signal activated
1	AnalogOutput02OK	0	Electrical signal deactivated
		1	Electrical signal activated
2 - 7	Reserved	0	

4.4.5.8.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.5.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.4.6 X20AO2632-1

4.4.6.1 General information

The module is equipped with two outputs with 16-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 analog outputs
- Either current or voltage signal possible
- Extended signal range
- 16-bit digital converter resolution

4.4.6.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.6.8.4 General information

The module provides two analog outputs. Each channel can output a voltage range of ±11 V or a current range of 0 to 22 mA.

The module also has a time-based watchdog monitor. The user can activate this feature channel-by-channel as needed.

4.4.6.8.5 Analog output - Configuration

Each channel is configured independently. The user can also define an optional time-based monitor. To make this possible, two watchdog timers were implemented, which can be assigned to the outputs.

4.4.6.8.5.1 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±11 V voltage signal (default)
- 0 to 22 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 7	Reserved	0	
8	Channel 1	0	Voltage signal
		1	Current signal
9	Channel 2	0	Voltage signal
		1	Current signal
10 - 15	Reserved	0	

4.4.6.8.5.2 Configuring the time-based watchdog monitor

Name:
Cfo_Channel01TimeMode to Cfo_Channel02TimeMode

This register is used to activate or configure the time-based watchdog monitor for the analog output channels.

Possibilities per channel:

- Validation timer data type: General choice 16 or 32 bit
- Validation window: The maximum value can be further limited within the data type.
- Timer allocation: A separate timer is available for each channel. However, all channels can be configured with the same validation timer, whereby the same settings must be made for the data type and window in the TimeMode registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 4	Max. validation time	00000	Disabled
		00001	2 µs
		00010	4 µs
		00011	8 µs
		...	...
		11111	2,147,483,648 µs (~35 min)
5 - 7	Reserved	0	
8	Timer allocation	0	ValidationTimer01 (default for channel 1)
		1	ValidationTimer02 (default for channel 2)
9 - 14	Reserved	0	
15	Time format	0	16-bit
		1	32-bit

4.4.6.8.6 Analog output - Communication

In standard mode, the module's outputs are enabled. Based on the configuration and AnalogOutput value, they output the corresponding current or voltage.

If the application requires time-based monitoring of the outputs, then a validation timer can be assigned to each channel. The validation timer register assigns a validity duration to the current output value. When validation is enabled, the module compares the validation time with the Nettime of the X2X Link. If the transferred validity duration is exceeded, the module disables the channel and resets the output. The "safety shutdown" state will not be reset until a new and valid validation time has been transferred. If enabled, the module reports which state it is currently in via the channel's error status bit.

If the value of the validation timer is incremented in each task cycle, the valid validation time will be calculated as follows:

Nettime of the X2X Link master (which the module is connected to)	
+	Timespan for transferring data from the X2X Link master to the CPU (higher-level system)
+	Cycle time of task class (including tolerance)
+	Timespan for transferring the data from the CPU to the module
+	Timespan allowed by the application (e.g. for tolerating failure of an X2X Link cycle)
=	Valid validation time

The AnalogOutputEnableByte is enabled during time-based monitoring. If the timer expires prematurely, the corresponding bit in the AnalogOutputOkayByte is reset and the output drops out. This provides an easy way to achieve a defined state.

4.4.6.8.6.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput02

These registers provide the standardized output values. Once a permitted value is received, the module outputs the respective current or voltage.

Information:

The value "0" disables the channel status LED.

Data type	Value	
INT	-32767 to 32767	Voltage; Bus controller default setting: 0
	0 to 32767	Current

4.4.6.8.6.2 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.4.6.8.6.3 Transfer of the timestamp

Name:
ValidationTimer01 to ValidationTimer02

When an output is being monitored, these registers must provide the timestamp which, when reached, will cause the output to shut down automatically. The values must be provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	
INT	-32768 to 32767	Nettime timestamp of the current output value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current output value

4.4.6.8.6.4 Enabling/disabling the output channels

Name:
AnalogOutput01Enable to AnalogOutput02Enable
AnalogOutput01EnableReadback to AnalogOutput02EnableReadback

The "OutputEnable" byte is only needed for the channels with activated time-based monitoring. The individual bits are used to enable/disable the respective channels. To receive reliable feedback about the current state of the module, the byte was also implemented so that it can be read cyclically.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01Enable AnalogOutput01EnableReadback	0	Output deactivated
		1	Output activated
1	AnalogOutput02Enable AnalogOutput02EnableReadback	0	Output deactivated
		1	Output activated
2 - 7	Reserved	0	

4.4.6.8.6.5 Checking the output values

Name:
AnalogOutput01OK to AnalogOutput02OK

These registers are only needed for channels with activated time-based monitoring. The individual bits report whether the respective channel is actually generating the required voltage or current.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01OK	0	Electrical signal deactivated
		1	Electrical signal activated
1	AnalogOutput02OK	0	Electrical signal deactivated
		1	Electrical signal activated
2 - 7	Reserved	0	

4.4.6.8.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.6.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.4.7 X20(c)AO4622

4.4.7.1 General information

The module is equipped with four outputs with 13-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

- 4 analog outputs
- Either current or voltage signal possible
- 13-bit digital converter resolution

4.4.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.4.7.5 LED status indicators

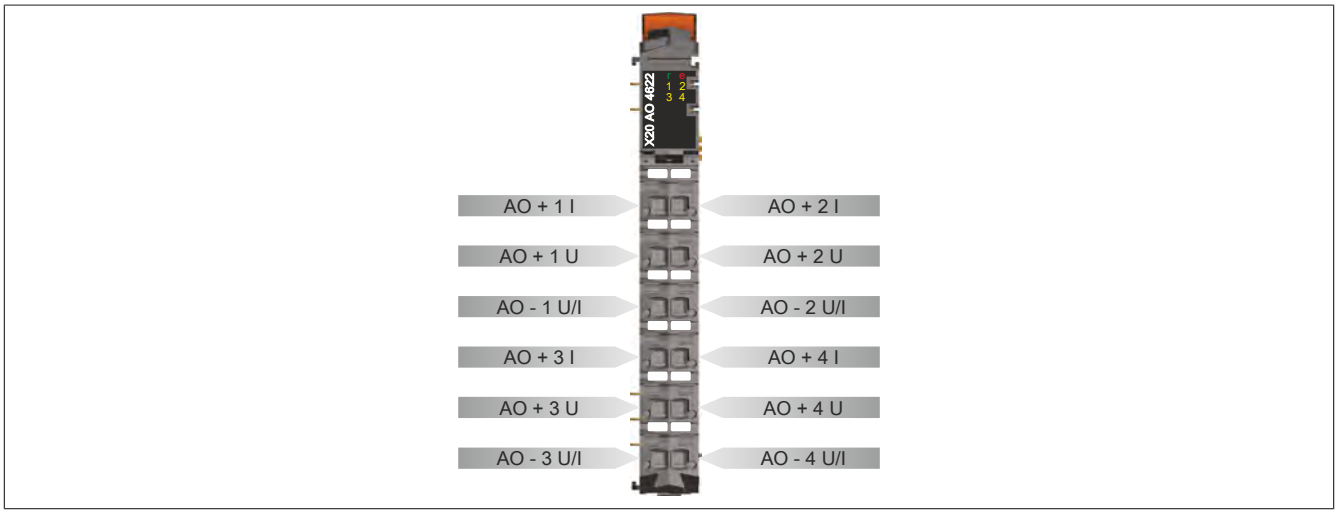
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Orange	Off	Value = 0
			On	Value ≠ 0

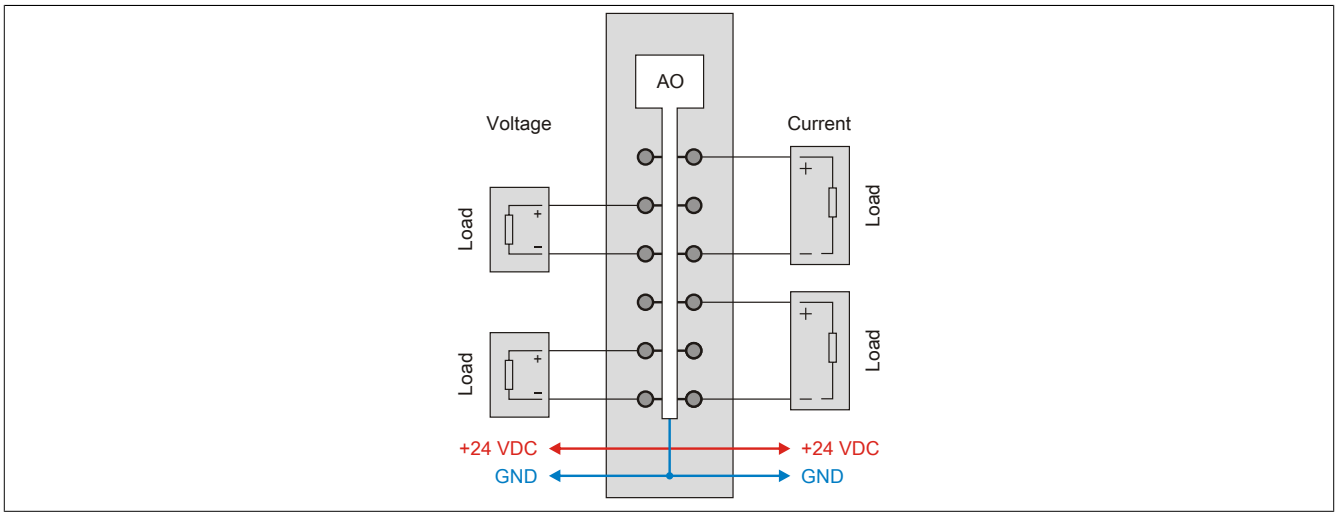
1) Depending on the configuration, a firmware update can take up to several minutes.

4.4.7.6 Pinout

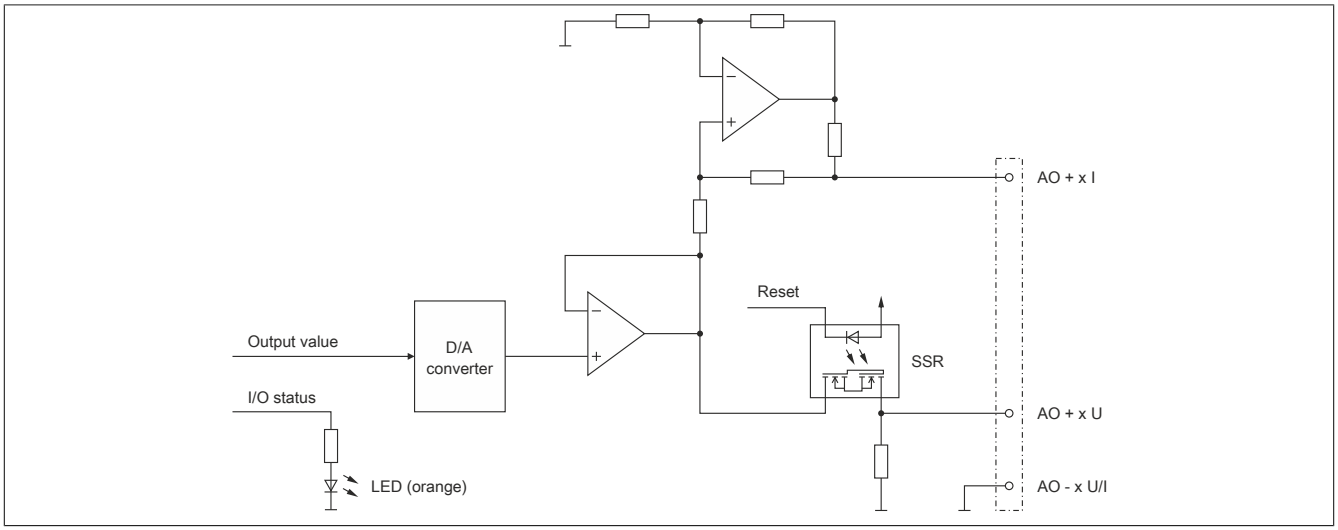
Each channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.



4.4.7.7 Connection example



4.4.7.8 Output circuit diagram



4.4.7.9 Derating

To ensure proper operation, the following items must be taken into consideration:

- The following derating listings must be taken into consideration
- For mixed operation with one current output, the average of both derating curves should be used
- For mixed operation with two or three current outputs, the derating for the current outputs should be used

4.4.7.10 Register description

4.4.7.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.7.10.2 Function model 0 - Standard and function model 1 - I/O with fast reaction

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
18	ConfigOutput01	USINT				•
Analog signal - Communication						
0	AnalogOutput01	INT			•	
2	AnalogOutput02	INT			•	
4	AnalogOutput03	INT			•	
6	AnalogOutput04	INT			•	

4.4.7.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
18	-	ConfigOutput01	USINT				•
Analog signal - Communication							
0	0	AnalogOutput01	INT			•	
2	2	AnalogOutput02	INT			•	
4	4	AnalogOutput03	INT			•	
6	6	AnalogOutput04	INT			•	

1) The offset specifies the position of the register within the CAN object.

4.4.7.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.7.10.4 Function model comparison

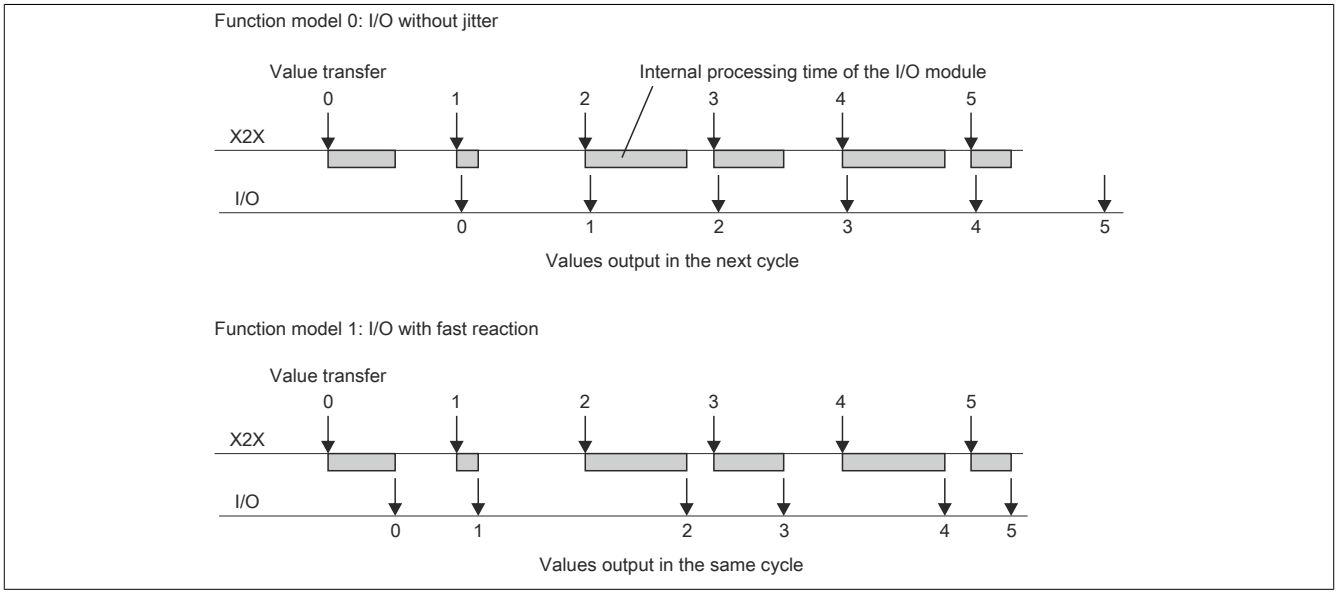
Function model 0: I/O without jitter (standard)

Corrected values are output in the next cycle if the minimum cycle is ≥400 µs in order to reduce jitter to a minimum.

Function model 1: I/O with fast reaction

Corrected values are output in the same cycle if the minimum cycle is ≥400 µs (optimized reactions).

Comparison of the two function models



4.4.7.10.5 Analog outputs

Each channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.

4.4.7.10.5.1 Output values of the analog output

Name:
AnalogOutput01 to AnalogOutput04

These registers provide the standardized output values. Once a permitted value is received the module outputs the respective current or voltage.

Data type	Value	Information
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA
	0 to 32767	Current signal 4 to 20 mA[1)]

1) From upgrade version 1.0.2.0 or hardware revision "I0"

4.4.7.10.5.2 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 4
...		...	
3	Channel 4	0	Voltage signal
		1	Current signal, measurement range corresponding to bit 7
4	Channel 1: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal
...		...	
7	Channel 4: Current measurement range	0	0 to 20 mA current signal
		1	4 to 20 mA current signal

4.4.7.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.4.7.10.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
400 µs

4.4.8 X20(c)AO4632

4.4.8.1 General information

The module is equipped with four outputs with 16-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

- 4 analog outputs
- Either current or voltage signal possible
- 16-bit digital converter resolution

4.4.8.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.4.8.10 Register description

4.4.8.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.8.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration						
0	ConfigOutput01	UINT				•
Analog signal - Communication						
Index * 2	AnalogOutput0N (Index N = 1 to 4)	INT			•	
10 + Index * 4	AnalogOutputDelayed0N (Index N = 0 to 3)	INT			•	
12	OutputDelayConfig00	UINT			•	
18	OutputDelayConfig01	UINT			•	
14	AnalogOutputLatchTime00	UINT	•			
22	AnalogOutputLatchTime01	UINT	•			
20	Error	UINT	•			

4.4.8.10.3 Function model 254 - Bus controller

Register	Offset[1]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog signal - Configuration							
0	-	ConfigOutput01	UINT				•
Analog signal - Communication							
10 + Index * 4	Index * 2 - 2	AnalogOutput0N (Index N = 1 to 4)	INT			•	

1) The offset specifies the position of the register within the CAN object.

4.4.8.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.8.10.4 Analog output - Configuration

4.4.8.10.4.1 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 7	Reserved	0	
8	Channel 1	0	Voltage signal
		1	Current signal
...		...	
11	Channel 4	0	Voltage signal
		1	Current signal
12 - 15	Reserved	0	

4.4.8.10.5 Analog output - Configuration

4.4.8.10.5.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput04

These registers provide the standardized output values. Once a permitted value is received, the module outputs the respective current or voltage.

Information:

The value "0" disables the channel status LED.

Data type	Value	
INT	-32767 to 32767	Voltage; Bus controller default setting: 0
	0 to 32767	Current

4.4.8.10.5.2 Value for delayed output

Name:
AnalogOutputDelayed00 to AnalogOutputDelayed03

These registers contain the values with which the analog outputs are overwritten after the delay configured with OutputDelayConfig0x has expired.

Data type	Value	Output Signal
INT	-32768 to 32767	Voltage signal -10 VDC to 10 VDC
	0 to 32767	Current signal 0 mA to 20 mA

4.4.8.10.5.3 Configuration of the output delay

Name:
OutputDelayConfig00 to OutputDelayConfig01

Two configurations independent from each other can be created using these registers.

The delay time after which AnalogOutputDelay0x should overwrite the channel can be configured using bits 0 to 13. Using bits 14 and 15, the channel is determined for which the configuration is valid.

Each channel can only be overwritten once. No additional channel can be overwritten while the respective time is running.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 13	Delay time for the selected channel	x	Time in µs
14 - 15	Channel	00	Analog output 01
		01	Analog output 02
		10	Analog output 03
		11	Analog output 04

4.4.8.10.5.4 Delay time for the output value

Name:
AnalogOutputLatchTime00 to AnalogOutputLatchTime01

These registers can be used to read when the respective overwrite value was actually written on the output.

Data type	Value
UINT	Actual delay time

4.4.8.10.5.5 Error register for counter

Name:
Error

There are some limitations because two timers are used. This register is available to the user for reporting these potential errors.
The error bits are deleted as soon as a valid state is reset.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Analog output 01	0	OK
		1	Has already been overwritten
...		...	
3	Analog output 04	0	OK
		1	Has already been overwritten
4	Timer 01	0	OK
		1	Already in use
5	Timer 02	0	OK
		1	Already in use
6	Timer 01 and 02	0	OK
		1	Both timers refer to the same channel number
7 - 15	Reserved		

4.4.8.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.8.10.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.4.9 X20(c)AO4632-1

4.4.9.1 General information

The module is equipped with four outputs with 16-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

- 4 analog outputs
- Either current or voltage signal possible
- Extended signal range
- 16-bit digital converter resolution

4.4.9.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.4.9.10 Register description

4.4.9.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.4.9.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog output - Configuration						
0	ConfigOutput01	UINT				•
590 + Index*4	Cfo_Channel0NTimeMode (Index N = 1 to 4)	UINT				•
Analog output - Communication						
Index * 2	AnalogOutput0N (Index N = 1 to 4)	INT			•	
457	SDCLifeCount	SINT	•			
794 + Index*8	ValidationTimer0N (Index N = 1 to 4)	INT			•	
796 + Index*8	ValidationTimer0N (Index N = 1 to 4)	DINT			•	
833	Enabling/disabling the output channels	USINT	•		•	
	AnalogOutput01Enable, ~Readback	Bit 0				
	...	...				
	AnalogOutput04Enable, ~Readback	Bit 3				
835	Checking the output values	USINT	•			
	AnalogOutput01OK	Bit 0				
	...	...				
	AnalogOutput04OK	Bit 3				

4.4.9.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Analog output - Configuration							
0	-	ConfigOutput01	UINT				•
Analog output - Communication							
10 + Index * 4	Index * 2 - 2	AnalogOutput0N (Index N = 1 to 4)	INT			•	

1) The offset specifies the position of the register within the CAN object.

4.4.9.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.9.10.4 General information

The module provides four analog outputs. Each channel can output a voltage range of ±11 V or a current range of 0 to 22 mA.

The module also has a time-based watchdog monitor. The user can activate this feature on a channel-by-channel basis as needed.

4.4.9.10.5 Analog output - Configuration

Each channel is configured independently. The user can also define an optional time-based monitor. To make this possible, four watchdog timers were implemented, which can be assigned to the outputs.

4.4.9.10.5.1 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±11 V voltage signal (default)
- 0 to 22 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 7	Reserved	0	
8	Channel 1	0	Voltage signal
		1	Current signal
...		...	
11	Channel 4	0	Voltage signal
		1	Current signal
12 - 15	Reserved	0	

4.4.9.10.5.2 Configuring the time-based watchdog monitor

Name:
Cfo_Channel01TimeMode to Cfo_Channel04TimeMode

This register is used to activate or configure the time-based watchdog monitor for the analog output channels.

Possibilities per channel:

- Validation timer data type: General choice 16 or 32 bit
- Validation window: The maximum value can be further limited within the data type.
- Timer allocation: A separate timer is available for each channel. However, all channels can be configured with the same validation timer, whereby the same settings must be made for the data type and window in the TimeMode registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 4	Max. validation time	00000	Disabled
		00001	2 µs
		00010	4 µs
		00011	8 µs
		...	...
		11111	2,147,483,648 µs (~35 min)
5 - 7	Reserved	0	
8 - 9	Timer allocation	00	ValidationTimer01 (default for channel 1)
		01	ValidationTimer02 (default for channel 2)
		10	ValidationTimer03 (default for channel 3)
		11	ValidationTimer04 (default for channel 4)
10 - 14	Reserved	0	
15	Time format	0	16-bit
		1	32-bit

4.4.9.10.6 Analog output - Communication

In standard mode, the module's outputs are enabled. Based on the configuration and AnalogOutput value, they output the corresponding current or voltage.

If the application requires time-based monitoring of the outputs, then a validation timer can be assigned to each channel. The validation timer register assigns a validity duration to the current output value. When validation is enabled, the module compares the validation time with the Nettime of the X2X Link. If the transferred validity duration is exceeded, the module disables the channel and resets the output. The "safety shutdown" state will not be reset until a new and valid validation time has been transferred. If enabled, the module reports which state it is currently in via the channel's error status bit.

If the value of the validation timer is incremented in each task cycle, the valid validation time will be calculated as follows:

Nettime of the X2X Link master (which the module is connected to)	
+	Timespan for transferring data from the X2X Link master to the CPU (higher-level system)
+	Cycle time of task class (including tolerance)
+	Timespan for transferring the data from the CPU to the module
+	Timespan allowed by the application (e.g. for tolerating failure of an X2X Link cycle)
=	Valid validation time

The AnalogOutputEnableByte is enabled during time-based monitoring. If the timer expires prematurely, the corresponding bit in the AnalogOutputOkayByte is reset and the output drops out. This provides an easy way to achieve a defined state.

4.4.9.10.6.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput04

These registers provide the standardized output values. Once a permitted value is received, the module outputs the respective current or voltage.

Information:

The value "0" disables the channel status LED.

Data type	Value	
INT	-32767 to 32767	Voltage; Bus controller default setting: 0
	0 to 32767	Current

4.4.9.10.6.2 SDC counter register

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.4.9.10.6.3 Transfer of the timestamp

Name:
ValidationTimer01 to ValidationTimer04

When an output is being monitored, these registers must provide the timestamp which, when reached, will cause the output to shut down automatically. The values must be provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	
INT	-32768 to 32767	Nettime timestamp of the current output value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current output value

4.4.9.10.6.4 Enabling/disabling the output channels

Name:
AnalogOutput01Enable to AnalogOutput04Enable
AnalogOutput01EnableReadback to AnalogOutput04EnableReadback

The "OutputEnable" byte is only needed for the channels with activated time-based monitoring. The individual bits are used to enable/disable the respective channels. To receive reliable feedback about the current state of the module, the byte was also implemented so that it can be read cyclically.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01Enable AnalogOutput01EnableReadback	0	Output deactivated
		1	Output activated
...		...	
3	AnalogOutput04Enable AnalogOutput04EnableReadback	0	Output deactivated
		1	Output activated
4 - 7	Reserved	0	

4.4.9.10.6.5 Checking the output values

Name:
AnalogOutput01OK to AnalogOutput04OK

These registers are only needed for channels with activated time-based monitoring. The individual bits report whether the respective channel is actually generating the required voltage or current.

Data type	Value
USINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	AnalogOutput01OK	0	Electrical signal deactivated
		1	Electrical signal activated
...		...	
3	AnalogOutput04OK	0	Electrical signal deactivated
		1	Electrical signal activated
4 - 7	Reserved	0	

4.4.9.10.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.9.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.4.10 X20AO4635

4.4.10.1 General information

The module is equipped with four outputs with 16-bit (including sign) digital converter resolution. It is possible to select between the current and voltage signal using different connection terminal points.

- 4 analog outputs
- Either current or voltage signal possible
- 16-bit digital converter resolution
- Low temperature drift

8	AnalogOutput04	INT			●	

4.4.10.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
Configuration							
0	-	ConfigOutput01	UINT				●
Communication							
2	0	AnalogOutput01	INT			●	
4	2	AnalogOutput02	INT			●	
6	4	AnalogOutput03	INT			●	
8	6	AnalogOutput04	INT			●	

1) The offset specifies the position of the register within the CAN object.

4.4.10.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.4.10.9.4 Analog outputs

Each channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.

4.4.10.9.4.1 Output values of the analog outputs

Name:
AnalogOutput01 to AnalogOutput04

These registers provide the standardized output values. Once a permitted value is received, the module outputs the respective current or voltage.

Information:

The value "0" disables the channel status LED.

Data type	Value	
INT	-32767 to 32767	Voltage; Bus controller default setting: 0
	0 to 32767	Current

4.4.10.9.4.2 Setting the channel type

Name:
ConfigOutput01

This register can be used to set the channel type of the outputs.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal. The following output signals can be set:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 7	Reserved	0	
8	Channel 1	0	Voltage signal
		1	Current signal
...		...	
11	Channel 4	0	Voltage signal
		1	Current signal
12 - 15	Reserved	0	

4.4.10.9.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.4.10.9.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.5 Bus controllers

The bus controllers adhere to the completely modular strategy used for the I/O modules. Made up of a base module, a supply module to supply the voltage for the entire system, and a fieldbus interface, the bus controller is an extremely flexible fieldbus connection.

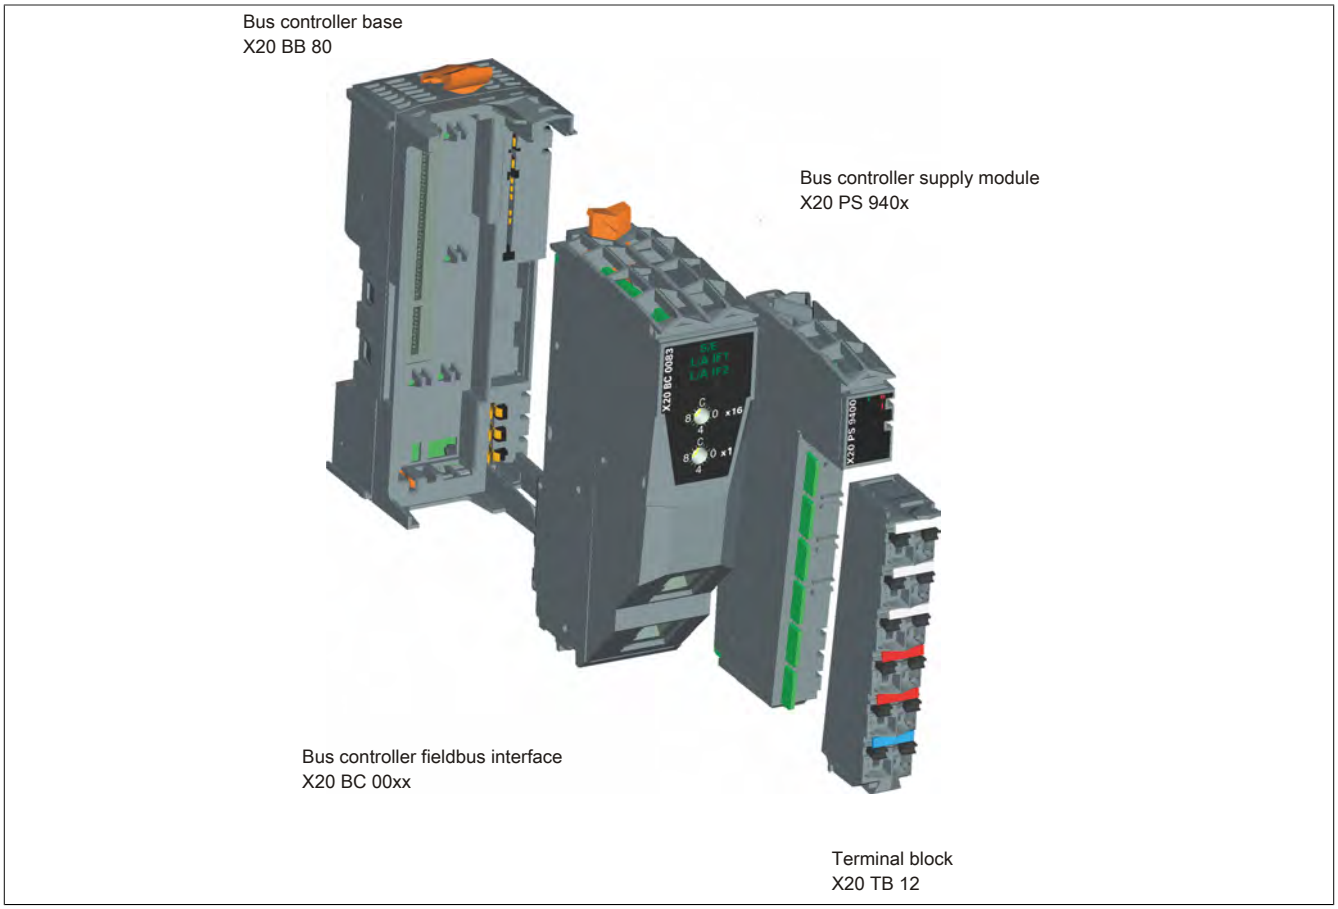

Figure 164: The four parts of a bus controller - fieldbus interface, base module, supply module, terminal block

The entire backplane can be preinstalled. With the removable terminals, the entire system can be wired separately from the electronics module. The individual modules are put in place during commissioning. This is where the I/O system is adapted to the fieldbus being used.

Unlike the Compact CPU with integrated fieldbus connection, the bus controller does not need to be programmed in order to transfer or receive the I/O data on the fieldbus. It can be configured on the fieldbus master.

4.5.2 X20BC0043

4.5.2.1 General information

CAN (Controller Area Network) systems are widespread in the field of automation technology. CAN topology is based on a line structure and uses twisted wire pairs for data transfer. CANopen is a higher-layer protocol based on CAN. As a standardized protocol, it provides a high degree of flexibility for implementing a wide range of configurations.

The X20BC0043-10 bus controller makes it possible to connect up to 253 X2X Link I/O nodes to CANopen. A transition between IP20 and IP67 protection outside of the control cabinet is possible by aligning X20, X67 or XV modules one after the other as needed at distances up to 100m. All CANopen transmission types such as synchronous, event and polling modes are supported together with PDO linking, life/node guarding, emergency objects, and much more.

- Fieldbus: CANopen
- I/O configuration via the fieldbus
- 20 receiver PDOs and 20 sender PDOs
- Select between entry of a fixed transfer rate or automatic transfer rate detection.
- Integrated terminating resistor

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

The B&R FieldbusDESIGNER can be used to create configuration files (e.g. DCF files) in six easy steps. All other function models are also supported by transferring configuration data to the bus controller (e.g. from the master environment with an SDO download or via the serial interface).

The B&R FieldbusDESIGNER is available free of charge in the download section of the B&R website www.br-automation.com.

4.5.2.2 Order data

Model number	Short description	Figure

Operation	
Horizontal installation	0 to 55°C
Vertical installation	0 to 50°C
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x TB2105 terminal block separately Order 1x X20TB12 terminal block separately Order 1x X20PS9400 or X20PS9402 power supply module separately Order 1x X20BB80 bus base separately
Spacing 3)	37.5 $^{+0.2}$ mm

Table 105: X20BC0043 - Technical data

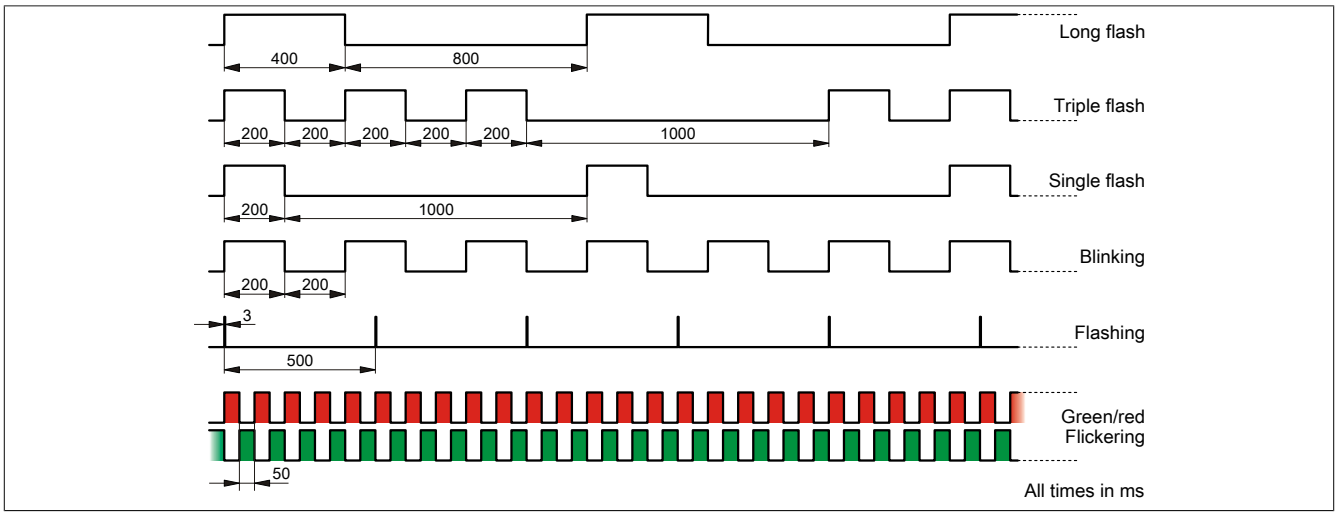
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.2.4 LED status indicators

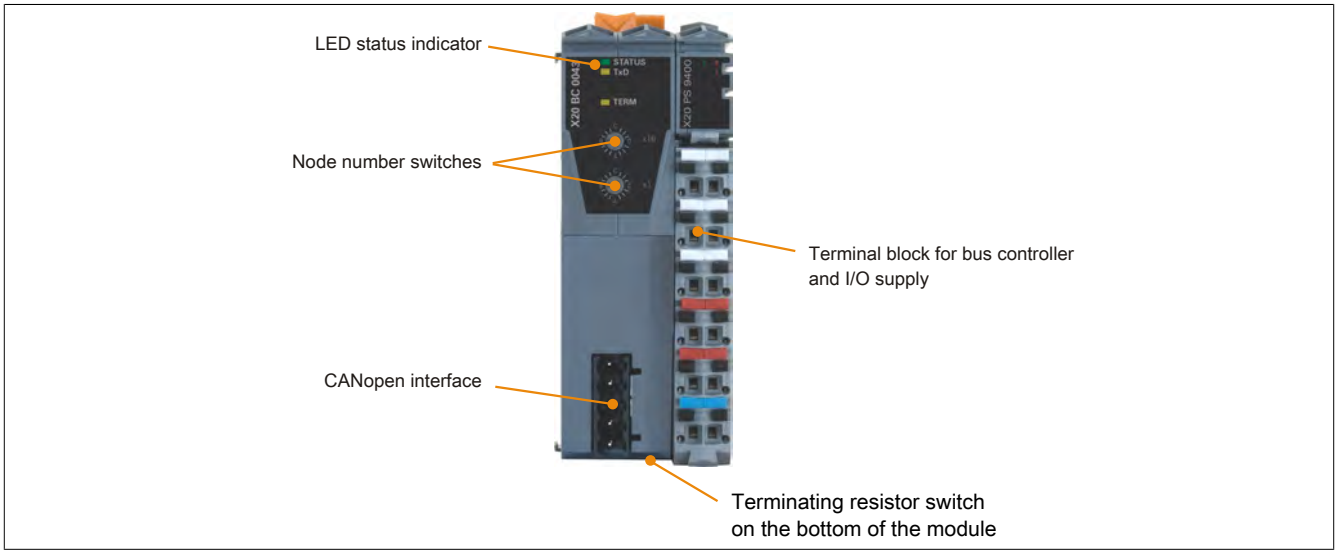
Figure	LED	Color	Status	Description
	STATUS[1]	Green	Off	No power supply
			Blinking	PREOPERATIONAL mode
			On	RUN mode
			Single flash	STOP mode
			Flashing	Flash delete in progress
		Red	Off	No power supply or everything is OK
			Single flash	Bus errors
			On	Bus errors: Bus is off
			Triple flash	Transfer rate selection
			Long flash	Invalid node switch position
		Green/red	Flickering	Transfer rate detection in progress
	TxD	Yellow	Off	The bus controller is not transmitting any data via the CANopen fieldbus
			On	The bus controller is transmitting data via the CANopen fieldbus
	TERM	Yellow	Off	The terminating resistor integrated in the bus controller is turned off
			On	The terminating resistor integrated in the bus controller is turned on

1) The "STATUS" LED is a green/red dual LED.

Status LED - Blinking patterns



4.5.2.5 Operating and connection elements

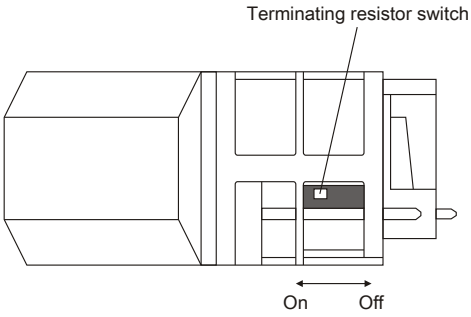


4.5.2.6 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	**Terminal**	**Function**	
	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.5.2.7 Terminating resistor



A terminating resistor is already integrated on the bus controller. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.5.2.8 Node number and transfer rate

Node numbers and transfer rates are configured using the two bus controller number switches.

The transfer rate can be specified in two ways:

- Automatic detection by bus controller (see 4.5.2.9 "Automatic transfer rate detection")
- Fixed definition by user (see 4.5.2.10 "Setting the transfer rate")

Switch position	Node number	Transfer rate
0x00	Not allowed	-
0x01 - 0x7F	1 - 127	Automatically set by the bus controller (default) or fixed setting by the user
0x80 - 0x88	-	Sets a fixed transfer rate
0x89	-	Sets automatic transfer rate detection
0x8A - 0x8F	Not allowed	-
0x90	Clearing the parameters See section 4.5.2.11 "Clearing parameters"	-
0x91 - 0xFF	Not allowed	-

4.5.2.9 Automatic transfer rate detection

After booting, the bus controller goes into "Listen only" mode. This means the bus controller behaves passively on the bus and only listens.

The bus controller attempts to receive valid objects. If receive errors occur, the controller switches to the next transfer rate in the lookup table.

If no objects are received, all transfer rates are tested cyclically. This procedure is repeated until valid objects are received.

Lookup table

The controller tests the transfer rate according to this table. Beginning with the starting transfer rate (1000 kbit/s), the controller switches to the next lower transfer rate. At the end of the table, the bus controller restarts the search from the beginning.

Transfer rate
1000 kbit/s
800 kbit/s
500 kbit/s
250 kbit/s
125 kbit/s
100 kbit/s
50 kbit/s
20 kbit/s
10 kbit/s

4.5.2.10 Setting the transfer rate

The bus controller will detect the transfer rate automatically by default. Switch positions 0x80 - 0x88 can be used to set a fixed transfer rate, or 0x89 can be used to enable automatic transfer rate detection.

Switch position	Transfer rate
0x80	1000 kbit/s
0x81	800 kbit/s
0x82	500 kbit/s
0x83	250 kbit/s
0x84	125 kbit/s
0x85	100 kbit/s
0x86	50 kbit/s
0x87	20 kbit/s
0x88	10 kbit/s
0x89	Automatic transfer rate detection

Table 106: Possible transfer rates

Programming the transfer rate

1. Turn off the power supply to the bus controller.
2. Define the transfer rate to be programmed by setting the node numbers (0x80 - 0x89)
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED blinks with a red triple-flash (transfer rate is now programmed).
5. Turn off the power supply to the bus controller.
6. Set the desired node number (0x01 - 0x7F).
7. Turn on the power supply to the bus controller.
8. The bus controller now boots with the set node number and the programmed transfer rate.

4.5.2.11 Clearing parameters

Various parameters can be stored in the bus controller's flash memory:

- Communication parameters
- Vendor-specific parameters
- Application parameters (device profile)
- Programmed transfer rate

Clearing the parameters using switch position 0x90 returns the bus controller to its factory settings.

Clearing the parameters listed above

1. Turn off the power supply to the bus controller.
2. Set the node number to 0x90.
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED flashes green. The node number switch must be set to 0x00 and then back to 0x090 within this time window of 5 seconds (rotate the top switch).
5. Wait until the "MS" LED blinks with a red double-flash (parameters have been cleared).
6. Turn off the power supply to the bus controller.
7. Set the desired node number (0x01 - 0x7F).
8. Turn on the power supply to the bus controller.
9. The bus controller boots with the set node number and automatic transfer rate detection.

4.5.2.12 Additional documentation and import files (EDS)

Additional documentation about bus controller functions as well as the necessary import files for the master engineering tool are available in the Downloads section of the B&R website (www.br-automation.com).

4.5.3 X20BC0043-10

4.5.3.1 General information

CAN (Controller Area Network) systems are widespread in the field of automation technology. CAN topology is based on a line structure and uses twisted wire pairs for data transfer. CANopen is a higher-layer protocol based on CAN. As a standardized protocol, it provides a high degree of flexibility for implementing a wide range of configurations.

The X20BC0043-10 bus controller makes it possible to connect up to 253 X2X Link I/O nodes to CANopen. A transition between IP20 and IP67 protection outside of the control cabinet is possible by aligning X20, X67 or XV modules one after the other as needed at distances up to 100m. All CANopen transmission types such as synchronous, event and polling modes are supported together with PDO linking, life/node guarding, emergency objects, and much more.

- Fieldbus: CANopen
- Auto-configuration of I/O modules
- I/O configuration via the fieldbus (also supported by the B&R FieldbusDESIGNER)
- Constant response times even with large amounts of data (max. 32 Rx and 32 Tx PDOs)
- Configurable I/O cycle (0.5 to 4 ms)
- Possible to configure the transfer rate or have it detected automatically
- Heartbeat consumer and producer
- Emergency producer
- 2x SDO server, NMT slave
- Simple bootup (autostart)
- Terminal access via the serial interface on the X20PS9400
- Integrated terminating resistor

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

The B&R FieldbusDESIGNER can be used to create configuration files (e.g. DCF files) in six easy steps. All other function models are also supported by transferring configuration data to the bus controller (e.g. from the master environment with an SDO download or via the serial interface).

The B&R FieldbusDESIGNER is available free of charge in the download section of the B&R website www.br-automation.com.

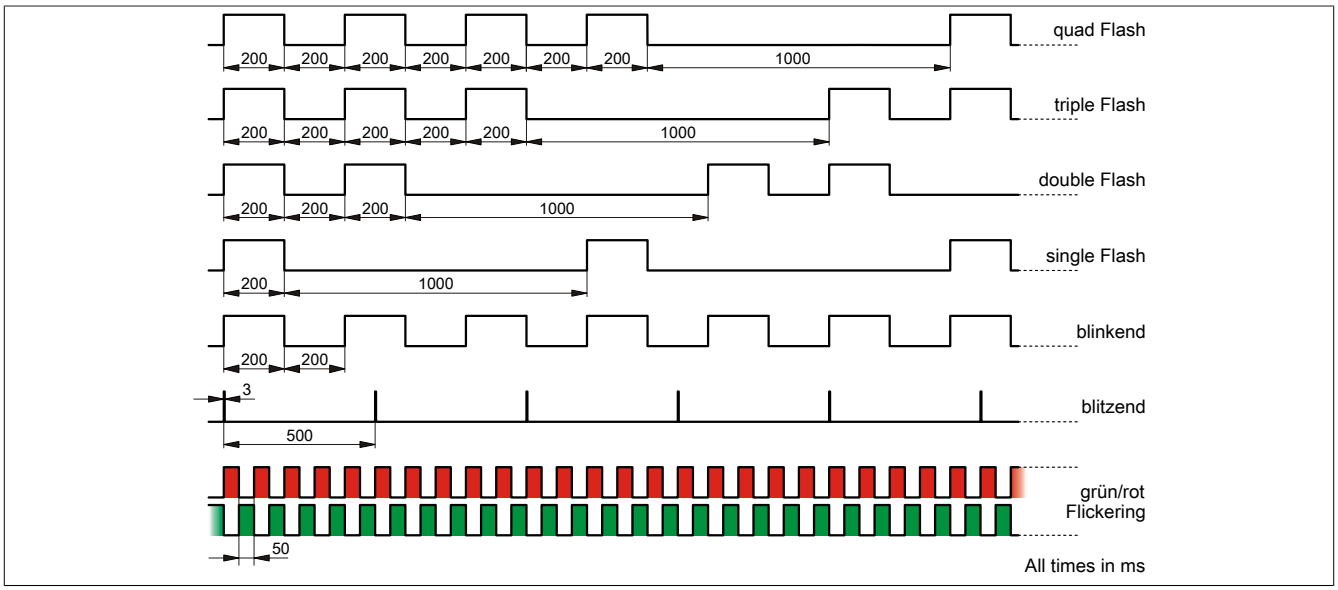
4.5.3.4 LED status indicators

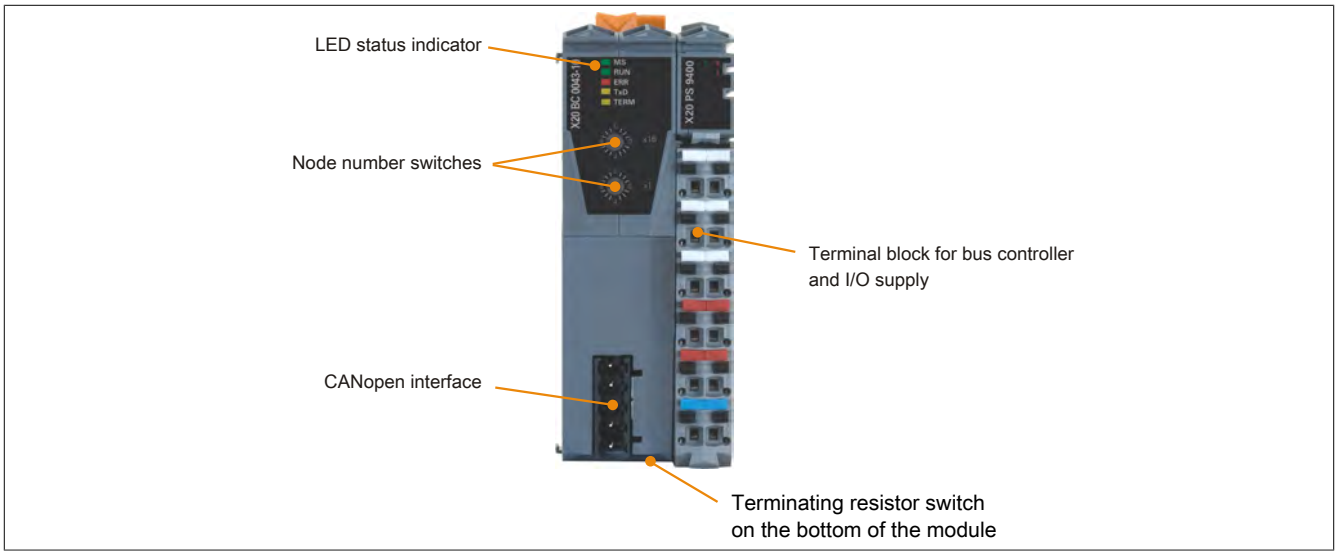
Figure	LED	Color	Status	Description
	MS1)	Green	Off	No power supply
			Flashing	5 second window for deleting all configuration settings
			On	Boot procedure OK, I/O modules OK
		Red	Double flash	Successfully erased flash memory
			Triple flash	Successfully saved transfer rate
			Quad flash	Successfully saved configuration
			On	I/O modules: Error message or incorrect configuration
	RUN	Green	Off	No power supply
			Single flash	STOP mode
			Triple flash	Firmware download in progress
			Blinking	PREOPERATIONAL mode
			On	OPERATIONAL mode
	ERR	Red	Off	No power supply or everything is OK
			Single flash	CAN warning limit reached
			Double flash	Node guarding / heartbeat error
			Blinking	Invalid node number or configuration
			On	Bus errors: Bus off
	RUN/ERR	Green/red	Flickering	Transfer rate detection in progress
	TxD	Yellow	Off	The bus controller is not transmitting any data via the CANopen fieldbus
			On	The bus controller is transmitting data via the CANopen fieldbus
	TERM	Yellow	Off	The terminating resistor integrated in the bus controller is turned off
			On	The terminating resistor integrated in the bus controller is turned on

1) The "MS" LED is a green/red dual LED. The LED blinks red several times immediately after startup. This is a boot message, however, and not an error.

Status LEDs - Blinking patterns



4.5.3.5 Operating and connection elements

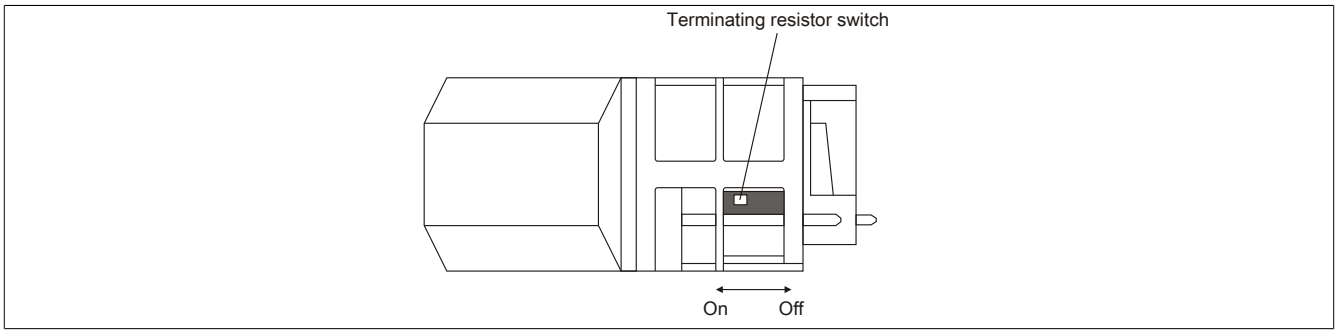


4.5.3.6 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
	Terminal	Function	
 1 5	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	
5-pin male multipoint connector			

4.5.3.7 Terminating resistor



A terminating resistor is already integrated on the bus controller. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.5.3.8 Node number and transfer rate

Node numbers and transfer rates are configured using the two bus controller number switches.

The transfer rate can be specified in two ways:

- Automatic detection by bus controller (see 4.5.2.9 "Automatic transfer rate detection")
- Fixed definition by user (see 4.5.2.10 "Setting the transfer rate")

Switch position	Node number	Transfer rate
0x00	Not allowed	-
0x01 - 0x7F	1 - 127	Automatically set by the bus controller (default) or fixed setting by the user
0x80 - 0x88	-	Sets a fixed transfer rate
0x89	-	Sets automatic transfer rate detection
0x8A - 0x8F	Not allowed	-
0x90	Clearing the parameters See section 4.5.2.11 "Clearing parameters"	-
0x91	Not allowed	-
0x92	Save configuration[1)] See section 4.5.3.11 "Save automatic configuration"	-
0x93 - 0xFF	Not allowed	-

1) This function is available starting with Hardware version E0 or Firmware version V0001.0107.

4.5.3.9 Automatic transfer rate detection

After booting, the bus controller goes into "Listen only" mode. This means the bus controller behaves passively on the bus and only listens.

The bus controller attempts to receive valid objects. If receive errors occur, the controller switches to the next transfer rate in the lookup table.

If no objects are received, all transfer rates are tested cyclically. This procedure is repeated until valid objects are received.

Lookup table

The controller tests the transfer rate according to this table. Beginning with the starting transfer rate (1000 kbit/s), the controller switches to the next lower transfer rate. At the end of the table, the bus controller restarts the search from the beginning.

Transfer rate
1000 kbit/s
800 kbit/s
500 kbit/s
250 kbit/s
125 kbit/s
100 kbit/s
50 kbit/s
20 kbit/s
10 kbit/s

4.5.3.10 Setting the transfer rate

The bus controller will detect the transfer rate automatically by default. Switch positions 0x80 - 0x88 can be used to set a fixed transfer rate, or 0x89 can be used to enable automatic transfer rate detection.

Switch position	Transfer rate
0x80	1000 kbit/s
0x81	800 kbit/s
0x82	500 kbit/s
0x83	250 kbit/s
0x84	125 kbit/s
0x85	100 kbit/s
0x86	50 kbit/s
0x87	20 kbit/s
0x88	10 kbit/s
0x89	Automatic transfer rate detection

Table 109: Possible transfer rates

Programming the transfer rate

1. Turn off the power supply to the bus controller.
2. Define the transfer rate to be programmed by setting the node numbers (0x80 - 0x89)
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED blinks with a red triple-flash (transfer rate is now programmed).
5. Turn off the power supply to the bus controller.
6. Set the desired node number (0x01 - 0x7F).
7. Turn on the power supply to the bus controller.
8. The bus controller now boots with the set node number and the programmed transfer rate.

4.5.3.11 Save automatic configuration

The node number position 0x92 can be used to save automatically generated configurations. This makes it possible to work with a standardized configuration without having to adapt the application to changes associated with service work or different development stages for example.

1. Turn off the power supply to the bus controller.
2. Set the node number to 0x90.
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED flashes green.
5. The node number switch must be set to 0x00 and then back to 0x90 within this time window of 5 seconds (rotate the top switch).
6. Wait until the "MS" LED blinks with a red double-flash (parameters have been cleared).
7. Turn off the power supply to the bus controller.
8. Set the node number to 0x92.
9. Turn on the power supply to the bus controller.
10. Wait until the "MS" LED flashes green.
11. The node number switch must be set to 0x02 and then back to 0x092 within this time window of 5 seconds (rotate the top switch).
12. Wait until the "MS" LED blinks with a red quad-flash (parameters have been saved).
13. Turn off the power supply to the bus controller.
14. Set the desired node number (0x01 - 0x7F).
15. Turn on the power supply to the bus controller.
16. The bus controller boots with the set node number and automatic transfer rate detection.

Information:

A mapping tool for decoding the saved PDO mapping is available in the Download section of the B&R website (www.br-automation.com).

Information:

This function is available starting with Hardware version E0 or Firmware version V0001.0107.

4.5.3.12 Clearing parameters

Various parameters can be stored in the bus controller's flash memory:

- Communication parameters
- Vendor-specific parameters
- Application parameters (device profile)
- Programmed transfer rate

Clearing the parameters using switch position 0x90 returns the bus controller to its factory settings.

Clearing the parameters listed above

1. Turn off the power supply to the bus controller.
2. Set the node number to 0x90.
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED flashes green. The node number switch must be set to 0x00 and then back to 0x090 within this time window of 5 seconds (rotate the top switch).
5. Wait until the "MS" LED blinks with a red double-flash (parameters have been cleared).
6. Turn off the power supply to the bus controller.
7. Set the desired node number (0x01 - 0x7F).
8. Turn on the power supply to the bus controller.
9. The bus controller boots with the set node number and automatic transfer rate detection.

4.5.3.13 Additional documentation and import files (EDS)

Additional documentation about bus controller functions as well as the necessary import files for the master engineering tool are available in the Downloads section of the B&R website (www.br-automation.com).

4.5.4 X20BC0053

4.5.4.1 General information

DeviceNet was developed by Allen Bradley as a CAN bus based automation network. It is based on a producer/consumer protocol. From the user's point of view, all data is handled separately from CAN bus transfer possibilities (e.g. longer data packets are automatically fragmented by DeviceNet). Access occurs using I/O messages with defined properties.

The bus controller makes it possible to connect X2X Link I/O nodes to DeviceNet. It has automatic transfer rate detection, auto scan, automatic mapping and automatic configuration of the I/O modules. Explicit messaging, change of state, cyclic, polled and bit strobe are supported as transfer modes. In addition to the standard communication objects, there are also manufacturer-specific objects used to represent the modular X20 System in the best manner possible.

X20 and other modules that are based on X2X Link can be connected to the bus controller. The entire configuration of this type of modular system is supported by the DeviceNet standard. Allen Bradley developed the modular I/O configuration to simplify the necessary configuration steps. The DeviceNet bus controllers from B&R also support this type of configuration.

- Fieldbus: DeviceNet
- I/O configuration via the fieldbus
- Support of both linear and modular (Allen Bradley) configuration systems
- Auto scan, automatic I/O mapping of the I/Os
- Automatic I/O configuration (starting with Rev. D0, firmware version 1.23)
- Integrated terminating resistor

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

4.5.4.3 Technical data

Product ID	X20BC0053
Short description	
Bus controller	DeviceNet adapter (slave)
General information	
B&R ID code	0x1F1B
Status indicators	Module status, bus function, 24V DeviceNet voltage, data transfer, terminating resistor.

Table 111: X20BC0053 - Technical data

Product ID	X20BC0053
Diagnostics	
24 V DeviceNet voltage	Yes, with LED status indicators (MOD and NET)
Module status	Yes, using status LED and software
Bus function	Yes, using status LED
Data transfer	Yes, using status LED
Terminating resistor	Yes, using status LED
Power consumption	
Bus	1.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Fieldbus - X2X Link	No
Fieldbus - I/O	Yes
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 1)	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Interfaces	
Fieldbus	DeviceNet adapter (slave)
Design	5-pin male multipoint connector
Max. distance	500 m
Transfer rate	Max. 500 kbit/s
Default transfer rate	Automatic transfer rate detection
Min. cycle time 2)	
Fieldbus	No limitations
X2X Link	400 µs
Synchronization between bus systems possible	No
Terminating resistor	Integrated in the module
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	0 to 55°C
Vertical installation	0 to 50°C
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x TB2105 terminal block separately Order 1x X20TB12 terminal block separately Order 1x X20PS9400 or X20PS9402 power supply module separately Order 1x X20BB80 bus base separately
Spacing 3)	37.5 $^{+0.2}$ mm

Table 111: X20BC0053 - Technical data

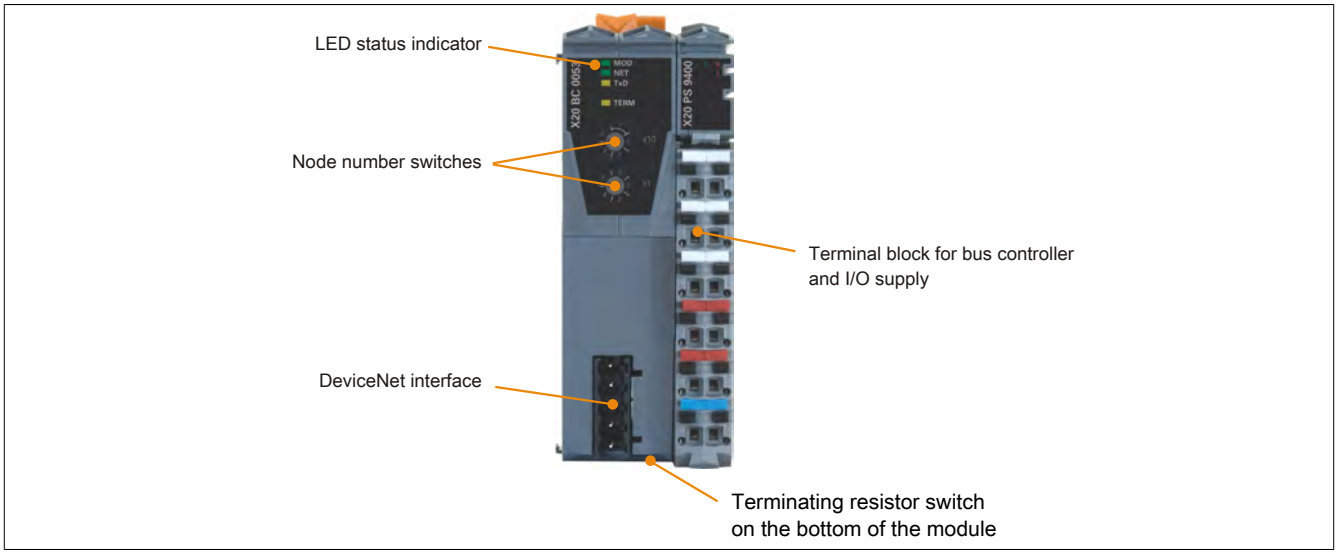
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.4.4 LED status indicators

Figure	LED	Color	Status	Description
	MOD[1]	Green	Off	Bus sense error: If the "NET" LED is also "off", there is no 24 V DeviceNet voltage. No transfer rate: If the PS9400's "RUN" LED is active (PREOPERATIONAL or RUN mode), the automatic transfer rate detection is still running or no transfer rate could be detected.
			On	RUN mode: The 24 V DeviceNet voltage is OK and the module is operating under normal conditions.
			Blinking	Standby mode: Configuration is missing, incomplete, or incorrect.
		Red	Blinking	Recoverable Fault mode:
		Green/red	Blinking	Module is performing a self test.
	NET[1]	Green	Off	No power, offline: • Bus sense error: If the "MOD" LED is also off, there is no 24 V DeviceNet voltage. • No transfer rate: If the PS9400's "RUN" LED is active (PREOPERATIONAL or RUN mode), the automatic transfer rate detection is still running or no transfer rate could be detected. • Module has not yet completed a duplicate MAC-ID test.
			Blinking	Online, not connected: • The module has carried out the duplicate MAC-ID test and is online. • There is no established connection to a master/scanner.
			On	Everything is OK: A connection to the master/scanner (explicit or I/O) is set up.
		Red	Blinking	Connection timeout: The time for an I/O connection has expired.
			On	Critical connection error - fieldbus communication no longer possible: • Duplicate MAC ID error • Bus off • Receive/transmit overrun
	TxD	Yellow	Off	The bus controller is not transmitting any data via the DeviceNet fieldbus
			On	The bus controller is transmitting data via the DeviceNet fieldbus
	TERM	Yellow	Off	The terminating resistor integrated in the bus controller is turned off
			On	The terminating resistor integrated in the bus controller is turned on

1) The "MOD" and "NET" LEDs are green/red dual LEDs.

4.5.4.5 Operating and connection elements



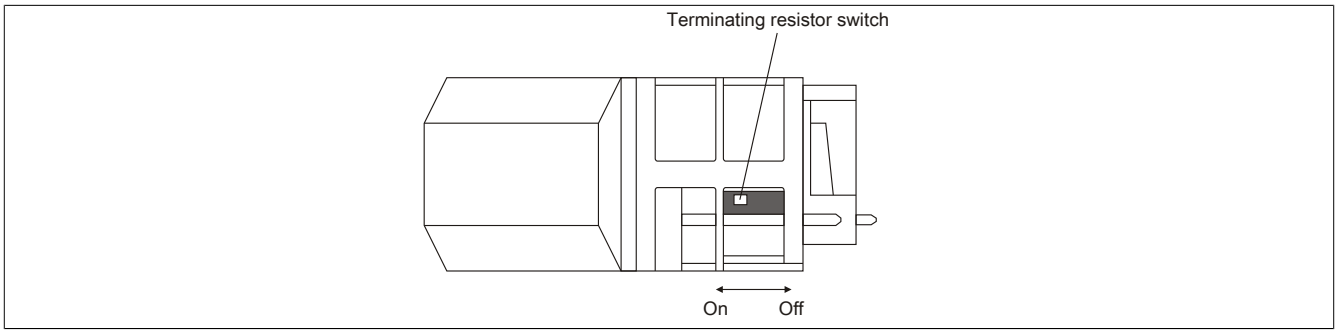
4.5.4.6 DeviceNet interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
 5-pin male multipoint connector	**Terminal**	**DeviceNet**	
	1	CAN⊥ (V-)	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	V+	Supply voltage[1)]

1) The 24 VDC in the DeviceNet network must be fed in externally in order to guarantee correct operation and data exchange. 24 VDC is not made available by the device.

4.5.4.7 Terminating resistor

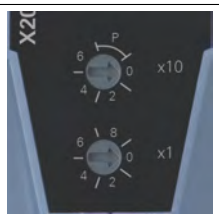


A terminating resistor is already integrated on the bus controller. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.5.4.8 Node number

The MAC ID is configured using the two address switches on the bus controller.

The configurable range lies between 0 and 63. This value range is required in the DeviceNet specifications for a DeviceNet device.



Switch position	MAC ID
00 - 63	0 - 63
64	The MAC ID can be configured by setting the address switch using the master/scanner software.
65 - 89	Not permitted
90	"Clearing parameters"
91 - 94	Not permitted
95	"Automatic configuration"
96 - 99	Not permitted

4.5.4.9 Automatic transfer rate detection

After booting, the bus controller goes into "Listen only" mode. This means the bus controller behaves passively on the bus and only listens.

The bus controller attempts to receive valid objects. If receive errors occur, the controller switches to the next transfer rate in the lookup table.

If no objects are received, all transfer rates are tested cyclically. This procedure is repeated until valid objects are received, indicating that the correct transfer rate has been determined. Only transfer rates permitted by the DeviceNet specification are tested.

Lookup table

The controller tests the transfer rate according to this table. Beginning with the starting transfer rate (500 kbit/s), the controller switches to the next lower transfer rate. At the end of the table, the bus controller restarts the search from the beginning.

Transfer rate
500 kbit/s
250 kbit/s
125 kbit/s

Table 112: Transfer rate lookup table

Information:

While automatic transfer rate recognition is running, both DeviceNet LEDs are switched off (because there is no LED status definition in the DeviceNet specifications for this status).

To ensure that the module has been supplied and booted, this manufacturer specific status definition requires the X20PS9400 RUN LED to be active.

4.5.4.10 Clearing parameters

Various parameters can be stored in the bus controller's flash memory. Deleting these parameters using switch position 90 returns the bus controller to its factory settings.

Deleting the parameters

1. Turn off the power supply to the bus controller.
2. Set the node number to 90
3. Turn on the power supply to the bus controller.
4. Wait until the "MOD" LED flashes green for 5 s (3 ms on / 500 ms off). The node number switch "x10" must be set to 0 and then back to 9 within this time window.
5. Wait until the "MOD" LED blinks with a red double-flash (parameters have been cleared).
6. Turn off the power supply to the bus controller.
7. Set the desired node number (00 - 63).
8. Turn on the power supply to the bus controller.
9. The bus controller boots with the set node number and automatic transfer rate detection.

4.5.4.11 Automatic configuration of the I/O modules

The automatic configuration of the connected I/O modules by the bus controller is supported starting with Rev.D0 (firmware ≥V 1.23) of the bus controller.

To prevent the configuration data from being accidentally overwritten on the bus controller, the procedure described below must be followed when creating the configuration data. When doing this, it is important that all required I/O modules are also started when booting the bus controller (i.e. supplied with power). This is especially important when using potential groups (E-stop switches).

The automatic configuration sets the following attributes of class 0x65 on the individual I/O modules:

- Module type (0x01)
- Input length (0x03)
- Output length (0x05)

Additional parameters are not set. That means that the connected modules are configured with their standard settings and standard I/O lengths. This can be changed by editing the parameters in the respective master engineering tool.

Automatic configuration

1. Turn off the power supply to the bus controller.
2. Set node number switch to 95 (this is done by turning "x10" switch right to the position "P" and the "x1" switch to 5).
3. Turn on the power supply to the bus controller.
4. Wait until the "MOD" LED starts blinking green (3 ms on / 500 ms off). This phase of green blinking lasts 5 s. The node number "x10" switch must be set to 0 within this time frame and then set back to 9.
5. Wait until the "MOD" LED blinks (4 red flashes). The old configuration data is now deleted completely and overwritten with the new values from the connected I/O modules.
6. Turn off the power supply to the bus controller.
7. Set the desired node number (00 to 63).
8. Turn on the power supply to the bus controller.
9. The bus controller boots using the set node number, automatic transfer rate recognition and standard settings from the connected I/O modules.

4.5.4.12 Additional documentation and import files (EDS)

Additional documentation about bus controller functions as well as the necessary import files for the master engineering tool are available in the Downloads section of the B&R website (www.br-automation.com).

4.5.5 X20BC0063

4.5.5.1 General information

PROFIBUS DP is based on the physics of the RS485 interface. Data transfer is controlled using a hybrid bus access procedure. Active stations receive communication rights via a token passing procedure and can then access all stations on the network according to the master-slave principle. The maximum time of circulation for a token can be configured, which results in a defined cycle time.

Access represents various services for the user for both cyclic and for non-cyclic data transfer.

The bus controller makes it possible to connect X2X Link I/O nodes to PROFIBUS DP. It supports PROFIBUS DP with all of its options and other additional properties. In addition to the device, module, and channel diagnostics provided in the PROFIBUS standard, it is also possible, for example, to switch to the slot diagnostics option in S7 format. X20 or other modules that are based on X2X Link can be connected to the bus controller. Modular system configurations are optimally supported by PROFIBUS DP.

- Fieldbus: PROFIBUS DP
- I/O configuration via the fieldbus
- Extensive device, module, and channel diagnosis according to PROFIBUS DP standard
- Communication with X2X Link I/O nodes even works when some nodes are missing or without power

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

4.5.5.2 Order data

Model number	Short description	Figure

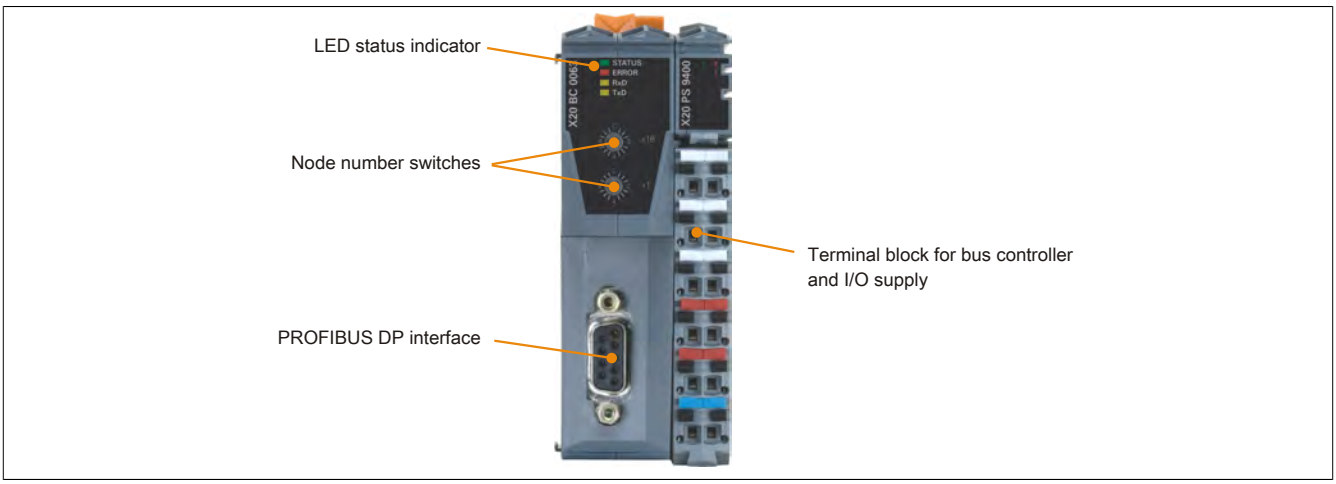
<tr><td colspan="3">For a more detailed description see the section 4.5.5.5 "State diagnostics via the Status/Error LEDs".</td></tr>
<tr><td>RxD</td><td colspan="3">This yellow LED lights up when the bus controller is receiving data from the PROFIBUS DP fieldbus.</td></tr>
<tr><td>TxD</td><td colspan="3">This yellow LED lights up when the bus controller is sending data via the PROFIBUS DP fieldbus.</td></tr>
</table>

4.5.5.5 State diagnostics via the Status/Error LEDs

The condition of the PROFIBUS DP bus controller is diagnosed using the LED status indicators "STATUS" and "ERROR".

STATUS (Green)	ERROR (Red)	Function	Solution
Off	Off	HARDWARE FAULT / POWER FAIL	• Check wiring of supply voltage.
On	On	BUS OFF • Baud rate not detected • No connection to the DP master • DP master not active	• Check the PROFIBUS network • Check the PROFIBUS master
On	Blinking	WAIT FOR CONFIG • Transfer rate has been detected, but the PROFIBUS master has not yet configured the bus controller	• Check the node number switch • Check the slave address in the master configuration
Blinking	Off	DATA EXCHANGE - DIAGNOSTICS • The bus controller is still initializing the I/O modules • The I/O modules configured by the master cannot be found • An error has occurred on one or more I/O modules (short circuit, etc.)	• Initialization can take a few seconds depending on the number of I/O modules connected • Check the wiring and power supply for the I/O modules • Read diagnostic messages in the respective PROFIBUS master's engineering tool
On	Off	DATA EXCHANGE • Cyclic data exchange with the PROFIBUS DP master	
Blinking	Blinking	CONFIG ERROR • One or more I/O modules found do not match with the configuration of the PROFIBUS DP master • The configuration received from the PROFIBUS master is invalid	• Check the wiring of the X2X Link and the order of I/O modules • Check configuration of the PROFIBUS master • Read diagnostic messages in the respective PROFIBUS master's engineering tool • Check the configuration being used - it is possible that the number of configured I/O modules is too high
Off	Blinking	SERVICE MODE - BOOT • The bus controller's node number has been set to 255 (0xFF) - after 2 s the bus controller starts in service mode	• Set a valid node number
Single flash	Single flash	HARDWARE FAULT	

4.5.5.6 Operating and connection elements



4.5.5.7 PROFIBUS DP interface

Interface	Pinout		
	Pin	RS485	
 9-pin female DSUB connector	1	Reserved

	4	CNTR-P	Transmit enable
	5	DGND	Electrically isolated supply
	6	CP	Electrically isolated supply
	7	Reserved	
	8	RxD/TxD-N	Data\[2]
	9	CNTR-N	Transmit enable\
	CNTR ... Directional switch for external repeater		

1) Cable color: Red
2) Cable color: Green

4.5.5.8 PROFIBUS DP node number switches

The PROFIBUS DP node number is configured using both number switches of the bus controller.

Switch position	Node number
0x00	Not allowed
0x01 - 0x7D	1 to 125
0x7E - 0xFF	Not allowed

4.5.5.9 Automatic transfer rate detection

After booting or after a communication timeout, the bus controller goes into the status "Baud Search". This means the bus controller behaves passively on the bus.

The bus controller always begins the search for the configured transfer rate with the highest transfer rate. If a complete error-free telegram is not received during monitoring time, then the search is continued using the next lowest transfer rate.

Transfer rate
12 Mbit/s
6 Mbit/s
3 Mbit/s
1.5 Mbit/s
500 kbit/s
187.5 kbit/s
93.75 kbit/s
45.45 kbit/s
19.2 kbit/s
9.6 kbit/s

Table 115: Transfer rates supported by the bus controller

4.5.5.10 Additional documentation and import files (EDS)

Additional documentation about bus controller functions as well as the necessary import files for the master engineering tool are available in the Downloads section of the B&R website (www.br-automation.com).

4.5.6 X20BC0073

4.5.6.1 General information

The bus controller makes it possible to connect X2X Link I/O nodes to CAN I/O. CAN I/O is a transfer protocol based on standard CAN bus fully integrated in the B&R system. From the user's point of view, it doesn't matter if I/O points are operated locally or remotely via CAN I/O.

Up to 43 logic I/O modules can be connected to the bus controller. Up to 16 of them can be analog modules.

- Fieldbus: CAN bus
- Automatic firmware update via the fieldbus
- Integrated I/O access in B&R Automation Studio
- Integrated terminating resistor

Information:

The bus controller is unable to detect modules after a gap in the X2X Link station numbers. This can be caused by:

- **X20 modules not being connected**
- **Modules with integrated node number switch, such as the X20BM05**

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

4.5.6.2 Order data

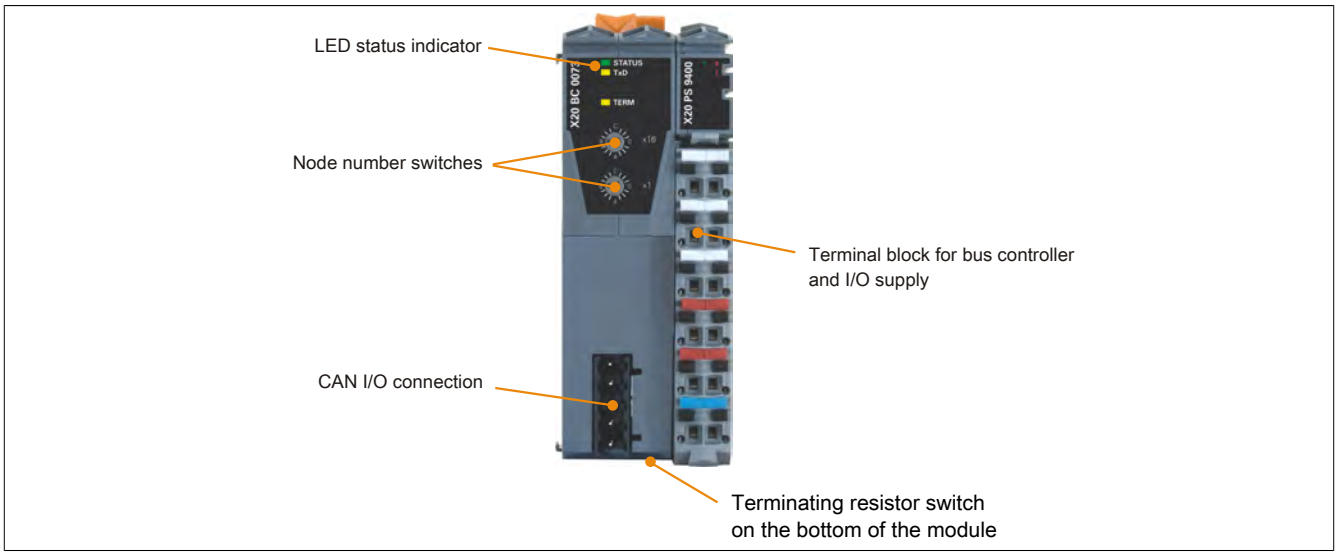
4.5.6.4 LED status indicators

Figure	LED	Color	Status	Description
	STATUS[1)]	Green	Off	No power supply
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	On	CAN connection reports BusOff status
		Green/red	Flickering	Transfer rate detection in progress
		Green blinking / red single flash		PREOPERATIONAL mode; CAN connection reports: Warning limit reached
		Steady green / single red flash		RUN mode; CAN connection reports: Warning limit reached
	TxD	Yellow	Off	The bus controller is not transmitting any data via the CAN I/O fieldbus
			On	The bus controller is transmitting data via the CAN I/O fieldbus
	TERM	Yellow	Off	The terminating resistor integrated in the bus controller is turned off
			On	The terminating resistor integrated in the bus controller is turned on

1) The "STATUS" LED is a green/red dual LED.

4.5.6.5 Operating and connection elements

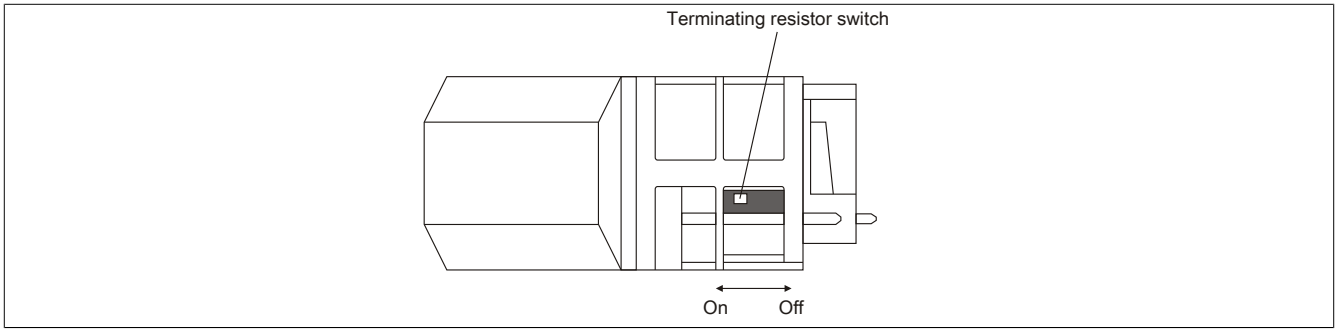


4.5.6.6 CAN bus interface

The interface is a 5-pin multipoint plug. The 0TB2105 terminal block must be ordered separately.

Interface	Pinout		
	Terminal	Function	
 5-pin male multipoint connector	1	CAN⊥	CAN ground
	2	CAN_L	CAN low
	3	SHLD	Shield
	4	CAN_H	CAN high
	5	NC	

4.5.6.7 Terminating resistor



A terminating resistor is already integrated on the bus controller. It can be turned on and off with a switch on the bottom of the housing. An active terminating resistor is indicated by the "TERM" LED.

4.5.6.8 Node number and transfer rate

Node numbers and transfer rates are configured using the two bus controller number switches. The switch positions 0x00 to 0x40 and 0x60 enable automatic transfer rate detection (see section 4.5.6.9 "Automatic transfer rate detection" on page 744). The rest of the switch positions have a fixed transfer rate (see table).

Switch position	Node number	Transfer rate
0x00[1)]	From EEPROM	From EEPROM
0x01 - 0x3F	1 - 63	Automatic
0x40[1)]	From EEPROM	From EEPROM
0x41 - 0x5F	1 - 31	1000 kbit/s
0x60[1)]	From EEPROM	From EEPROM
0x61 - 0x7F	1 - 31	800 kbit/s
0x80	Reserved	-
0x81 - 0x9F	1 - 31	500 kbit/s
0xA0	Reserved	-
0xA1 - 0xBF	1 - 31	250 kbit/s
0xC0	Reserved	-
0xC1 - 0xDF	1 - 31	125 kbit/s
0xE0	Reserved	-
0xE1 - 0xFE	1 - 31	20 kbit/s
0xFF	Reserved	-

1) When one of these numbers is configured, the bus controller uses the operating parameters from the internal EEPROM. The EEPROM is programmed using the CANIO library.

4.5.6.9 Automatic transfer rate detection

After booting, the bus controller goes into "Listen only" mode. This means the bus controller behaves passively on the bus and only listens.

The bus controller attempts to receive valid objects. If receive errors occur, the controller switches to the next transfer rate in the lookup table.

If no objects are received, all transfer rates are tested cyclically. This procedure is repeated until valid objects are received.

Starting transfer rate

The bus controller begins the search with this transfer rate. The starting transfer rate can be defined in two different ways:

- Read from EEPROM
- Using the last detected transfer rate after a software reset (command code 20)

Lookup table

The controller tests the transfer rate according to this table. Beginning with the starting transfer rate, the controller switches to the next lower transfer rate. At the end of the table, the bus controller restarts the search from the beginning.

Transfer rate
1000 kbit/s
500 kbit/s
250 kbit/s
125 kbit/s
50 kbit/s
20 kbit/s
10 kbit/s

4.5.6.10 SG4

This module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. If the two versions are different, the Automation Runtime firmware is loaded to the module.

The latest firmware is made available automatically when updating Automation Runtime.

4.5.6.11 Logical I/O modules

Up to 43 I/O modules can be connected to the bus controller (up to 16 can be analog modules). This value refers not to the physical but the logical I/O module slots.

Information:

Physical I/O modules can take up more than one digital or analog slot.

The following table lists all X67 modules capable of using CAN bus and how many logical digital and analog slots are needed.

Module	Digital module slots	Analog module slots

4.5.7 X20(c)BC0083

4.5.7.1 General information

The bus controller makes it possible to connect X2X Link I/O nodes to POWERLINK. It is also possible to operate the X2X Link cycle synchronously 1:1 or synchronous to POWERLINK using a prescaler.

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) ensures that the standard remains open and is continually developed: www.ethernet-powerlink.org

- POWERLINK
- I/O configuration and Firmware update via the fieldbus
- Integrated hub for efficient cabling

4.5.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.5.7.3 Order data

Model number	Short description	Figure

Transport	-40 to 85°C	
Relative humidity		
Operation	5 to 95%, non-condensing	Up to 100%, condensing
Storage	5 to 95%, non-condensing	
Transport	5 to 95%, non-condensing	
Mechanical characteristics		
Note	Order 1x X20TB12 terminal block separately Order 1x X20PS9400 or X20PS9402 power supply module separately Order 1x X20BB80 bus base separately	Order 1x X20TB12 terminal block separately Order 1x X20cPS9400 power supply module separately Order 1x X20cBB80 bus base separately
Spacing [3]	37.5 $^{+0.2}$ mm	

Table 119: X20BC0083, X20cBC0083 - Technical data

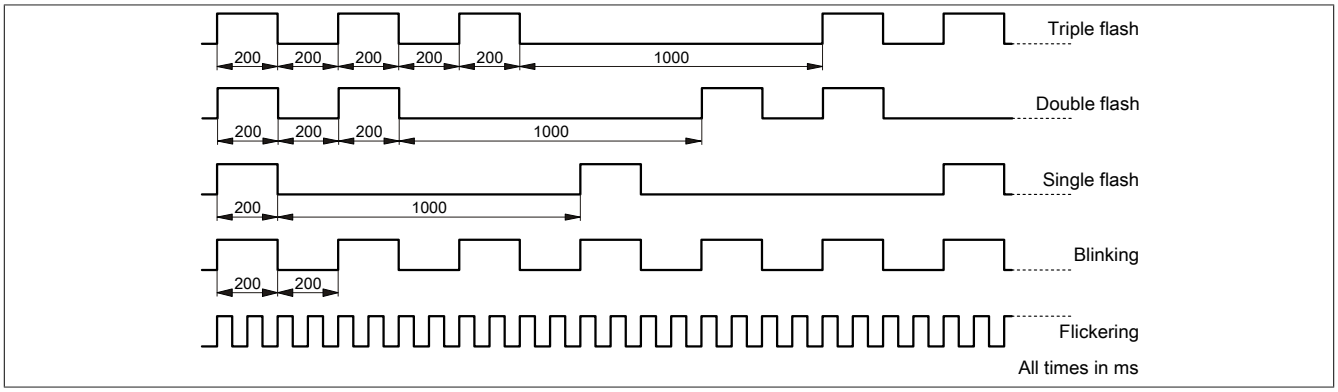
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.7.5 LED status indicators

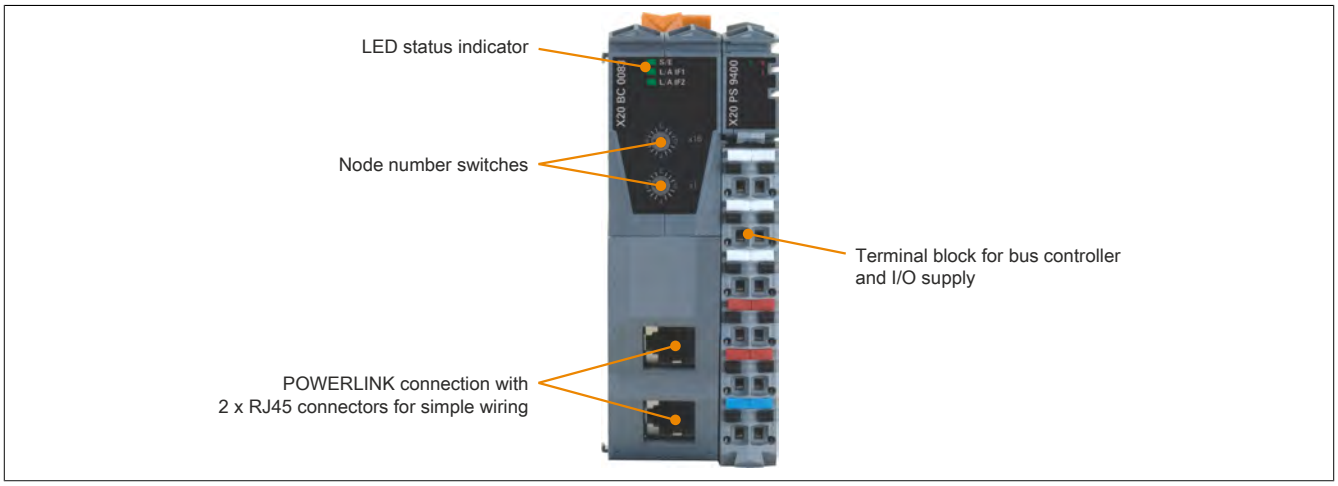
Figure	LED	Color	Status	Description
	S/E[1]	Green	Off	No power supply or mode is NOT_ACTIVE. The controlled node (CN) is either not getting power, or it is in the NOT_ACTIVE state. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the module. If no POWERLINK communication is detected during these 5 seconds, the CN goes into the BASIC_ETHERNET state (flickering). If POWERLINK communication is detected before this time passes, however, the CN goes directly into the PRE_OPERATIONAL_1 state.
			Flickering	BASIC_ETHERNET mode. The CN has not detected any POWERLINK communication. It is possible to communicate directly with the CN in this state (e.g. with UDP, IP, etc.). If POWERLINK communication is detected while in this state, the CN goes into the PRE_OPERATIONAL_1 state.
			Single flash	PRE_OPERATIONAL_1 mode. When operated on a POWERLINK V1 manager, the CN goes directly into the PRE_OPERATIONAL_2 state. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then goes into the PRE_OPERATIONAL_2 state.
			Double flash	PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. Issuing a command (POWERLINK V2) or setting the data valid flag in the output data (POWERLINK V1) then switches to the READY_TO_OPERATE state.
			Triple flash	READY_TO_OPERATE mode. In a POWERLINK V1 network, the CN automatically switches to the OPERATIONAL state as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command.
			On	OPERATIONAL mode. PDO mapping is active and cyclic data is being evaluated.
			Blinking	STOPPED mode. No output data is produced or input data supplied. It is only possible to enter or leave this state after the manager has given the appropriate command.
		Red	On	The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: • The LED blinks red several times immediately after startup. This is not an error. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via Dynamic Node Allocation (DNA).
	L/A IFx	Green	On	Link established to the remote station
			Blinking	A link to the remote station has been established and there is activity on bus.

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LEDs - Blinking patterns



4.5.7.6 Operating and connection elements



4.5.7.7 POWERLINK node number

The node number for the POWERLINK node is set using the two number switches. Node numbers between 0x01 and 0xEF are permitted.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node Operation as a controlled node.
0xF0 - 0xFF	Reserved, switch position not permitted

4.5.7.8 Dynamic Node Allocation (DNA)

The node numbers of all POWERLINK bus controllers can be assigned dynamically. This has the following advantages:

- No need to set the node number switch
- Easier installation
- Reduced error sources

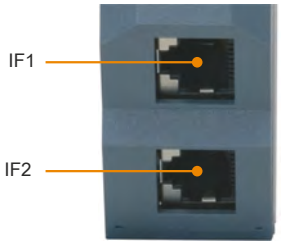
For information about configuration as well as an example, see the AS help system (Communication → POWERLINK → General information → Dynamic Node Allocation (DNA)).

Information:

The IF1 interface must always be used as the input from the preceding node.

4.5.7.9 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.5.7.10 SG3

This module is not supported on SG3 targets.

4.5.7.11 SG4

This module comes with preinstalled firmware. The firmware is also part of the Automation Runtime operating system for the PLC. If the two versions are different, the Automation Runtime firmware is loaded to the module.

The latest firmware is made available automatically when updating Automation Runtime.

4.5.8 X20(c)BC0087

4.5.8.1 General information

Established in 1979, the Modbus protocol has approved the use of Ethernet with both Modbus TCP and Modbus UDP. Today, Modbus TCP is an open Internet draft standard introduced by Schneider Automation to the Internet Engineering Task Force (IETF), the organization responsible for Internet standardization. The Modbus services and object model have been preserved since the original version and left unchanged for use with the TCP/IP transmission medium.

Modbus/UDP differs from Modbus TCP in that it uses connectionless communication via UDP/IP. The advantages of faster and easier communication with UDP/IP also brings with it the disadvantage of requiring error detection and correction in the application layer.

This bus controller makes it possible to connect X2X Link I/O nodes to Modbus via Ethernet. The bus controller can be operated on B&R controllers through the use of Automation Studio or on third-party systems with Modbus TCP or UDP master functionality.

- Fieldbus: Modbus/TCP, Modbus/UDP
- I/O configuration via the fieldbus
- DHCP-capable
- Bootp-capable
- Integrated double switch for efficient cabling
- Configurable I/O cycle (0.5 to 4 ms)
- Response time: <1 - 8 ms (depending on the load on the integrated switch)
- Validity check for command sequences before execution

> **Information:**
>
> **Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.**
>
> **All other function models are supported when configured accordingly. The B&R FieldbusDESIGNER is available at no cost in the Downloads section of the B&R website www.br-automation.com.**

4.5.8.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

> **For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.**

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

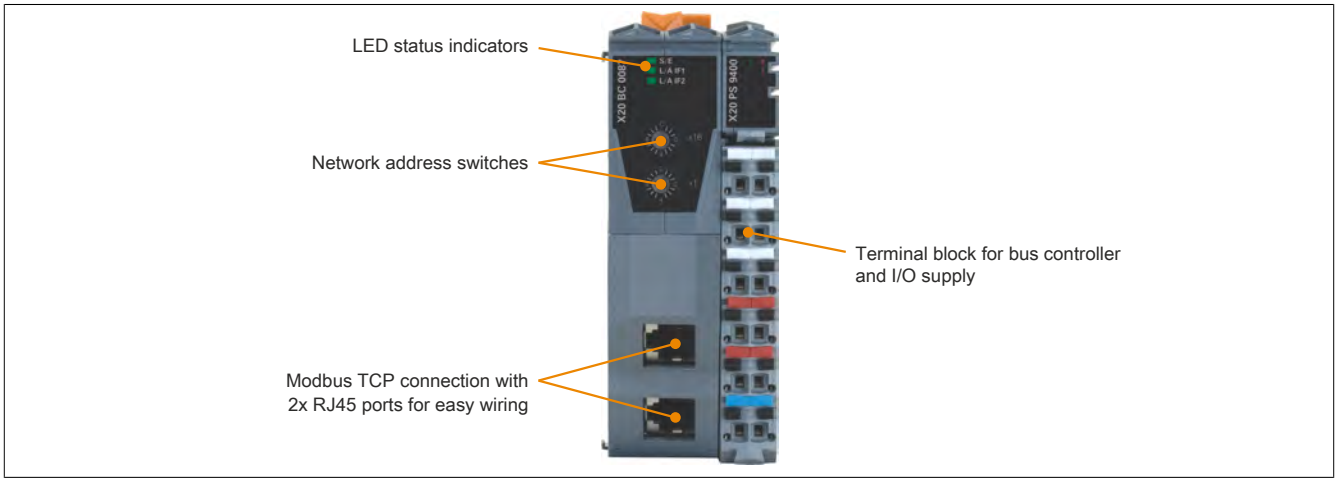
4.5.8.5 LED status indicators

Figure	LED	Color	Status	Description
	S/E[1]	Green	On	Indicates that there is at least one client connection
			2 pulses	Indicates that there are no client connections
			4 pulses	Indicates that the controller is waiting for an address from the DHCP server
			Blinking	Initialization of connected I/O modules
		Red	2 pulses	Watchdog timeout
			3 pulses	Faulty I/O module configuration data
			4 pulses	Indicates that the controller has detected an IP address being used twice
			5 pulses	Indicates a missing, defective or incorrect I/O module
			6 pulses	Error reading flash memory. Last write operation was incomplete or contained errors.[2]
			On	Indicates a major unrecoverable fault
	L/A IFx	Green	Blinking	Ethernet activity taking place on the RJ45 port (IF1, IF2) indicated by the respective LED
			On	Indicates an established connection (link), but no communication is taking place
			Off	Indicates that no physical Ethernet connection exists

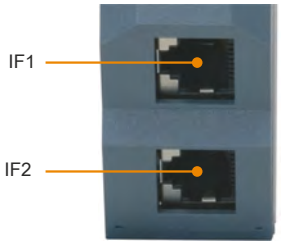
1) The Status/Error LED "S/E" is a green/red dual LED. The LED blinks red several times immediately after startup. This is a boot message, however, and not an error.
2) Possible cause: The bus controller received a command to save, but was switched off before saving was complete. In this case, the bus controller continues to use the old configuration and indicates the failed write operation with a blink code.

4.5.8.6 Operating and connection elements



4.5.8.7 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
Shielded RJ45	8	Termination	

4.5.8.8 Modbus/TCP network address switch

Switch position	Description
0x00	This switch position is the factory default setting. In this position, the address switches have no effect on system parameters. The bus controller parameters in flash memory are used (IP address and port number). The bus controller is started with factory default values if valid flash data is not present.
0x01 - 0x7F	The last position of the IP address saved in flash memory is changed to the address switch value. The IP address saved in flash memory is not changed. The port number is read from flash memory.
0x80 - 0xEF	When set within this range, the bus controller runs in DHCP mode. The current hostname is then passed on to the DNS server. A hostname is generated according to how the address switches are set. **Example** The generated hostname is made up of three elements: "br" + "mb" + address switch value (three decimal places). This means, for example, that the following hostname is generated for address switch setting 0xD7 (dec. 215): "brmb215"
0xF0	Auto Store mode: The IP settings are taken from the DHCP or BooTP server. If the IP settings differ from the values stored in the flash memory, then the current IP parameters are saved. This function is only available with Firmware version >= 1.39.
0xF1 - 0xFD	Reserved (same function as position 0xFF)
0xFE	Initializes all bus controller parameters with default values during booting. No values are read from flash memory. The communication parameters correspond to the values assigned with switch setting 0xFF.
0xFF	Initializes all communication parameters with default values. All other bus controller parameters are read from flash memory. Default parameters: • IP address: 192.168.100.1 • Subnet mask: 255.255.255.0 • Gateway: 192.168.100.254 • Primary NetBIOS name: "br" + MAC address • Secondary NetBIOS name: "br" + "mb" + address switch value (decimal) • Port number: 502 • X2X Link configuration: 4 ms cycle time • X2X Link cable length: 0 m

4.5.8.9 Setting the IP address (default value)

Changes to the network address switches are only applied after a restart. If the bus controller is restarted with the address switch value 0xFF, it is initialized with the IP address 192.168.100.1. This address is also the factory default setting. The port number is set to 502 (reserved for Modbus).
This IP address can be used to establish a connection to the bus controller. The internationally unique MAC address is listed on the housing side of the bus controller. The combination of "br" and the MAC address results in a unique name (primary NetBIOS name) that also makes it possible to access the bus controller.

Example of the primary NetBIOS name:

MAC address:	00-60-65-00-49-02
Resulting NetBIOS name:	br006065004902

This means that, without additional parameter changes, either the default IP address 192.168.100.1 or the NetBIOS name "br+MAC" can be used to communicate with the controller.

Since NetBIOS is being used, the bus controller can only be accessed via this name if there are no intermediary routers or gateways in the way.

4.5.8.10 Automatic IP assignment by a DHCP server

If a network address switch setting between 0x80 and 0xEF is configured, the bus controller will attempt to request an IP address from the DHCP server. The assigned IP address can be queried with a "ping" command together with the hostname. The bus controller registers this hostname on the DHCP server, which should forward it to a DNS server.

Example The hostname (DNS name) is made up of three elements:
"br" + "mb" + Address switch value (3 decimal places)
This means, for example, that the following hostname is generated for address switch setting 0xD7 (dec. 215): "brmb215".

If DNS service is not available on the network, the bus controller's two NetBIOS names can also be used for access. The secondary NetBIOS name is identical to the hostname. If the address switches are set to 0x00, it is identical to the primary NetBIOS name. The bus controller can only be reached via its NetBIOS name if no other routers or gateways are in the way.

4.5.8.11 Changing the IP address with the network address switches

The address switches can be used to change the last byte in the IP address configured on the bus controller. The IP address saved in flash memory is not changed. If the address switches are set to 0x00, the bus controller applies the IP address last saved to flash memory. Switch positions between 0x01 and 0x7F cause the last position of the IP address (the lowest byte) to be overwritten by the value of the address switch. This provides the user a quick and easy way to address a large number of bus controllers. In short, an IP address between 192.168.100.1 and 192.168.100.127 can be selected for a bus controller using the address switches without requiring any additional software configuration.

4.5.8.12 Information about NetBIOS names

In addition to the hostname used to register on the register on the DHCP server, the bus controller also has so-called NetBIOS names. These are used to access the bus controller from a PC using its name (as opposed to its IP address). This is only possible if no routers or gateways are in the way, however.

The primary NetBIOS name is always composed of the prefix "br" and the MAC address from the bus controller (see 4.5.8.10 "Automatic IP assignment by a DHCP server").

The secondary NetBIOS name corresponds to the primary NetBIOS name at address switch position 0x00. This is necessary because there may be several bus controllers with the address switch 0x00 in a network segment. In this case, the IP address from flash memory is used.

For all other address switch positions, the secondary NetBIOS name is generated from the network address switch value (as in DHCP mode): "br" + "mb" + Address switch value (3 decimal places).
A hostname defined explicitly by the user will be used for the secondary NetBIOS name regardless of the address switch value.

This makes it possible to access the bus controller with the NetBIOS name configured using the address switches. This is also possible if the controller was not configured for use with a DHCP server (address switch setting between 0x01 and 0x7F).

4.5.8.13 Saving an IP address to flash memory

The IP parameters in flash memory can be changed via the Modbus protocol, the ModbusTCP Toolbox or the Telnet interface. The ModbusTCP Toolbox can be downloaded from the B&R website.
The IP address, subnet and gateway are all defined in the address range 0x1003 to 0x100E. Each has a length of 4 words. The data is applied by writing the constant 0xC1 to the address 0x1140 ("Write Single Register" fc6, addr. 0x1140, data 0xC1). The new settings are applied after the bus controller is restarted.

4.5.9 X20(c)BC0088

4.5.9.1 General information

EtherNet/IP is a fieldbus based on EtherNet/IP that was developed by Allen-Bradley (Rockwell Automation) and later handed off to the Open DeviceNet Vendor Association (ODVA) as an open standard. In 1998, a working group at ControlNet International developed a procedure for setting the published Common Industrial Protocol to Ethernet. EtherNet/IP was published in March 2000 as an open industrial automation standard based on this procedure.

The bus controller makes it possible to connect X2X Link I/O nodes to EtherNet/IP. The bus controller can be operated via the X20IF10D1-1 interface module or by 3rd-party systems with EtherNet/IP scanner functionality.

- Fieldbus: EtherNet/IP
- Integrated 3-port switch for efficient cabling
- Auto-configuration of I/O modules
- Can be configured by the scanner (master) using configuration assembly
- Web interface
- DHCP-capable
- Configurable I/O cycle (0.5 to 4 ms)
- Minimum fieldbus cycle time (also requested packet interval or RPI): 1 ms

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

FieldbusDESIGNER can be used to create configuration files (e.g. EDS files, binary files) in six easy steps. All other function models are also supported by transferring configuration data to the bus controller (e.g. using its web interface or the scanner via a "Configuration Assembly").

FieldbusDESIGNER is available at no cost in the Downloads section of the B&R website www.br-automation.com.

4.5.9.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Table 123: X20BC0088, X20cBC0088 - Technical data

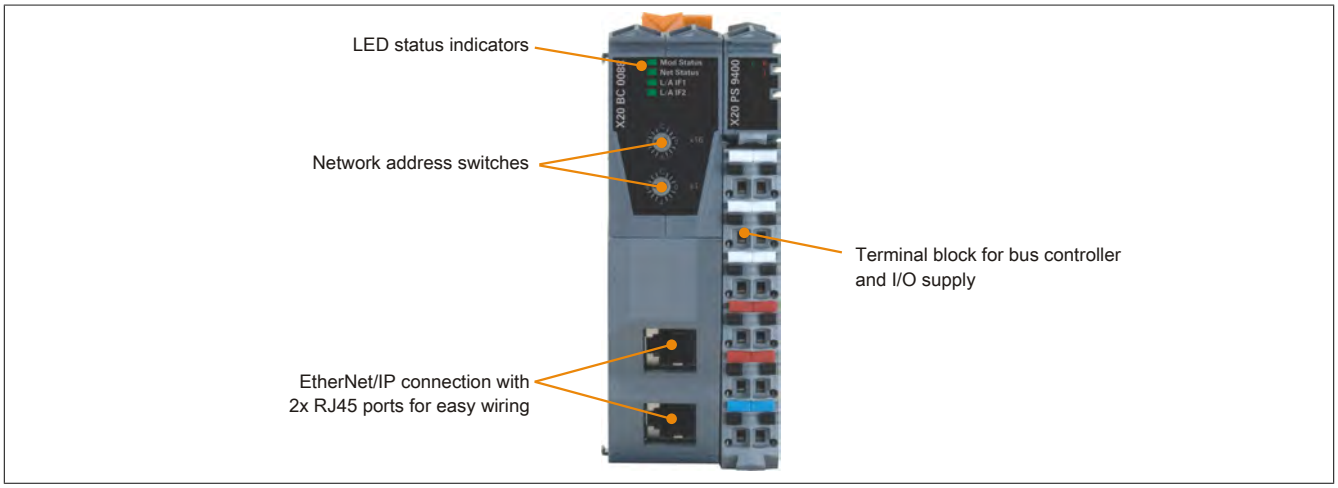
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.9.5 LED status indicators

Figure	LED	Color	Status	Description
	Mod status[1]	Green	On	Indicates that there is at least one client connection
			Blinking	Bus controller not yet configured
			Flickering	HTTP file upload (firmware or configuration file)
		Red	On	Major unrecoverable fault.
			Blinking	Major recoverable fault.
		Green/Red	Blinking	Initialization / Self-test
	Net status[1]	Green	On	Indicates at least one established active scanner (master) connection
			Blinking	Indicates no established active scanner (master) connection
		Red	Off	Indicates no IP address has been assigned
			On	Indicates an IP address has been used more than once
			Blinking	Indicates a timeout on at least one connection
		Green/Red	Blinking	Initialization / Self-test
	L/A IFx	Green	Blinking	Ethernet activity taking place on the RJ45 port (IF1, IF2) indicated by the respective LED
			On	Indicates an established connection (link), but no communication is taking place
			Off	Indicates that no physical Ethernet connection exists

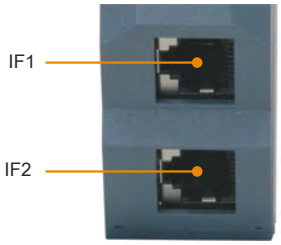
1) The "Mod status" and "Net status" LEDs are green/red dual LEDs.

4.5.9.6 Operating and connection elements



4.5.9.7 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1	1	RXD	Receive data

	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
Shielded RJ45	8	Termination	

4.5.9.8 EtherNet/IP address switching positions

Switch position	Description
0x00	The IP address saved in flash memory is used. The adapter is started via DHCP if attribute 3 (configuration control) of the TCP/IP interface object was set to DHCP.
0x01 to 0x7F	The last position of the IP address saved in flash memory is changed to the address switch value. The IP address saved in the flash memory is not changed. All other adapter parameters are read from the flash memory and are used without being changed.
0x80 to 0xEF	The bus controller runs in this range in DHCP mode. The DNS server is informed of the current host name. A host name is generated according to the setting of the network address switch. Example: The generated host name is made up of three elements: "br" + "eip" + address switch number (three decimal places) This means that a address switch number of e.g. 0xD7 (dec. 215) would result in the following host name: "breip215"
0xF0 to 0xFD	Reserved (same function as position 0xFF).
0xFE	All bus controller parameters are initialized with default values during the boot procedure. No values are read from the flash. The communication parameters are equal to the values as with the switch setting 0xFF.
0xFF	All communication parameters are initialized with default values. All other bus controller parameters are read from the flash. The default parameters: • IP address: 192,168,100.1 • Network mask: 255,255,255.0 • Gateway: 192,168,100,254 • Primary NetBIOS name: "br" + MAC address • Secondary NetBIOS name: "br" + "eip" + address switch number (decimal) • X2X Link configuration: 1 ms cycle time • X2X Link cable length: 0 m

4.5.9.9 Setting the IP address (default value)

Changes to the network address switch are only applied after a restart (power cycle). If the bus controller is restarted with the address switch number 0xFF, it is initialized with the IP address 192.168.100.1. This address is also the default address upon delivery.
This IP can be used to establish a connection to the bus controller. The internationally unique MAC address is listed on the housing side of the bus controller. The combination of "br" and the MAC address results in a unique name (primary NetBIOS name) that also makes it possible to access the bus controller.

Example for the primary NetBIOS names:

MAC address:	00-60-65-00-49-02
Resulting NetBIOS name:	br006065004902

This means that, without additional parameter changes, either the default IP address 192.168.100.1 or the NetBIOS name "br+MAC" can be used to communicate with the controller.

The bus controller can only be accessed via this name if there are no intermediary routers or gateways because the NetBIOS method is used.

4.5.9.10 Automatic IP assignment by DHCP server

At an address switch position between 0x80 and 0xEF, the bus controller attempts to request an IP address from the DHCP server. To query this IP address, simply run a "ping" command with the host name. The bus controller registers this host name on the DHCP server, which should forward it to a DNS server.

Example: The host name (DNS name) is made up of three elements:
"br" + "eip" + address switch value (three decimal places)
This means that a address switch value of e.g. 0xD7 (dec. 215) would result in the following host name: "breip215"

If DNS service is not available on the network, the bus controller's two NetBIOS names can also be used for access. The secondary NetBIOS name is identical to the host name; at address switch value 0x00, it is identical with the primary NetBIOS name. The bus controller can only be reached via its NetBIOS name if no other routers or gateways are in the way.

4.5.9.11 Changing the IP address with the network address switches

The address switches can be used to change the last byte in the IP address configured on the bus controller. The IP address saved in flash memory is not changed. If the address switches are set to 0x00, the bus controller applies the IP address last saved to flash memory. Switch positions between 0x01 and 0x7F cause the last position of the IP address (the lowest byte) to be overwritten by the value of the address switch. This provides the user a quick and easy way to address a large number of bus controllers. In short, an IP address between 192.168.100.1 and 192.168.100.127 can be selected for a bus controller using the address switches without requiring any additional software configuration.

4.5.9.12 Saving an IP address in flash memory

The IP parameters in the flash memory can be changed via the EtherNet/IP protocol or using the Telnet interface (see EtherNet/IP in User's Manual). If the IP address should be set via the TCP/IP object (class 0xF5), then the new address is only saved in the flash if the instance attribute 3 (Configuration Control) of the TCP/IP object is set at 0 (see CIP specification).

4.5.10 X20(c)BC00E3

4.5.10.1 General information

PROFINET (Process Field Network) is an Industrial Ethernet protocol. It uses TCP/IP and is real-time capable.

PROFINET IO was developed for real-time (RT) and synchronous communication (IRT = Isochronous Real Time). The designations RT and IRT merely describe the real-time properties for communication taking place within PROFINET IO. PROFINET IO defines how all data is exchanged between controllers (masters) and devices (slaves) and how parameter settings and diagnostics are handled. The bus system is designed to exchange data between Ethernet-based field devices using the producer/consumer model.

X20 modules or other modules that are based on X2X Link can be connected to the bus controller. Modular system configurations are optimally supported by PROFINET. Using the device description file (GSDML format), it is very easy to handle project configuration in the respective engineering tool from the manufacturer of the master device.

- Fieldbus: PROFINET RT
- I/O configuration via the fieldbus
- Conformance Class B
- Minimum cycle time 1 ms
- Integrated switch for cabling multiple slaves
- 100 Mbit/s full duplex mode
- Up to 1440 bytes of input data and up to 1440 bytes of output data are possible
- Implemented web interface
- PROFINET diagnostics and module diagnostics during runtime from within the master environment
- Module and switch diagnostics during runtime using the Web interface or SNMP

4.5.10.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

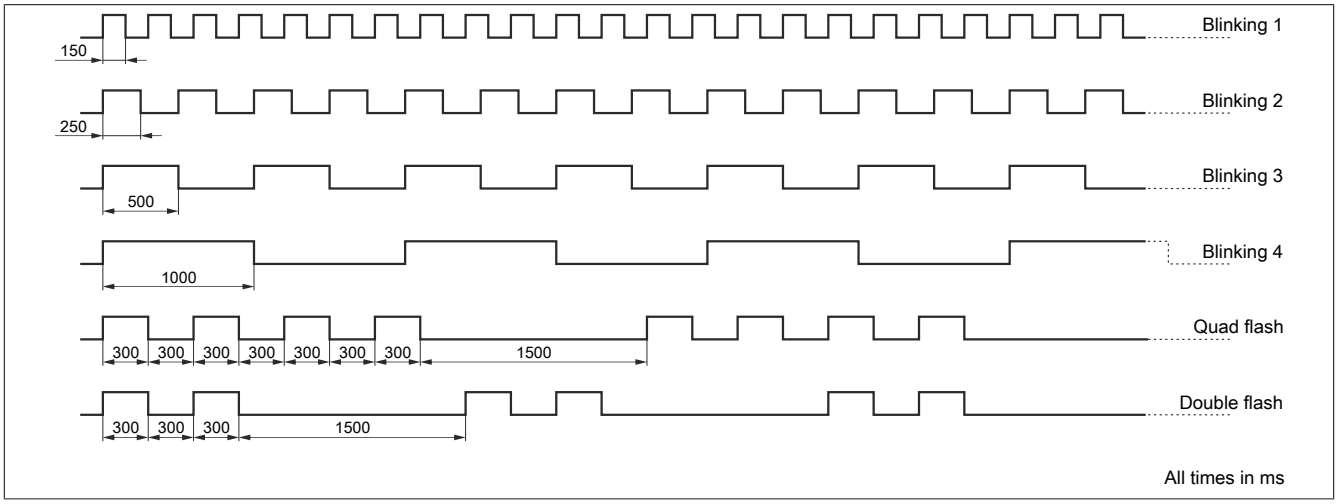
4.5.10.5 LED status indicators

The following table lists the status LEDs available on the bus controller. Exact blink times are specified in the timing diagram in the next section.

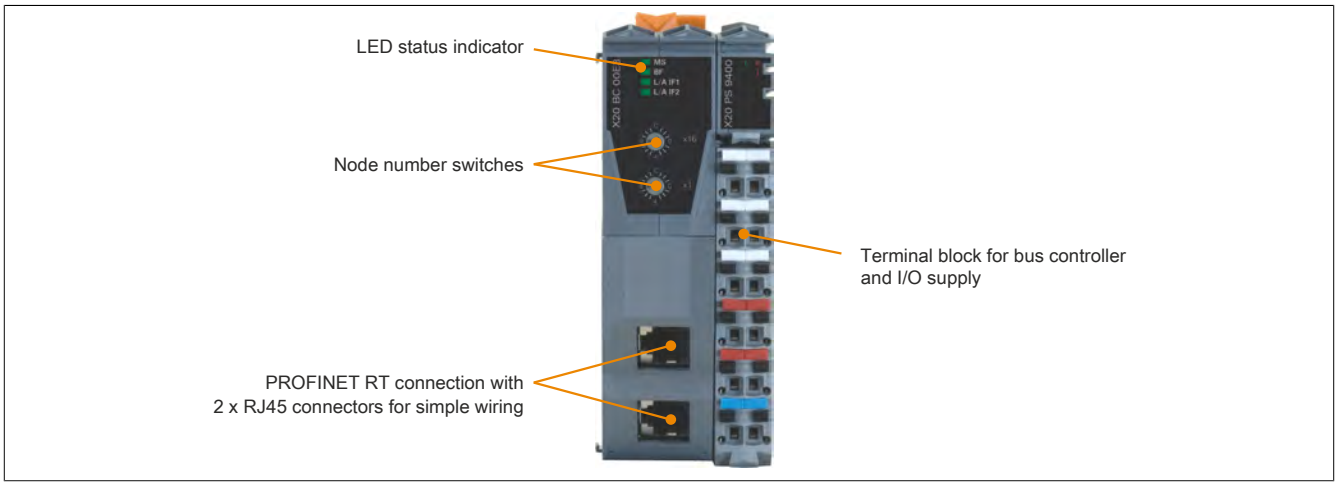
Figure	LED	Color	Status	Description
	MS[1]	Green	Off	The PROFINET master is in "Stop" mode.
			Quad flash	The bus controller does not have a valid IP address (0.0.0.0). It will wait in this state until it is assigned an IP address from the PROFINET master or from an external source. This state can also occur if the bus controller is being operated in DHCP mode.
			Double flash	An unacknowledged alarm is pending on the bus controller.
			Blinking 1	The bus controller is in the initialization phase. This boot phase is where all connected I/O modules are initialized.
			Blinking 3	The bus controller is configuring the connected I/O modules. The configuration is transferred to the bus controller via the PROFINET master.
			On	A connection to a PROFINET master has been established. The master and slave are both in OPERATIONAL mode and data is being exchanged between them. This mode also indicates that the master itself is in RUN mode.
		Red	Blinking 4	The bus controller has detected an error. However, it can still be corrected in the master environment during runtime.
			Blinking 1	The bus controller has detected an error. This error cannot be corrected during runtime; a restart is required.
	BF[1]	Green	Blinking 2	Device identification ("blink" function in step 7 when searching for existing Ethernet stations).
			On	A connection to a PROFINET master has been established.
		Red	On	Not connected to a PROFINET Master
	L/A IFx	Green	Off	No physical Ethernet connection exists.
			Blinking	The respective LED blinks when Ethernet activity is detected on the corresponding RJ45 port (IF1, IF2).
			On	Connection (link) established, but no communication is taking place.

1) The "MS" and "BF" LEDs are green/red dual LEDs.

Status LEDs - Blinking patterns

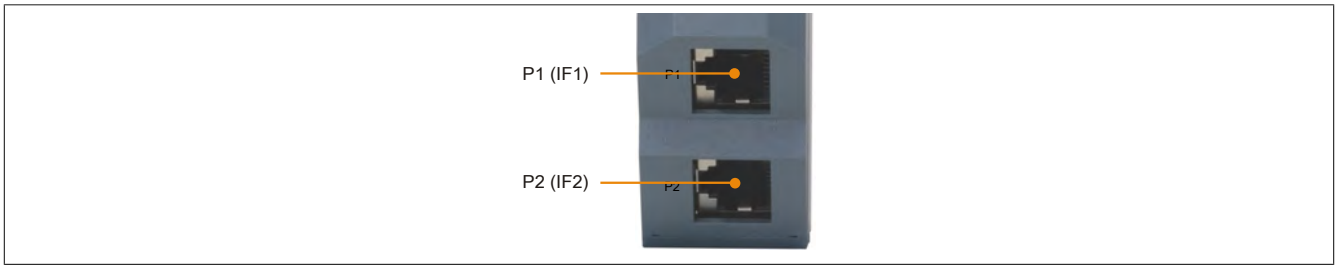


4.5.10.6 Operating and connection elements



4.5.10.7 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.5.10.8 Node number switches

The bus controller has 2 node number switches. The bus controller can be set to different operating modes using certain, pre-defined switch positions. They can also be used to configure various additional parameters (PROFINET device name, DHCP mode, etc.).

Switch position	Description
0x00	All parameters are loaded from flash memory: Default PROFINET initialization via the DCP protocol (factory state)
0x01 - 0xEF	These switch positions generate a valid PROFINET device name. This name is composed as follows: "brpnXXX". XXX refers to the decimal value of the node number switch position. The system automatically adds any necessary leading zeros.
0xF0	Clears flash (see 4.5.10.9 "Erasing flash memory" on page 768)
0xF1 - 0xFD	Reserved, switch position not permitted
0xFE	IP address via DHCP server
0xFF	All parameters set to default: PME mode

Default PROFINET factory state - Node number switch position 0x00

Parameter	Value
IP address	0.0.0.0
Subnet mask	0.0.0.0
Gateway	0.0.0.0
PROFINET device name	"" ... no factory default name

Default parameters - Node number switch position 0xFF

Parameters cannot be changed by the master in node switch position 0xFF.

Parameter	Value
IP address	192,168,100.1
Subnet mask	255,255,255.0
Gateway	192,168,100,254
PROFINET device name	x20bc00e3

4.5.10.9 Erasing flash memory

Erasing flash memory using switch position 0xF0 returns the bus controller to its factory state.

Procedure

1. Turn off the power supply to the bus controller.
2. Set the node number to 0xF0.
3. Turn the power supply to the bus controller back on.
4. Wait until the "MS" LED flashes green for 5 s. The node number switch must be set to 0x00 and then back to 0xF0 within this time window of 5 seconds (rotate the top switch).
5. Wait until the "MS" LED blinks with a red double-flash (flash has been cleared).
6. Turn off the power supply to the bus controller.
7. Set the desired node number (0x00 - 0xEF)
8. Turn the power supply to the bus controller back on.
9. The bus controller boots with the configured node number.

4.5.10.10 Web interface

The integrated Web interface gives the user an overview of the bus controller's network parameters, the configured I/O modules and the switch configuration. The starting page includes information regarding specific bus controller settings such as IP address, host name and the PROFINET device name. In addition, the web page provides information about the current firmware version. Information concerning module diagnostics is incorporated into a tree structure. Expanding and collapsing the individual module nodes provides an overview of the configured I/O modules. In addition, various package counters are read from the integrated switch. This makes diagnosing errors on the network quick and easy.

Network parameters concerning the bus controller itself can be read, but they cannot be modified. The bus controller's IP configuration is handled during booting or by the PROFINET master when a connection is established.

Each page of the Web interface contains help information that describes the functions and parameters displayed on that page. The link to this information can be found in the upper right corner of the page in the form of a question mark.

A connection to the web interface is established by entering the **current IP address** or the unique **host name** in a Web browser. Some functions require authentication.

The host name is composed of a predefined text and a unique MAC address. For example, if the bus controller has the MAC address 00:60:65:11:22:33, this will result in the following host name: **br006065112233.**

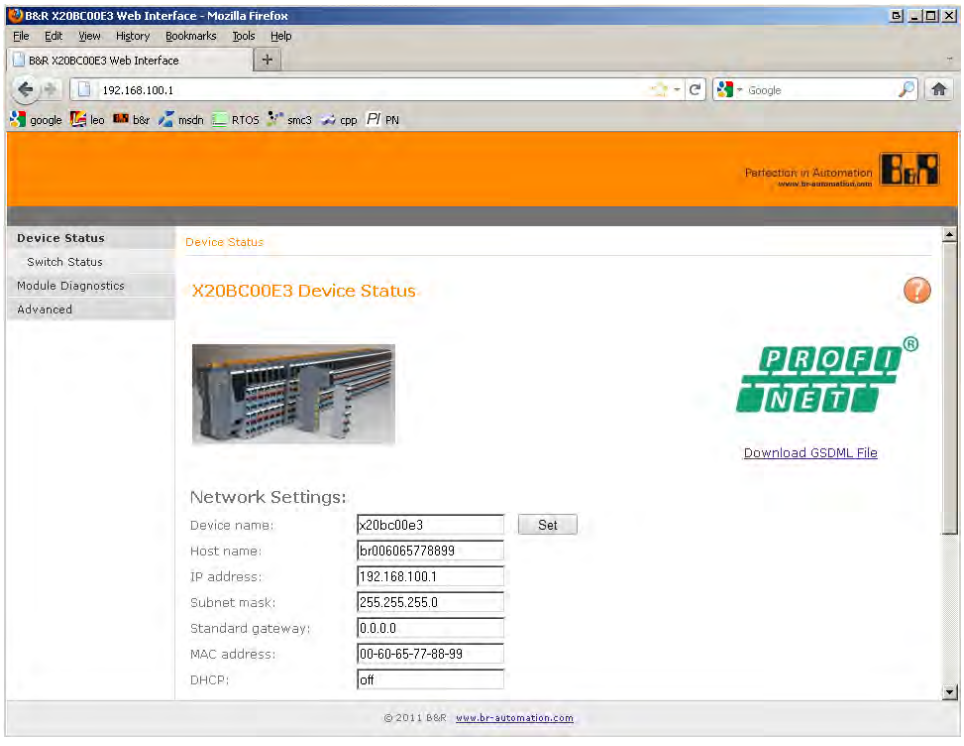
Default parameters for the web interface

IP address:	192.168.100.1
Username:	admin
Password:	B&R

Information:

Take note of the node number switch position.

Please note that authentication parameters are case-sensitive.



4.5.11 X20BC00G3

4.5.11.1 General information

EtherCAT is an Ethernet-based fieldbus developed by Beckhoff. The protocol is suitable for hard and soft real-time requirements in automation technology. In addition to a ring structure, which becomes logically necessary because of the summation frame telegram used, the EtherCAT technology also physically supports topologies such as line, tree, star (limited) and combinations of these topologies. B&R's X20BC80G3 (expandable bus controller module) and X20HB88G0 (stand alone junction base module) are available for implementing these topologies.

EtherCAT slave devices take the data designated for them from a telegram as it is passing through the device. Input data is also inserted in the telegram as it is passing through. The X20BC00G3 bus controller allows X2X Link I/O modules to be coupled to EtherCAT and can be operated on any EtherCAT master system. A transition between IP20 and IP67 protection outside of the control cabinet is possible by aligning X20, X67 or XV modules one after the other as needed at distances up to 100 m.

Master systems without FoE (File Access over EtherCAT) support require an appropriate configuration tool to transfer the configuration (optional).

- Fieldbus: EtherCAT
- Auto-configuration of I/O modules
- I/O configuration and firmware update via the fieldbus (FoE)
- Full support of the modular slice concept via CoE (CANopen over EtherCAT)
- Configurable I/O cycle (0.2 to 4 ms)
- Synchronization between the fieldbus and X2X Link
- X20BC80G3 module type with two additional output ports (X20HB28G0)

Information:

Only the default function model is supported (see respective module description) when the bus controller automatically configures multi-function modules.

All other function models are supported when configured accordingly (see EtherCAT user's manual). The easy-to-use B&R FieldbusDESIGNER can help in this regard and is available for free download from www.br-automation.com/designer.

Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20PS9400 or X20PS9402 power supply module separately Order 1x X20BB80 bus base separately
Spacing 3)	37.5 $^{+0.2}$ mm

Table 127: X20BC00G3 - Technical data

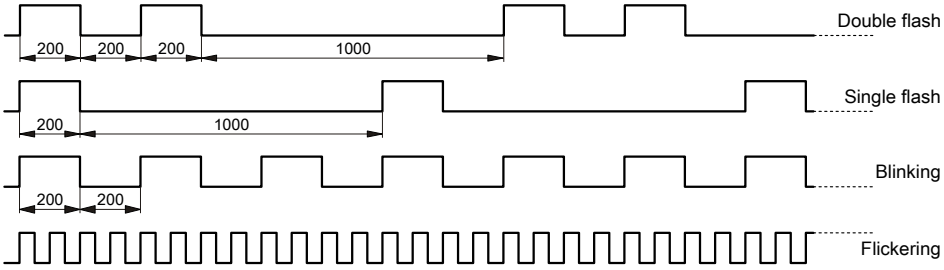
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.11.4 LED status indicators

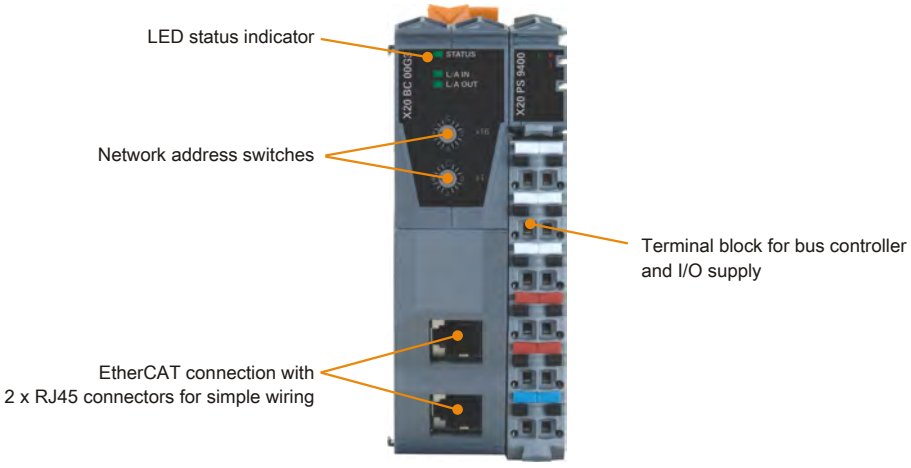
Figure	LED	Color	Status	Description
	STATUS[1]	Green	On	The bus controller is OPERATIONAL.
			Blinking	PREOPERATIONAL status
			Single flash	SAFE-OPERATIONAL status
			Flickering	The bus controller has started and is not yet in INIT status or it is in BOOTSTRAP status (e.g.while downloading firmware).
			Off	INIT status
		Red	On	A critical communication or application error has occurred.
			Blinking	Invalid configuration data
			Single flash	The bus controller has an internal error and changed the EtherCAT status on its own
			Double flash	Watchdog timeout (process data watchdog or EtherCAT watchdog)
			Flickering	Error in the start procedure (INIT status has been achieved, but the error indicator bit in the AL status register is set)
			Off	No error
	L/A IN L/A OUT	Green	Blinking	The respective LED blinks when Ethernet activity is present (PORT OPEN) on the corresponding RJ45 port (IN, OUT).
			On	Connection (link) established, however no communication (PORT OPEN).
			Off	No physical Ethernet connection exists (PORT CLOSED).

1) The "STATUS" LED is a green/red dual LED and is used to indicate EtherCAT states ERROR and RUN.

Status LEDs - Blinking patterns

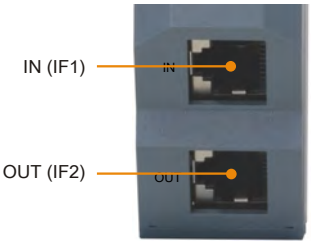


4.5.11.5 Operating and connection elements



4.5.11.6 RJ45 ports

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.5.11.7 EtherCAT network address switch

A slave alias address can be set using the two network address switches on the bus controller. During the initialization phase (during start-up), the bus controller writes the value of the address switch to the ESC register 0x12 or 0x13. However, the value is only accepted in the register if the value of the switch value is between 0x00 and 0xFA (decimal 250).

Switch position	Description
0x00 to 0xFA	Writes the address switch value to the "Station Alias" register.
0xFB to 0xFE	Address switch value not used. ESC Alias registers not changed.
0xFF	Address switch value not used. ESC Alias registers not changed. The bus controller boots with the default values if the address switch is set to the value "0xFF" before a restart. All set parameters remain unchanged in flash memory.

The master determines whether the alias address is used for the slave addressing by setting the corresponding bit in the ESC DL control register (bit 24).

4.5.12 X20BC0143-10

4.5.12.1 General information

CAN (Controller Area Network) systems are widespread in the field of automation technology. CAN topology is based on a line structure and uses twisted wire pairs for data transfer. CANopen is a higher-layer protocol based on CAN. As a standardized protocol, it provides a high degree of flexibility for implementing a wide range of configurations.

The X20BC0043-10 bus controller makes it possible to connect up to 253 X2X Link I/O nodes to CANopen. A transition between IP20 and IP67 protection outside of the control cabinet is possible by aligning X20, X67 or XV modules one after the other as needed at distances up to 100m. All CANopen transmission types such as synchronous, event and polling modes are supported together with PDO linking, life/node guarding, emergency objects, and much more.

- Fieldbus: CANopen
- Auto-configuration of I/O modules
- I/O configuration via the fieldbus (also supported by the B&R FieldbusDESIGNER)
- Constant response times even with large amounts of data (max. 32 Rx and 32 Tx PDOs)
- Configurable I/O cycle (0.5 - 4 ms)
- Possible to configure the transfer rate or have it detected automatically
- Heartbeat consumer and producer
- Emergency producer
- 2x SDO server, NMT slave
- Simple bootup (autostart)
- Terminal access via the serial interface on the X20PS9400

Information:

Only the standard function model (see the respective module description) is supported when the bus controller is used together with multi-function modules it has automatically configured itself.

The B&R FieldbusDESIGNER can be used to create configuration files (e.g. DCF files) in six easy steps. All other function models are also supported by transferring configuration data to the bus controller (e.g. from the master environment with an SDO download or via the serial interface).

The B&R FieldbusDESIGNER is available free of charge in the download section of the B&R website www.br-automation.com.

Table 129: X20BC0143-10 - Technical data

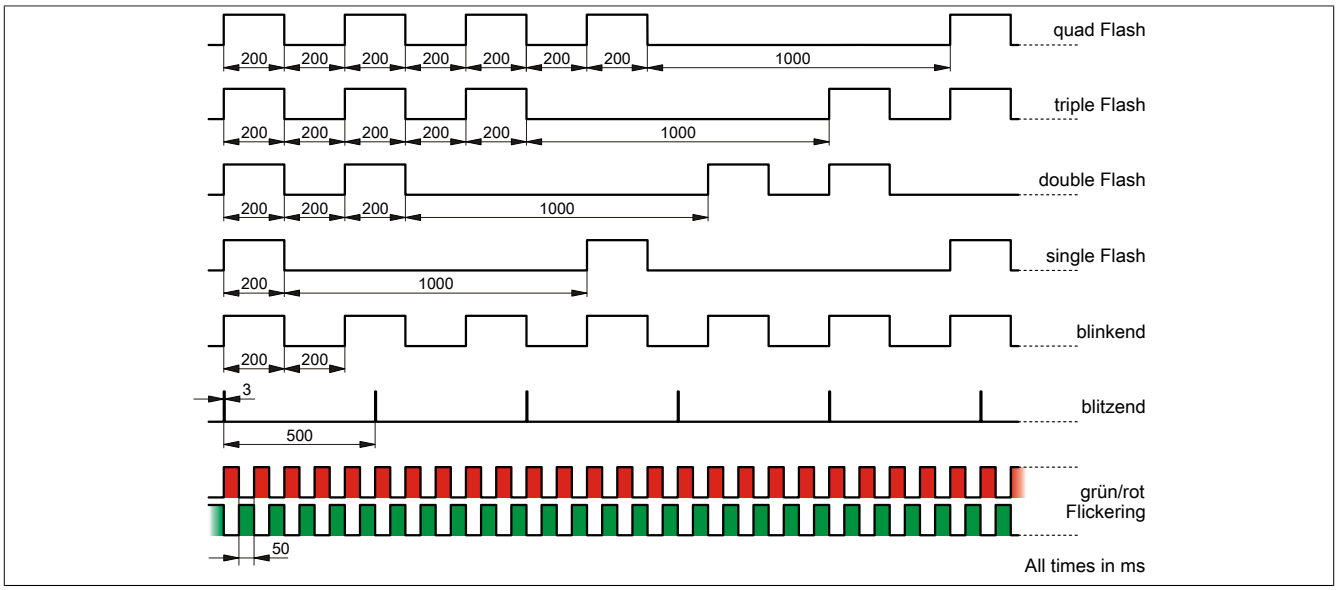
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring.
3) Spacing is based on the width of the X20BB80 bus base. In addition, an X20PS9400 or X20PS9402 supply module is always required for the bus controller.

4.5.12.4 LED status indicators

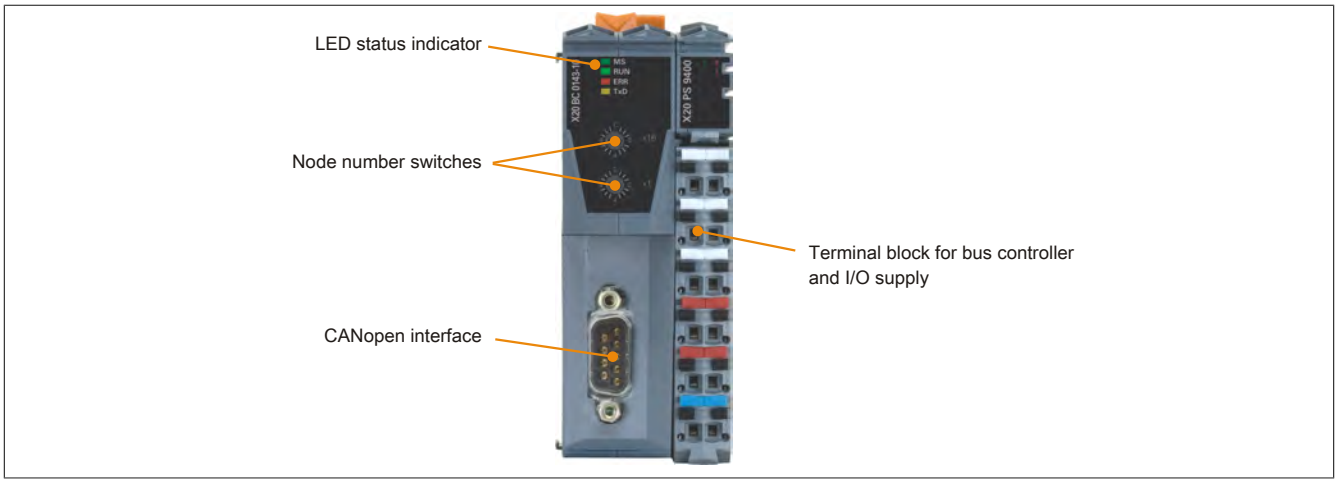
Figure	LED	Color	Status	Description
	MS [1]	Green	Off	No power supply
			Flashing	5 s window for deleting all configuration settings
			On	Boot procedure OK, I/O modules OK
		Red	Double flash	Successfully erased flash memory
			Triple flash	Successfully saved transfer rate
			Quad flash	Successfully saved configuration
			On	I/O modules: Error message or incorrect configuration
	RUN	Green	Off	No power supply
			Single flash	STOP mode
			Triple flash	Firmware download in progress
			Blinking	PREOPERATIONAL mode
			On	OPERATIONAL mode
	ERR	Red	Off	No power supply or everything is OK
			Single flash	CAN warning limit reached
			Double flash	Node guarding / heartbeat error
			Blinking	Invalid node number or configuration
			On	Bus errors: Bus off
	RUN/ERR	Green/red	Flickering	Transfer rate detection in progress
	TxD	Yellow	Off	The bus controller is not transmitting any data via the CANopen fieldbus
			On	The bus controller is transmitting data via the CANopen fieldbus

1) The "MS" LED is a green/red dual LED. The LED blinks red several times immediately after startup. This is a boot message, however, and not an error.

Status LEDs - Blinking patterns



4.5.12.5 Operating and connection elements



4.5.12.6 CAN bus interface

The CAN bus interface is a 9-pin DSUB plug.

Interface	Pin	CAN	
	1	Reserved	
	2	CAN_L	CAN low
	3	CAN_GND	CAN ground
	4	Reserved	
	5	Reserved	
	6	Reserved	
	7	CAN_H	CAN high
	8	Reserved	
	9	Reserved	

4.5.12.7 Node number and transfer rate

Node numbers and transfer rates are configured using the two bus controller number switches.

The transfer rate can be specified in two ways:

- Automatic detection by bus controller (see 4.5.2.9 "Automatic transfer rate detection")
- Fixed definition by user (see 4.5.2.10 "Setting the transfer rate")

Switch position	Node number	Transfer rate
0x00	Not allowed	-
0x01 - 0x7F	1 - 127	Automatically set by the bus controller (default) or fixed setting by the user
0x80 - 0x88	-	Sets a fixed transfer rate
0x89	-	Sets automatic transfer rate detection
0x8A - 0x8F	Not allowed	-
0x90	Clearing the parameters See section 4.5.2.11 "Clearing parameters"	-
0x91	Not allowed	-
0x92	Save configuration[1)] See section 4.5.3.11 "Save automatic configuration"	-
0x93 - 0xFF	Not allowed	-

1) This function is available starting with Hardware version E0 or Firmware version V0001.0107.

4.5.12.8 Automatic transfer rate detection

After booting, the bus controller goes into "Listen only" mode. This means the bus controller behaves passively on the bus and only listens.

The bus controller attempts to receive valid objects. If receive errors occur, the controller switches to the next transfer rate in the lookup table.

If no objects are received, all transfer rates are tested cyclically. This procedure is repeated until valid objects are received.

Lookup table

The controller tests the transfer rate according to this table. Beginning with the starting transfer rate (1000 kbit/s), the controller switches to the next lower transfer rate. At the end of the table, the bus controller restarts the search from the beginning.

Transfer rate
1000 kbit/s
800 kbit/s
500 kbit/s
250 kbit/s
125 kbit/s
100 kbit/s
50 kbit/s
20 kbit/s
10 kbit/s

4.5.12.9 Setting the transfer rate

The bus controller will detect the transfer rate automatically by default. Switch positions 0x80 - 0x88 can be used to set a fixed transfer rate, or 0x89 can be used to enable automatic transfer rate detection.

Switch position	Transfer rate
0x80	1000 kbit/s
0x81	800 kbit/s
0x82	500 kbit/s
0x83	250 kbit/s
0x84	125 kbit/s
0x85	100 kbit/s
0x86	50 kbit/s
0x87	20 kbit/s
0x88	10 kbit/s
0x89	Automatic transfer rate detection

Table 130: Possible transfer rates

Programming the transfer rate

1. Turn off the power supply to the bus controller.
2. Define the transfer rate to be programmed by setting the node numbers (0x80 - 0x89)
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED blinks with a red triple-flash (transfer rate is now programmed).
5. Turn off the power supply to the bus controller.
6. Set the desired node number (0x01 - 0x7F).
7. Turn on the power supply to the bus controller.
8. The bus controller now boots with the set node number and the programmed transfer rate.

4.5.12.10 Save automatic configuration

The node number position 0x92 can be used to save automatically generated configurations. This makes it possible to work with a standardized configuration without having to adapt the application to changes associated with service work or different development stages for example.

1. Turn off the power supply to the bus controller.
2. Set the node number to 0x90.
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED flashes green.
5. The node number switch must be set to 0x00 and then back to 0x90 within this time window of 5 seconds (rotate the top switch).
6. Wait until the "MS" LED blinks with a red double-flash (parameters have been cleared).
7. Turn off the power supply to the bus controller.
8. Set the node number to 0x92.
9. Turn on the power supply to the bus controller.
10. Wait until the "MS" LED flashes green.
11. The node number switch must be set to 0x02 and then back to 0x092 within this time window of 5 seconds (rotate the top switch).
12. Wait until the "MS" LED blinks with a red quad-flash (parameters have been saved).
13. Turn off the power supply to the bus controller.
14. Set the desired node number (0x01 - 0x7F).
15. Turn on the power supply to the bus controller.
16. The bus controller boots with the set node number and automatic transfer rate detection.

Information:

A mapping tool for decoding the saved PDO mapping is available in the Download section of the B&R website (www.br-automation.com).

Information:

This function is available starting with Hardware version E0 or Firmware version V0001.0107.

4.5.12.11 Clearing parameters

Various parameters can be stored in the bus controller's flash memory:

- Communication parameters
- Vendor-specific parameters
- Application parameters (device profile)
- Programmed transfer rate

Clearing the parameters using switch position 0x90 returns the bus controller to its factory settings.

Clearing the parameters listed above

1. Turn off the power supply to the bus controller.
2. Set the node number to 0x90.
3. Turn on the power supply to the bus controller.
4. Wait until the "MS" LED flashes green. The node number switch must be set to 0x00 and then back to 0x090 within this time window of 5 seconds (rotate the top switch).
5. Wait until the "MS" LED blinks with a red double-flash (parameters have been cleared).
6. Turn off the power supply to the bus controller.
7. Set the desired node number (0x01 - 0x7F).
8. Turn on the power supply to the bus controller.
9. The bus controller boots with the set node number and automatic transfer rate detection.

4.5.12.12 Additional documentation and import files (EDS)

Additional documentation about bus controller functions as well as the necessary import files for the master engineering tool are available in the Downloads section of the B&R website (www.br-automation.com).

4.6 Bus controllers system modules

The X20 system bus controllers are made up of a bus controller fieldbus interface, a bus controller system module and an X20TB12 terminal block.

Bus controller system modules include the base module and the supply modules.

4.6.1 Brief information

Product ID	Short description	on page
X20BB80	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included	782
X20PS9400	X20 power supply module, for bus controller and internal I/O supply, X2X Link supply	784
X20PS9402	X20 supply module, for bus controller and internal I/O supply, X2X Link supply, supply not electrically isolated	791
X20cBB80	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included	782
X20cPS9400	X20 power supply module, coated, for bus controller and internal I/O supply, X2X Link supply	784

4.6.2 X20(c)BB80

4.6.2.1 General information

The following modules are used on the bus module:

- Base module (BC, HB, etc.)
- Supply module

The left and right end plates are included in the delivery.

- Bus base

4.6.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

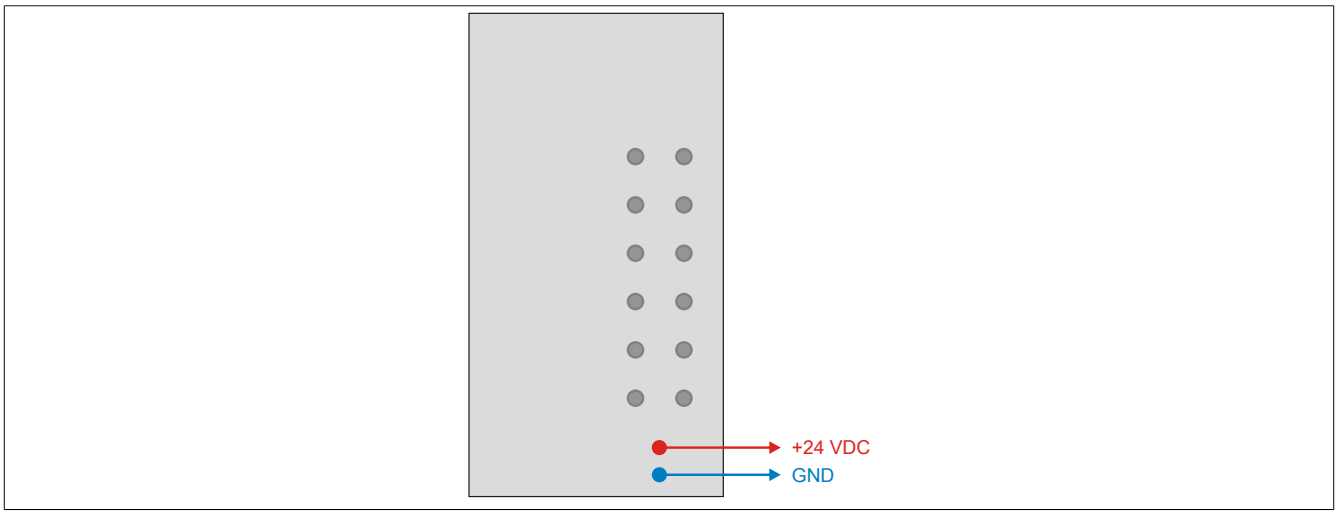
4.6.2.5 Voltage routing



4.6.3 X20(c)PS9400

4.6.3.1 General information

The supply module is used together with an X20 bus controller. It is equipped with a feed for the bus controller, the X2X Link and the internal I/O supply.

- Supply for the bus controller, X2X Link and internal I/O supply
- Feed and bus controller / X2X Link supply electrically isolated
- Redundancy of bus controller / X2X Link supply possible by operating multiple supply modules simultaneously
- Service interface (RS232)

4.6.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Table 134: X20PS9400, X20cPS9400 - Technical data

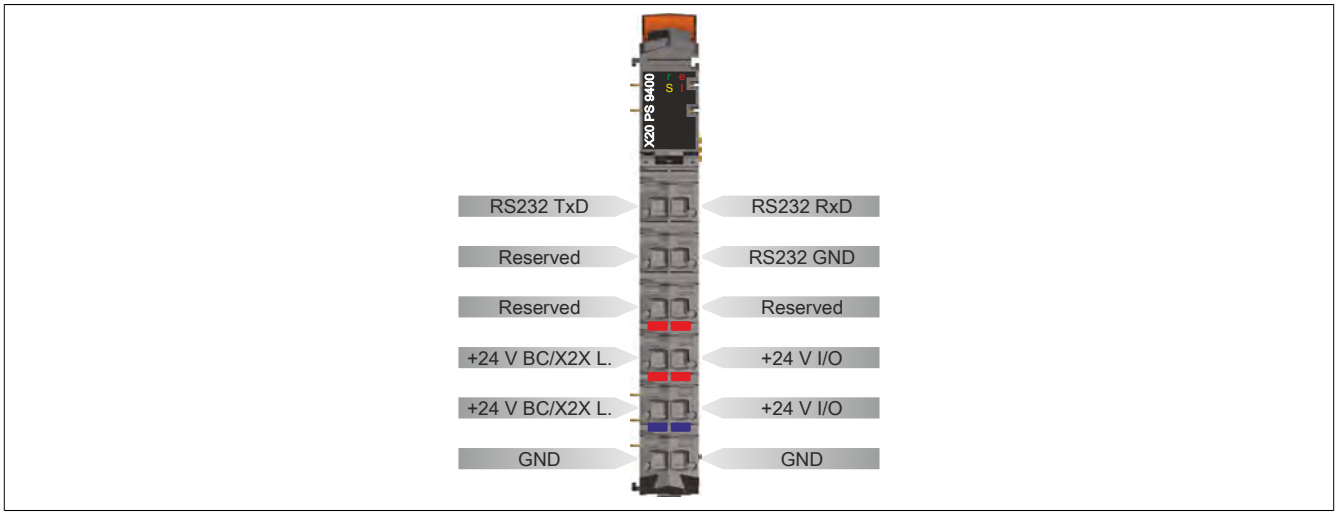
1) The specified values are maximum values. The exact calculation is also available for download as a data sheet with the other module documentation on the B&R website.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

4.6.3.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

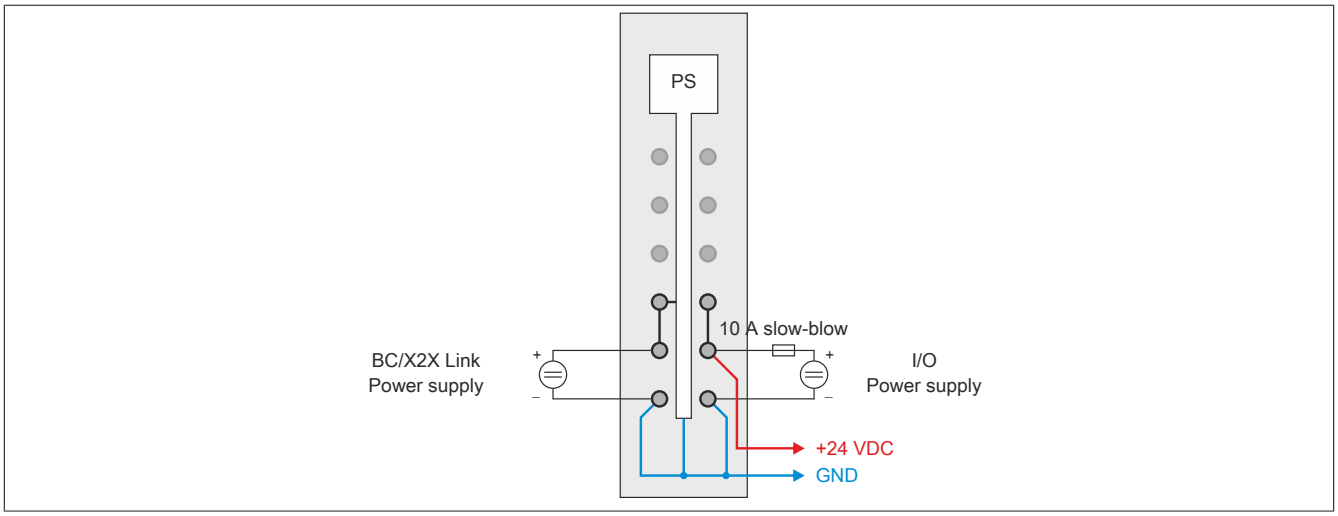
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The bus controller / X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for bus controller / X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	I	Red	Off	The bus controller / X2X Link supply is within the valid limits
			On	The bus controller / X2X Link supply for the power supply is overloaded
	S	Yellow	Off	No data traffic via service interface
			On	Data is being transmitted via the service interface

4.6.3.6 Pinout

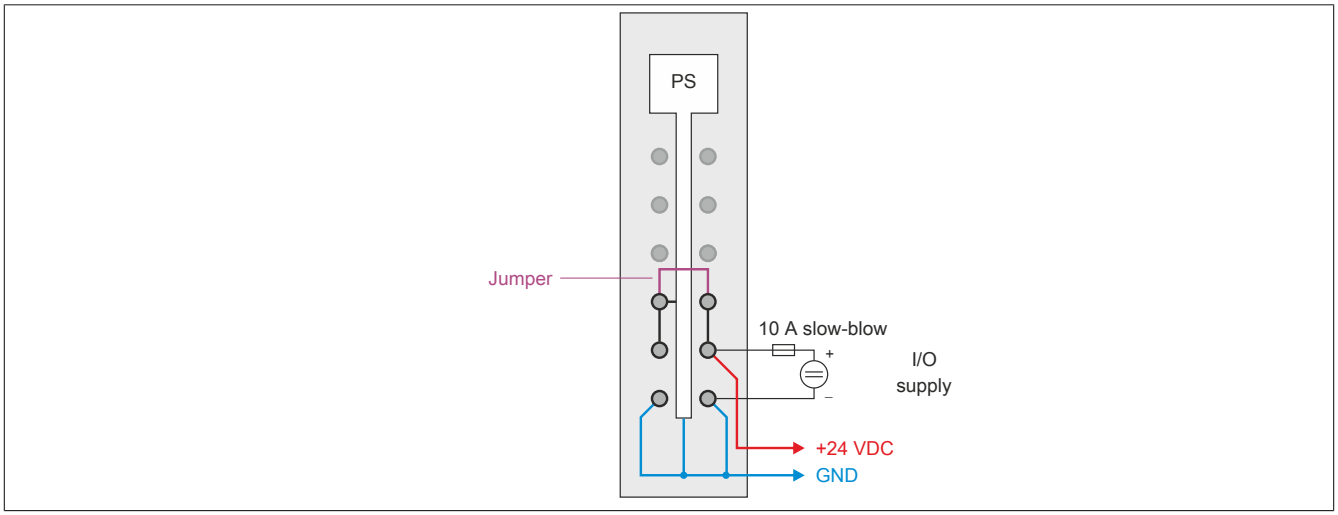


4.6.3.7 Connection examples

With 2 separate supplies

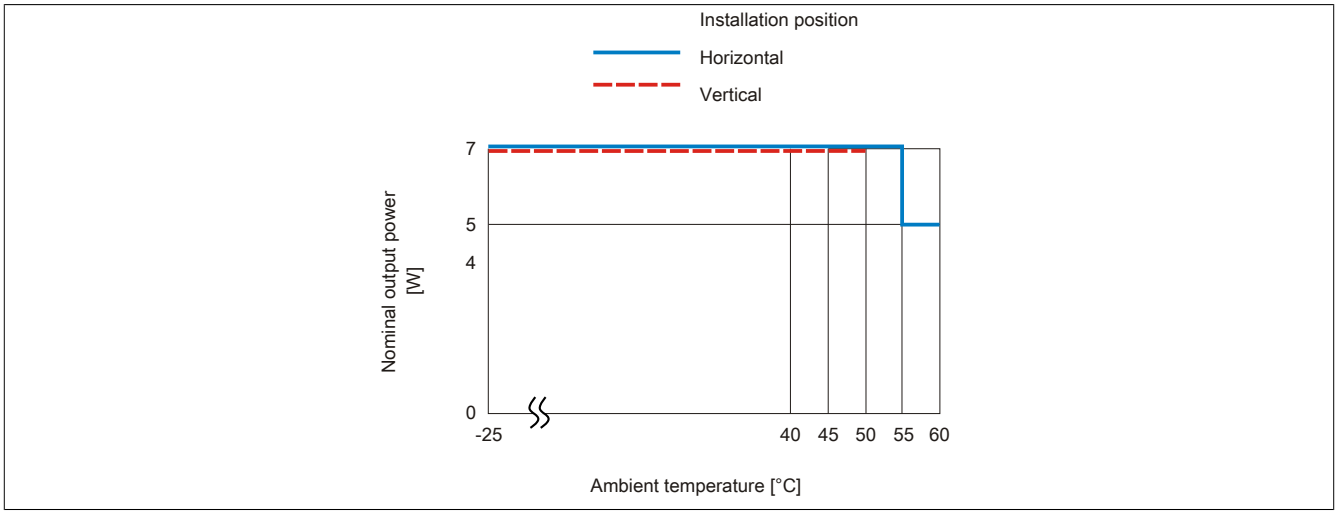


With a supply and jumper



4.6.3.8 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.6.3.9 Using the service interface

The RS232 service interface is not for use in a machine or system application. It is only intended to be used to update the firmware on various bus controllers and X2X modules as well as to save settings.

4.6.3.10 Register description

4.6.3.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.6.3.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.6.3.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
2	2	SupplyCurrent	UINT	•			
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.6.3.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.6.3.10.4 Module status

Name:
Module status

The following voltage and current states of the module are monitored in this register:

Bus supply current:	A bus supply current of >2.3A is displayed as a warning.
Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Warning - overcurrent (>2.3 A) or undervoltage (<4.7 V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.6.3.10.5 Bus supply current

Name:
SupplyCurrent

This register displays the bus supply current measured at a resolution of 0.1 A.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.6.3.10.6 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.6.3.10.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.6.3.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.6.4 X20PS9402

4.6.4.1 General information

The supply module is used together with an X20 bus controller. It is equipped with a feed for the bus controller, the X2X Link and the internal I/O supply.

The module is designed to supply power for smaller X20 systems. Potential groups are able to be formed. An expansion or redundancy of the X2X Link with the X20PS3300 or X20PS3310 supply module is not possible. Expansion of the X20 system with a bus transmitter is not permitted either.

- Supply for the bus controller, X2X Link and internal I/O supply
- Low-cost supply module for small X20 system
- Feed and bus controller / X2X Link supply not electrically isolated
- Expansion or redundancy of bus controller / X2X Link supply not possible by operating multiple supply modules simultaneously

4.6.4.2 Order data

Model number	Short description	Figure

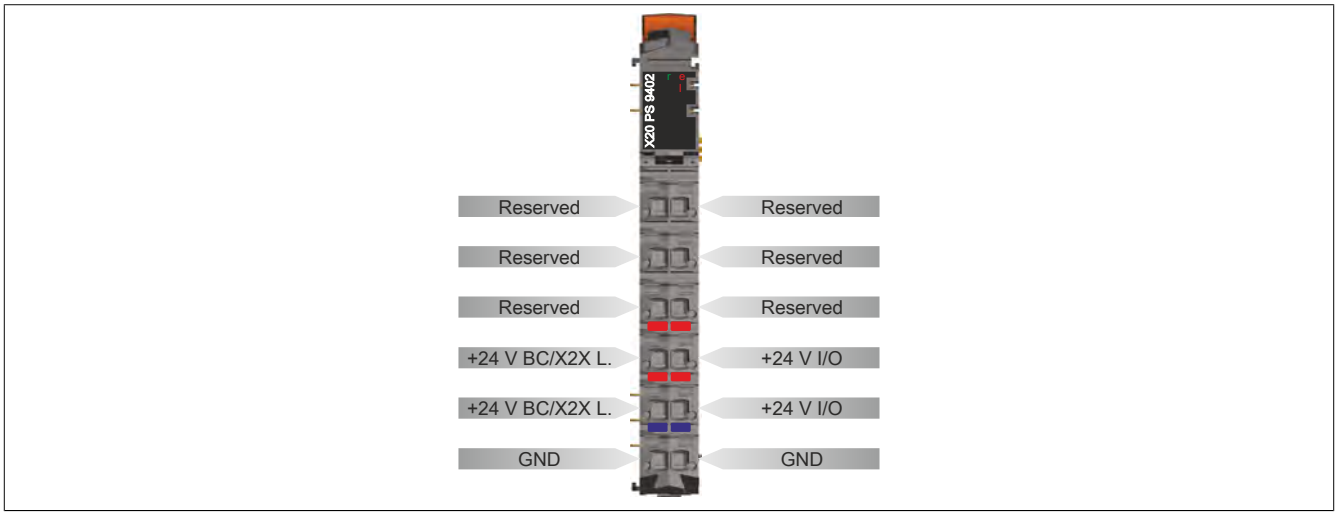
4.6.4.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

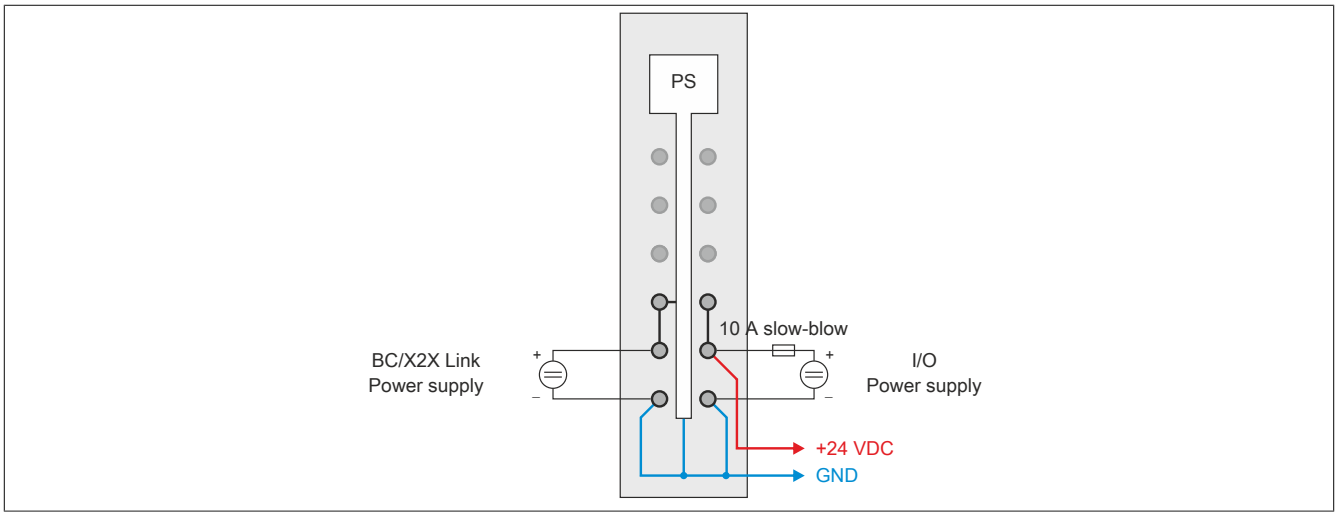
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The bus controller / X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for bus controller / X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware

4.6.4.5 Pinout

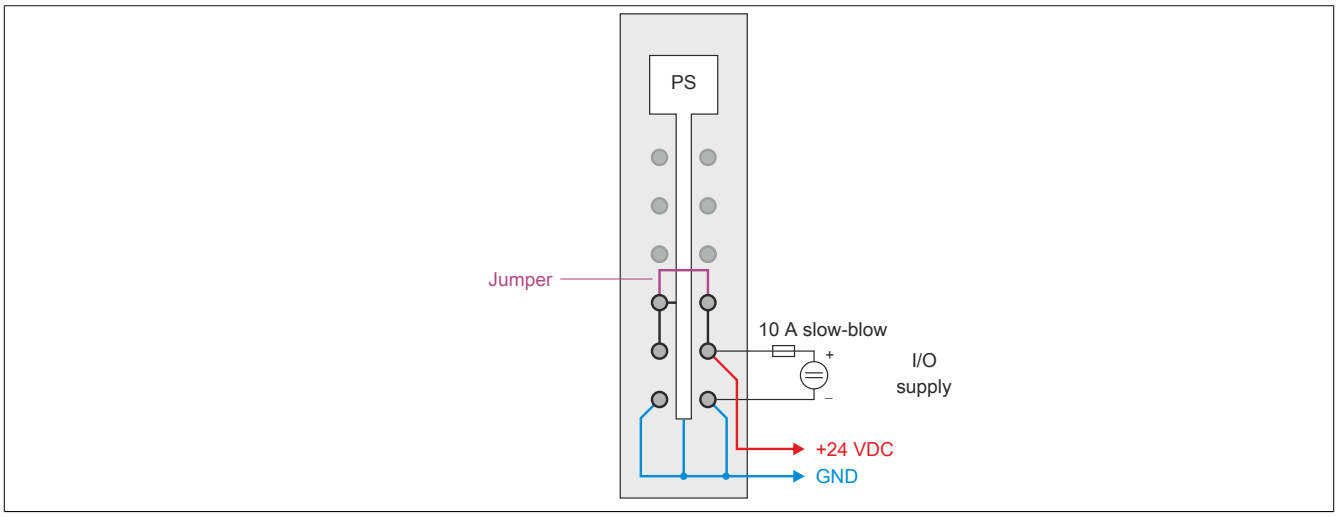


4.6.4.6 Connection examples

With 2 separate supplies

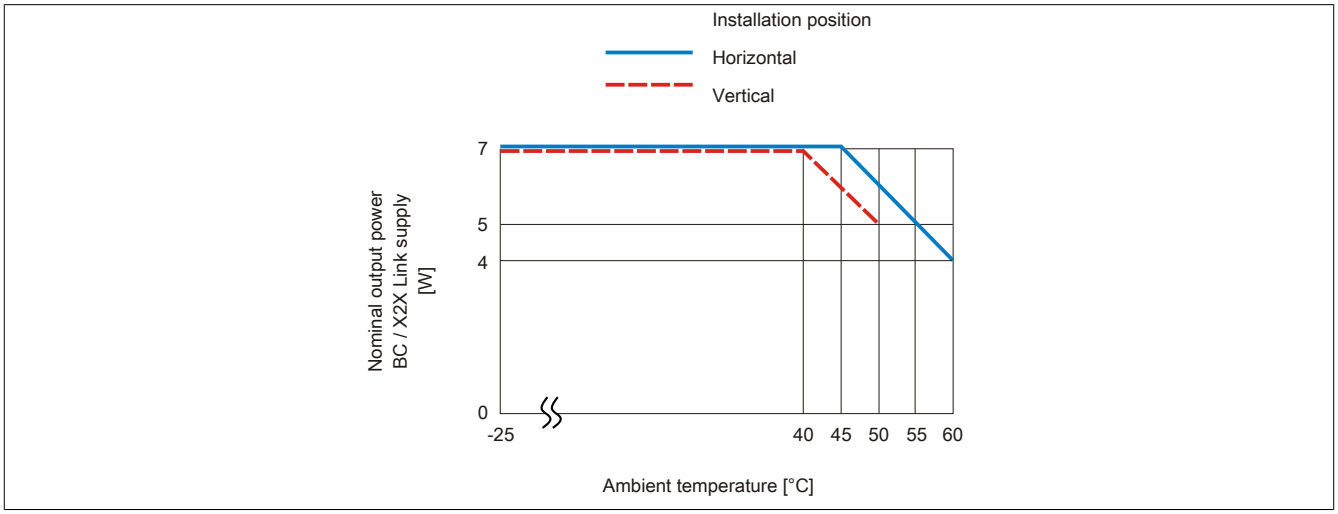


With a supply and jumper



4.6.4.7 Derating for bus controller / X2X Link supply

The rated output current for the bus controller / X2X Link supply is 7.0 W. Derating must be taken into consideration based on mounting orientation.



4.6.4.8 Register description

4.6.4.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.6.4.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
4	SupplyVoltage	USINT	•			

4.6.4.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.6.4.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.6.4.8.4 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Bus supply warning - Undervoltage (<4.7V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.6.4.8.5 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.6.4.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.6.4.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.7 Bus modules

In the X20 system, a bus module takes the place of a rack.

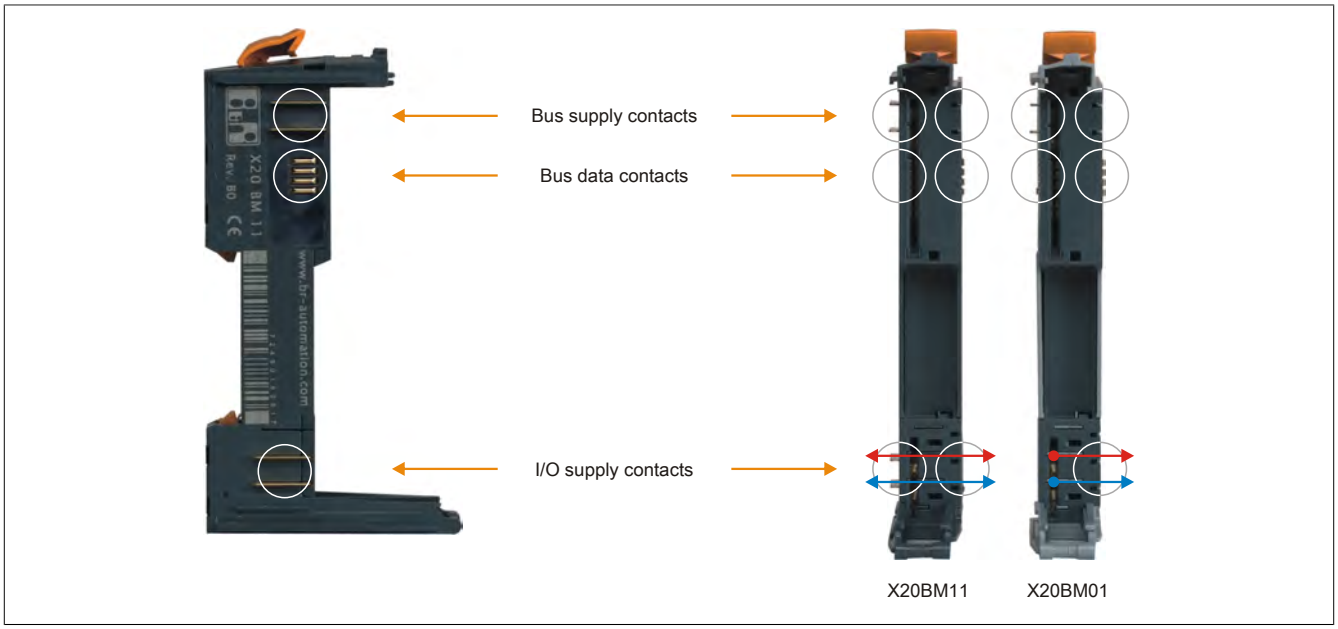


Figure 165: The bus module replaces the rack in the X20 system

The bus module is the backbone of the X20 system regarding the bus supply and bus data as well as the I/O supply for the electronics modules. Each bus module is an active bus station, even without an electronics module. There are two variations of the bus module:

- Interconnected I/O supply
- I/O supply isolated to the left (for power supply modules)

4.7.1 Brief information

Product ID	Short description	on page
X20BM01	X20 power supply bus module, 24 VDC keyed, internal I/O supply interrupted to the left	798
X20BM05	X20 power supply bus module, with node number switch, 24 VDC keyed, internal I/O supply interrupted to the left	800
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	802
X20BM12	X20 bus module, 240 VDC keyed, internal I/O supply continuous	804
X20BM15	X20 bus module, with node number switch, 24 VDC keyed, internal I/O supply continuous	806
X20BM21	X20 power supply bus module, for double-width modules, 24 VDC keyed, internal I/O supply interrupted to the left	808
X20BM31	X20 bus module for double-width modules, 24 VDC keyed, internal I/O supply continuous	810
X20BM32	X20 bus module for double-width modules, 240 VAC keyed, internal I/O supply continuous	812
X20cBM01	X20 power supply bus module, coated, 24 VDC keyed, internal I/O supply interrupted to the left	798
X20cBM11	X20 bus module, coated, 24 VDC keyed, internal I/O supply continuous	802
X20cBM12	X20 bus module, coated, 240 VAC keyed, internal I/O supply continuous	804
X20cBM31	X20 bus module, coated, for double-width modules, 24 VDC keyed, internal I/O supply continuous	810
X20cBM32	X20 bus module, coated, for double-width modules, 240 VAC keyed, internal I/O supply continuous	812

4.7.2 X20(c)BM01

4.7.2.1 General information

The bus module is the base for all supply modules.

- Basis for all power supply modules
- For creating voltage groups
- The internal I/O supply is isolated to the left

4.7.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

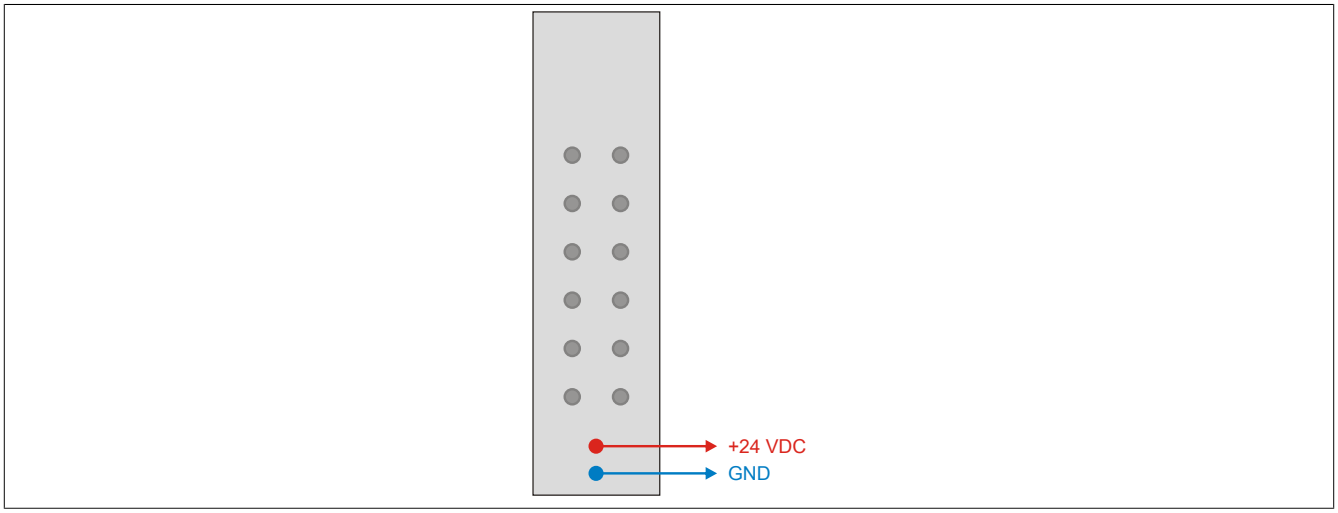
4.7.2.5 Voltage routing



4.7.3 X20BM05

4.7.3.1 General information

The bus modules have node number switches that can be used to set permanent addresses. Placing one of these modules at the beginning of an X20 block ensures a unique address. The addresses of subsequent modules are automatically set in ascending order starting at this address. This simple feature greatly increases the flexibility of applications.

Another advantage: Addresses can be set independently of which specific I/O modules are used. All that is required are the respective bus modules. This provides logistical advantages with respect to cost and the variety of parts.

- The bus module is the base for all X20 supply modules
- For creating voltage groups
- The internal I/O supply is isolated to the left
- Manual node number assignment
- Independent of electronics module
- Manual and automatic addressing can be combined as desired

4.7.3.2 Order data

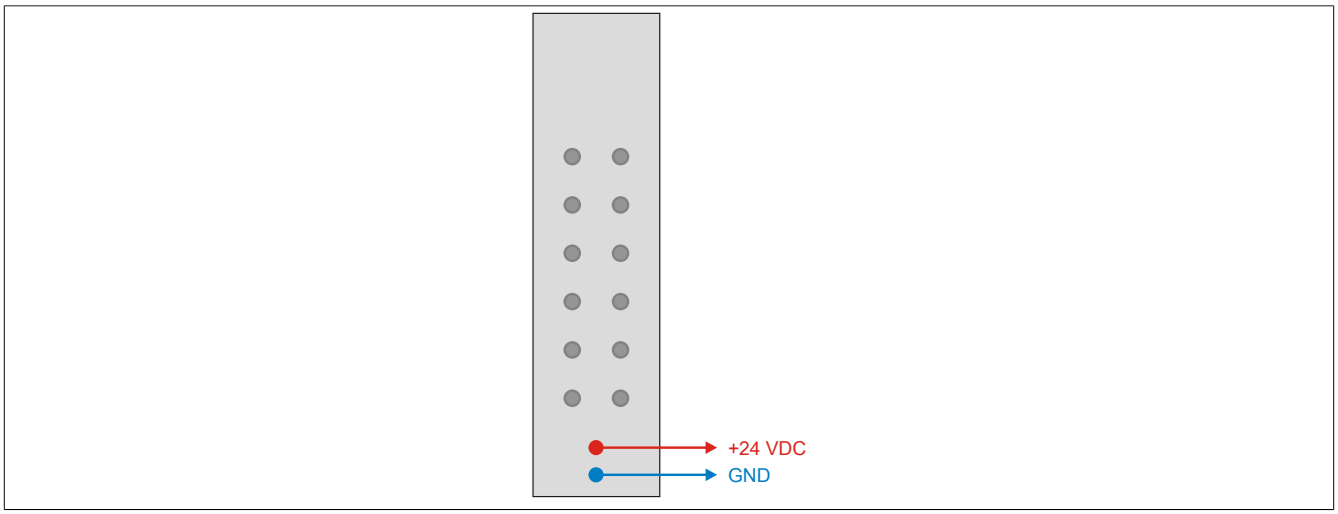
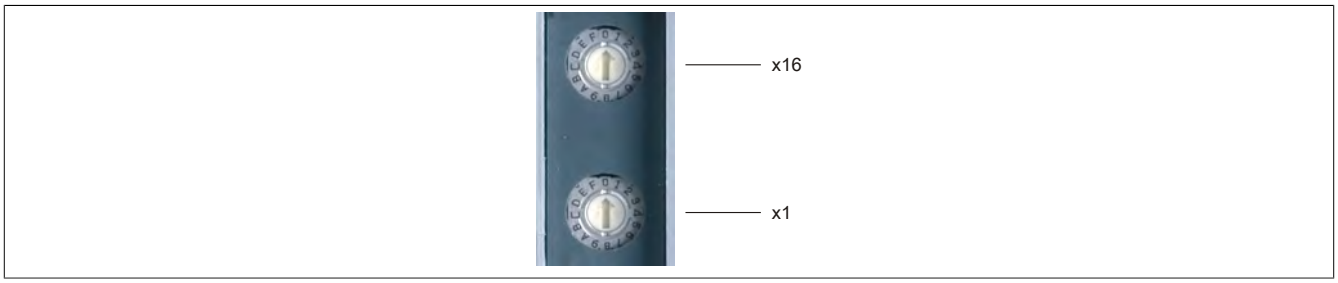
4.7.3.4 Voltage routing



4.7.3.5 Node number switches



The X2X Link address of the module is set using the node number switches (0x01 to 0xFD).

Setting node number 0x00 causes the X2X Link address to be assigned automatically.

4.7.4 X20(c)BM11

4.7.4.1 General information

The bus module serves as the base for all 24 VDC X20 I/O modules. The internal I/O supply is interconnected.

- Bus module for 24 VDC I/O modules
- The internal I/O supply is interconnected

4.7.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

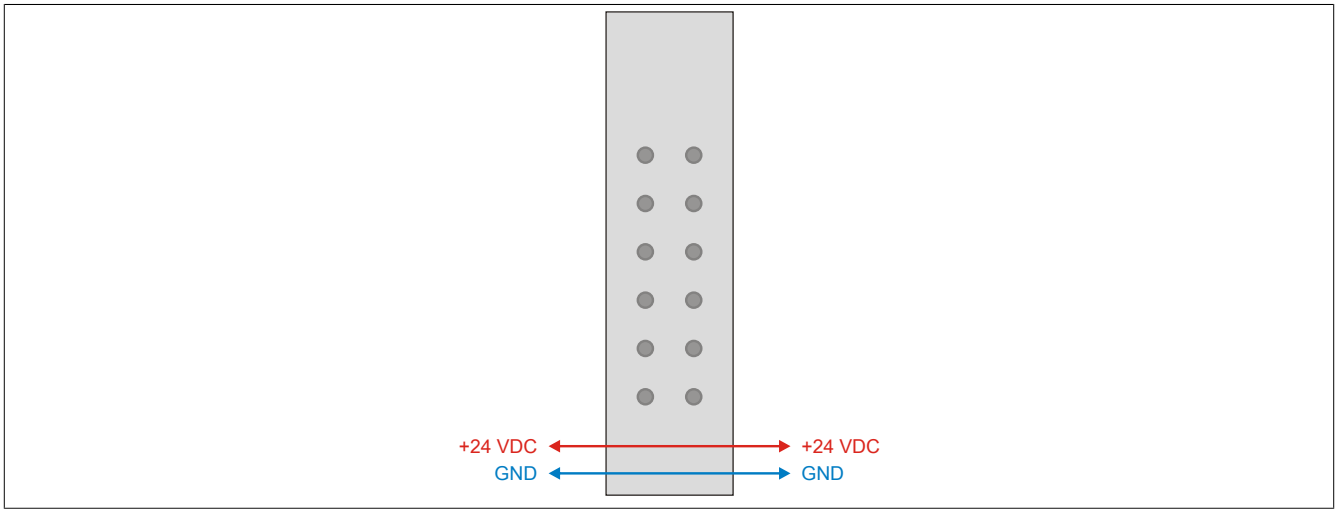
4.7.5.5 Voltage routing



4.7.6 X20BM15

4.7.6.1 General information

The bus modules have node number switches that can be used to set permanent addresses. Placing one of these modules at the beginning of an X20 block ensures a unique address. The addresses of subsequent modules are automatically set in ascending order starting at this address. This simple feature greatly increases the flexibility of applications.

Another advantage: Addresses can be set independently of which specific I/O modules are used. All that is required are the respective bus modules. This provides logistical advantages with respect to cost and the variety of parts.

- The bus module is the base for all X20 24 VDC I/O modules
- The internal I/O supply is interconnected
- Manual node number assignment
- Independent of electronics module
- Manual and automatic addressing can be combined as desired

4.7.6.2 Order data

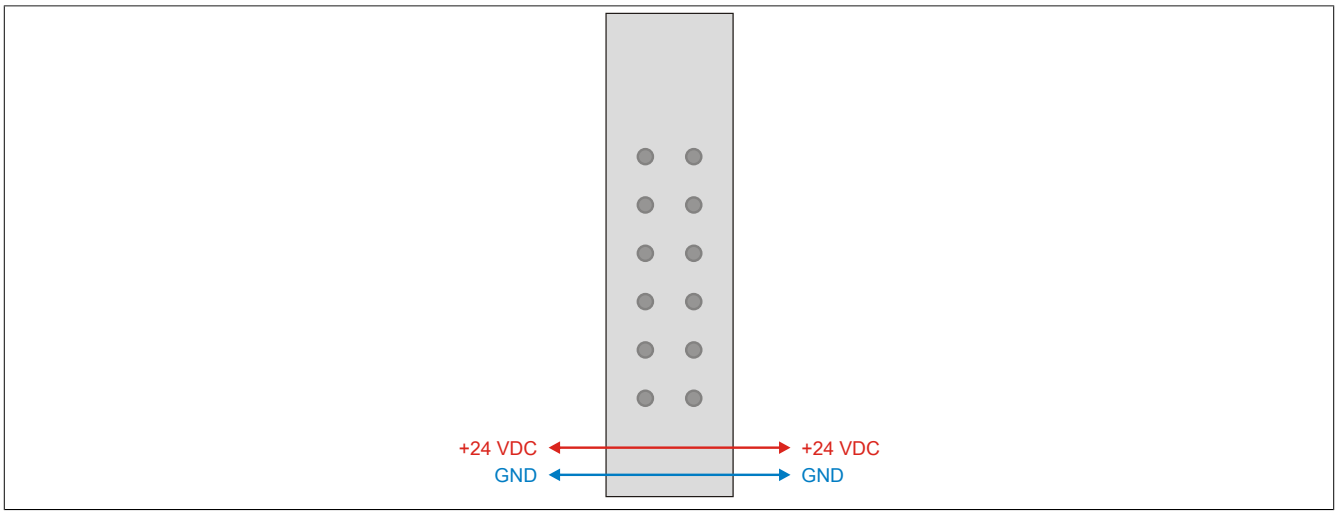
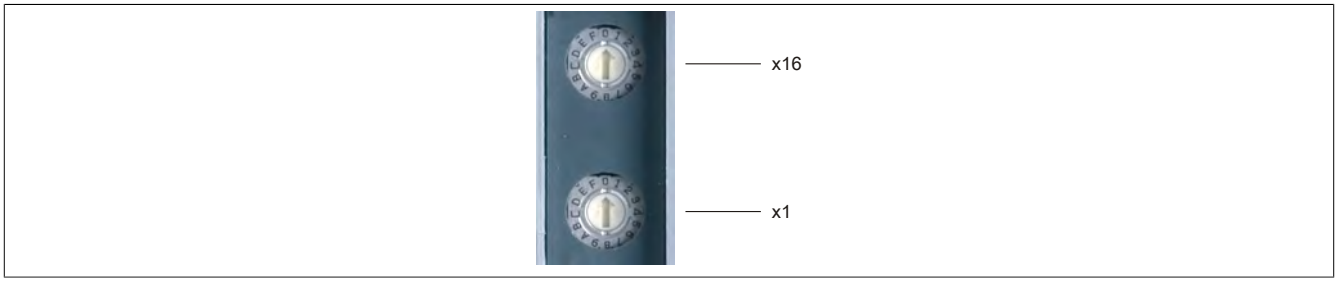
4.7.6.4 Voltage routing



4.7.6.5 Node number switches



The X2X Link address of the module is set using the node number switches (0x01 to 0xFD).

Setting node number 0x00 causes the X2X Link address to be assigned automatically.

4.7.7 X20BM21

4.7.7.1 General information

The bus module serves as a basis for all double-width X20 I/O modules. The internal I/O supply is isolated to the left. This allows the bus module to be used to set up a separate voltage group if the X20BT9100 bus transmitter is used for the supply.

- For creating voltage groups
- The internal I/O supply is isolated to the left

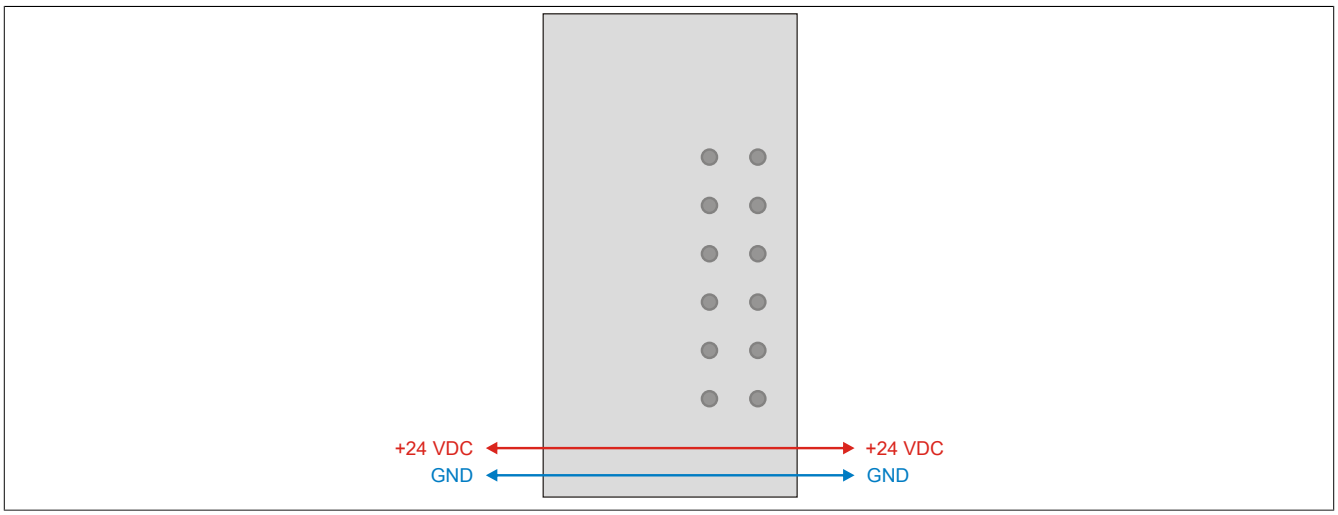
4.7.9.5 Voltage routing



4.8 Bus receivers and Bus transmitters

The bus receiver X20BR9300is used to connect the X20 system directly to the remote X2X Link backplane. The bus transmitter X20BT9100 is used to connect to the next station.

4.8.1 Brief information

Product ID	Short description	on page
X20BR9300	X20 bus receiver, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	815
X20BT9100	X20 bus transmitter, X2X Link, supply for internal I/O supply	821
X20BT9400	X20 bus transmitter X2X Link, feed for internal I/O supply, X2X Link supply for X67 modules, reverse polarity protection, short circuit protection, overload protection, parallel connection possible, redundancy operation possible	828
X20cBR9300	X20 bus receiver, coated, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	815
X20cBT9100	X20 bus transmitter, coated, X2X Link, supply for internal I/O supply	821

4.8.2 X20(c)BR9300

4.8.2.1 General information

The bus receiver is used to connect the X20 System to the X2X Link. The module is equipped with a feed for the X2X Link as well as the internal I/O supply.

The left and right end plates are included in the delivery.

- X2X Link bus receiver
- Feed for X2X Link and internal I/O supply
- Electrical isolation of feed and X2X Link supply
- Redundancy of X2X Link supply possible by operating multiple supply modules simultaneously
- Operation only on the slot to the far left

4.8.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Spacing	12.5$^{+0.2}$ mm	

Table 154: X20BR9300, X20cBR9300 - Technical data

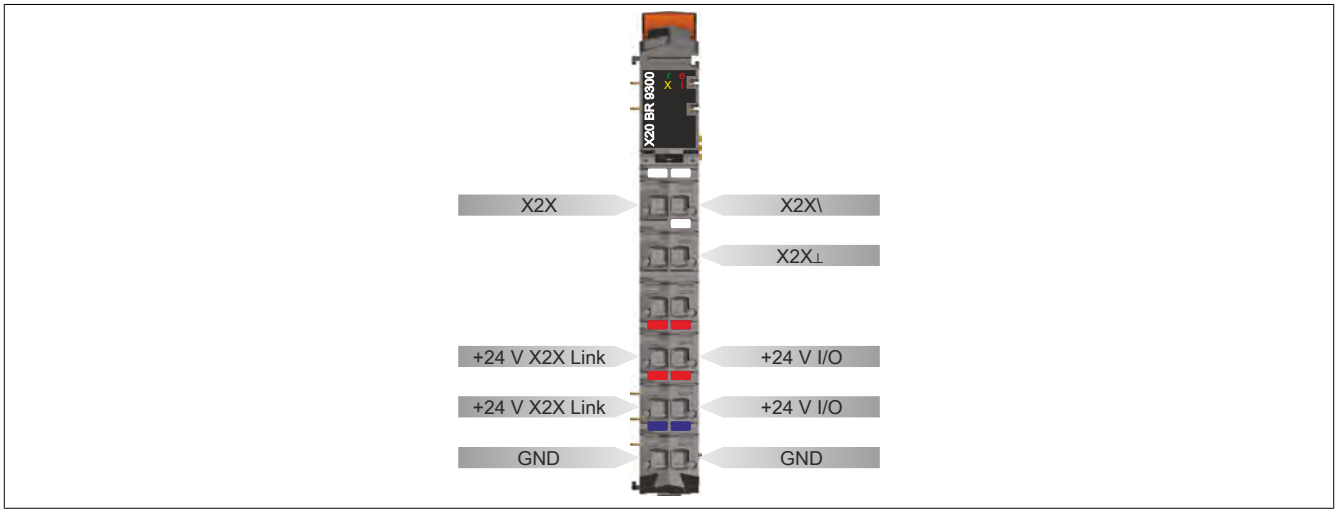
1) The specified values are maximum values. The exact calculation is also available for download as a data sheet with the other module documentation on the B&R website.
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

4.8.2.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

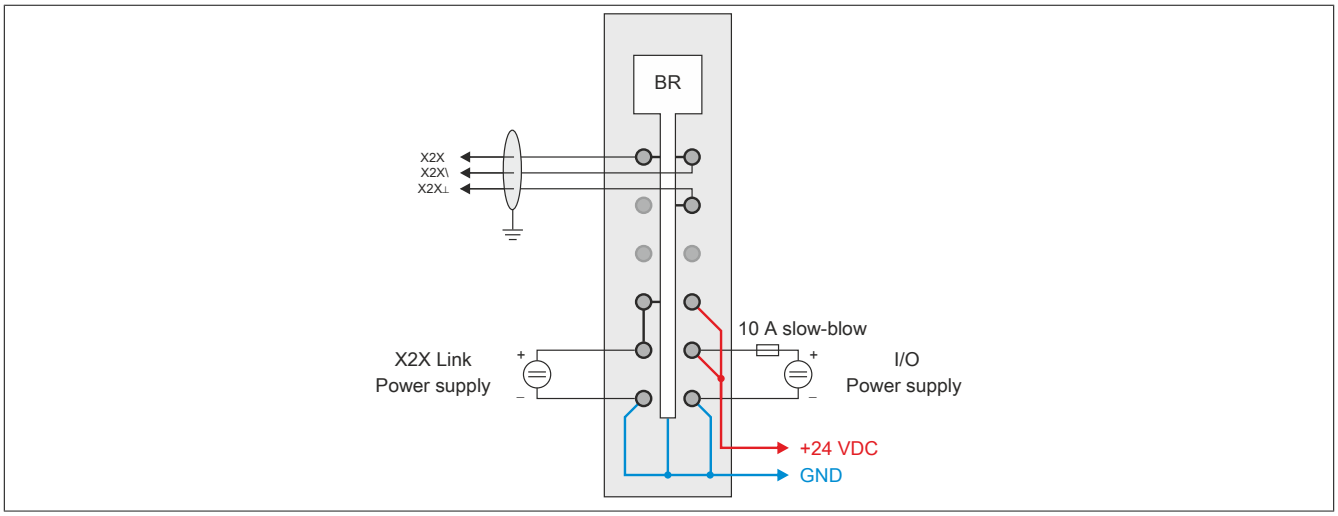
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • X2X Link power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	X	Orange	Off	No communication at the X2X Link
			On	X2X Link communication in progress
	l	Red	Off	X2X Link supply in the acceptable range
			On	X2X Link power supply is overloaded Solution: Use an additional feed module X20PS3300

4.8.2.6 Pinout

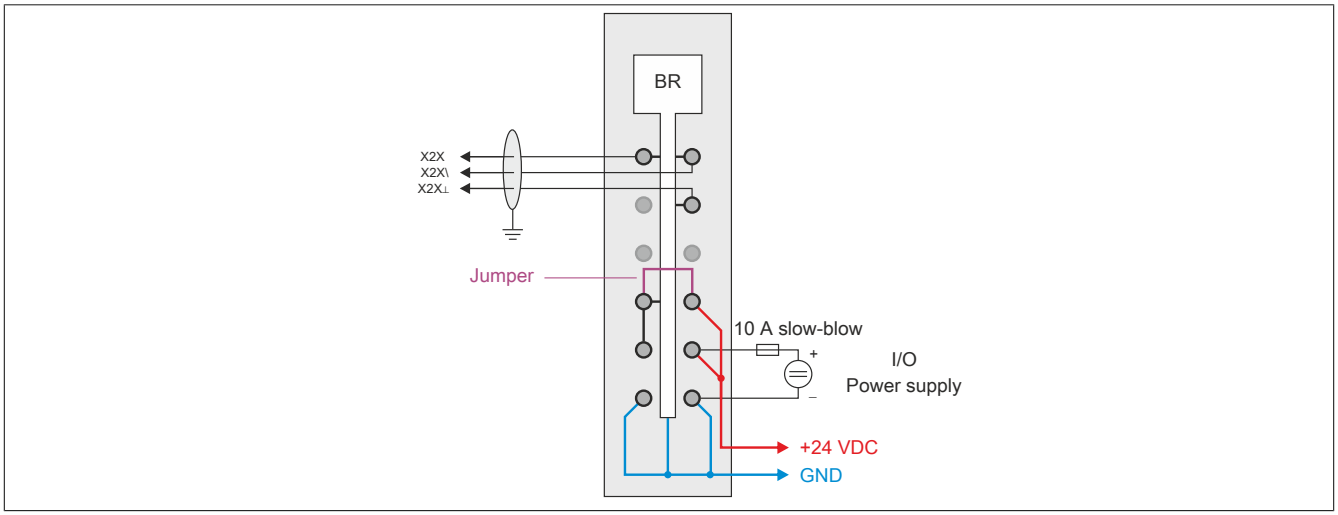


4.8.2.7 Connection examples

With two separate supplies

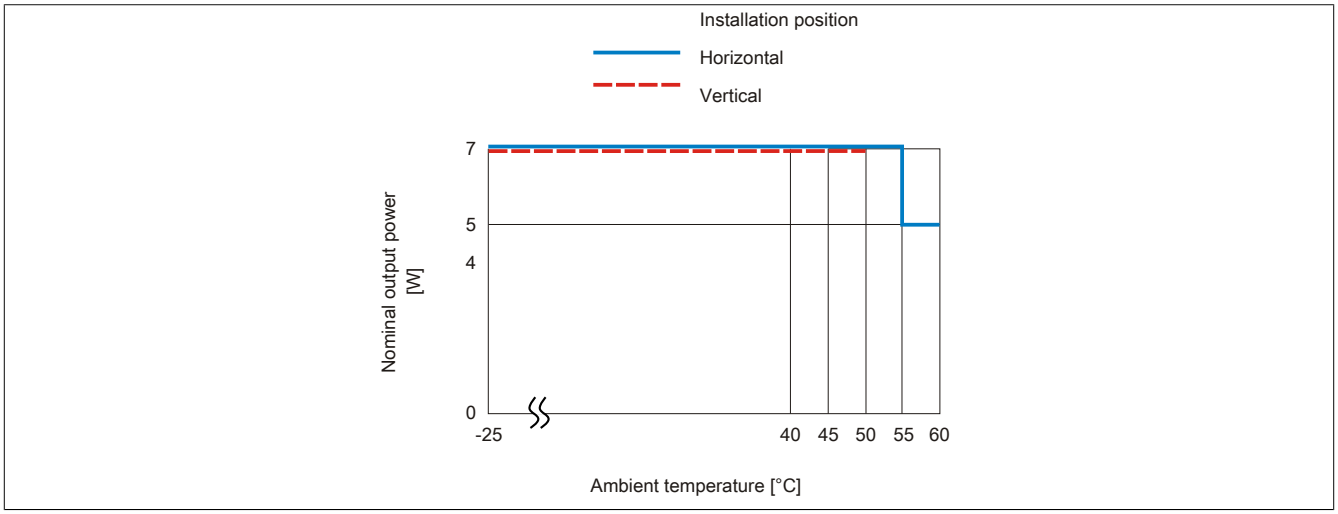


With a supply and jumper



4.8.2.8 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.8.2.9 Register description

4.8.2.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.8.2.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.8.2.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
2	2	SupplyCurrent	UINT	•			
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.8.2.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.8.2.9.4 Module status

Name:
Module status

The following voltage and current states of the module are monitored in this register:

Bus supply current:	A bus supply current of >2.3A is displayed as a warning.
Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Warning - overcurrent (>2.3 A) or undervoltage (<4.7 V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.8.2.9.5 Bus supply current

Name:
SupplyCurrent

This register displays the bus supply current measured at a resolution of 0.1 A.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.8.2.9.6 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.8.2.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.8.2.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.8.3 X20(c)BT9100

4.8.3.1 General information

The bus transmitter provides for the seamless expansion of the X20 System. The stations can be up to 100 m away from each other.

- X2X Link bus transmitter
- For seamless expansion of the system
- Up to 100 m segment lengths
- Feed for internal I/O supply
- Operation only on the slot to the far right

Information:

The bus transmitter modules may only be operated with a bus module where the internal I/O supply is connected through (e.g. X20BM11).

If the incoming voltage is used for internal I/O supply, then this potential group must not be supplied by any other module. An I/O module with bus module X20BM01 should be used to separate the potential group.

4.8.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Spacing	12.5$^{+0.2}$ mm	

Table 156: X20BT9100, X20cBT9100 - Technical data

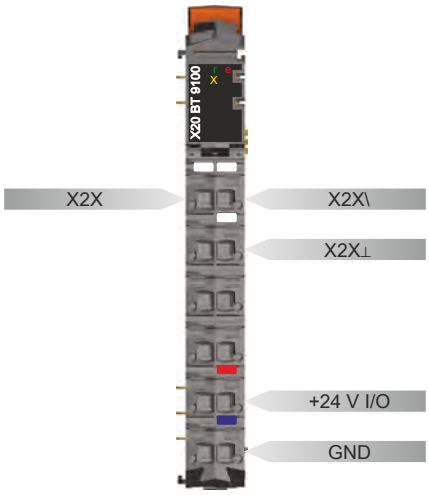
1) The specified values are maximum values. The exact calculation is also available for download as a data sheet with the other module documentation on the B&R website.
2) Ta min.: 0°C
Ta max.: See environmental conditions

4.8.3.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

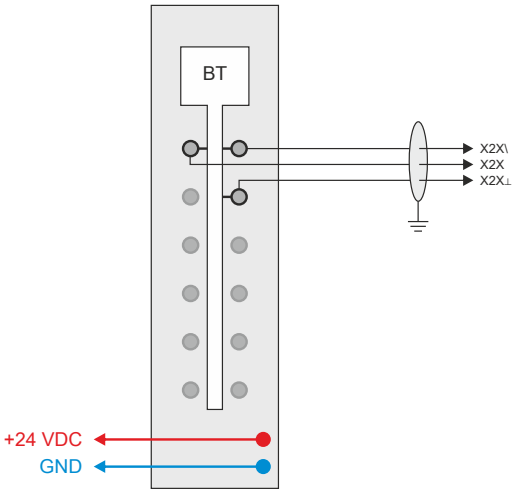
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • I/O supply too low • X2X bus supply too low
	e + r	Red on / Green single flash		Invalid firmware
	X	Orange	Off	No communication at the X2X Link
			On	X2X Link communication in progress

4.8.3.6 Pinout



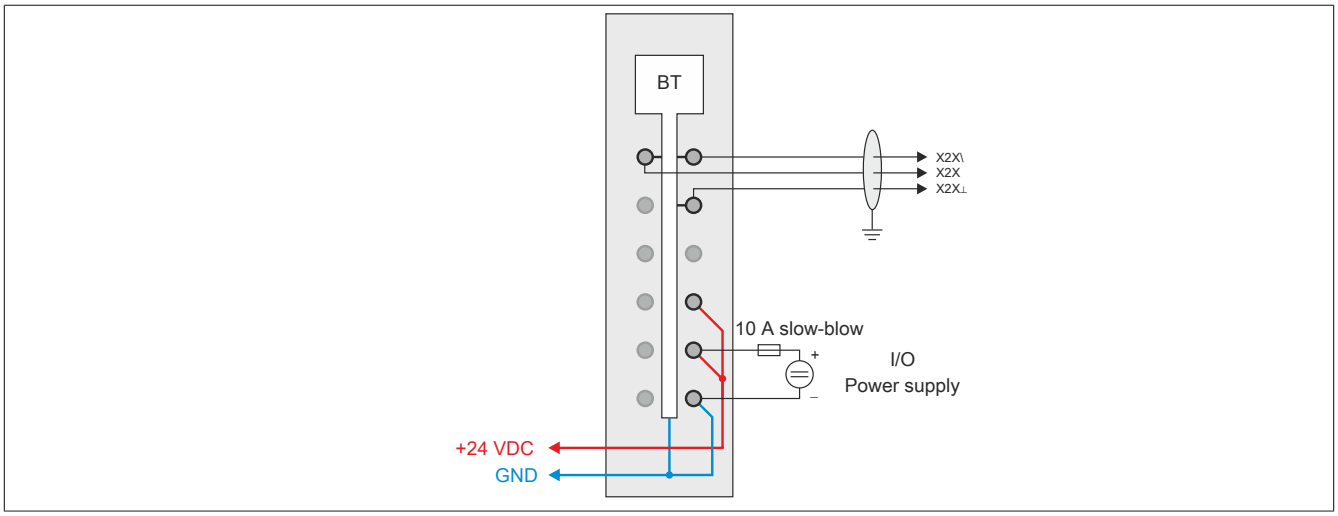
4.8.3.7 Connection examples

No feed for internal I/O supply



With feed for internal I/O supply

See also 3.19.2 "Supply via bus transmitter".



4.8.3.8 Supply via bus transmitter

The bus transmitter has an integrated internal I/O supply feed. This saves a power supply module for the last potential group.

Keep in mind: this potential group is separated from the rest of the potential groups by an I/O module with the bus module.

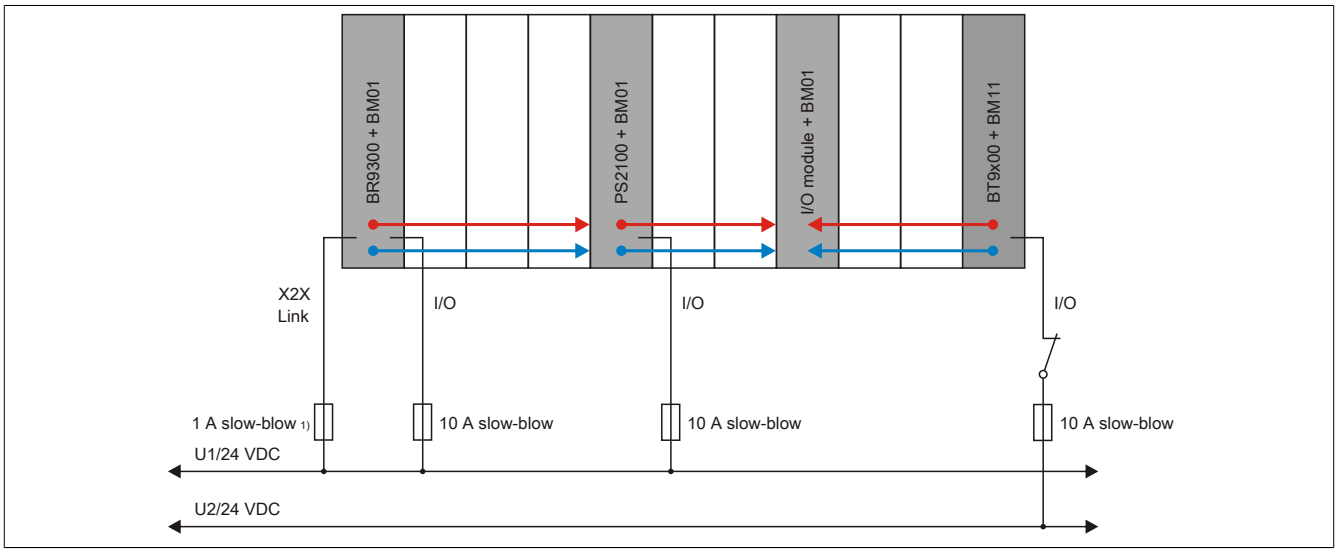


Figure 166: Protection when supplied via bus transmitter

1) Recommended for line protection.

4.8.3.9 Connection to next X2X Link I/O node

The bus transmitter establishes the connection to the next X2X Link based I/O node. It is important to be sure that only the data lines are connected on. X2X Link supply is system dependant.

System	X2X Link supply
X67 system	System supply X67PS1300
Remote I/O with X2X Link (XX modules)	24 VDC external supply
Remote valve terminal connection (XV modules)	24 VDC external supply

Table 157: X20BT9100 - System-dependent X2X Link supply

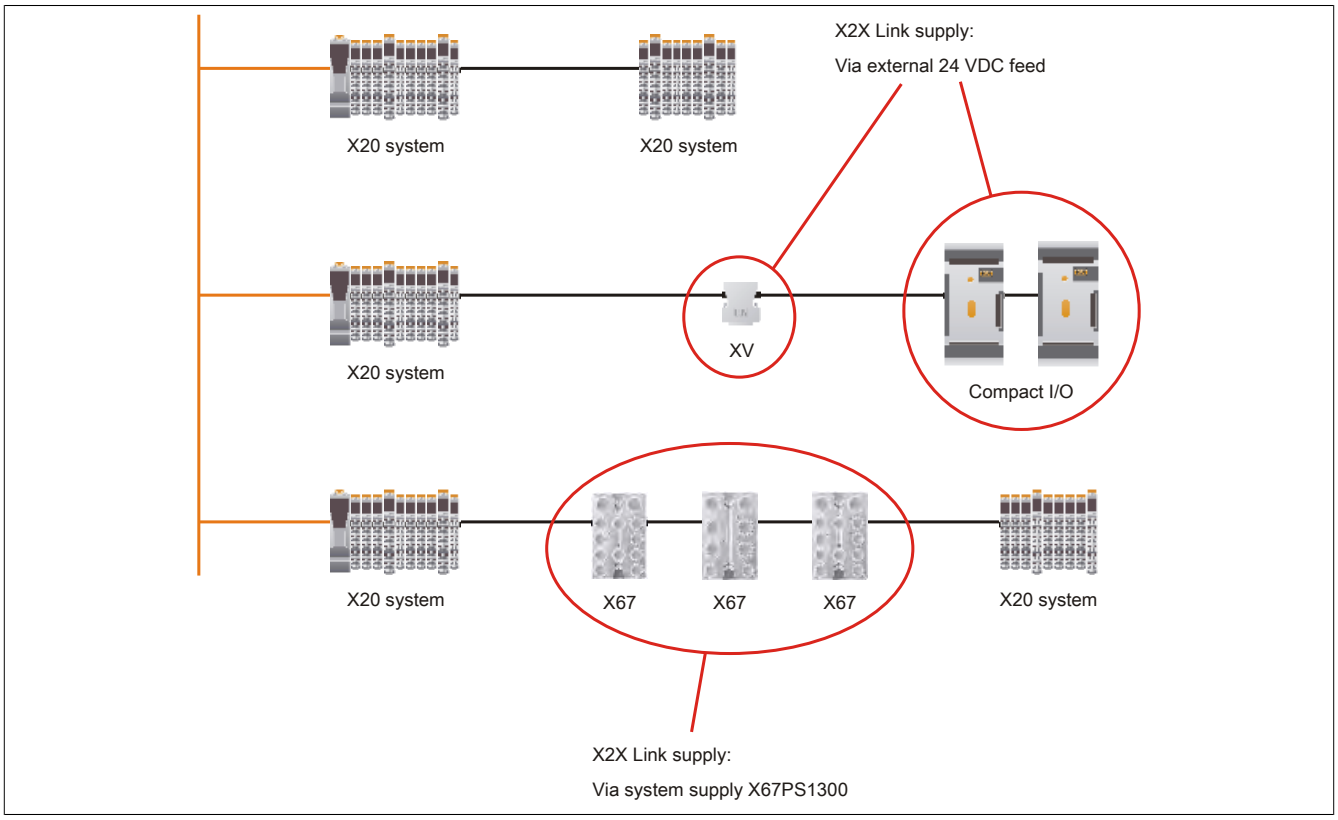

Figure 167: X2X Link supply depending on the system

4.8.3.10 Register description

4.8.3.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.8.3.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
4	SupplyVoltage	USINT	•			

4.8.3.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.8.3.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.8.3.10.4 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Bus supply warning - Undervoltage (<4.7V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.8.3.10.5 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.8.3.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.8.3.10.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.8.4 X20BT9400

4.8.4.1 General information

To connect an X20 system to an X67 system, a bus transmitter is simple added to the end of the X20 block, so that the X2X Link cable can be connected. The bus transmitter also provides the X2X supply voltage for the X67 system. There is no longer a need for an X67 system supply module.

- X2X Link bus transmitter
- For seamless expansion of the system
- Up to 100 m segment lengths
- Feed for internal I/O supply
- Integrated X2X Link supply for the X67 system
- Operation only on the slot to the far right

Information:

The bus transmitter modules may only be operated with a bus module where the internal I/O supply is connected through (e.g. X20BM11).

If the incoming voltage is used for internal I/O supply, then this potential group must not be supplied by any other module. An I/O module with bus module X20BM01 should be used to separate the potential group.

4.8.4.2 Order data

Spacing	12.5 $^{+0.2}$ mm

Table 159: X20BT9400 - Technical data

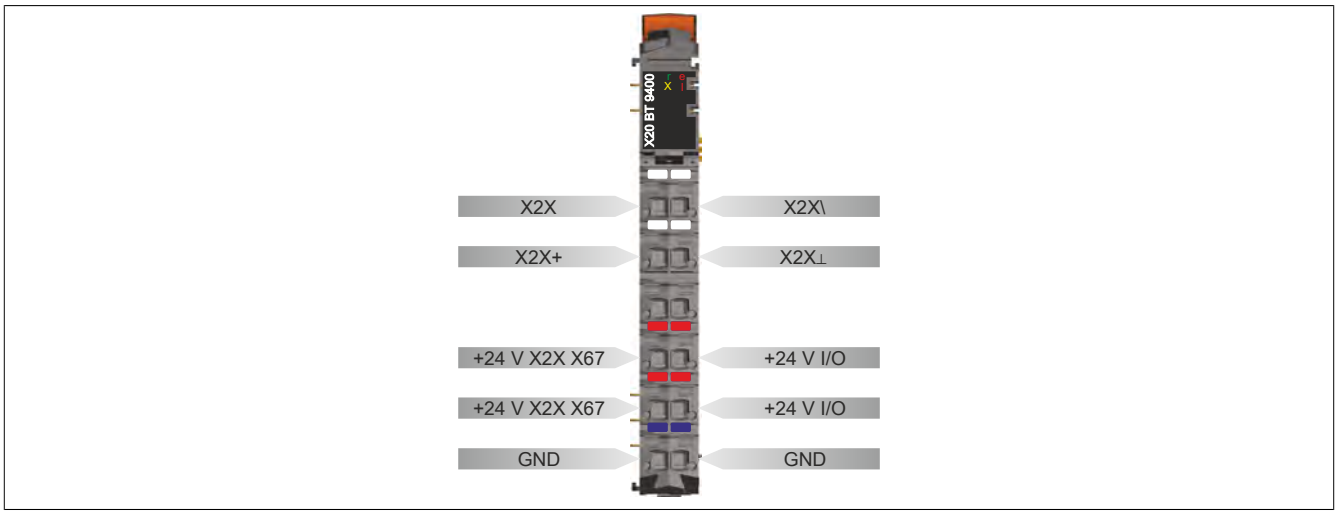
1) The specified values are maximum values. The exact calculation is also available for download as a data sheet with the other module documentation on the B&R website.
2) Ta min.: 0°C
Ta max.: See environmental conditions
3) Only the PS1300 can be used for calculating the total number of X67 modules.

4.8.4.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

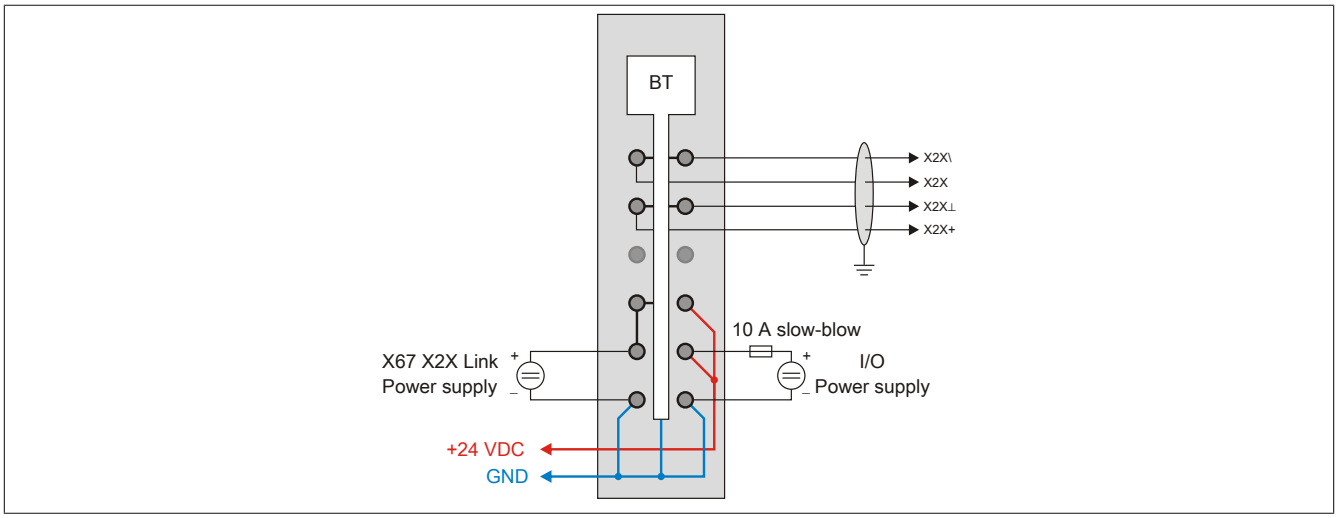
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • I/O supply too low • X2X Link voltage too low
	e + r	Red on / Green single flash		Invalid firmware
	X	Orange	Off	No X2X Link communication
			On	X2X Link communication active
	l	Red	Off	The X67 / X2X Link supply is within the valid limits
			On	The X67 / X2X Link supply for the power supply is overloaded **Remedy:** Use additional X67PS1300 supply modules

4.8.4.5 Pinout

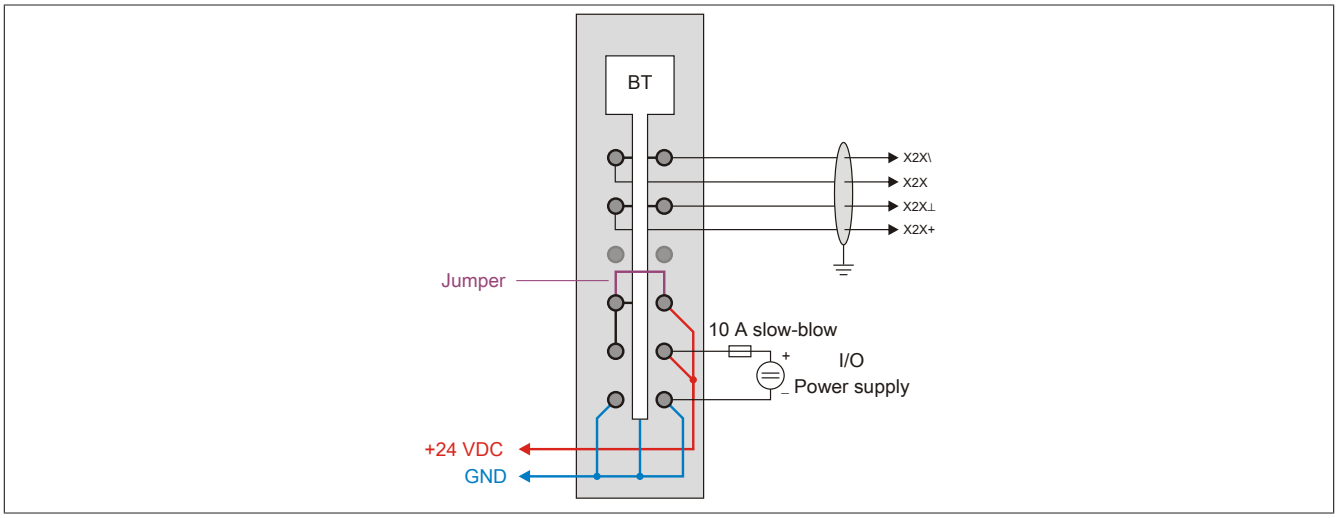


4.8.4.6 Connection examples

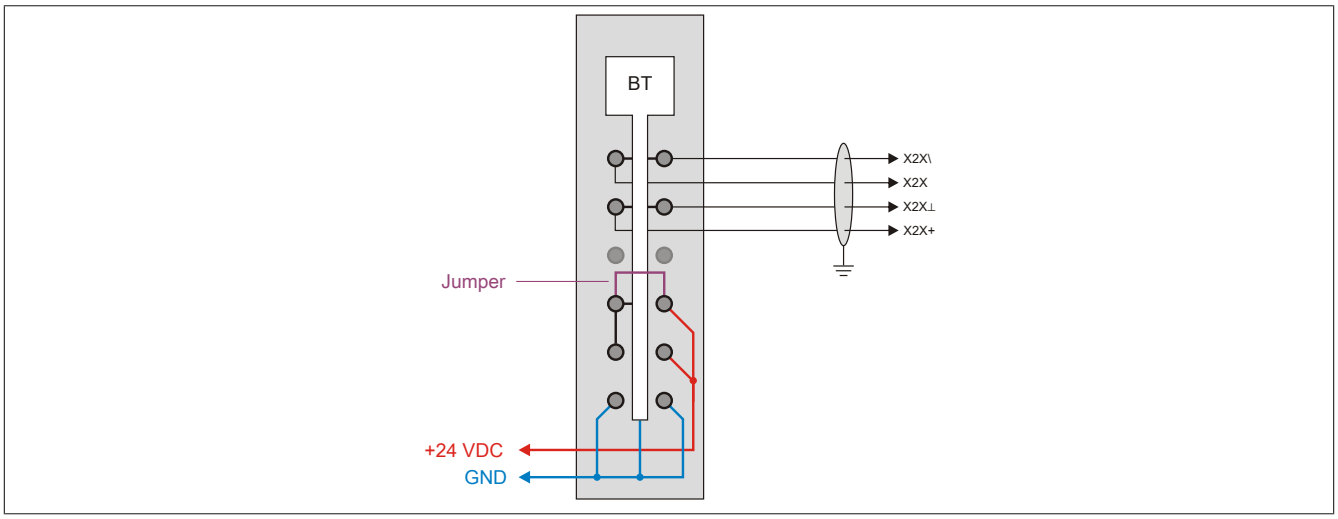
With 2 separate supplies



With a supply and jumper



No feed for internal I/O supply



4.8.4.7 Supply via bus transmitter

The bus transmitter has an integrated internal I/O supply feed. This saves a power supply module for the last potential group.

Keep in mind: this potential group is separated from the rest of the potential groups by an I/O module with the bus module.

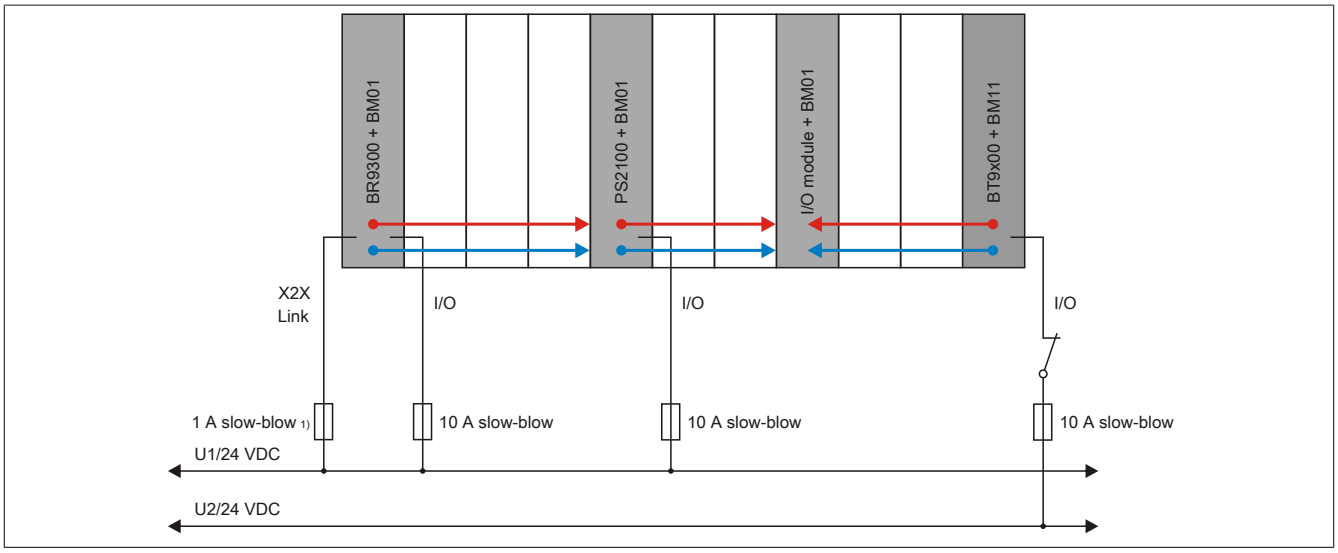


Figure 168: Protection when supplied via bus transmitter

1) Recommended for line protection.

4.8.4.8 Connection between X20 and X67 system

The bus transmitter establishes the link between the X20 system and the X67 system. In addition to the data lines, the X2X Link supply is also fed through. The module can supply up to 8 X67 modules. An additional X67 supply module is only needed if operating more than 8 X67 modules.

Information:

Only the X67PS1300 system supply module can be used for calculating the total number of X67 modules.

4.8.4.9 Register description

4.8.4.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.8.4.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.8.4.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
2	2	SupplyCurrent	UINT	•			
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.8.4.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.8.4.9.4 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

X67 bus supply current:	An X67 bus supply current of >0.4 A is displayed as a warning.
X67 bus supply voltage:	A bus supply voltage of <18 V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	X67 bus supply warning for undervoltage (18 V) or when over-current (0.4 A)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.8.4.9.5 X67 bus supply current

Name:
SupplyCurrent

This register shows the X67 bus supply current with a resolution of 0.01 A.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.8.4.9.6 X67 bus supply voltage

Name:
SupplyVoltage

This register shows the X67 bus supply voltage with a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.8.4.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.8.4.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.9 Compact CPUs

The modular structure of the Compact CPUs allows the user to assemble a CPU that meets their unique power supply and interface requirements.

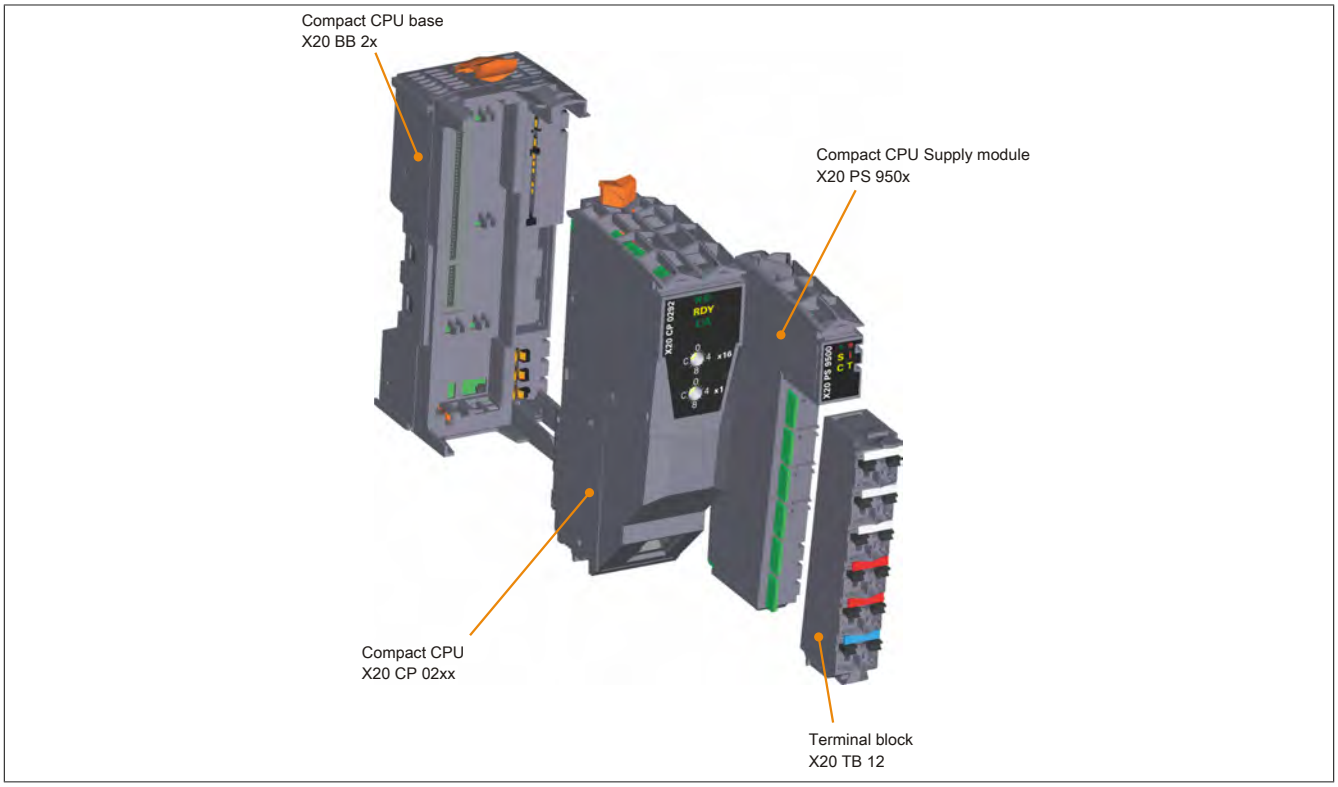

Figure 169: The four parts of the Compact CPU - Compact CPU, bus module, supply module, terminal block

Adaptable to individual requirements

- Embedded µP 25 with Ethernet on-board
- Embedded µP 16 with or without Ethernet on-board

- Bus module with RS232 connection
- Bus module with RS232 and CAN bus connections

- Supply module for Compact CPU, X2X Link bus supply and I/O
- RS232 interface connection
- CAN bus connection
- Without or without electrical isolation of the CPU/X2X Link supply

- 12-pin terminal block

The battery-free CPU

To meet the high demands of the market, the Compact CPU was designed to run without a battery. This makes it completely maintenance-free. The following features make operation without a buffer battery possible.

The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor.

This FRAM stores its contents ferroelectrically. Unlike normal SRAM, this does not require a battery.

Compact design

Despite the sleek profile of only 37.5 mm, the CPU supply, the X2X Link bus supply, and the I/O module supply are integrated in the CPU. No additional power modules are necessary.

4.9.1 Brief information

Product ID	Short description	on page
X20CP0201	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, order bus base, power supply module and terminal block separately	837
X20CP0291	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 1 Ethernet interface 100 Base-T, order bus base, power supply module and terminal block separately	837
X20CP0292	X20 compact CPU, µP 25, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, 3 Ethernet interface 750 Base-T, order bus base, power supply module and terminal block separately	837

4.9.2 X20CP0201, X20CP0291, X20CP0292

4.9.2.1 General information

Compact CPUs are ideal for situations where cycle times in the millisecond range are sufficient and a cost-benefit analysis plays a decisive role. A range of models with CAN and Ethernet can adapt optimally to all demands. The result: extremely sleek automation solutions.

- Embedded µP 16 / µP 25 with additional I/O processor
- 100/750 kB User SRAM
- 1 MB / 3 MB User FlashPROM
- X20CP0291 and X20CP0292: Onboard Ethernet
- Only 37.5 mm wide
- No battery

4.9.2.2 Order data

CP0201

CP0291, CP0292

Model number	Short description
	Compact CPUs
X20CP0201	X20 compact CPU, µP 16, 100 kB SRAM, 1 MB FlashPROM, support of RS232, CAN bus according to compact CPU base, order bus base, power supply module and terminal block separately

Note	Order 1x X20TB12 terminal block separately Order 1x X20PS9500 or X20PS9502 power supply module separately Order 1x X20BB22 or X20BB27 compact CPU base separately		
Spacing 7)	$37.5^{+0.2}$ mm		

Table 161: X20CP0201, X20CP0291, X20CP0292 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions
2) The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor. The gold foil capacitor is completely charged after 18 continuous hours of operation.
3) This FRAM stores its contents ferroelectrically. Therefore, no backup battery is needed.
4) Not buffered.
5) For technical data, see the data sheet for the X20PS9500 power supply module.
6) For technical data, see the data sheet for the X20PS9502 power supply module.
7) Spacing is based on the width of the compact CPU base X20BB22 or X20BB27. An X20PS9500 or X20PS9502 supply module is also always required for the CPU.

4.9.2.4 LED status indicators

X20CP0201

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
		Red	On	SERVICE mode
			Off	1)
	RDY	Yellow	On	SERVICE mode
			Off	1)

1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

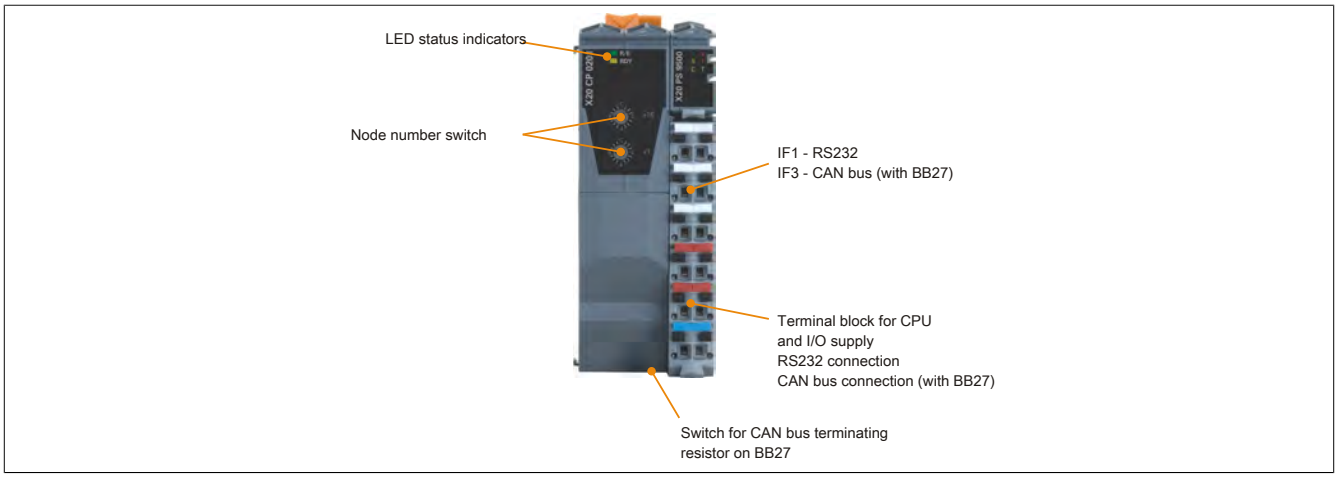
X20CP029x

Figure	LED	Color	Status	Description
	R/E	Green	On	Application running
		Red	On	SERVICE mode
			Off	1)
	RDY	Yellow	On	SERVICE mode
			Off	1)
	L/A	Green	On	A link to the peer station has been established.
			Blinking	A link to the peer station has been established. Indicates Ethernet activity is taking place on the bus.

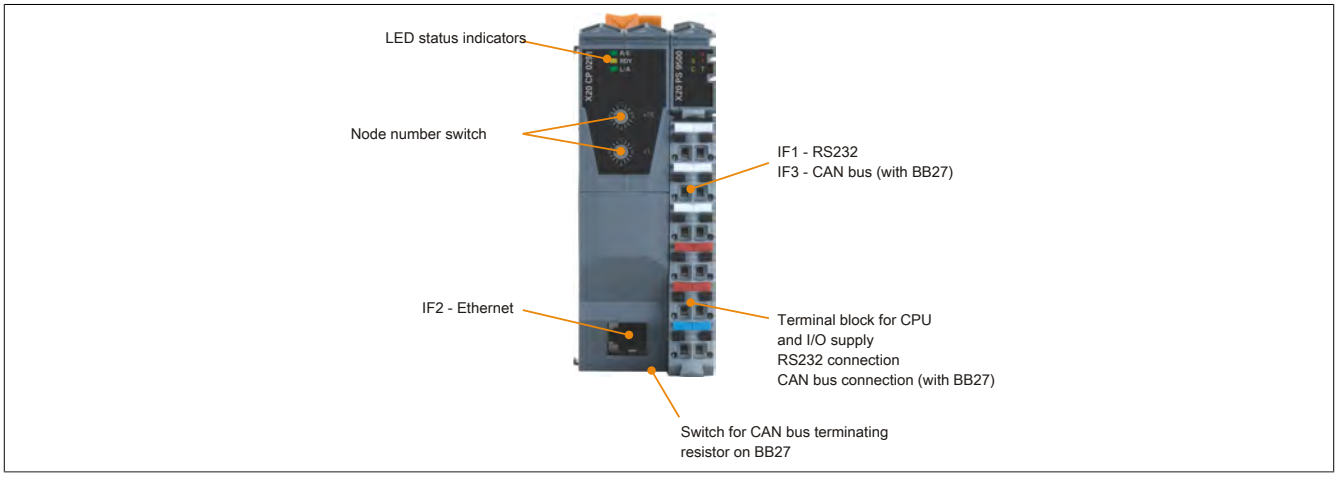
1) BOOT mode: R/E and RDY LEDs are off and the power supply LED is blinking

4.9.2.5 Operating and connection elements

X20CP0201



X20CP0291 and X20CP0292



4.9.2.6 Node number switches

The node number is set using the two hex switches. The switch setting can be evaluated by the application program at any time. The operating system only evaluates the switch position when the device is switched on.

Switch position	Operating mode	Description
0x00	BOOT	In this switch position, the operating system can be installed via the RS232 interface configured as the online interface. User Flash is deleted only after the update begins.
0x01 - 0xFE	RUN	RUN mode, the application is running.
0xFF	Diagnostics	Boots the CPU in Diagnostics mode. Program sections in User RAM and User FlashPROM are not initialized. Following diagnostics mode, the CPU always boots with a **cold restart**.

X20CP0201

When used with the X20BB27 bus module, the X20CP0201 has access to a CAN bus interface. The INA2000 station number for CAN is set using the node number switches.

X20CP0291 and X20CP0292

Both of these CPUs are equipped with an onboard Ethernet interface. When used with the X20BB27 bus module, they also have access to a CAN bus interface.

The number set using the two hex switches defines the INA2000 station number of both the CAN and the Ethernet interface.

4.9.2.7 Ethernet interface (IF2)

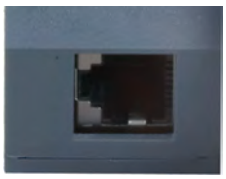


Figure 170: X20 compact CPUs - Ethernet interface for X20CP0291 and X20CP0292

The X20CP0291 and X20CP0292 are equipped with an Ethernet interface. The connection is made using a 100 BASE-T twisted pair RJ45 socket.

Pinout

Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).

Information:

The Ethernet interface (IF2) is not suited for POWERLINK.

Starting with operating system version 1.07, CPUs have a default IP address.

IP address: 192.168.0.1
Subnet mask: 255.255.0.0

4.9.2.8 Programming the system flash memory

General information

CPUs are delivered with a runtime system. When delivered, the node number switch is set to switch position 0x00 (bootstrap loader mode).

A suitable switch position must be set (0x01 to 0xFE) in order to boot the PLC in RUN mode. Updating the runtime system is only possible in RUN mode.

Runtime system update

The runtime system can be updated via the programming environment. When updating the runtime system via an online connection, the following procedure must be carried out:

1. An online runtime system update is only possible if the processor is in RUN mode. For this to be true, the node number must be set to a value in the range 0x01 to 0xFE.
2. Switch on the power.
3. The runtime system update is performed via the existing online connection. The online connection can be established via the onboard serial RS232 interface, for example. If a CPU has an Ethernet interface, then it too can be used to perform the update.
4. Start B&R Automation Studio.
5. Start the update procedure by selecting **Online** from the **Project** menu. Select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions given by B&R Automation Studio.
6. A window opens up for setting the runtime system version. The runtime system version is already pre-selected by the project settings made by the user. The drop-down menu can be used to select one of the runtime system versions stored in the project. Clicking on the **Browse** button allows a runtime system version to be loaded from the hard drive or CD.

   Clicking on **Next** opens a pop-up window that allows the user to select whether modules with target memory SYSTEM ROM should be transferred during the subsequent runtime system update. If not, these modules can also be transferred later during an application download.

   Clicking on **Next** opens a dialog box where the user can set the CAN transfer rate, CAN ID and CAN node number (the CAN node number set here is only relevant if an interface module does not have a CAN node number switch). The CAN node number must be between decimal 01 and 99. Assigning a unique node number is especially important with online communication over a CAN network (INA2000 protocol).
7. The update procedure is started by clicking on **Next**. Update progress is shown in a message box.

   > **Information:**
   >
   > **User flash memory is deleted.**
8. When the update procedure is complete, the online connection is reestablished automatically.
9. The PLC is now ready for use.

Updating the runtime system is possible not only via an online connection, but also via a CAN network, serial network (INA2000 protocol) or Ethernet network, depending on the system configuration.

4.10 Compact CPUs system modules

The X20 system Compact CPUs consist of the Compact CPU, Compact CPU system modules and the X20TB12 terminal block.

The Compact CPU system modules also include the X20BB22 and X20BB27 base modules as well as the X20PS9500 supply module for supplying the entire system with voltage.

4.10.1 Brief information

Product ID	Short description	on page
X20BB22	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	844
X20BB27	X20 compact CPU base, for compact CPU and compact CPU power supply module, base for integrated RS232 and CAN bus interface, X20 connection, X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	846
X20PS9500	X20 supply module for compact and fieldbus CPUs and internal I/O supply, X2X Link supply	848
X20PS9502	X20 supply module, for compact and fieldbus CPUs and internal I/O supply, X2X Link supply, supply not electrically isolated	854

4.10.2 X20BB22

4.10.2.1 General information

The bus module is the base for all X20 Compact CPUs.

The left and right end plates are included in the delivery.

- Base for all X20 Compact CPUs
- RS232 connection

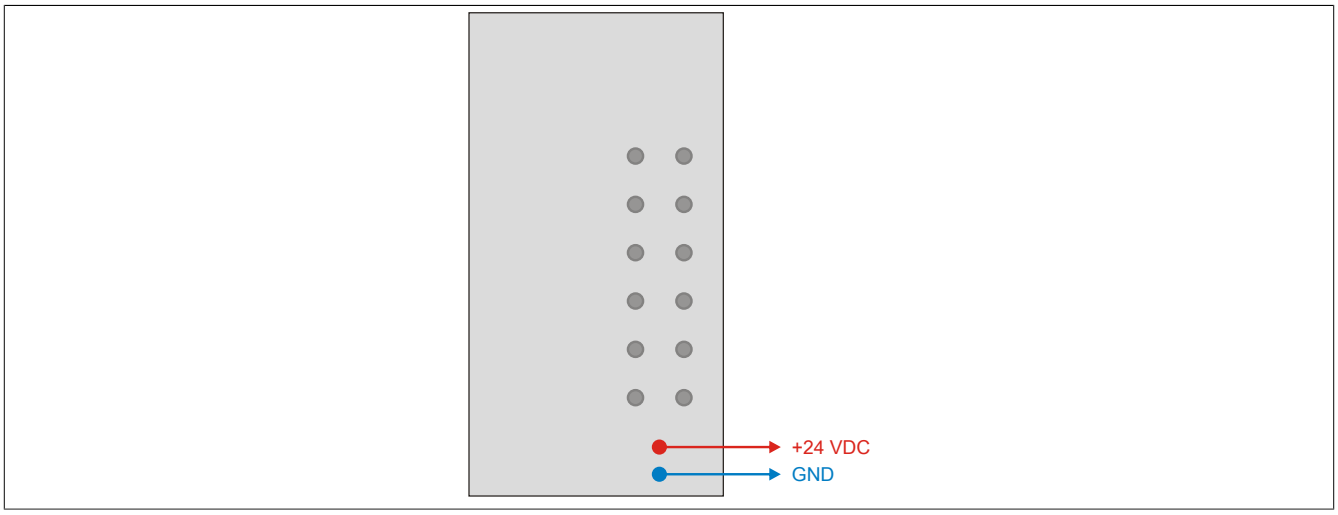
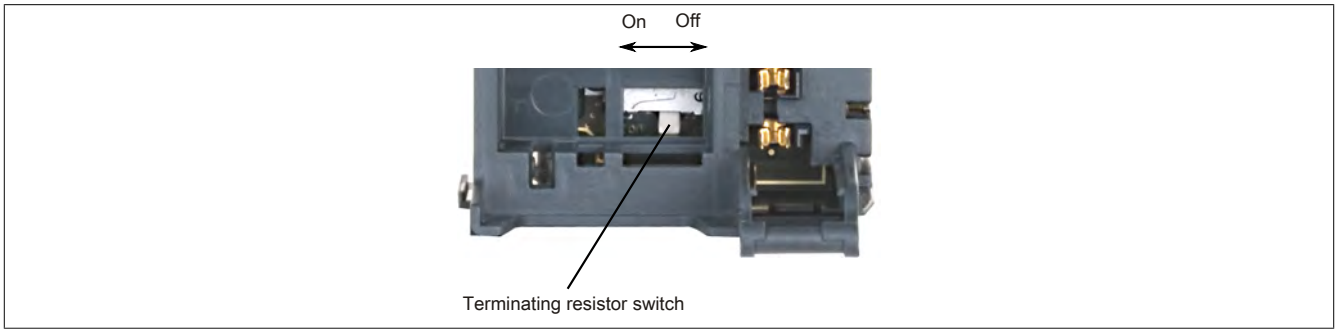
4.10.3.4 Voltage routing



4.10.3.5 Terminating resistor for CAN bus



The bus module has an integrated CAN bus terminating resistor. The terminating resistor is turned on and off with a switch. An active terminating resistor is indicated on the supply module by the "T" LED.

4.10.4 X20PS9500

4.10.4.1 General information

The supply module is used together with an X20 compact or fieldbus CPU. It has a feed for the compact or fieldbus CPU, the X2X Link and the internal I/O supply.

- Supply for the compact or fieldbus CPU, X2X Link, and internal I/O supply
- Electrical isolation of feed and CPU / X2X Link supply
- Redundancy of CPU / X2X Link supply possible by operating multiple supply modules simultaneously
- RS232 interface configurable as online interface
- CAN bus

Table 167: X20PS9500 - Technical data

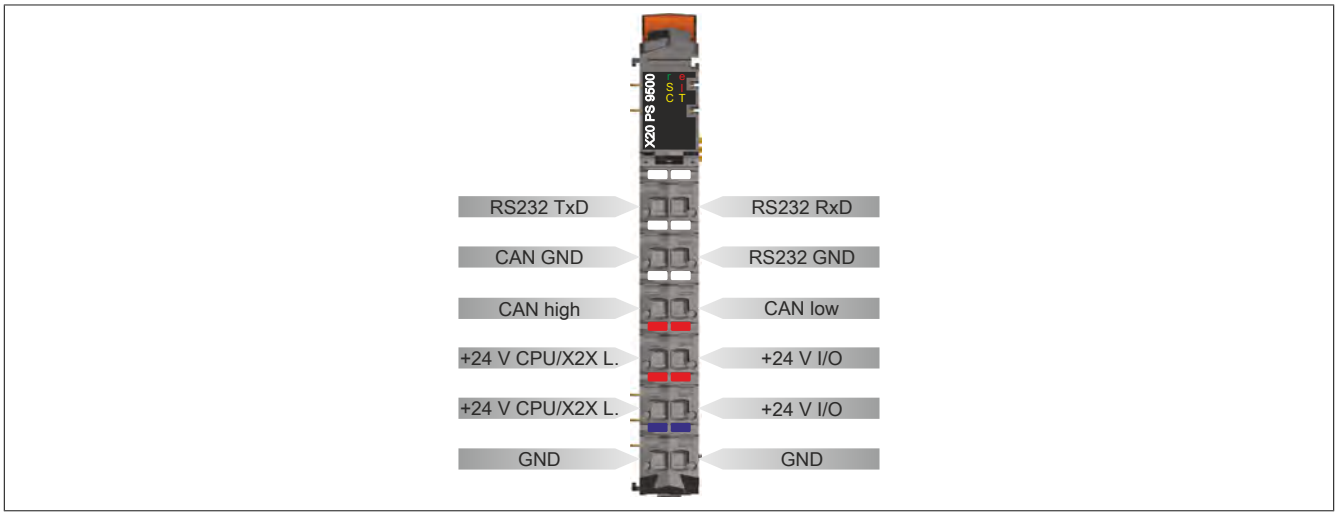
1) CAN bus only when used with the X20BB27, X20BB37 or X20BB47 bus module.
2) The specified values are maximum values. The calculation is also available for download as a data sheet with the other module documentation on the B&R website.
3) Ta min.: 0°C
   Ta max.: See environmental conditions
4) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

4.10.4.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

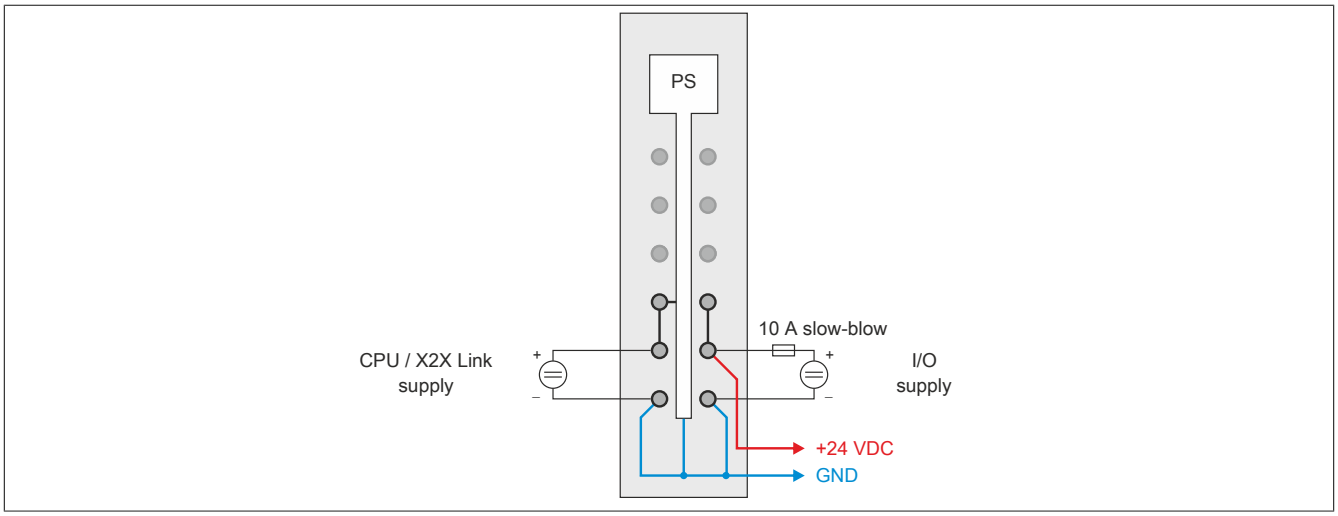
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The CPU / X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for CPU / X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	I	Red	Off	The CPU / X2X Link supply is within the valid limits
			On	The CPU / X2X Link supply for the power supply is overloaded
	S	Yellow	Off	The CPU does not send data via the RS232 interface.
			On	The CPU sends data via the RS232 interface.
	C	Yellow	Off	The CPU is not sending data via the CAN bus interface.
			On	The CPU is sending data via the CAN bus interface.
	T	Yellow	Off	The terminating resistor integrated in the BB27 or BB37 bus module is turned off.
			On	The terminating resistor integrated in the BB27 or BB37 bus module is turned on.

4.10.4.5 Pinout

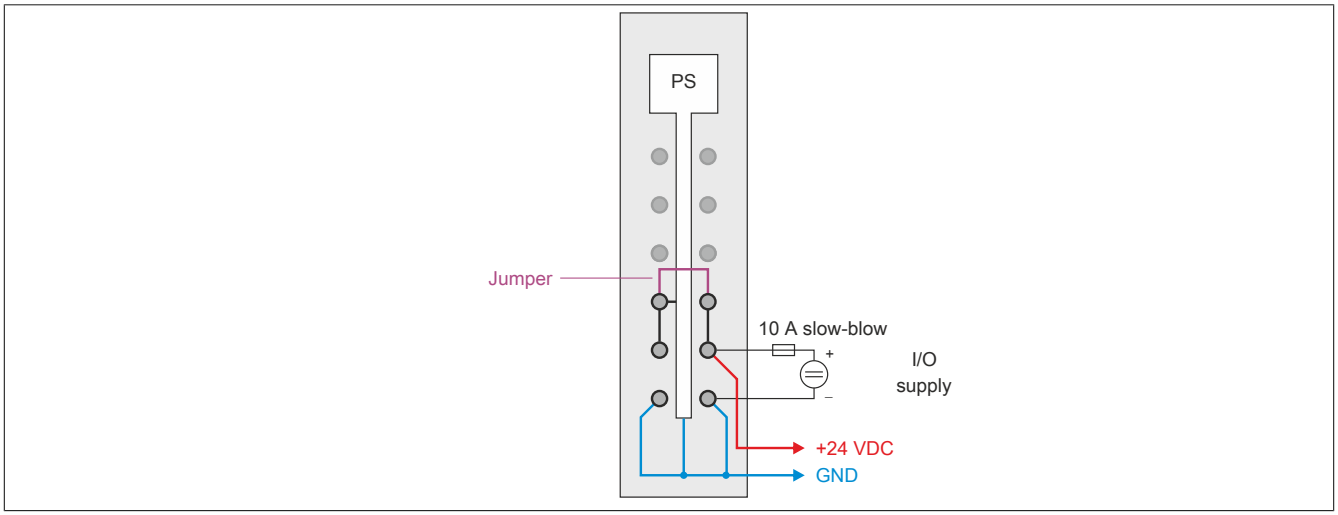


4.10.4.6 Connection examples

With 2 separate supplies

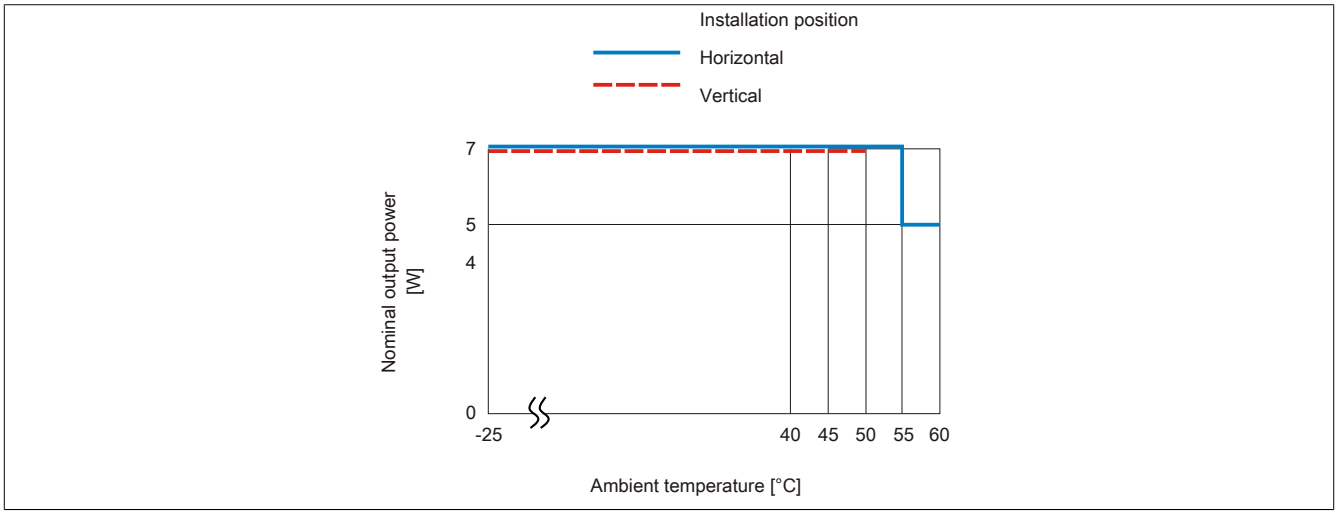


With a supply and jumper



4.10.4.7 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.10.4.8 Register description

4.10.4.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.10.4.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.10.4.8.3 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply current:	A bus supply current of >2.3A is displayed as a warning.
Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Warning - overcurrent (>2.3 A) or undervoltage (<4.7 V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.10.4.8.4 Bus supply current

Name:
SupplyCurrent

This register displays the bus supply current measured at a resolution of 0.1 A.

Function model	Data type
0 - Standard	USINT

4.10.4.8.5 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT

4.10.4.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.10.4.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.10.5 X20PS9502

4.10.5.1 General information

The supply module is used together with an X20 Compact or Fieldbus CPU. It is equipped with a feed for the Compact or Fieldbus CPU, the X2X Link and the internal I/O supply.

The module is intended as a low-cost supply module for small X20 Systems. Voltage groups are able to be formed. An expansion or redundancy of the X2X Link with the X20PS3300 or X20PS3310 supply module is not possible. Expansion of the X20 System with a bus transmitter is not permitted either.

- Supply for the Compact or Fieldbus CPU, X2X Link, and internal I/O supply
- Low-cost supply module for small X20 Systems
- No electrical isolation of feed and CPU / X2X Link supply
- Expansion or redundancy of CPU / X2X Link supply not possible by operating multiple supply modules simultaneously
- RS232 can be configured as an online interface
- CAN bus

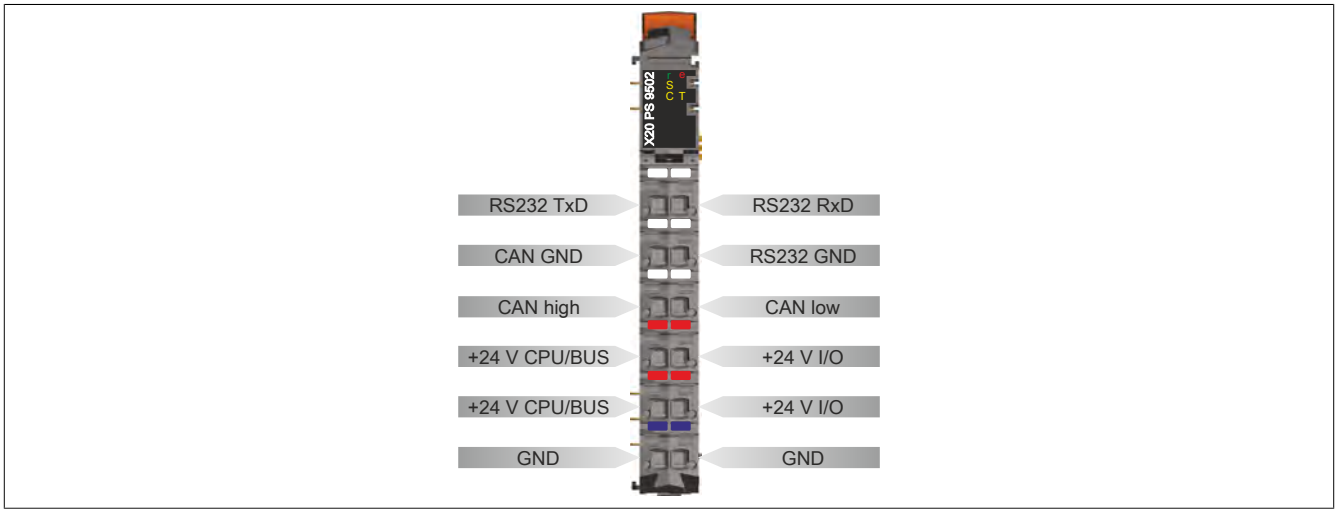
4.10.5.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

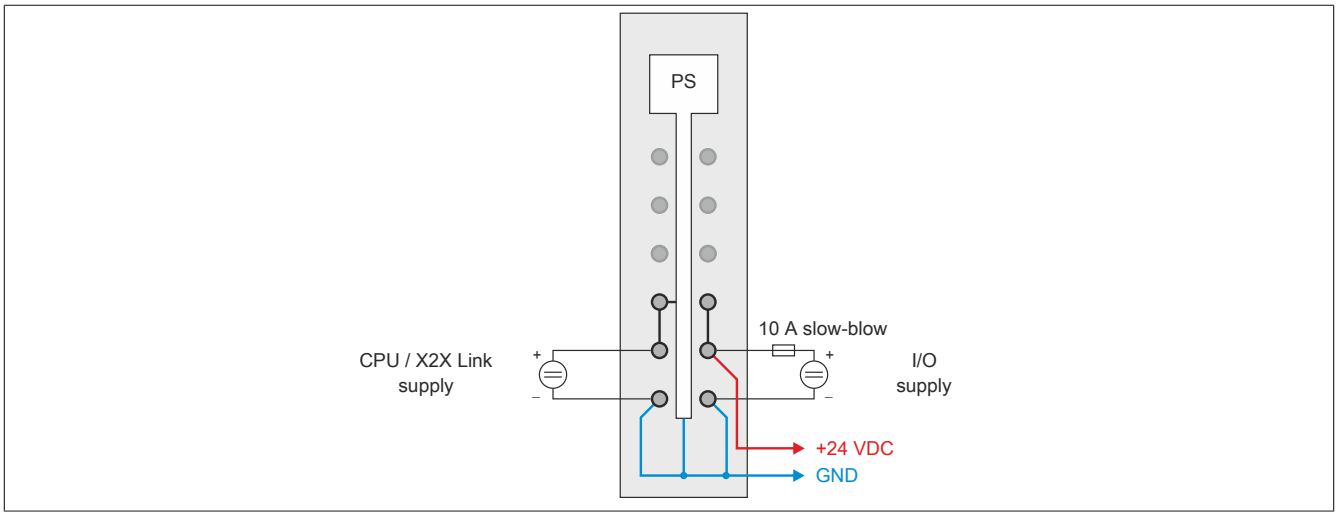
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The CPU / X2X Link power supply is overloaded • I/O supply too low • Input voltage for CPU / X2X Link too low
	e + r	Red on / Green single flash		Invalid firmware
	S	Yellow	Off	The CPU does not send data via the RS232 interface.
			On	The CPU sends data via the RS232 interface.
	C	Yellow	Off	The CPU does not send data via the CAN bus interface.
			On	The CPU sends data via the CAN bus interface.
	T	Yellow	Off	The terminating resistor integrated in the X20BB27 or X20BB37 bus module is turned off.
			On	The terminating resistor integrated in the X20BB27 or X20BB37 bus module is turned on.

4.10.5.5 Pinout

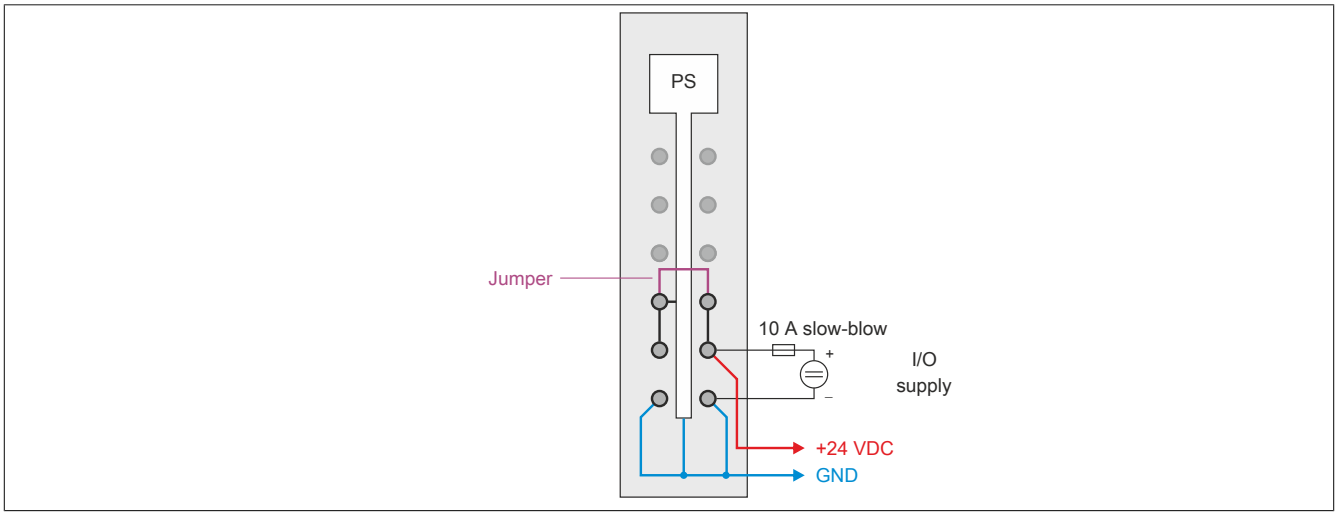


4.10.5.6 Connection examples

With 2 separate supplies

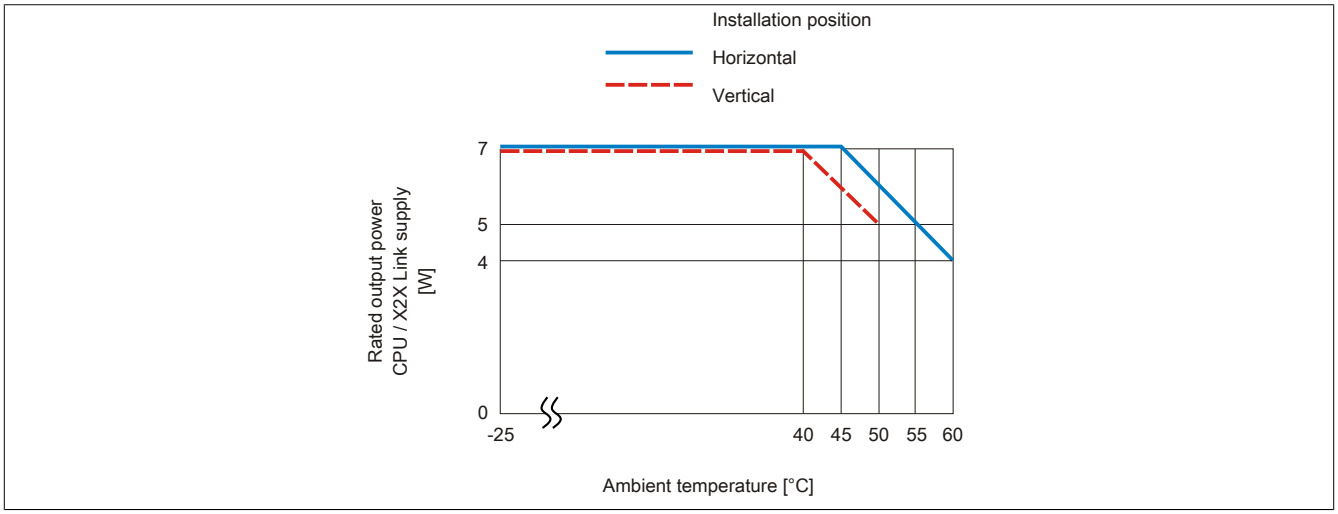


With a supply and jumper



4.10.5.7 Derating for CPU / X2X Link supply

The rated output power for the CPU / X2X Link supply is 7.0W. Derating may be necessary depending on the mounting orientation.



4.10.5.8 Register description

4.10.5.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.10.5.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
4	SupplyVoltage	USINT	•			

4.10.5.8.3 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	A supply voltage of <20.4V is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Bus supply warning - Undervoltage (<4.7V)
1		0	Reserved
2	StatusInput02	0	I/O supply above the warning level of 20.4V
		1	I/O supply below the warning level of 20.4V
3 - x		0	Reserved

4.10.5.8.4 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.10.5.8.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.10.5.8.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.11 Counter modules

Counter modules are used for position detection. Each signal on a counter module is assigned to a status LED.

4.11.1 Brief information

Product ID	Short description	on page
X20CM1941	X20 resolver module, 14-bit resolver input, converter up to 12-bit ABR output	860
X20DC1176	X20 digital counter module, 1 ABR incremental encoder, 5 V 600 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module	867
X20DC1178	X20 digital counter module, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit, encoder monitoring, NetTime module	883
X20DC1196	X20 digital counter module, 1 ABR incremental encoders, 5 V, 600 kHz input frequency, 4x evaluation	898
X20DC1198	X20 digital counter module, 1 SSI absolute encoder, 5 V, 1 Mbit/s, 32-bit	908
X20DC11A6	X20 digital counter module, 1 ABR incremental encoder, 5 V 5 MHz input frequency, 4x evaluation, encoder monitoring, NetTime module	915
X20DC1376	X20 digital counter module, 1 ABR incremental encoder, 24 V 100 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module	931
X20DC137A	X20 digital counter module, 1x ABR incremental encoder, 24 V (differential), 300 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module	946
X20DC1396	X20 digital counter module, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation	961
X20DC1398	X20 digital counter module, 1 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit	971
X20DC1976	X20 digital counter module, 1x ABR incremental encoder, 5 V (single ended), 250 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module	978
X20DC2190	X20 digital counter module, ultrasonic transducer module, interfaces: EP start/stop, DPI/IP, 2 transducer rods, 4 path evaluation	994
X20DC2395	X20 digital counter module, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function	1008
X20DC2396	X20 digital counter module, 2 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation	1048
X20DC2398	X20 digital counter module, 2 SSI absolute encoder, 24 V, 125 kbit/s, 32-bit	1059
X20DC4395	X20 digital counter module, 2 SSI absolute encoder, 24 V, 2 ABR incremental encoder, 24 V, 4 AB incremental encoders, 24 V, 8 event counters or 4 PWM, local time measurement function	1066
X20cDC1198	X20 digital counter module, coated, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit	908
X20cDC1396	X20 digital counter module, coated, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation	961
X20cDC2395	X20 digital counter module, coated, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function	1008

4.11.2 X20CM1941

4.11.2.1 General information

The module is equipped with a resolver input and a configurable ABR output.

- Resolver input (differential), with angular position and cyclic counter
- 14-bit resolution for the angular position
- ABR output (configurable)

4.11.2.2 Order data

Model number	Short description	Figure

Ta max.: See environmental conditions
2) Configurable

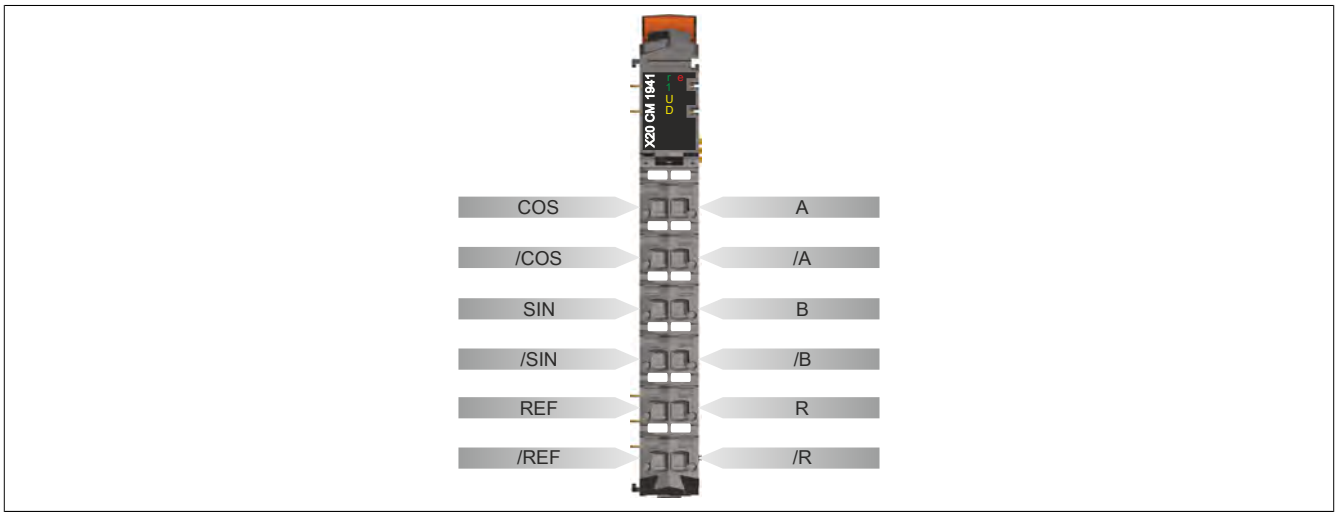
4.11.2.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

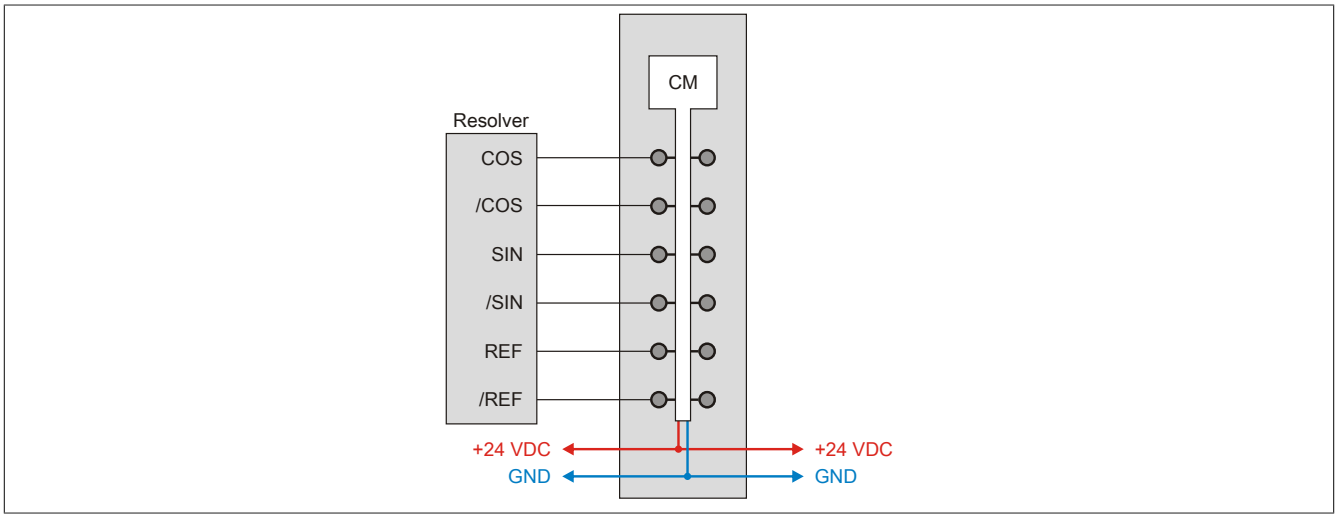
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1	Green	On	Resolver connected and OK
			Off	Open line or no resolver connected
	U	Orange		UP: Counts up
	D	Orange		DOWN: Counts down

1) Depending on the configuration, a firmware update can take up to several minutes.

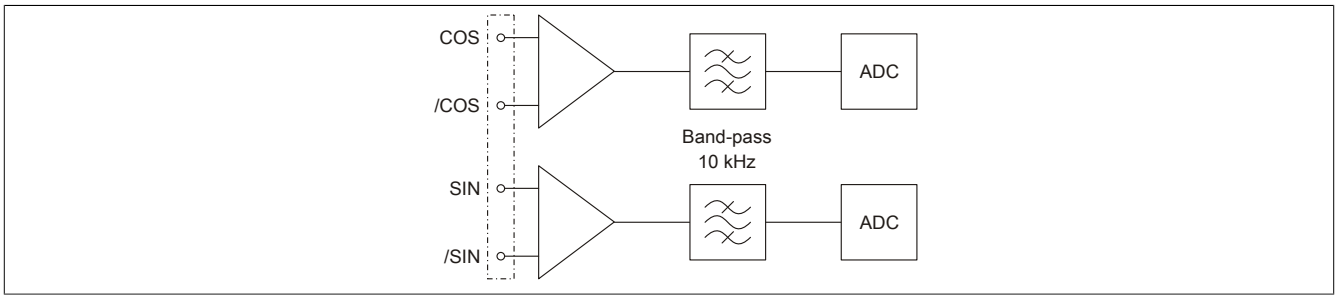
4.11.2.5 Pinout



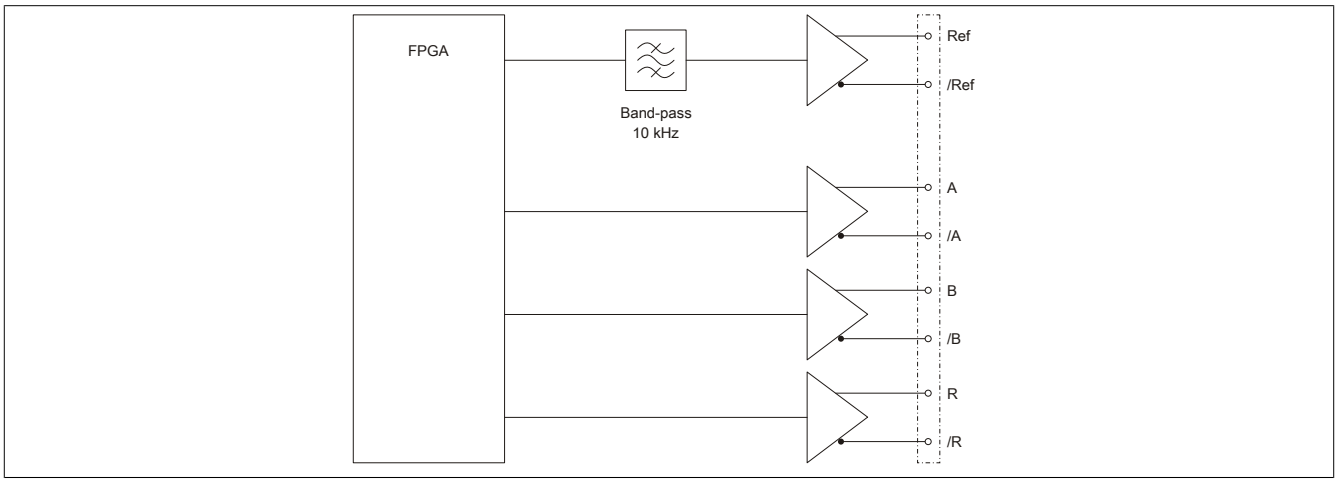
4.11.2.6 Connection example



4.11.2.7 Input circuit diagram



4.11.2.8 Output circuit diagram



4.11.2.9 ABR encoder

Up to firmware version 4

The module measures the resolver's current angular position every 100 µs. The value for A, B or R is generated immediately from the highest value bits (depending on configuration bit 8 to 10).

Firmware version 5 or higher

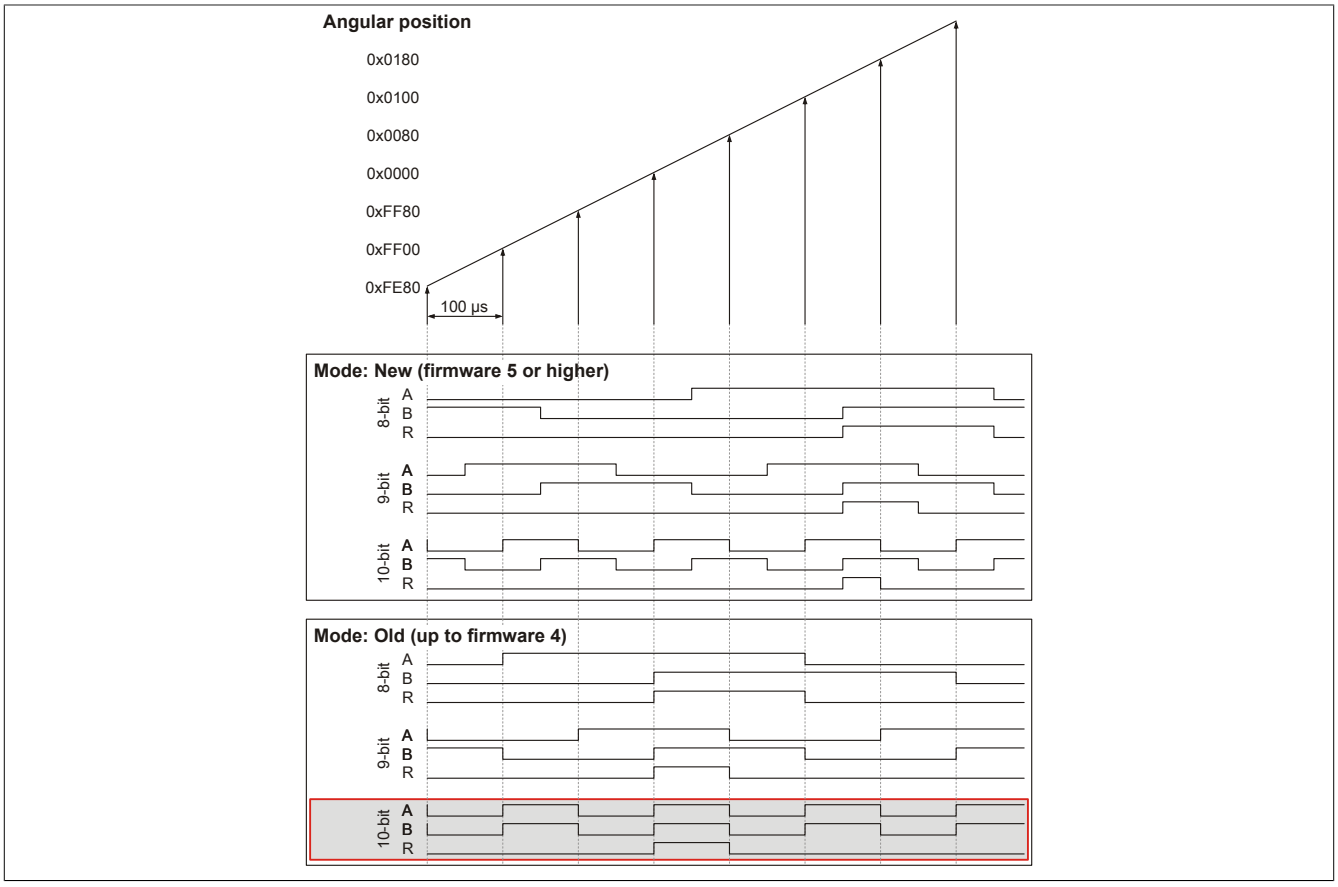
The procedure shown above reaches its limits as soon as more than one LSB difference occurs from one position measurement to the next since only one edge of A or B is possible every 100 µs.

To achieve higher clock rates on the ABR encoder (and therefore higher rotational speeds) while simultaneously improving temporal jitter, the ABR signal is no longer derived directly from the most recent measurement value, but rather generated through interpolation between consecutive position measurements determined every 100 µs.

Information:

In comparison to firmware versions ≤4, the ABR outputs have a constant time offset of 250 µs. See also "Comparison of the timing of the ABR outputs between Firmware version 4 and 5".

Comparison of the timing of the ABR outputs between Firmware version 4 and 5



4.11.2.10 Register description

4.11.2.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.2.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
20	ConfigOutput01	UINT				•
22	ConfigOutput02	USINT				•
Communication						
0	Position	DINT	•			
10	StatusInput	USINT	•			

4.11.2.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
20	-	ConfigOutput01	UINT				•
22	-	ConfigOutput02	USINT				•
Communication							
0	0	Position	DINT	•			
10	4	StatusInput	USINT	•			

1) The offset specifies the position of the register within the CAN object.

4.11.2.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.2.10.4 Set the zero position

Name:
ConfigOutput01

This register can be used to set or move the zero position for the resolver. The zero position/offset specification refers to the current resolver position.

Data type	Value
UINT	0 to 65535

4.11.2.10.5 Encoder emulation configuration

Name:
ConfigOutput02

This register can be used to configure the resolution of the ABR emulation.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Number of bits	0	8-bit = 256 increments/rotation
		1	9-bit = 512 increments/rotation
		2	10-bit = 1024 increments/rotation
		3	11-bit = 2048 increments/rotation
		4	12-bit = 4096 increments/rotation
		5 - 7	Not permitted
3 - 7	Reserved	-	

4.11.2.10.6 Current encoder position

Name:
Position

The current angle position of the resolver is shown in this register. The value consists of:

- The two upper bytes, which correspond to the number of rotations counted from -32768 (0x8000xxxx) to +32767 (0x7FFFxxxx)
- The two lower bytes, which correspond to the angle position within the current rotation 1 LSB = 360° / 65536

The position value can, however, be interpreted exactly as an individual 32-bit long angle with resolution 1 / 65536 * 360°.

Data type	Value	Information
DINT	0x0000xxxx to 0xFFFFxxxx	Number of rotations (cyclic)
	0xxxxx0000 to 0xxxxxFFFF	Angle position within the current rotation

Example

0x7FFF0080 corresponds to 32767 rotations, and 128 / 65536 * 360 = 0.703°.

4.11.2.10.7 Connection status

Name:
StatusInput

This register shows a potential open line between the module and the encoder.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Open line	0	No open line
		1	Open line
1- 7	Reserved	-	

4.11.2.10.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.11.2.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
200 µs

4.11.3 X20DC1176

4.11.3.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 5 V encoder signal. The encoder inputs are monitored (A, B, R, A\, B\, R\).

- 1 ABR incremental encoder 5 V
- Encoder input monitoring
- 2 additional inputs, e.g. for latch input
- 5 VDC, 24 VDC and GND for encoder supply

4.11.3.2 Order data

Model number	Short description	Figure

1) The offset specifies the position of the register within the CAN object.

4.11.3.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.3.8.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.3.8.4.1 Enabling error monitoring for the signal lines

Name:
CfO_BWCNTEnableMaskChannel7_0

This register requires individually enabling error monitoring for each of the signal channels. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers BW_Channel_x.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enable error monitoring for signal A lines	0	Error monitoring - Encoder Signal A disabled
		1	Error monitoring - Encoder Signal A enabled - Only default in bus controller function model
1	Enable error monitoring for signal B lines	0	Error monitoring - Encoder Signal B disabled
		1	Error monitoring - Encoder Signal B enabled - Only default in bus controller function model
2	Enable error monitoring for signal R lines	0	Error monitoring - Encoder Signal R disabled
		1	Error monitoring - Encoder Signal R enabled - Only default in bus controller function model
3 - 7	Reserved	0	

4.11.3.8.4.2 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

4.11.3.8.4.3 Setting the latch mode

Name:
CfO_LatchMode

This register is used to set the latch mode:

- Single shot latch mode:
  The latch function must be enabled/set. After a successful latch procedure, the activation must be reset in order for a new latch procedure to be activated.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired.

A changed counter state on Encoder01LatchCount indicates that the latch procedure has been performed. The counter value is stored in the latch register Encoder01Latch.

Data type	Value	Information
USINT	0	Single shot latch procedure
	1	Continuous latch procedure

4.11.3.8.4.4 Signal channels for triggering latch procedure

Name:
CfO_LatchComparator

This register defines the signal channels and their level for triggering the latch procedure.

- This mainly configures which channels are linked to generate the latch event. All three signals from the encoder and digital input 1 can be used for the "AND" operation.
- The "active voltage level" needed for the latch procedure can now be used according to the physical signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Defines signal level for encoder signal A	0	Low
		1	High
1	Defines signal level for encoder signal B	0	Low
		1	High
2	Defines signal level for encoder signal R	0	Low
		1	High
3	Defines signal level for digital input 1	0	Low
		1	High
4	Use encoder signal A to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal A
5	Use encoder signal B to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal B
6	Use encoder signal R to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal R
7	Use digital input 1 to trigger latch procedure	0	Disabled
		1	Latch function linked to digital input 1

4.11.3.8.4.5 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_SIframeGenID"

Name:
CfO_SIframeGenID

Data type	Value	Information
USINT	9	Only default in the bus controller module

Constant register "CfO_SystemCycleTime"

Name:
CfO_SystemCycleTime

Cycle time of encoder acquisition in 1/8 µs steps. 1 encoder value is acquired as the counter value per cycle.

Data type	Value	Information
UINT	800	800 = 100 µs; only default in the bus controller module

Constant register "CfO_PhyIOConfigCh01"

Name:
CfO_PhyIOConfigCh01

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh02"

Name:
CfO_PhyIOConfigCh02

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh03"

Name:
CfO_PhyIOConfigCh03

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh04"

Name:
CfO_PhyIOConfigCh04

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh05"

Name:
CfO_PhyIOConfigCh05

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_CounterCycleSelect"

Name:
CfO_CounterCycleSelect

Data type	Value	Information
USINT	2	Only default in the bus controller module

Constant register "CfO_CounterMode"

Name:
CfO_CounterMode

Data type	Value	Information
USINT	3	Only default in the bus controller module

4.11.3.8.5 Encoder - Communication

4.11.3.8.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.3.8.5.2 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.3.8.5.3 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.3.8.5.4 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.3.8.5.5 Counter value at the time of the last latch

Name:
Encoder01Latch

The counter value at the time of the last latch is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.3.8.5.6 Counter value of latch event

Name:
Encoder01LatchCount

The latch events are counted and stored in a cyclic 8-bit counter. This counter is incremented with each latch event, thereby indicating a new occurrence. The new latched counter value is stored in the respective latch register.

Data type	Value
SINT	-128 to 127

4.11.3.8.5.7 Encoder commands

Name:
Encoder01Command

This register can be used to

1 reset the counter value. The counter is kept at zero until this command is reset.
2 enable the latch procedure. If the latch configuration is valid and matches the hardware signals, then this activation causes the counter value to be saved in the latch register.

The two different latch configurations that are possible (see section 4.11.3.8.4.3 "Setting the latch mode") must be handled as follows:

- Single shot latch mode:
  After successful latching, indicated by the latch event counter, activation must be reset before any more latching is possible. The activation must be set again if additional latching is needed.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired. The latch event counter is incremented with each event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01Reset	0	Do not reset
		1	Set encoder value to 0
1	Encoder01LatchEnable	0	Do not activate latch
		1	Latching
2 - 7	Reserved	0	

4.11.3.8.5.8 Input status of signal lines

Name:
Encoder01_A
Encoder01_B
Encoder01_R
DigitalInput01 to DigitalInput02

This register displays the input status of the signal lines from the encoder and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01_A	0/1	Input state of encoder signal A
1	Encoder01_B	0/1	Input state of encoder signal B
2	Encoder01_R	0/1	Input state of encoder signal R
3	Reserved	0	
4	DigitalInput01	0/1	Input state - Digital input 1
5	DigitalInput02	0/1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.3.8.5.9 Error status of signal lines

The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Status of signal lines

Name:
BW_Channel_A
BW_Channel_B
BW_Channel_R

This register displays the error states of the signal lines from the encoder. The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_A	0	No error in encoder signal A
		1	Open line, short circuit or voltage level too low
1	BW_Channel_B	0	No error in encoder signal B
		1	Open line, short circuit or voltage level too low
2	BW_Channel_R	0	No error in encoder signal R
		1	Open line, short circuit or voltage level too low
3 - 7	Reserved	0	

Acknowledging error status of signal lines

Name:
BW_QuitChannel_A
BW_QuitChannel_B
BW_QuitChannel_R

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_A	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal A
1	BW_QuitChannel_B	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal B
2	BW_QuitChannel_R	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal R
3 - 7	Reserved	0	

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

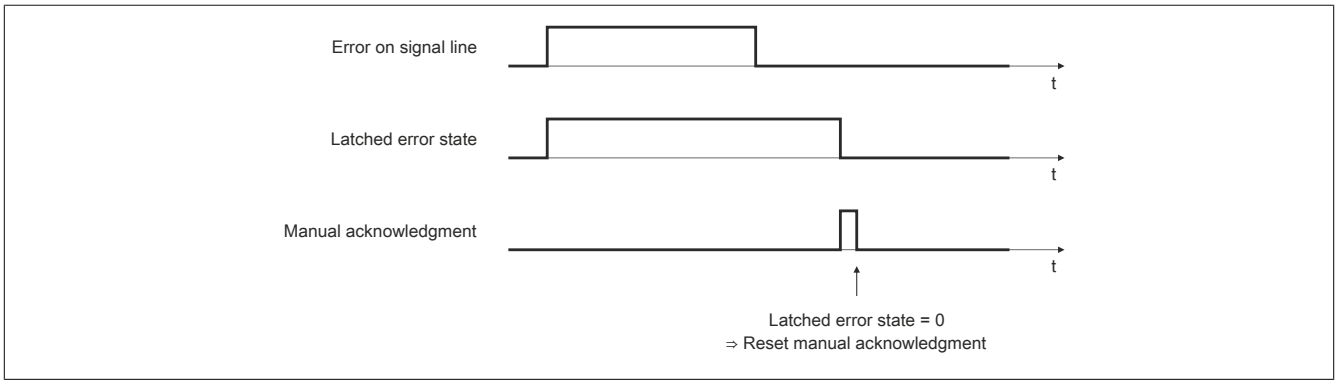

Figure 171: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

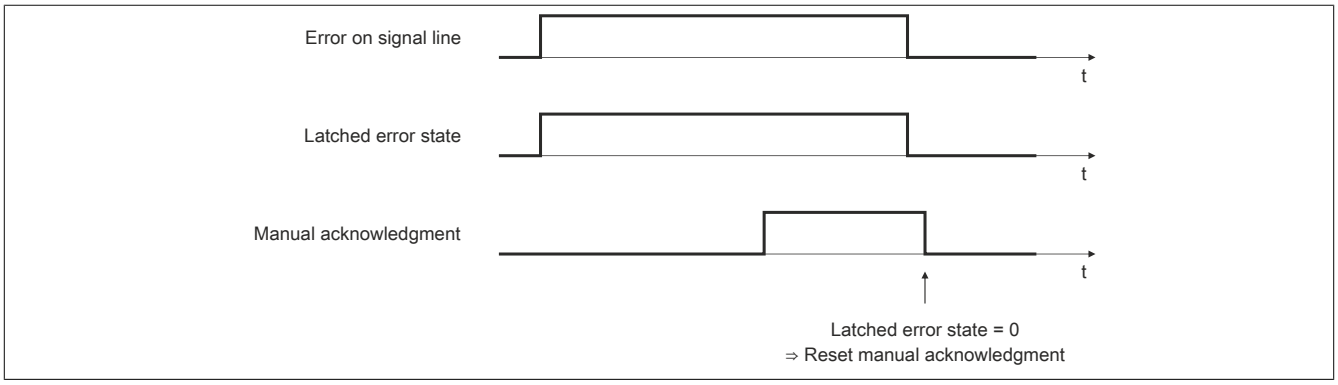

Figure 172: Cause of error not yet corrected before being acknowledged

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

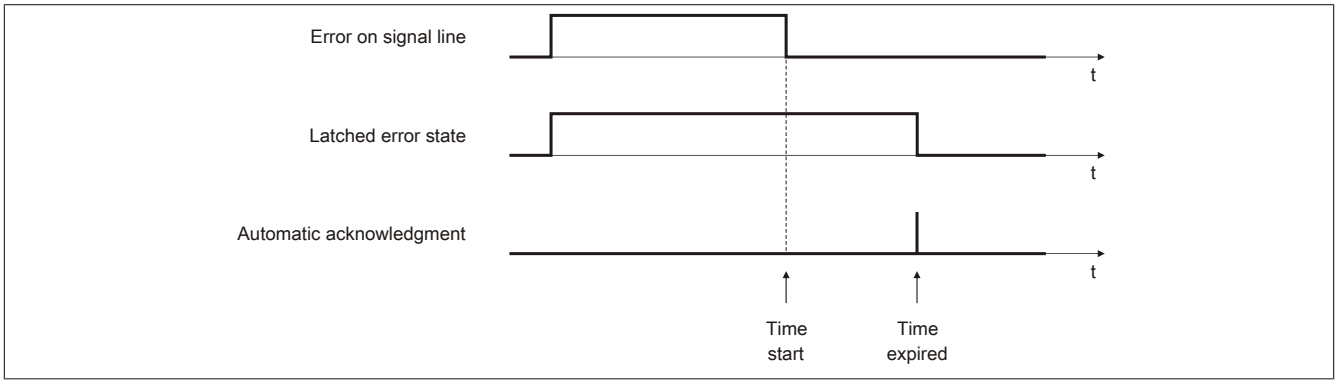

Figure 173: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

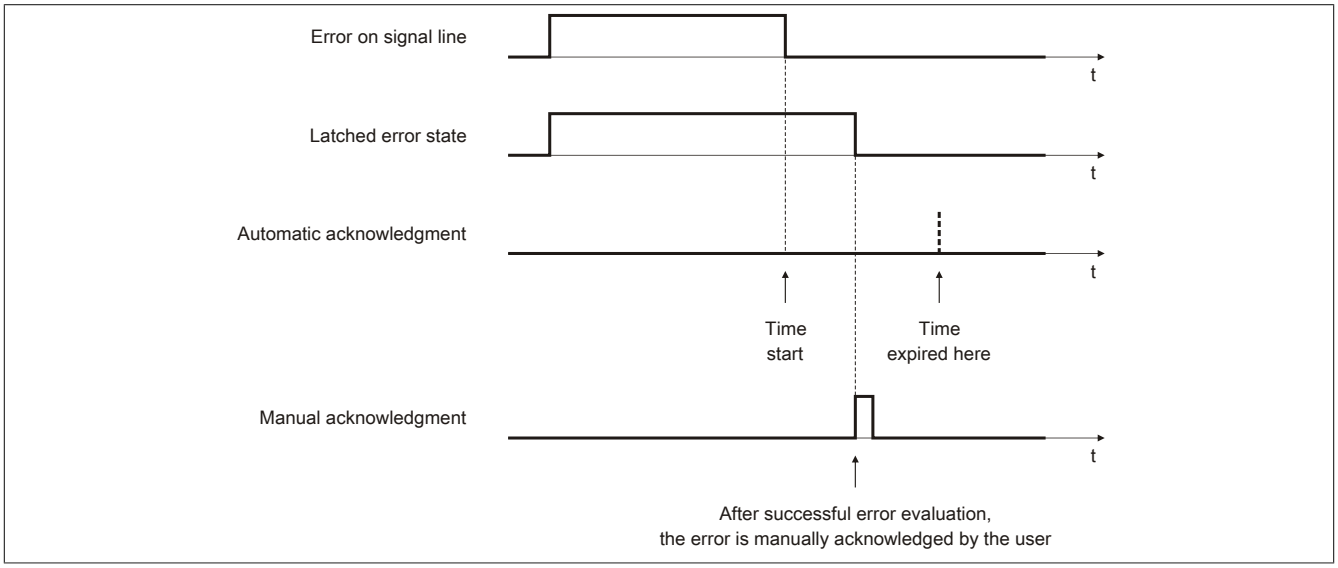

Figure 174: Automatic and manual acknowledge used

4.11.3.8.5.10 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.3.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.3.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.4 X20DC1178

4.11.4.1 General information

This module is equipped with one input for SSI absolute encoders with 5 V encoder signal. The data signal is monitored (Data, Data\).

- 1 SSI absolute encoder 5 V
- Monitoring the data signal
- 2 additional inputs
- 5 VDC, 24 VDC and GND for encoder supply

4.11.4.2 Order data

Model number	Short description	Figure
	Counter functions

Product ID	X20DC1178
Short description	
I/O module	1 SSI absolute encoder 5 V
General information	
B&R ID code	0xA708
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.1 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Quantity	2
Nominal voltage	24 VDC
Input voltage	24 VDC (-15% / +20%)
Input current at 24 VDC	Approx. 3.3 mA
Input filter	
Hardware	≤2 µs
Software	-
Connection type	3-wire connections
Input circuit	Sink
Input resistance	7.03 kΩ

Table 175: X20DC1178 - Technical data

Product ID	X20DC1178
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
SSI absolute encoder	
Counter size	Encoder-dependent up to 32-bit
Max. transfer rate	1 Mbit/s
Keying	Gray/Binary
Encoder signal	5 V, symmetrical
Isolation voltage between encoder and bus	500 V_{eff}
Overload behavior of the encoder supply	Short circuit protection, overload protection
Transfer rate	125 kbit/s / 250 kbit/s / 500 kbit/s / 1 Mbit/s
Encoder supply	
5 VDC	±5%, module-internal, max. 300 mA
24 VDC	Module-internal, max. 300 mA
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20

4.11.4.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	Either the encoder monitor has detected a line fault on the encoder inputs or a transfer error has occurred. The status bits must be evaluated in order to provide a more detailed definition of this error. The following error states are detected: • Open line • Short-circuit or voltage level too low • SSI cycle time violation • Parity error
			On	Error or reset status
	D1	Green		Input status - Data signal
	1 - 2	Green		Input state of the corresponding digital input

1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.4.5 Pinout

Shielded cables must be used for all signal lines.

1) The offset specifies the position of the register within the CAN object.

4.11.4.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.4.9.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.4.9.4.1 Setting the SSI sampling cycle time

The following two registers define the cycle time for SSI sampling.

Setting the interrupt

Name:

CfO_CycleSelect

This register assigns the principle interrupt setting:

- **Timer configuration (time setting with CfO_SystemCyclePrescaler register):** The SSI transfer can be started independently of the X2X cycle. The timer is synchronized with X2X Link.
- **AOAI:** Configuration with X2X interrupt, one-time start of the SSI transfer in the X2X cycle. The SSI transfer may require an entire X2X cycle.
- **SOSI:** Configuration with X2X interrupt, one-time start of the SSI transfer in the X2X cycle. The reaction time can be optimized with this setting if the SSI transfer doesn't exceed half of an X2X cycle.

Data type	Value	Filter
USINT	3	Timer [µsec] ... Time setting with register CfO_SystemCyclePrescaler
	10	AOAI
	14	SOSI

Setting the cycle time

Name:

CfO_SystemCyclePrescaler

The desired cycle time must be configured additionally for the timer setting using this register.

Data type	Value	Filter
USINT	1	50 µs
	2	100 µs
	4	200 µs
	8	400 µs
	16	800 µs
	0	All other settings in the CfO_CycleSelect register

4.11.4.9.4.2 Setting operating parameters

Name:
CfO_PhysicalMode

This register defines the operating parameters for the SSI encoder to correctly evaluate the data from the encoder.

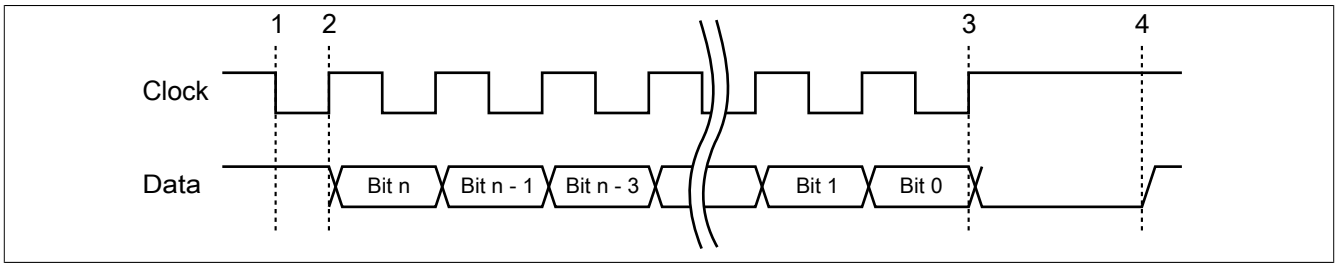
- **Parity:** Data with or without parity; an error is reported if there is an even or uneven parity mismatch.
- **Monoflop check:** The encoder uses the monoflop to signal the readiness to accept a new clock cycle.
- **Data coding:** Binary or gray coding of the data bits
- **Clock rate:** Speed of data transfer

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1	Parity bit	00	No parity bit (no clock bit output)
		01	Even parity bit
		10	Uneven parity bit
		11	Ignore parity bit (clock bit is output, but the result is ignored)
2 - 3	Monostable multivibrator testing	00	No monostable multivibrator check (no clock bit output)
		01	Check - Low level
		10	Check - High level
		11	Check - Ignore level (clock bit is output, but the result is ignored)
4	Data coding	0	Binary coding
		1	Gray coding
5	Reserved	0	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.11.4.9.4.3 Number of data bits

Name:

Cfo_DataBits

This register can be used to define the number of SSI encoder data bits.

Data type	Value	Filter
USINT	1 to 32	Number of SSI data bits

4.11.4.9.4.4 Leading zeros of the encoder

Name:

Cfo_NullBits

This register can be used to define the number of SSI encoder leading zeros.

Data type	Value	Filter
USINT	1 to 32	Number of leading zeros

4.11.4.9.4.5 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

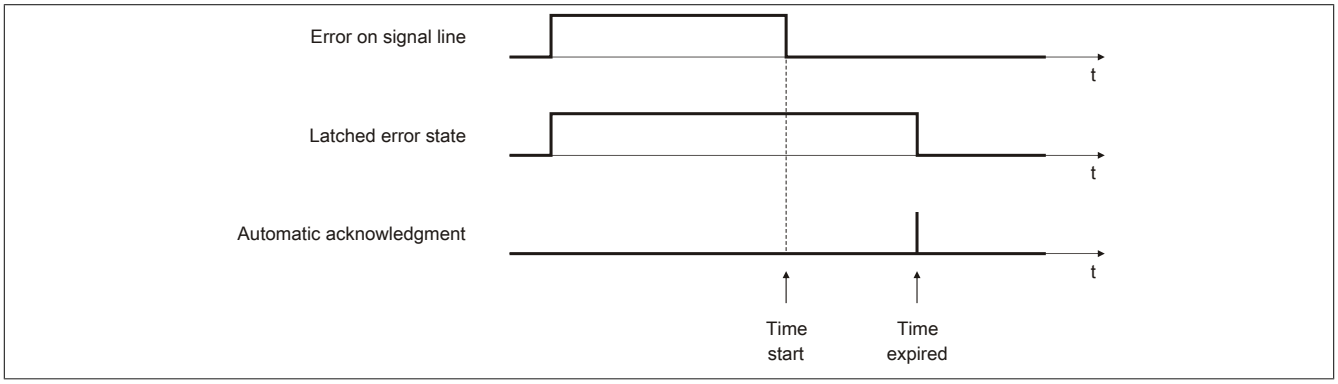


Figure 175: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

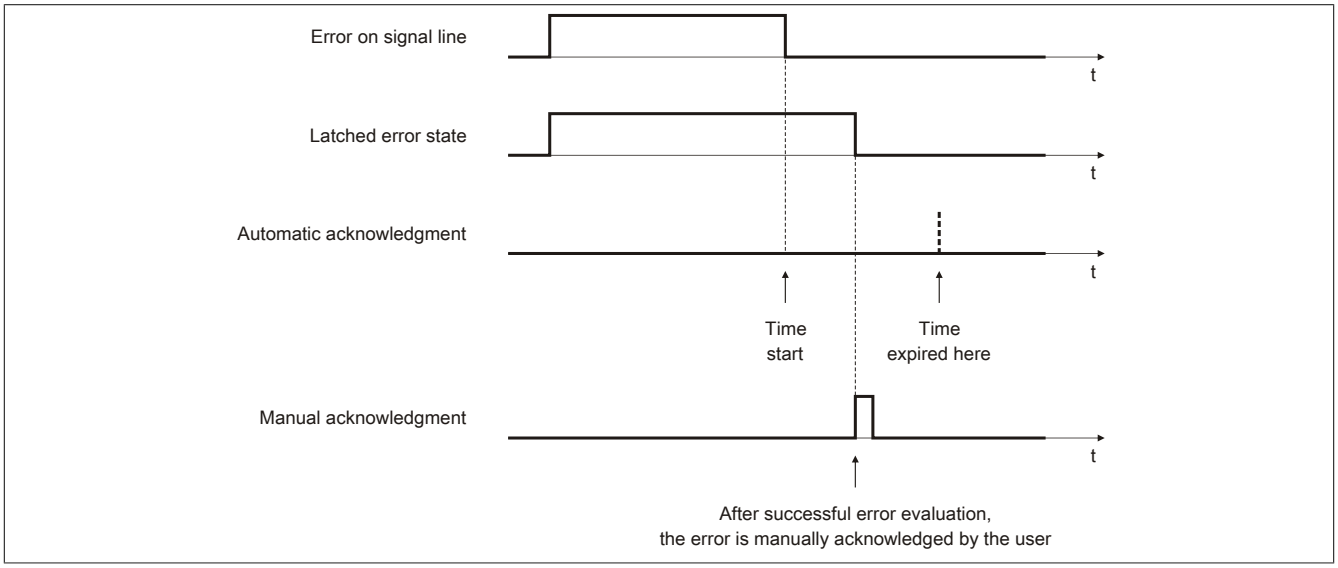

Figure 176: Automatic and manual acknowledge used

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

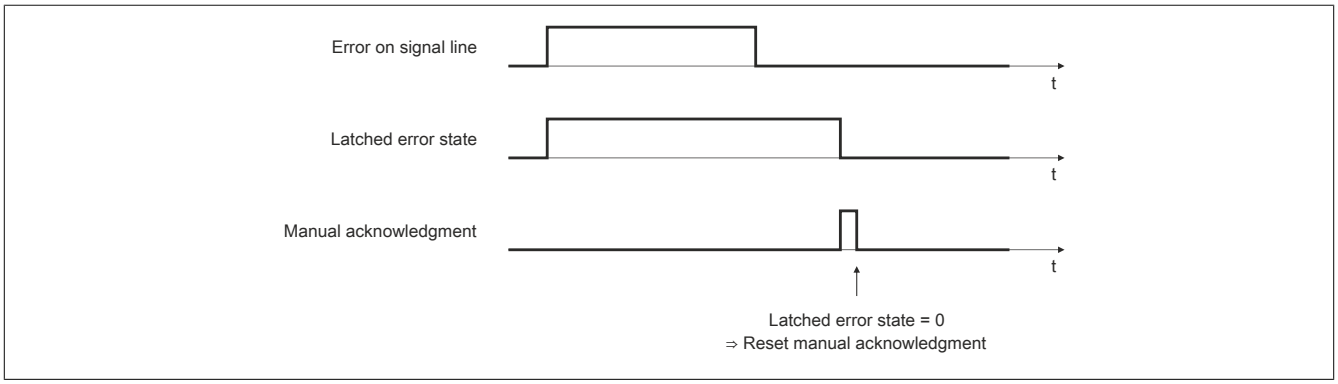

Figure 177: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

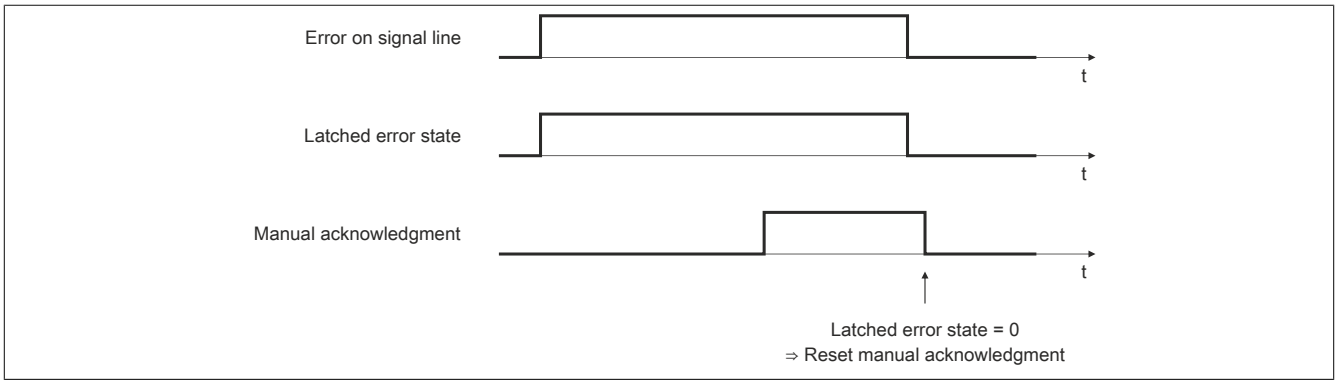

Figure 178: Cause of error not yet corrected before being acknowledged

4.11.4.9.4.6 Enable/disable error monitoring for the signal channels

Name:
CfO_BWSSIEnableMaskChannel7_0

This register allows error monitoring for each of the signal channels to be enabled individually. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder signal D	0	Error monitoring switched off
		1	Error monitoring enabled
1 - 7	Reserved	0	

4.11.4.9.4.7 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

4.11.4.9.5 Encoder - Communication

4.11.4.9.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.4.9.5.2 Input status of signal lines

Name:
DigitalInput0 to DigitalInput02

This register displays the input states for the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Reserved	0	
4	DigitalInput01	0 or 1	Input state - Digital input 1
5	DigitalInput02	0 or 1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.4.9.5.3 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value.

Data type	Value
UDINT	0 to 4.294.967.295
DINT	-2.147.483.648 to 2.147.483.647
UINT[1)]	0 to 65535

1) Only available in function model 0

4.11.4.9.5.4 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.4.9.5.5 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.4.9.5.6 State of the encoder

Name:
EncoderCycleTimeViolation
EncoderDataError

This register displays the error states that occurred while determining the position. The error states are latched when they occur and are maintained until acknowledged.

A cycle time error is triggered if:

- Transfer is still active: This means that the defined cycle time is shorter than the time resulting from the sum of the data bits and stop bits and the clock rate.
- The monoflop level does not match the defined start level
- There is an error pending on the signal line (open line, short circuit).

A data error is triggered if:

- The parity bit does not match.
- An error occurs on the signal line (open line, short circuit) during transfer.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EncoderCycleTimeViolation	0	No error
		1	Error status - Cycle time violation
1	EncoderDataError	0	No error
		1	Error status - Data error
2 - 7	Reserved	0	

4.11.4.9.5.7 Acknowledging error status of the encoder

Name:
EncoderQuitCycleTimeViolation
EncoderQuitDataError

This register can be used to acknowledge the latched data error states from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	EncoderQuitCycleTimeViolation	0	No acknowledgment
		1	Confirmation of error status - Cycle time violation
1	EncoderQuitDataError	0	No acknowledgment
		1	Confirmation of error status - Data error
2 - 7	Reserved	0	

4.11.4.9.5.8 Status of signal lines

Name:
BW_Channel_D

This register displays the error state of the signal line from the encoder. The error state is latched when it occurs and is maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_D	0	No error - Encoder signal D
		1	Error status - Open line or short circuit (voltage level too low)
1 - 7	Reserved	0	

4.11.4.9.5.9 Acknowledging error status of the signal line

Name:
BW_QuitChannel_D

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bit must also be reset or else any repetition of the error will be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_D	0	No acknowledgment
		1	Acknowledgment of error status
1 - 7	Reserved	0	

4.11.4.9.5.10 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.4.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.4.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.5 X20DC1196

4.11.5.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 5 V encoder signal.

- 1 ABR incremental encoder 5 V
- 2 additional inputs e.g. for home enable switch
- 5 VDC, 24 VDC and GND for encoder supply

4.11.5.2 Order data

Model number	Short description	Figure
	Counter functions	
X20DC1196	X20 digital counter module, 1 ABR incremental encoders, 5 V, 600 kHz input frequency, 4x evaluation	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed

4.11.5.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	A1	Green		Input state of counter input A
	B1	Green		Input state of counter input B
	R1	Green		Input state of reference pulse R
	1 - 2	Green		Input state of the corresponding digital input

1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.5.5 Pinout

Shielded cables must be used for all signal lines.

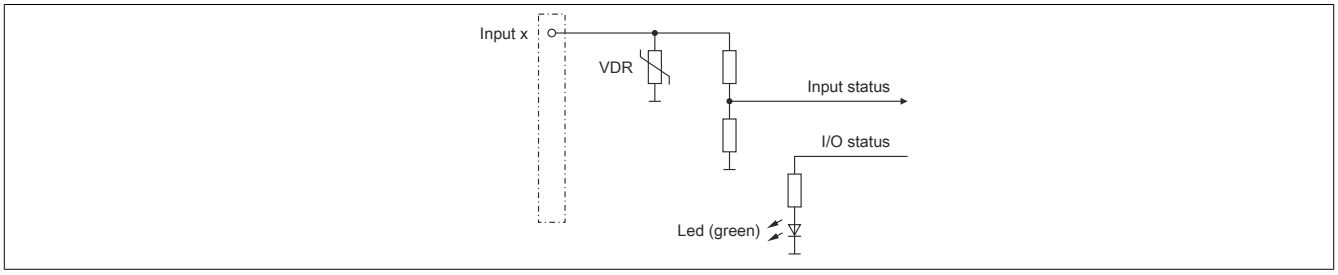
Standard inputs



4.11.5.8 Register description

4.11.5.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.5.8.2 Function model 0 - Standard and Function model 1 - Standard with 32-bit encoder counter value

The difference between function model 0 and function model 1 is the size of the data type for some registers.

- Function model 0 uses data type INT
- Function model 1 uses data type DINT (specified in parentheses)

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
4104	CfO_EdgeDetectFalling	USINT				•
4106	CfO_EdgeDetectRising	USINT				•
2064	CfO_PresetABR01_1(_32Bit)	(D)INT				•
2068	CfO_PresetABR01_2(_32Bit)	(D)INT				•
512	ConfigOutput24	UINT				•
522	ConfigOutput26	USINT				•
520	ConfigOutput27	USINT				•
Communication						
2116	ReferenceModeEncoder01	USINT			•	
2080	Encoder01	(D)INT	•			
264	Input state of digital inputs 1 to 2	USINT	•			
	DigitalInput01	Bit 4				
	DigitalInput02	Bit 5				
2118	StatusInput01	USINT	•			
40	Status of encoder supplies	USINT	•			
	PowerSupply01	Bit 0				
	PowerSupply02	Bit 1				

4.11.5.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
4104	-	CfO_EdgeDetectFalling	USINT				•
4106	-	CfO_EdgeDetectRising	USINT				•
2064	-	CfO_PresetABR01_1	INT				•
2068	-	CfO_PresetABR01_2	INT				•
512	-	ConfigOutput24	UINT				•
522	-	ConfigOutput26	USINT				•
520	-	ConfigOutput27	USINT				•
Communication							
2116	0	ReferenceModeEncoder01	USINT			•	
2080	0	Encoder01	INT	•			
264	2	Input state of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 4				
		DigitalInput02	Bit 5				
2118	4	StatusInput01	USINT	•			
40	3	Status of encoder supplies	USINT	•			
		PowerSupply01	Bit 0				
		PowerSupply02	Bit 1				

1) The offset specifies the position of the register within the CAN object.

4.11.5.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.5.8.4 ABR encoder - Configuration registers

4.11.5.8.4.1 Reference pulse

The following registers must be configured by a single acyclic write with the listed values so that the homing procedure is completed on the edge of the reference pulse.

The homing procedure can take place on:

- Rising edge
- Falling edge (default configuration)

Constant register "CfO_EdgeDetectFalling"

Name:

CfO_EdgeDetectFalling

Data type	Value	Filter
USINT	0x00	Configuration value for rising edge
	0x04	Configuration value for falling edge

Constant register "CfO_EdgeDetectRising"

Name:

CfO_EdgeDetectRising

Data type	Value	Filter
USINT	0x04	Configuration value for rising edge
	0x00	Configuration value for falling edge

Constant register "ConfigOutput24"

Name:

ConfigOutput24

This register contains the value for ABR encoder 1.

Data type	Value	Filter
UINT	0x1012	Configuration value for rising edge
	0x1002	Configuration value for falling edge

4.11.5.8.4.2 Setting the home position

Name:
Cfo_PresetABR01_1 to Cfo_PresetABR01_2

CfO_PresetABR01_1_32Bit to CfO_PresetABR01_2_32Bit (only in function model 1)

It is possible to specify two home positions with these registers through a one-off acyclic write, for example (default = 0). The configured values are applied to the counter values after a completed homing procedure.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.5.8.4.3 Homing with reference enable input

Regardless of the referencing mode, it is possible using this register to prevent the home position from being applied when the corresponding reference input voltage level occurs (see 4.11.5.8.5.2 "Input state of digital inputs 1 to 2": bit 4). The desired setting can be configured by a one-off acyclic write.

Voltage level for reference enable activation

Name:

ConfigOutput26

The voltage level of the digital inputs to activate reference enable is configured with this register.

Data type	Value	Filter
USINT	0x00	Reference enable is active at 0 VDC
	0x10	Reference enable for digital input 1 is active at 24 VDC
	0x20	Reference enable for digital input 2 is active at 24 VDC
	0x30	Reference enable for both digital inputs is active at 24 VDC

Reference enable of the input

Name:

ConfigOutput27

This register can be used to define whether the reference enable is activated.

Data type	Value	Filter
USINT	0x00	Reference enable input OFF (default)
	0x10	Reference enable input 1 enabled
	0x20	Reference enable input 2 enabled
	0x30	Reference enable input 1 and 2 enabled

4.11.5.8.5 ABR encoder - Configuration registers

4.11.5.8.5.1 Counter state of the encoder

Name:
Encoder01

The encoder values are represented as 16-bit or 32-bit counter values in this register.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.5.8.5.2 Input state of digital inputs 1 to 2

Name:
DigitalInput01 to DigitalInput02.

This register displays the input status of the encoders and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit	Name	Value	Information
0	Encoder A	0 or 1	Input state
1	Encoder B	0 or 1	Input state
2	Encoder A + B	0 or 1	Input state of reference pulse
4	DigitalInput01	0 or 1	Input state - Digital input 1
5	DigitalInput02	0 or 1	Input state - Digital input 2

4.11.5.8.5.3 Reading the referencing mode

Name:
ReferenceModeEncoder01

This register determines the referencing mode.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1		00	Referencing OFF
		01	Single shot referencing
		11	Continuous referencing
2 - 5		0	Bits permanently set = 0
6 - 7		00	Referencing OFF
		11	Bits permanently set = 1

This results in the following values:

Binary	Hex	Function
00000000	0x00	Referencing OFF
11000001	0xC1	Single shot referencing For a new start after the completed homing procedure: • Write value 0x00 • Wait until bit 0 to bit 3 of the StatusInput01 register takes on the value 0. Counter bits 4 to 7 are not erased • Switch homing procedure on again
11000011	0xC3	Continuous referencing Referencing occurs at every reference pulse.

It is important to know how the optional reference enable is configured. See section 4.11.5.8.4.3 "Homing with reference enable input"

4.11.5.8.5.4 Status of the homing procedure

Name:
StatusInput01

This register contains information regarding whether the referencing process is off, active or complete.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Reference pulse without homing[1)]	0	No reference impulse without homing has occurred yet
		1	At least a reference impulse without homing has occurred
1	State change	0 or 1	Changes with each reference pulse without homing
2	Reference pulse with homing[1)]	0	No homing has occurred yet
		1	At least one homing procedure has occurred
3	State change	0 or 1	Changes with each homing procedure that has taken place
4	Reference pulse	0	The last reference pulse didn't bring about a homing procedure
		1	The last reference pulse brought about a homing procedure
5 - 7	Counter	x	Free-running counter, increased with each reference pulse

1) Always 1 after the first reference pulse that has occurred

Examples of possible values:

Binary	Hex	Function
0x00000000	0x00	Referencing OFF or homing procedure already active
0x00111100	0x3CE	First homing procedure complete Reference value applied in the Encoder01 register
0xxxx11100	0xxB	Bits 5 to 7 are changed with each reference pulse
0xxxx1x100	0xxx	Continuously changing the bits with the "Continuous referencing" setting. The reference value is applied to the Encoder01 register on each reference pulse.

It is important to know how the optional reference enable (see section 4.11.5.8.4.3 "Homing with reference enable input" on page 904) is configured.

4.11.5.8.5.5 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.5.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.5.8.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.5.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.6 X20(c)DC1198

4.11.6.1 General information

This module is equipped with one input for SSI absolute encoders with 5 V encoder signal.

- 1 SSI absolute encoder 5 V
- 2 additional inputs
- 5 VDC, 24 VDC and GND for encoder supply

4.11.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.11.6.3 Order data

Model number	Short description	Figure
	Counter functions	
X20DC1198	X20 digital counter module, 1 SSI absolute encoder, 5 V, 1 Mbit/s, 32-bit	
X20cDC1198	X20 digital counter module, coated, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous

4.11.6.10 Register description

4.11.6.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.6.10.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
7176	ConfigOutput14	UINT				•
7172	ConfigAdvanced	UDINT				•
Communication						
7184	Encoder01	UDINT	•			
264	Input state of digital inputs 1 to 2	USINT	•			
	DigitalInput01	Bit 4				
	DigitalInput02	Bit 5				
40	Status of encoder supplies	USINT	•			
	PowerSupply01	Bit 0				
	PowerSupply02	Bit 1				

4.11.6.10.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
7176	-	ConfigOutput14	UINT				•
7172	-	ConfigAdvanced	UDINT				•
Communication							
7184	0	Encoder01	UDINT	•			
264	4	Input state of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 4				
		DigitalInput02	Bit 5				
40	5	Status of encoder supplies	USINT	•			
		PowerSupply01	Bit 0				
		PowerSupply02	Bit 1				

1) The offset specifies the position of the register within the CAN object.

4.11.6.10.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.6.10.4 SSI encoder configuration register

4.11.6.10.4.1 Standard configuration

Name:
ConfigOutput14

This configuration register is used to set the coding, the clock rate and the number of bits. Default = 0. This must be set once using an acyclic write command.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding

4.11.6.10.4.2 Extended configuration

Name:
ConfigAdvanced

This configuration register is used to set the coding, the clock rate, the number of bits and the monostable multivibrator settings. Default = 0. This must be set once using an acyclic write command.

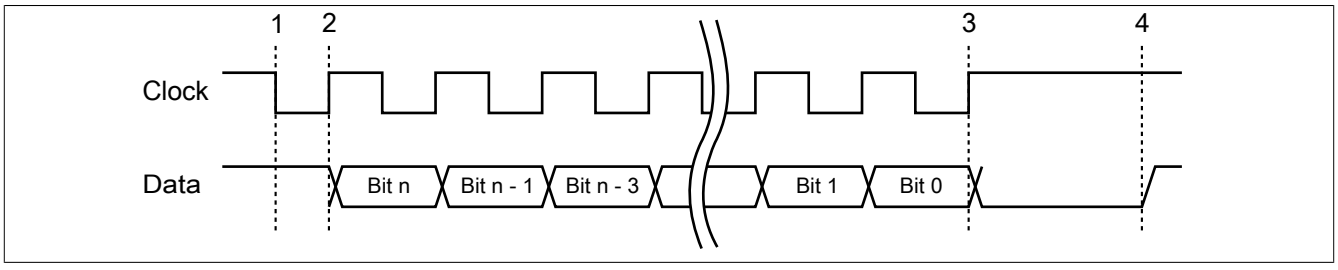
It only differs from ConfigOutput14 by data length and additional monostable multivibrator testing.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding
16 - 17	Monostable multivibrator testing	00	Check OFF, no additional clock bit
		01	Check set to High level
		10	Check set to Low level
		11	Level is clocked but ignored
18 - 31	Reserved	0	Reserved

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.11.6.10.5 SSI encoder - Configuration registers

4.11.6.10.5.1 SSI position values

Name:
Encoder01

The SSI encoder value is displayed as a 32-bit position value. The SSI position value is generated synchronously with the X2X cycle.

Data type	Value	Filter
UDINT	0 to 4,294,967,295	SSI position

4.11.6.10.5.2 Input state of digital inputs 1 to 2

Name:
DigitalInput01 to DigitalInput02

This register is used to indicate the input state of digital inputs 1 to 2.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
4	DigitalInput01	0 or 1	Input state - Digital input 1
5	DigitalInput02	0 or 1	Input state - Digital input 2

4.11.6.10.5.3 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.6.10.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.6.10.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.6.10.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.7 X20DC11A6

4.11.7.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 5 V encoder signal. The encoder inputs are monitored (A, B, R, A\, B\, R\).

- 1 ABR incremental encoder 5 V
- Encoder input monitoring (up to 250 kHz input frequency)
- 2 additional inputs, e.g. for latch input
- 5 VDC, 24 VDC and GND for encoder supply

4.11.7.2 Order data

4.11.7.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	The encoder monitor has detected a line fault on the encoder inputs. The status bits must be evaluated in order to provide a more detailed definition of this error. The following error states are detected: • Broken connection (up to 250 kHz input frequency) • Short-circuit or voltage level too low
			On	Error or reset status
	A1	Green		Input state of counter input A
	B1	Green		Input state of counter input B
	R1	Green		Input state of reference pulse R
	1 - 2	Green		Input state of the corresponding digital input

1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.7.5 Pinout

Shielded cables must be used for all signal lines.

1) The offset specifies the position of the register within the CAN object.

4.11.7.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.7.8.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.7.8.4.1 Enabling error monitoring for the signal lines

Name:
CfO_BWCNTEnableMaskChannel7_0

This register requires individually enabling error monitoring for each of the signal channels. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers BW_Channel_x.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enable error monitoring for signal A lines	0	Error monitoring - Encoder Signal A disabled
		1	Error monitoring - Encoder Signal A enabled - Only default in bus controller function model
1	Enable error monitoring for signal B lines	0	Error monitoring - Encoder Signal B disabled
		1	Error monitoring - Encoder Signal B enabled - Only default in bus controller function model
2	Enable error monitoring for signal R lines	0	Error monitoring - Encoder Signal R disabled
		1	Error monitoring - Encoder Signal R enabled - Only default in bus controller function model
3 - 7	Reserved	0	

4.11.7.8.4.2 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

4.11.7.8.4.3 Setting the latch mode

Name:
CfO_LatchMode

This register is used to set the latch mode:

- Single shot latch mode:
  The latch function must be enabled/set. After a successful latch procedure, the activation must be reset in order for a new latch procedure to be activated.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired.

A changed counter state on Encoder01LatchCount indicates that the latch procedure has been performed. The counter value is stored in the latch register Encoder01Latch.

Data type	Value	Information
USINT	0	Single shot latch procedure
	1	Continuous latch procedure

4.11.7.8.4.4 Signal channels for triggering latch procedure

Name:
CfO_LatchComparator

This register defines the signal channels and their level for triggering the latch procedure.

- This mainly configures which channels are linked to generate the latch event. All three signals from the encoder and digital input 1 can be used for the "AND" operation.
- The "active voltage level" needed for the latch procedure can now be used according to the physical signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Defines signal level for encoder signal A	0	Low
		1	High
1	Defines signal level for encoder signal B	0	Low
		1	High
2	Defines signal level for encoder signal R	0	Low
		1	High
3	Defines signal level for digital input 1	0	Low
		1	High
4	Use encoder signal A to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal A
5	Use encoder signal B to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal B
6	Use encoder signal R to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal R
7	Use digital input 1 to trigger latch procedure	0	Disabled
		1	Latch function linked to digital input 1

4.11.7.8.4.5 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_SIframeGenID"

Name:
CfO_SIframeGenID

Data type	Value	Information
USINT	9	Only default in the bus controller module

Constant register "CfO_SystemCycleTime"

Name:
CfO_SystemCycleTime

Cycle time of encoder acquisition in 1/8 µs steps. 1 encoder value is acquired as the counter value per cycle.

Data type	Value	Information
UINT	800	800 = 100 µs; only default in the bus controller module

Constant register "CfO_PhyIOConfigCh01"

Name:
CfO_PhyIOConfigCh01

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh02"

Name:
CfO_PhyIOConfigCh02

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh03"

Name:
CfO_PhyIOConfigCh03

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh04"

Name:
CfO_PhyIOConfigCh04

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh05"

Name:
CfO_PhyIOConfigCh05

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_CounterCycleSelect"

Name:
CfO_CounterCycleSelect

Data type	Value	Information
USINT	2	Only default in the bus controller module

Constant register "CfO_CounterMode"

Name:
CfO_CounterMode

Data type	Value	Information
USINT	3	Only default in the bus controller module

4.11.7.8.5 Encoder - Communication

4.11.7.8.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.7.8.5.2 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.7.8.5.3 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.7.8.5.4 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.7.8.5.5 Counter value at the time of the last latch

Name:
Encoder01Latch

The counter value at the time of the last latch is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.7.8.5.6 Counter value of latch event

Name:
Encoder01LatchCount

The latch events are counted and stored in a cyclic 8-bit counter. This counter is incremented with each latch event, thereby indicating a new occurrence. The new latched counter value is stored in the respective latch register.

Data type	Value
SINT	-128 to 127

4.11.7.8.5.7 Encoder commands

Name:
Encoder01Command

This register can be used to

1 reset the counter value. The counter is kept at zero until this command is reset.
2 enable the latch procedure. If the latch configuration is valid and matches the hardware signals, then this activation causes the counter value to be saved in the latch register.

The two different latch configurations that are possible (see section 4.11.3.8.4.3 "Setting the latch mode") must be handled as follows:

- Single shot latch mode:
  After successful latching, indicated by the latch event counter, activation must be reset before any more latching is possible. The activation must be set again if additional latching is needed.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired. The latch event counter is incremented with each event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01Reset	0	Do not reset
		1	Set encoder value to 0
1	Encoder01LatchEnable	0	Do not activate latch
		1	Latching
2 - 7	Reserved	0	

4.11.7.8.5.8 Input status of signal lines

Name:
Encoder01_A
Encoder01_B
Encoder01_R
DigitalInput01 to DigitalInput02

This register displays the input status of the signal lines from the encoder and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01_A	0/1	Input state of encoder signal A
1	Encoder01_B	0/1	Input state of encoder signal B
2	Encoder01_R	0/1	Input state of encoder signal R
3	Reserved	0	
4	DigitalInput01	0/1	Input state - Digital input 1
5	DigitalInput02	0/1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.7.8.5.9 Error status of signal lines

The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Status of signal lines

Name:
BW_Channel_A
BW_Channel_B
BW_Channel_R

This register displays the error states of the signal lines from the encoder. The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_A	0	No error in encoder signal A
		1	Open line, short circuit or voltage level too low
1	BW_Channel_B	0	No error in encoder signal B
		1	Open line, short circuit or voltage level too low
2	BW_Channel_R	0	No error in encoder signal R
		1	Open line, short circuit or voltage level too low
3 - 7	Reserved	0	

Acknowledging error status of signal lines

Name:
BW_QuitChannel_A
BW_QuitChannel_B
BW_QuitChannel_R

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_A	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal A
1	BW_QuitChannel_B	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal B
2	BW_QuitChannel_R	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal R
3 - 7	Reserved	0	

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

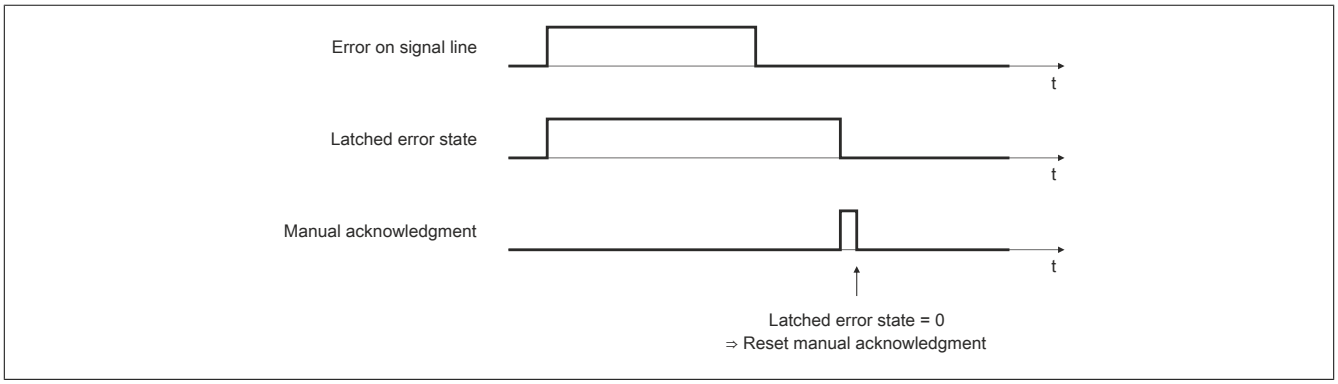

Figure 179: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

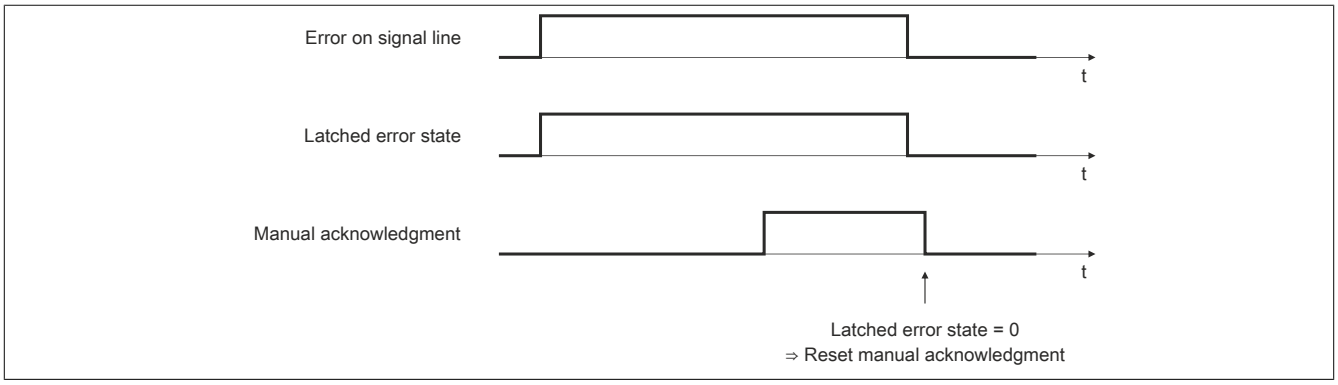

Figure 180: Cause of error not yet corrected before being acknowledged

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

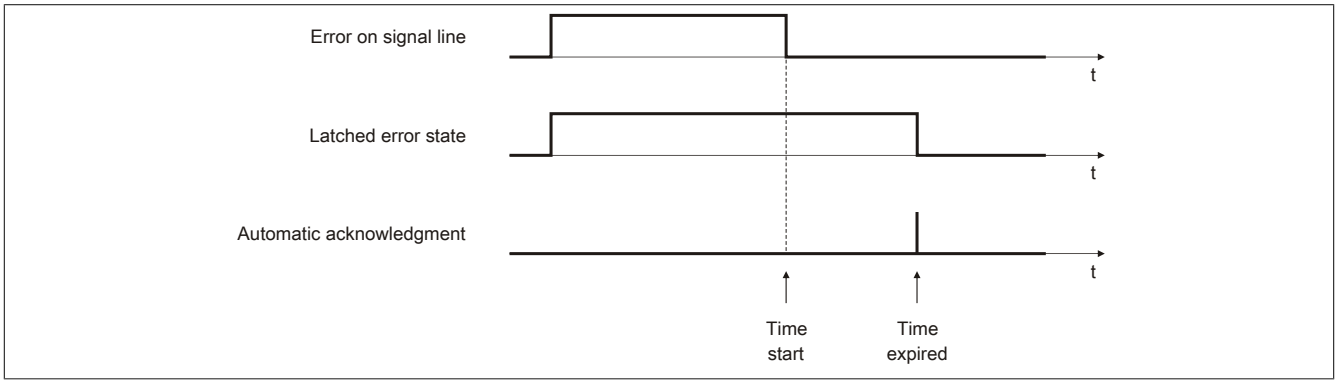

Figure 181: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

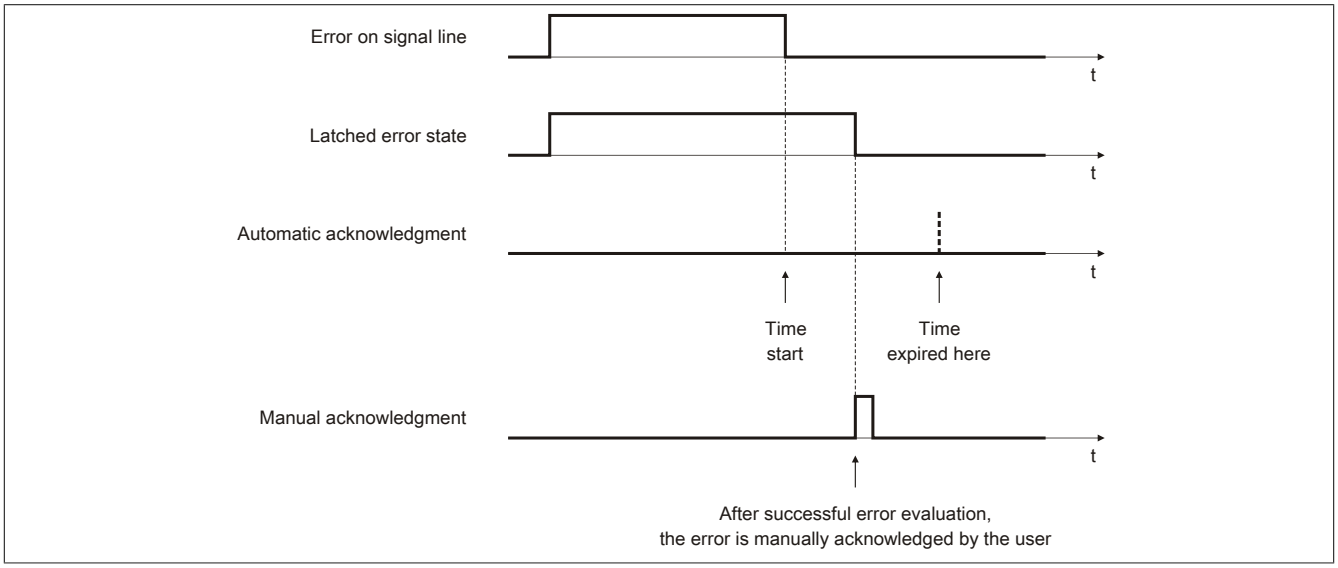

Figure 182: Automatic and manual acknowledge used

4.11.7.8.5.10 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.7.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.7.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.8 X20DC1376

4.11.8.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 24 V encoder signal. The encoder inputs are monitored (A, B, R).

- 1 ABR incremental encoder 24 V, asymmetric
- Encoder input monitoring
- 2 additional inputs, e.g. for latch input
- 24 VDC and GND for encoder supply

4.11.8.2 Order data

Model number	Short description	Figure

4.11.8.3 Technical data

Product ID	X20DC1376
Short description	
I/O module	1 ABR incremental encoder 24 V
General information	
Input voltage	24 VDC (-15% / +20%)
B&R ID code	0xA705
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.3 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Quantity	2
Nominal voltage	24 VDC
Input voltage	24 VDC (-15% / +20%)
Input current at 24 VDC	Approx. 3.3 mA
Input filter	
Hardware	≤2 µs
Software	-
Connection type	3-wire connections
Input circuit	Sink

Table 183: X20DC1376 - Technical data

Product ID	X20DC1376
Additional functions	Latch input
Input resistance	7.03 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
ABR incremental encoder	
Encoder inputs	24 V, asymmetrical (single-ended)
Counter size	16/32-bit
Input frequency	Max. 100 kHz
Evaluation	4x
Encoder supply	Module-internal, max. 600 mA
Input filter	
Hardware	≤1 µs
Software	-
Isolation voltage between encoder and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 183: X20DC1376 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.11.8.4 LED status indicators

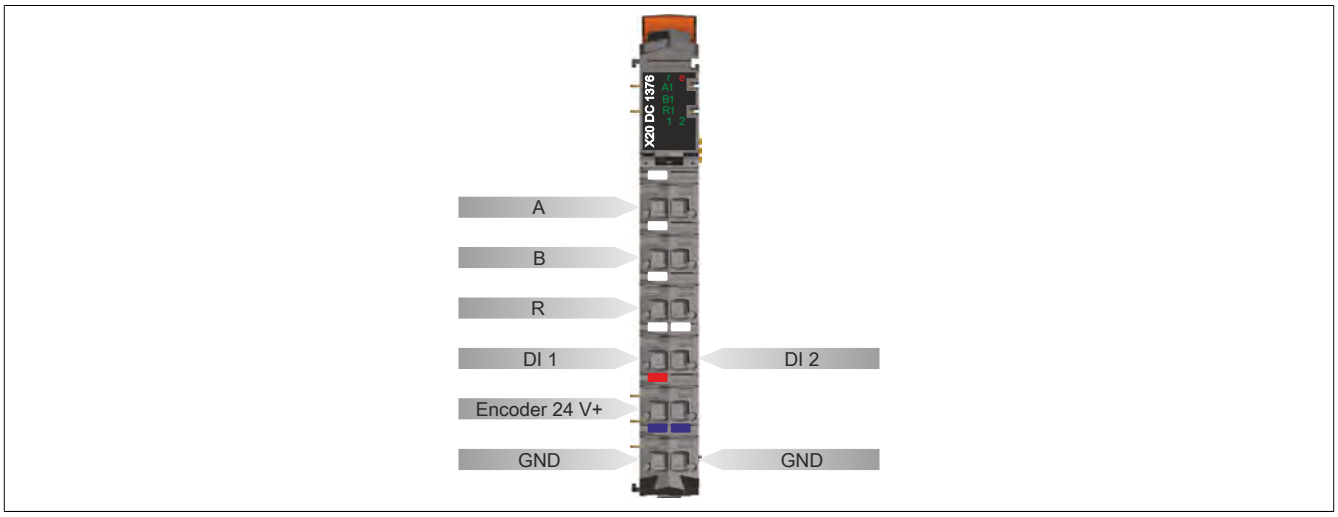
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	The encoder monitor has detected a line fault on the encoder inputs. The status bits must be evaluated in order to provide a more detailed definition of this error. The following error states are detected: • Open line • Short-circuit or voltage level too low
			On	Error or reset status
	A1	Green		Input state of counter input A
	B1	Green		Input state of counter input B
	R1	Green		Input state of reference pulse R
	1 - 2	Green		Input status - digital input

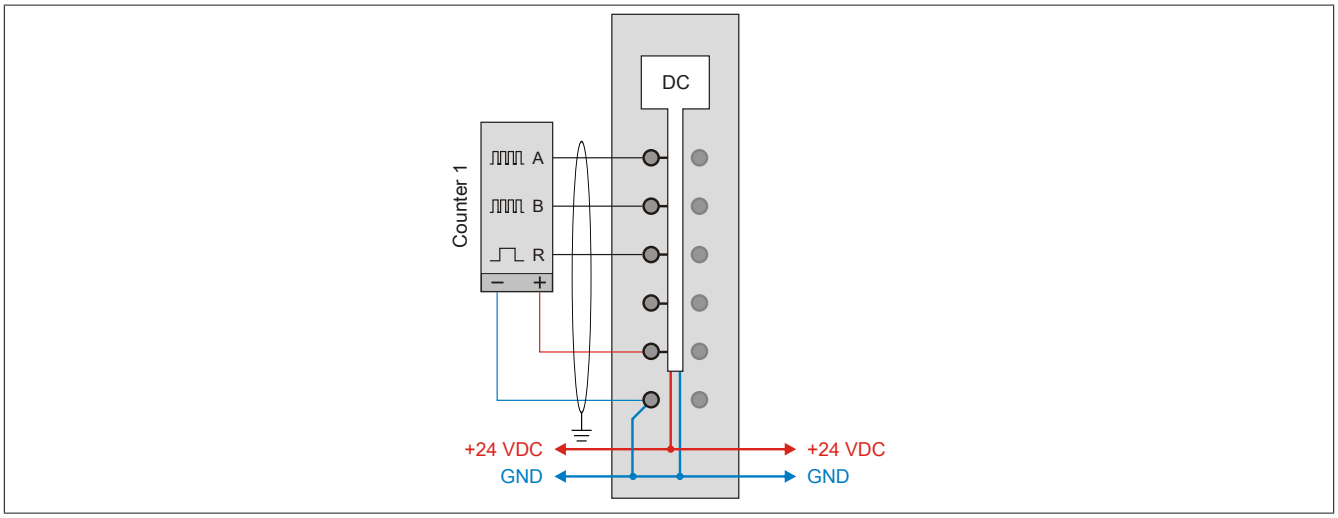
1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.8.5 Pinout

Shielded cables must be used for all signal lines.

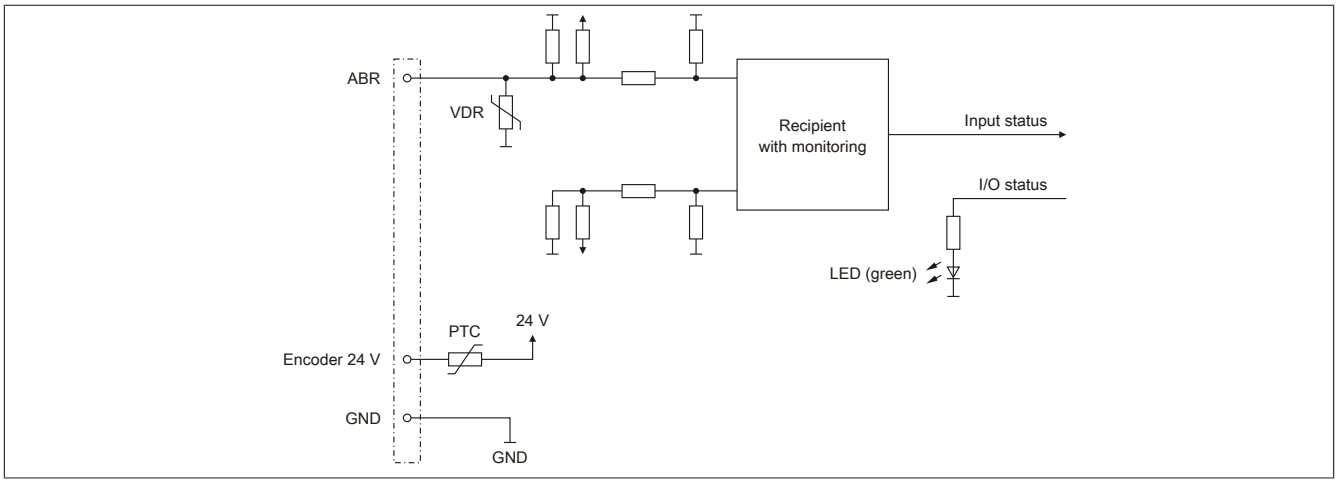


4.11.8.6 Connection example

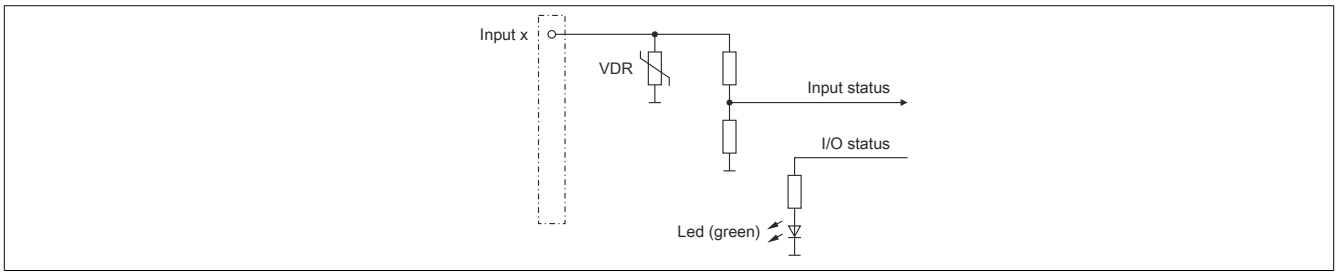


4.11.8.7 Input circuit diagram

Counter inputs



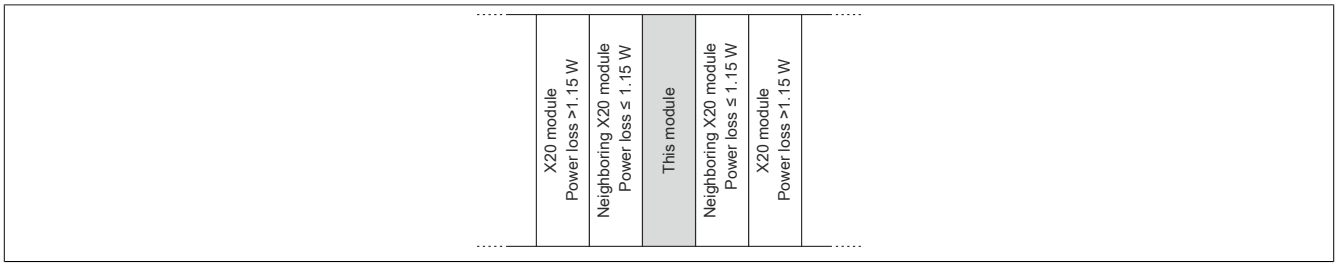
Standard inputs



4.11.8.8 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.11.8.9 Register description

4.11.8.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.8.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write

1) The offset specifies the position of the register within the CAN object.

4.11.8.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.8.9.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.8.9.4.1 Enabling error monitoring for the signal lines

Name:
CfO_BWCNTEnableMaskChannel7_0

This register requires individually enabling error monitoring for each of the signal channels. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers BW_Channel_x.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enable error monitoring for signal A lines	0	Error monitoring - Encoder Signal A disabled
		1	Error monitoring - Encoder Signal A enabled - Only default in bus controller function model
1	Enable error monitoring for signal B lines	0	Error monitoring - Encoder Signal B disabled
		1	Error monitoring - Encoder Signal B enabled - Only default in bus controller function model
2	Enable error monitoring for signal R lines	0	Error monitoring - Encoder Signal R disabled
		1	Error monitoring - Encoder Signal R enabled - Only default in bus controller function model
3 - 7	Reserved	0	

4.11.8.9.4.2 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

4.11.8.9.4.3 Setting the latch mode

Name:
CfO_LatchMode

This register is used to set the latch mode:

- Single shot latch mode:
  The latch function must be enabled/set. After a successful latch procedure, the activation must be reset in order for a new latch procedure to be activated.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired.

A changed counter state on Encoder01LatchCount indicates that the latch procedure has been performed. The counter value is stored in the latch register Encoder01Latch.

Data type	Value	Information
USINT	0	Single shot latch procedure
	1	Continuous latch procedure

4.11.8.9.4.4 Signal channels for triggering latch procedure

Name:
CfO_LatchComparator

This register defines the signal channels and their level for triggering the latch procedure.

- This mainly configures which channels are linked to generate the latch event. All three signals from the encoder and digital input 1 can be used for the "AND" operation.
- The "active voltage level" needed for the latch procedure can now be used according to the physical signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Defines signal level for encoder signal A	0	Low
		1	High
1	Defines signal level for encoder signal B	0	Low
		1	High
2	Defines signal level for encoder signal R	0	Low
		1	High
3	Defines signal level for digital input 1	0	Low
		1	High
4	Use encoder signal A to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal A
5	Use encoder signal B to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal B
6	Use encoder signal R to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal R
7	Use digital input 1 to trigger latch procedure	0	Disabled
		1	Latch function linked to digital input 1

4.11.8.9.4.5 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_SIframeGenID"

Name:
CfO_SIframeGenID

Data type	Value	Information
USINT	9	Only default in the bus controller module

Constant register "CfO_SystemCycleTime"

Name:
CfO_SystemCycleTime

Cycle time of encoder acquisition in 1/8 µs steps. 1 encoder value is acquired as the counter value per cycle.

Data type	Value	Information
UINT	800	800 = 100 µs; only default in the bus controller module

Constant register "CfO_PhyIOConfigCh01"

Name:
CfO_PhyIOConfigCh01

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh02"

Name:
CfO_PhyIOConfigCh02

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh03"

Name:
CfO_PhyIOConfigCh03

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh04"

Name:
CfO_PhyIOConfigCh04

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh05"

Name:
CfO_PhyIOConfigCh05

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_CounterCycleSelect"

Name:
CfO_CounterCycleSelect

Data type	Value	Information
USINT	2	Only default in the bus controller module

Constant register "CfO_CounterMode"

Name:
CfO_CounterMode

Data type	Value	Information
USINT	3	Only default in the bus controller module

4.11.8.9.5 Encoder - Communication

4.11.8.9.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.8.9.5.2 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.8.9.5.3 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.8.9.5.4 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.8.9.5.5 Counter value at the time of the last latch

Name:
Encoder01Latch

The counter value at the time of the last latch is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.8.9.5.6 Counter value of latch event

Name:
Encoder01LatchCount

The latch events are counted and stored in a cyclic 8-bit counter. This counter is incremented with each latch event, thereby indicating a new occurrence. The new latched counter value is stored in the respective latch register.

Data type	Value
SINT	-128 to 127

4.11.8.9.5.7 Encoder commands

Name:
Encoder01Command

This register can be used to

1 reset the counter value. The counter is kept at zero until this command is reset.
2 enable the latch procedure. If the latch configuration is valid and matches the hardware signals, then this activation causes the counter value to be saved in the latch register.

The two different latch configurations that are possible (see section 4.11.3.8.4.3 "Setting the latch mode") must be handled as follows:

- Single shot latch mode:
  After successful latching, indicated by the latch event counter, activation must be reset before any more latching is possible. The activation must be set again if additional latching is needed.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired. The latch event counter is incremented with each event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01Reset	0	Do not reset
		1	Set encoder value to 0
1	Encoder01LatchEnable	0	Do not activate latch
		1	Latching
2 - 7	Reserved	0	

4.11.8.9.5.8 Input status of signal lines

Name:
Encoder01_A
Encoder01_B
Encoder01_R
DigitalInput01 to DigitalInput02

This register displays the input status of the signal lines from the encoder and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01_A	0/1	Input state of encoder signal A
1	Encoder01_B	0/1	Input state of encoder signal B
2	Encoder01_R	0/1	Input state of encoder signal R
3	Reserved	0	
4	DigitalInput01	0/1	Input state - Digital input 1
5	DigitalInput02	0/1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.8.9.5.9 Error status of signal lines

The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Status of signal lines

Name:
BW_Channel_A
BW_Channel_B
BW_Channel_R

This register displays the error states of the signal lines from the encoder. The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_A	0	No error in encoder signal A
		1	Open line, short circuit or voltage level too low
1	BW_Channel_B	0	No error in encoder signal B
		1	Open line, short circuit or voltage level too low
2	BW_Channel_R	0	No error in encoder signal R
		1	Open line, short circuit or voltage level too low
3 - 7	Reserved	0	

Acknowledging error status of signal lines

Name:
BW_QuitChannel_A
BW_QuitChannel_B
BW_QuitChannel_R

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_A	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal A
1	BW_QuitChannel_B	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal B
2	BW_QuitChannel_R	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal R
3 - 7	Reserved	0	

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

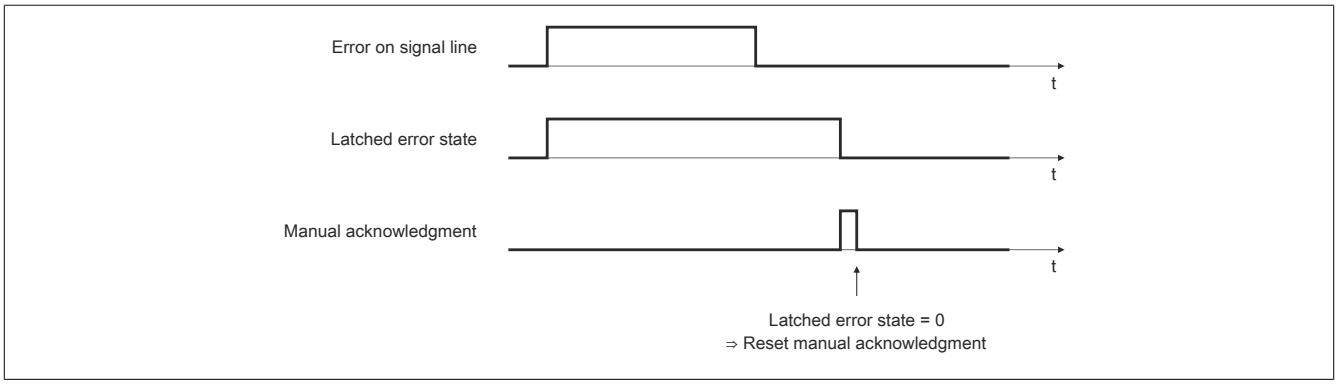

Figure 183: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

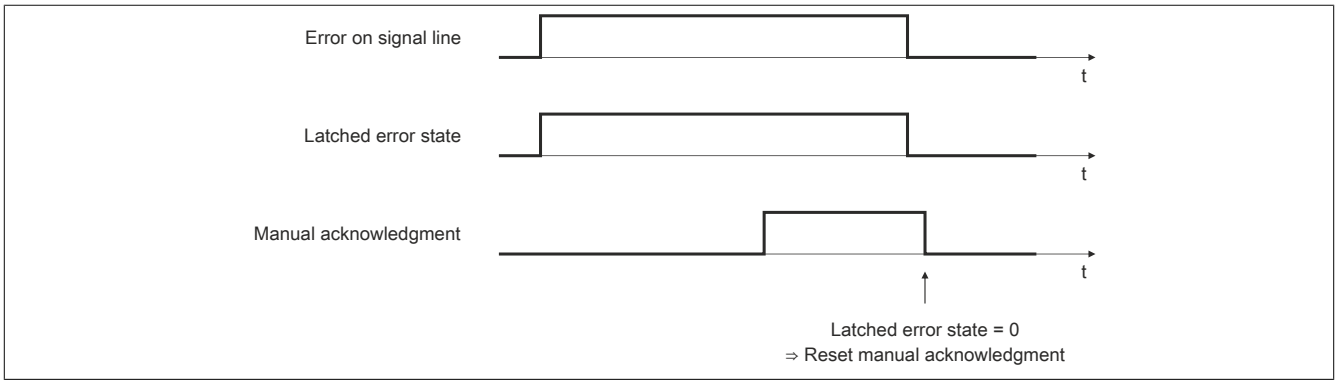

Figure 184: Cause of error not yet corrected before being acknowledged

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

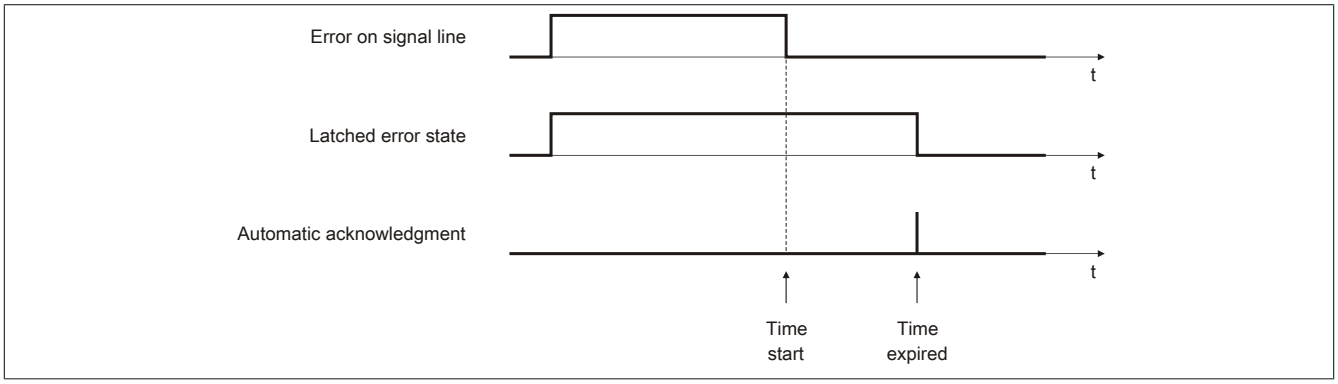

Figure 185: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

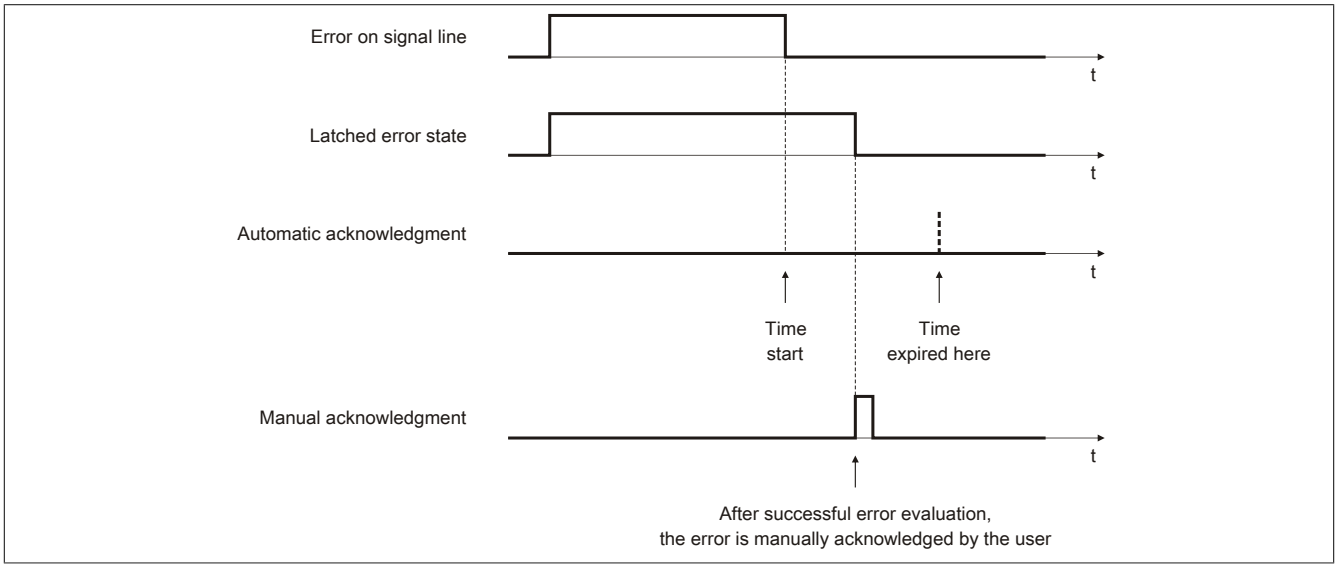

Figure 186: Automatic and manual acknowledge used

4.11.8.9.5.10 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.8.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.8.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.9 X20DC137A

4.11.9.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 24 V differential signals. The encoder inputs are monitored (A, B, R, A\, B\, R\).

- 1 ABR incremental encoder 24 V, differential
- Encoder input monitoring
- 2 additional inputs, e.g. for latch input
- 24 VDC and GND for encoder supply

4.11.9.2 Order data

Model number	Short description	Figure
	Counter functions	
X20DC137A	X20 digital counter module, 1x ABR incremental encoder, 24 V (differential), 300 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module

4.11.9.3 Technical data

Product ID	X20DC137A
Short description	
I/O module	1 ABR incremental encoder 24 V, differential
General information	
B&R ID code	0xDD28
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.2 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Quantity	2
Nominal voltage	24 VDC
Input voltage	24 VDC (-15% / +20%)
Input current at 24 VDC	Approx. 3.3 mA
Input filter	
Hardware	≤2 µs
Software	-
Connection type	3-wire connections
Input circuit	Sink
Additional functions	Latch input
Input resistance	7.03 kΩ

Table 185: X20DC137A - Technical data

Product ID	X20DC137A
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
ABR incremental encoder	
Encoder inputs	24 V, differential
Counter size	16/32-bit
Input frequency	Max. 300 kHz
Evaluation	4x
Encoder supply	Module-internal, max. 600 mA
Input filter	
Hardware	≤0.5 µs
Software	-
Common-mode range	-10 V ≤ V_{CM} ≤ +13 V
Overload behavior of the encoder supply	Short circuit protection, overload protection
Isolation voltage between encoder and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 185: X20DC137A - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.11.9.4 LED status indicators

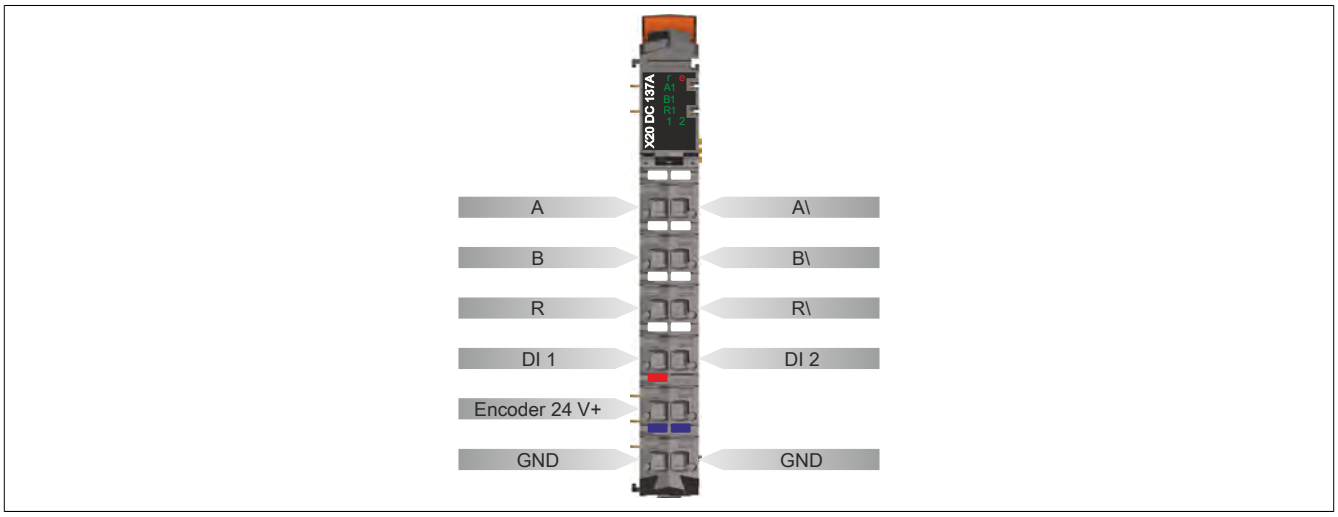
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	The encoder monitor has detected a line fault on the encoder inputs. The status bits must be evaluated in order to provide a more detailed definition of this error. The following error states are detected: • Open line • Short-circuit or voltage level too low
			On	Error or reset status
	A1	Green		Input state of counter input A
	B1	Green		Input state of counter input B
	R1	Green		Input state of reference pulse R
	1 - 2	Green		Input state of the corresponding digital input

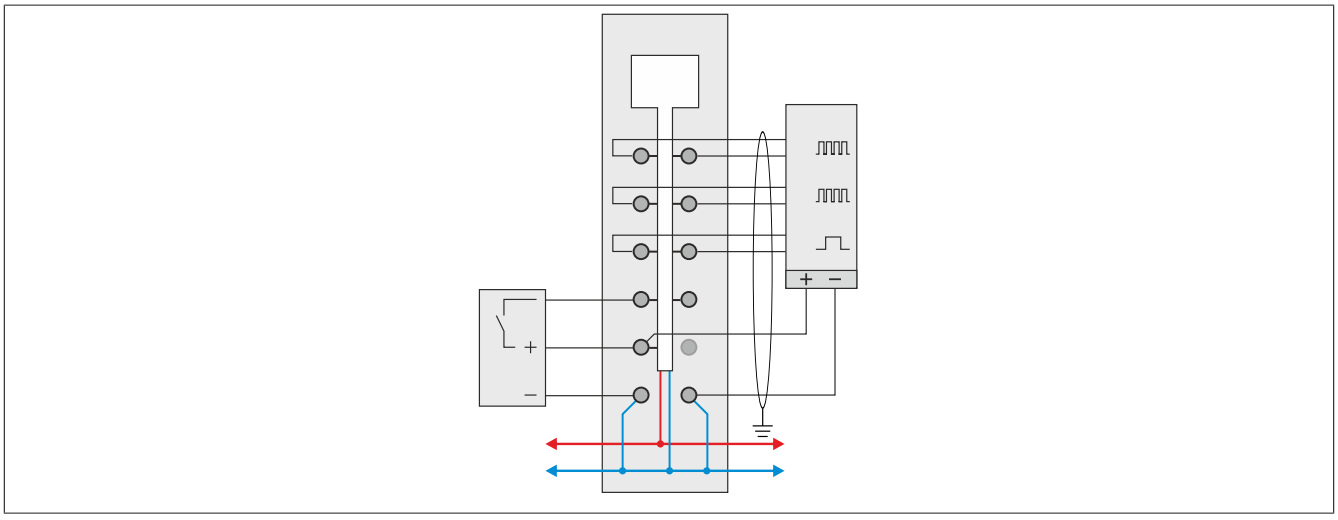
1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.9.5 Pinout

Shielded cables must be used for all signal lines.

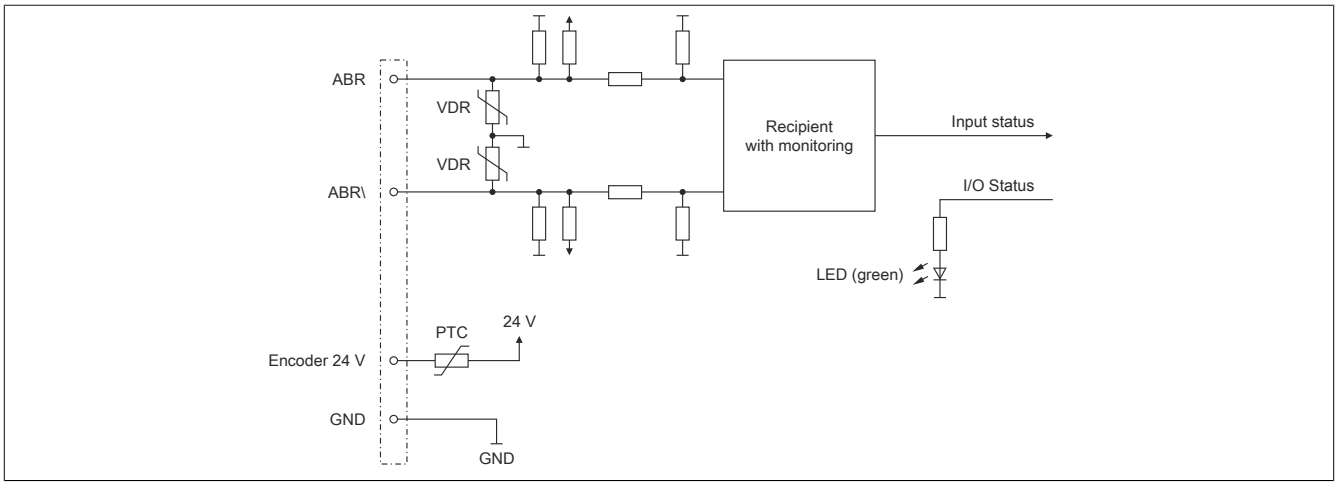


4.11.9.6 Connection example

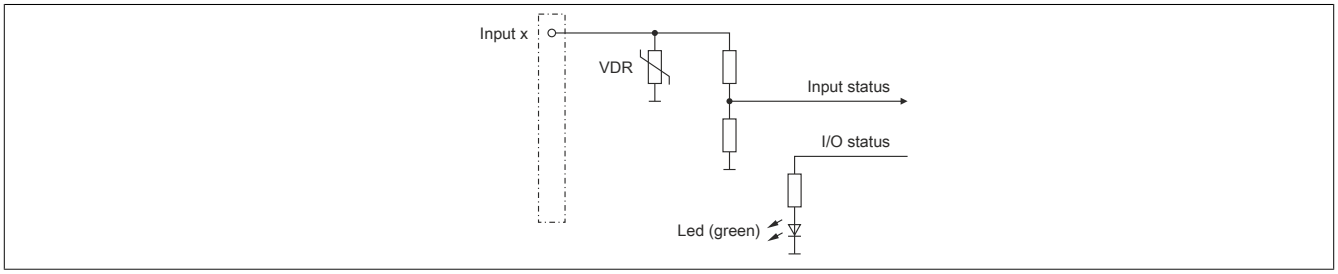


4.11.9.7 Input circuit diagram

Counter inputs



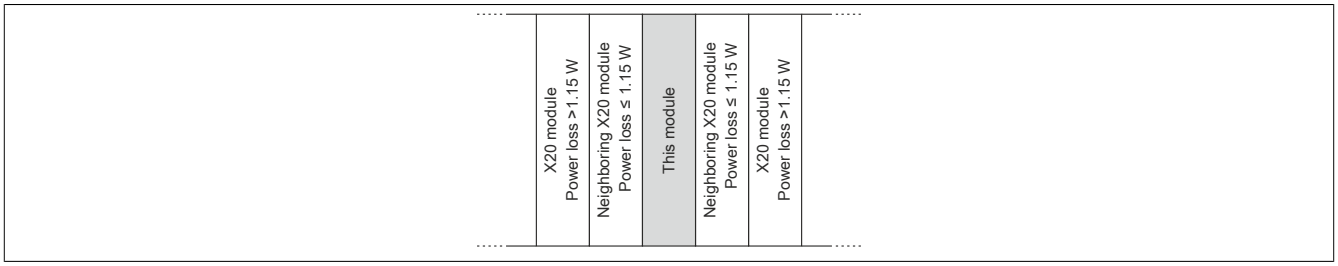
Standard inputs



4.11.9.8 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.11.9.9 Register description

4.11.9.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.9.9.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

4.11.9.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.9.9.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.9.9.4.1 Enabling error monitoring for the signal lines

Name:
CfO_BWCNTEnableMaskChannel7_0

This register requires individually enabling error monitoring for each of the signal channels. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers BW_Channel_x.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enable error monitoring for signal A lines	0	Error monitoring - Encoder Signal A disabled
		1	Error monitoring - Encoder Signal A enabled - Only default in bus controller function model
1	Enable error monitoring for signal B lines	0	Error monitoring - Encoder Signal B disabled
		1	Error monitoring - Encoder Signal B enabled - Only default in bus controller function model
2	Enable error monitoring for signal R lines	0	Error monitoring - Encoder Signal R disabled
		1	Error monitoring - Encoder Signal R enabled - Only default in bus controller function model
3 - 7	Reserved	0	

4.11.9.9.4.2 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

4.11.9.9.4.3 Setting the latch mode

Name:
CfO_LatchMode

This register is used to set the latch mode:

- Single shot latch mode:
  The latch function must be enabled/set. After a successful latch procedure, the activation must be reset in order for a new latch procedure to be activated.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired.

A changed counter state on Encoder01LatchCount indicates that the latch procedure has been performed. The counter value is stored in the latch register Encoder01Latch.

Data type	Value	Information
USINT	0	Single shot latch procedure
	1	Continuous latch procedure

4.11.9.9.4.4 Signal channels for triggering latch procedure

Name:
CfO_LatchComparator

This register defines the signal channels and their level for triggering the latch procedure.

- This mainly configures which channels are linked to generate the latch event. All three signals from the encoder and digital input 1 can be used for the "AND" operation.
- The "active voltage level" needed for the latch procedure can now be used according to the physical signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Defines signal level for encoder signal A	0	Low
		1	High
1	Defines signal level for encoder signal B	0	Low
		1	High
2	Defines signal level for encoder signal R	0	Low
		1	High
3	Defines signal level for digital input 1	0	Low
		1	High
4	Use encoder signal A to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal A
5	Use encoder signal B to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal B
6	Use encoder signal R to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal R
7	Use digital input 1 to trigger latch procedure	0	Disabled
		1	Latch function linked to digital input 1

4.11.9.9.4.5 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_SIframeGenID"

Name:
CfO_SIframeGenID

Data type	Value	Information
USINT	9	Only default in the bus controller module

Constant register "CfO_SystemCycleTime"

Name:
CfO_SystemCycleTime

Cycle time of encoder acquisition in 1/8 µs steps. 1 encoder value is acquired as the counter value per cycle.

Data type	Value	Information
UINT	800	800 = 100 µs; only default in the bus controller module

Constant register "CfO_PhyIOConfigCh01"

Name:
CfO_PhyIOConfigCh01

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh02"

Name:
CfO_PhyIOConfigCh02

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh03"

Name:
CfO_PhyIOConfigCh03

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh04"

Name:
CfO_PhyIOConfigCh04

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh05"

Name:
CfO_PhyIOConfigCh05

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_CounterCycleSelect"

Name:
CfO_CounterCycleSelect

Data type	Value	Information
USINT	2	Only default in the bus controller module

Constant register "CfO_CounterMode"

Name:
CfO_CounterMode

Data type	Value	Information
USINT	3	Only default in the bus controller module

4.11.9.9.5 Encoder - Communication

4.11.9.9.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.9.9.5.2 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.9.9.5.3 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.9.9.5.4 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.9.9.5.5 Counter value at the time of the last latch

Name:
Encoder01Latch

The counter value at the time of the last latch is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.9.9.5.6 Counter value of latch event

Name:
Encoder01LatchCount

The latch events are counted and stored in a cyclic 8-bit counter. This counter is incremented with each latch event, thereby indicating a new occurrence. The new latched counter value is stored in the respective latch register.

Data type	Value
SINT	-128 to 127

4.11.9.9.5.7 Encoder commands

Name:
Encoder01Command

This register can be used to

1 reset the counter value. The counter is kept at zero until this command is reset.
2 enable the latch procedure. If the latch configuration is valid and matches the hardware signals, then this activation causes the counter value to be saved in the latch register.

The two different latch configurations that are possible (see section 4.11.3.8.4.3 "Setting the latch mode") must be handled as follows:

- Single shot latch mode:
  After successful latching, indicated by the latch event counter, activation must be reset before any more latching is possible. The activation must be set again if additional latching is needed.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired. The latch event counter is incremented with each event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01Reset	0	Do not reset
		1	Set encoder value to 0
1	Encoder01LatchEnable	0	Do not activate latch
		1	Latching
2 - 7	Reserved	0	

4.11.9.9.5.8 Input status of signal lines

Name:
Encoder01_A
Encoder01_B
Encoder01_R
DigitalInput01 to DigitalInput02

This register displays the input status of the signal lines from the encoder and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01_A	0/1	Input state of encoder signal A
1	Encoder01_B	0/1	Input state of encoder signal B
2	Encoder01_R	0/1	Input state of encoder signal R
3	Reserved	0	
4	DigitalInput01	0/1	Input state - Digital input 1
5	DigitalInput02	0/1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.9.9.5.9 Error status of signal lines

The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Status of signal lines

Name:
BW_Channel_A
BW_Channel_B
BW_Channel_R

This register displays the error states of the signal lines from the encoder. The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_A	0	No error in encoder signal A
		1	Open line, short circuit or voltage level too low
1	BW_Channel_B	0	No error in encoder signal B
		1	Open line, short circuit or voltage level too low
2	BW_Channel_R	0	No error in encoder signal R
		1	Open line, short circuit or voltage level too low
3 - 7	Reserved	0	

Acknowledging error status of signal lines

Name:
BW_QuitChannel_A
BW_QuitChannel_B
BW_QuitChannel_R

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_A	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal A
1	BW_QuitChannel_B	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal B
2	BW_QuitChannel_R	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal R
3 - 7	Reserved	0	

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

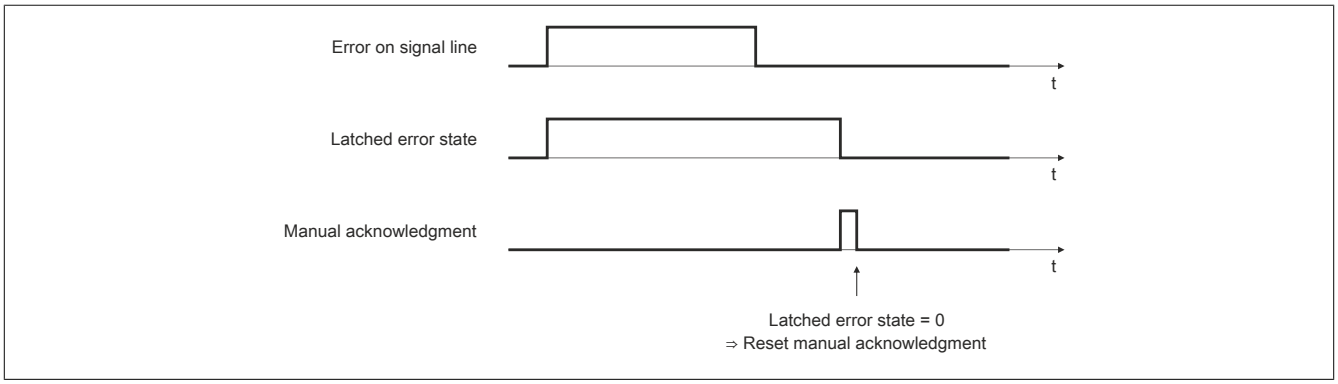

Figure 187: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

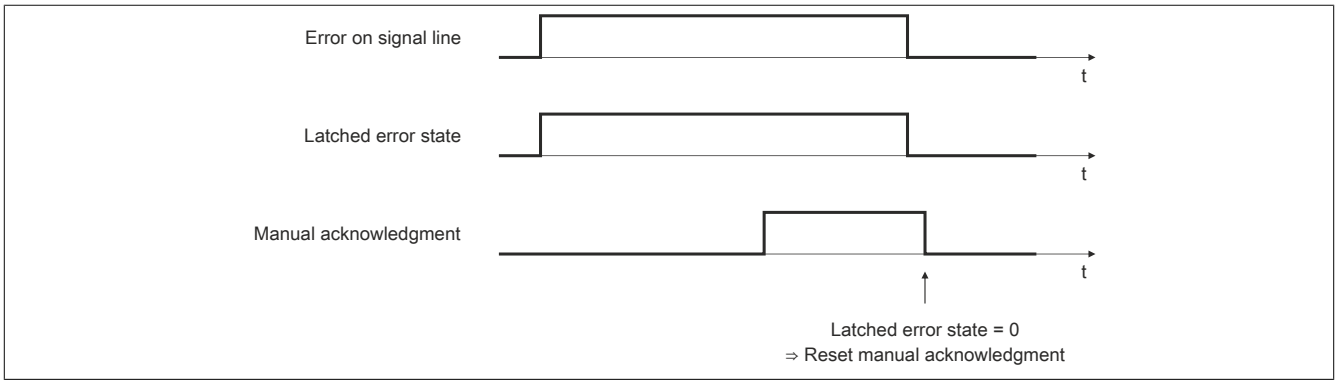

Figure 188: Cause of error not yet corrected before being acknowledged

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

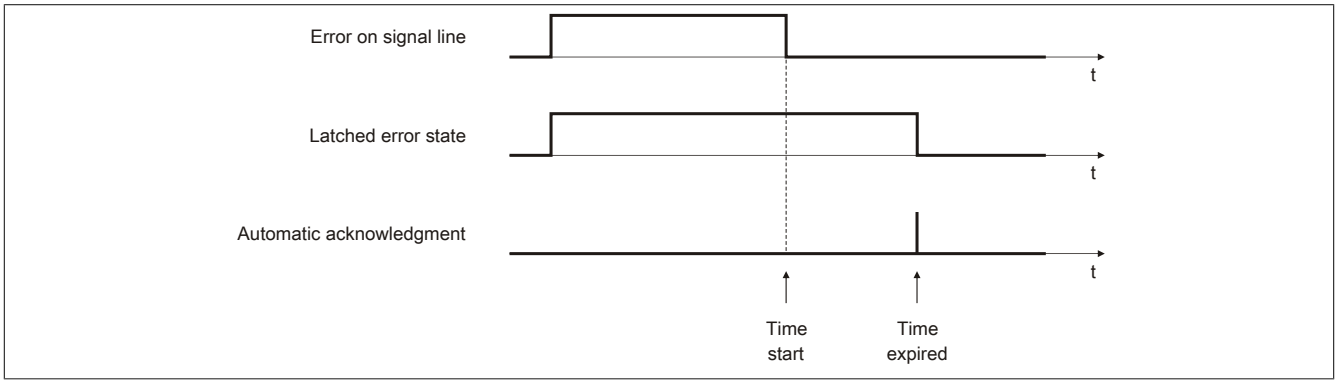

Figure 189: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

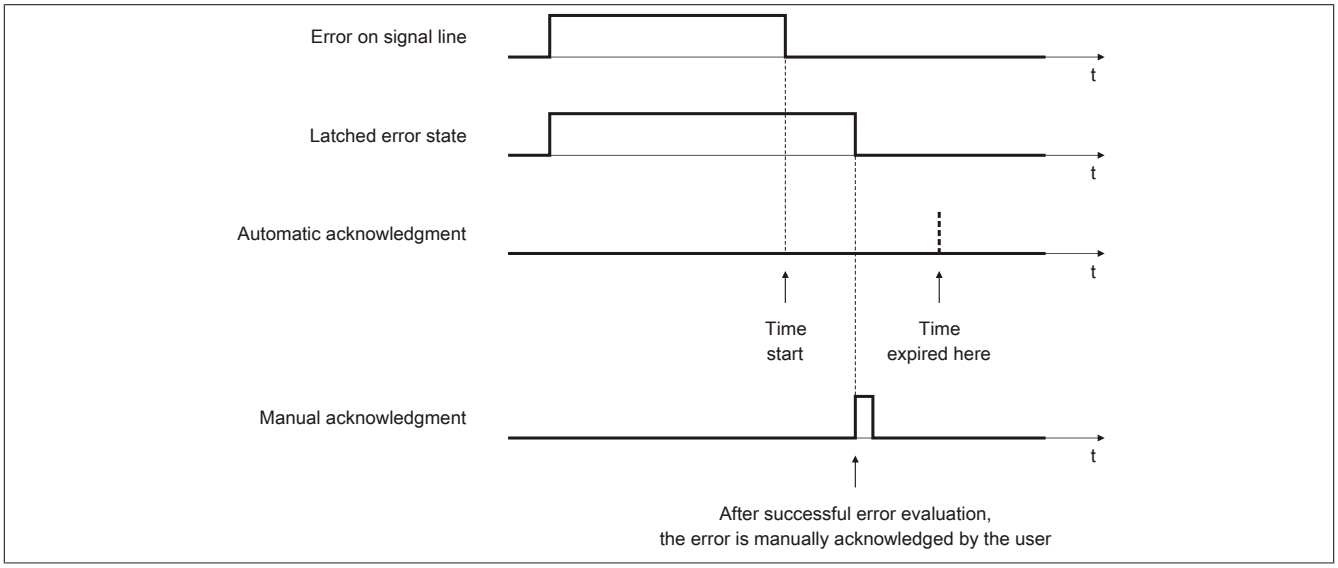

Figure 190: Automatic and manual acknowledge used

4.11.9.9.5.10 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.9.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.9.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.10 X20(c)DC1396

4.11.10.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 24 V encoder signal.

- 1 ABR incremental encoder 24 V
- 1 additional input e.g. for home enable switch
- 24 VDC and GND for encoder supply

4.11.10.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.11.10.9 Register description

4.11.10.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.10.9.2 Function model 0 - Standard and Function model 1 - Standard with 32-bit encoder counter value

The difference between function model 0 and function model 1 is the size of the data type for some registers.

- Function model 0 uses data type INT
- Function model 1 uses data type DINT (specified in parentheses)

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
4104	CfO_EdgeDetectFalling	USINT				•
4106	CfO_EdgeDetectRising	USINT				•
2064	CfO_PresetABR01_1(_32Bit)	(D)INT				•
2068	CfO_PresetABR01_2(_32Bit)	(D)INT				•
512	ConfigOutput24	UINT				•
522	ConfigOutput26	USINT				•
520	ConfigOutput27	USINT				•
Communication						
2116	ReferenceModeEncoder01	USINT			•	
2080	Encoder01	(D)INT	•			
264	Input state of the digital input	USINT	•			
	DigitalInput01	Bit 3				
2118	StatusInput01	USINT	•			
40	Status of encoder supply	USINT	•			
	PowerSupply01	Bit 0				

4.11.10.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
4104	-	CfO_EdgeDetectFalling	USINT				•
4106	-	CfO_EdgeDetectRising	USINT				•
2064	-	CfO_PresetABR01_1	INT				•
2068	-	CfO_PresetABR01_2	INT				•
512	-	ConfigOutput24	UINT				•
522	-	ConfigOutput26	USINT				•
520	-	ConfigOutput27	USINT				•
Communication							
2116	0	ReferenceModeEncoder01	USINT			•	
2080	0	Encoder01	INT	•			
264	2	Input state of the digital input	USINT	•			
		DigitalInput01	Bit 3				
2118	4	StatusInput01	USINT	•			
40	3	Status of encoder supply	USINT	•			
		PowerSupply01	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.11.10.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.10.9.4 ABR encoder - Configuration registers

4.11.10.9.4.1 Reference pulse

The following registers must be configured by a single acyclic write with the listed values so that the homing procedure is completed on the edge of the reference pulse.

The homing procedure can take place on:

- Rising edge
- Falling edge (default configuration)

Constant register "CfO_EdgeDetectFalling"

Name:

CfO_EdgeDetectFalling

Data type	Value	Filter
USINT	0x00	Configuration value for rising edge
	0x04	Configuration value for falling edge

Constant register "CfO_EdgeDetectRising"

Name:

CfO_EdgeDetectRising

Data type	Value	Filter
USINT	0x04	Configuration value for rising edge
	0x00	Configuration value for falling edge

Constant register "ConfigOutput24"

Name:

ConfigOutput24

This register contains the value for ABR encoder 1.

Data type	Value	Filter
UINT	0x1012	Configuration value for rising edge
	0x1002	Configuration value for falling edge

4.11.10.9.4.2 Setting the home position

Name:
Cfo_PresetABR01_1 to Cfo_PresetABR01_2

CfO_PresetABR01_1_32Bit to CfO_PresetABR01_2_32Bit (only in function model 1)

It is possible to specify two home positions with these registers through a one-off acyclic write, for example (default = 0). The configured values are applied to the counter values after a completed homing procedure.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.10.9.4.3 Homing with reference enable input

Regardless of the referencing mode, it is possible using this register to prevent the home position from being applied when the corresponding reference input voltage level occurs (see 4.11.10.9.5.2 "Input state of the digital input": bit 3). The desired setting can be configured by a one-off acyclic write.

Voltage level for reference enable activation

Name:

ConfigOutput26

This register is used to configure the active voltage level of the digital input for the reference enable.

Data type	Value	Filter
USINT	0x00	Reference enable is active at 0 VDC
	0x08	Reference enable is active at 24 VDC

Reference enable of the input

Name:

ConfigOutput27

This register can be used to define whether the reference enable is activated.

Data type	Value	Filter
USINT	0x00	Reference enable input OFF (default)
	0x08	Reference enable input activated

4.11.10.9.5 ABR encoder - Configuration registers

4.11.10.9.5.1 Counter state of the encoder

Name:
Encoder01

The encoder values are represented as 16-bit or 32-bit counter values in this register.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.10.9.5.2 Input state of the digital input

Name:
DigitalInput01

This register displays the input status of the encoder and the digital input.

Data type	Value
USINT	See bit structure.

Bit	Name	Value	Information
0	Encoder A	0 or 1	Input state
1	Encoder B	0 or 1	Input state
2	Encoder A + B	0 or 1	Input state of reference pulse
3	DigitalInput01	0 or 1	Input state - Digital input 1
4 - 7	Reserved	-	

4.11.10.9.5.3 Reading the referencing mode

Name:
ReferenceModeEncoder01

This register determines the referencing mode.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1		00	Referencing OFF
		01	Single shot referencing
		11	Continuous referencing
2 - 5		0	Bits permanently set = 0
6 - 7		00	Referencing OFF
		11	Bits permanently set = 1

This results in the following values:

Binary	Hex	Function
00000000	0x00	Referencing OFF
11000001	0xC1	Single shot referencing For a new start after the completed homing procedure: • Write value 0x00 • Wait until bit 0 to bit 3 of the StatusInput01 register takes on the value 0. Counter bits 4 to 7 are not erased • Switch homing procedure on again
11000011	0xC3	Continuous referencing Referencing occurs at every reference pulse.

It is important to know how the optional reference enable is configured. See section 4.11.10.9.4.3 "Homing with reference enable input"

4.11.10.9.5.4 Status of the homing procedure

Name:
StatusInput01

This register contains information regarding whether the referencing process is off, active or complete.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Reference pulse without homing[1)]	0	No reference impulse without homing has occurred yet
		1	At least a reference impulse without homing has occurred
1	State change	0 or 1	Changes with each reference pulse without homing
2	Reference pulse with homing[1)]	0	No homing has occurred yet
		1	At least one homing procedure has occurred
3	State change	0 or 1	Changes with each homing procedure that has taken place
4	Reference pulse	0	The last reference pulse didn't bring about a homing procedure
		1	The last reference pulse brought about a homing procedure
5 - 7	Counter	x	Free-running counter, increased with each reference pulse

1) Always 1 after the first reference pulse that has occurred

Examples of possible values:

Binary	Hex	Function
0x00000000	0x00	Referencing OFF or homing procedure already active
0x00111100	0x3CE	First homing procedure complete Reference value applied in the Encoder01 register
0xxxx11100	0xxB	Bits 5 to 7 are changed with each reference pulse
0xxxx1x100	0xxx	Continuously changing the bits with the "Continuous referencing" setting. The reference value is applied to the Encoder01 register on each reference pulse.

It is important to know how the optional reference enable (see section 4.11.10.9.4.3 "Homing with reference enable input" on page 967) is configured.

4.11.10.9.5.5 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.10.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.10.9.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.10.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.11 X20DC1398

4.11.11.1 General information

This module is equipped with one input for SSI absolute encoders with 24 V encoder signal.

- 1 SSI absolute encoder 24 V
- 1 additional input
- 24 VDC and GND for encoder supply

4.11.11.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.11.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
7176	ConfigOutput14	UINT				•
7172	ConfigAdvanced	UDINT				•
Communication						
7184	Encoder01	UDINT	•			
264	Input state of the digital input 1	USINT	•			
	DigitalInput01	Bit 3				
40	Status of encoder supply	USINT	•			
	PowerSupply01	Bit 0				

4.11.11.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
7176	-	ConfigOutput14	UINT				•
7172	-	ConfigAdvanced	UDINT				•
Communication							
7184	0	Encoder01	UDINT	•			
264	4	Input state of the digital input 1	USINT	•			
		DigitalInput01	Bit 3				
40	5	Status of encoder supply	USINT	•			
		PowerSupply01	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.11.11.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.11.9.4 SSI encoder configuration register

4.11.11.9.4.1 Standard configuration

Name:
ConfigOutput14

This configuration register is used to set the coding, the clock rate and the number of bits. Default = 0. This must be set once using an acyclic write command.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	11	125 kHz
8 - 13	SSI number of bits		Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding

4.11.11.9.4.2 Extended configuration

Name:
ConfigAdvanced

This configuration register is used to set the coding, the clock rate, the number of bits and the monostable multivibrator settings. Default = 0. This must be set once using an acyclic write command.

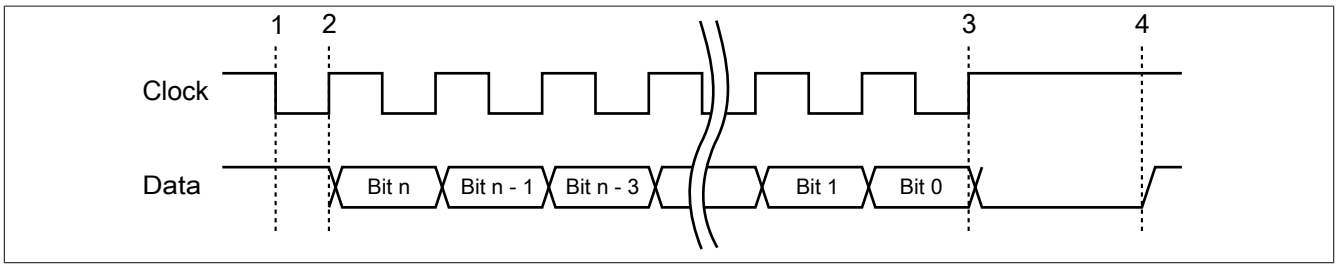
It only differs from ConfigOutput14 by data length and additional monostable multivibrator testing.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding
16 - 17	Monostable multivibrator check	00	Check OFF, no additional clock bit
		01	Check set to High level
		10	Check set to Low level
		11	Level is clocked but ignored
18 - 31	Reserved	0	

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.11.11.9.5 SSI encoder - Configuration registers

4.11.11.9.5.1 SSI position values

Name:
Encoder01

The SSI encoder value is displayed as a 32-bit position value. The SSI position value is generated synchronously with the X2X cycle.

Data type	Value	Filter
UDINT	0 to 4,294,967,295	SSI position

4.11.11.9.5.2 Input state of the digital input 1

Name:
DigitalInput01

This register displays the input state of the digital input.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
3	DigitalInput01	0 or 1	Input state - Digital input 1

4.11.11.9.5.3 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.11.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.11.9.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.11.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.12 X20DC1976

4.11.12.1 General information

The module is equipped with 1 input for an ABR incremental encoder with 5 V encoder signal. The encoder inputs are monitored (A, B, R).

- 1 ABR incremental encoder 5 V, asymmetric
- Encoder input monitoring
- 2 additional inputs, e.g. for latch input
- 5 VDC, 24 VDC and GND for encoder supply

4.11.12.2 Order data

Model number	Short description	Figure
	Counter functions	
X20DC1976	X20 digital counter module, 1x ABR incremental encoder, 5 V (single ended), 250 kHz input frequency, 4x evaluation, encoder monitoring, NetTime module	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 190: X20DC1976 - Order data

4.11.12.3 Technical data

Product ID	X20DC1976
Short description	
I/O module	1 ABR incremental encoder 5 V
General information	
B&R ID code	0xA707
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.2 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Type of signal lines	Shielded cables must be used for all signal lines
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Digital inputs	
Quantity	2
Nominal voltage	24 VDC
Input voltage	24 VDC (-15% / +20%)
Input current at 24 VDC	Approx. 3.3 mA
Input filter	
Hardware	<2 µs
Software	-
Connection type	3-wire connections
Input circuit	Sink
Additional functions	Latch input

Table 191: X20DC1976 - Technical data

Product ID	X20DC1976
Input resistance	7.03 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between channel and bus	500 V_{eff}
ABR incremental encoder	
Encoder inputs	5 V, asymmetrical (single-ended)
Counter size	16/32-bit
Input frequency	Max. 250 kHz
Evaluation	4x
Encoder supply	
5 VDC	±5%, module-internal, max. 300 mA
24 VDC	Module-internal, max. 300 mA
Input filter	
Hardware	≤600 ns
Software	-
Common-mode range	-10 V ≤ V_{CM} ≤ +13.2 V
Overload behavior of the encoder supply	Short circuit protection, overload protection
Isolation voltage between encoder and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5$^{+0.2}$ mm

Table 191: X20DC1976 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

4.11.12.4 LED status indicators

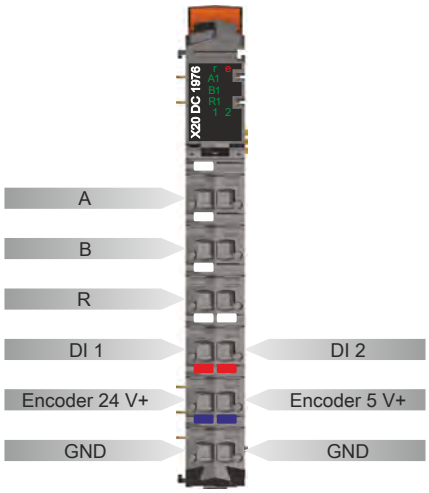
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	The encoder monitor has detected a line fault on the encoder inputs. The status bits must be evaluated in order to provide a more detailed definition of this error. The following error states are detected: • Open line • Short-circuit or voltage level too low
			On	Error or reset status
	A1	Green		Input state of counter input A
	B1	Green		Input state of counter input B
	R1	Green		Input state of reference pulse R
	1 - 2	Green		Input state of the corresponding digital input

1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.12.5 Pinout

Shielded cables must be used for all signal lines.



4.11.12.6 Connection example

4.11.12.8 Register description

4.11.12.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.12.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Encoder - Communication						
683	SDCLifeCount	SINT	•			
6342	Encoder01	INT	•			
6340		DINT				
6310	Encoder01TimeValid	INT	•			
6308		DINT

1) The offset specifies the position of the register within the CAN object.

4.11.12.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.12.8.4 Encoder - Configuration

The following registers are used for setting functions and configuring the module.

4.11.12.8.4.1 Enabling error monitoring for the signal lines

Name:
CfO_BWCNTEnableMaskChannel7_0

This register requires individually enabling error monitoring for each of the signal channels. "Open line", "short circuit" and "voltage level too low" are reported as error states. Any errors that occur are reported in the error status registers BW_Channel_x.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Enable error monitoring for signal A lines	0	Error monitoring - Encoder Signal A disabled
		1	Error monitoring - Encoder Signal A enabled - Only default in bus controller function model
1	Enable error monitoring for signal B lines	0	Error monitoring - Encoder Signal B disabled
		1	Error monitoring - Encoder Signal B enabled - Only default in bus controller function model
2	Enable error monitoring for signal R lines	0	Error monitoring - Encoder Signal R disabled
		1	Error monitoring - Encoder Signal R enabled - Only default in bus controller function model
3 - 7	Reserved	0	

4.11.12.8.4.2 Timing for automatic error acknowledgment

Name:
CfO_BWQuitTime_0

This register can be used to enable an additional automatic acknowledgment of the error status through timing. If a valid time is set, then the acknowledgment can still be made manually, the only difference is that automatic acknowledgment will take place on the module after the defined amount of time has passed. If the error state has not yet been corrected, then the error status remains and the time is reset. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages.
If the timing = 0, then acknowledgment is only possible using the cyclic acknowledgment registers.

Data type	Value	Information
UDINT	0	No automatic acknowledgment - Only default in bus controller function model
	1 to 2.147.483.647	Time for automatic acknowledgment [µs]

4.11.12.8.4.3 Setting the latch mode

Name:
CfO_LatchMode

This register is used to set the latch mode:

- Single shot latch mode:
  The latch function must be enabled/set. After a successful latch procedure, the activation must be reset in order for a new latch procedure to be activated.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired.

A changed counter state on Encoder01LatchCount indicates that the latch procedure has been performed. The counter value is stored in the latch register Encoder01Latch.

Data type	Value	Information
USINT	0	Single shot latch procedure
	1	Continuous latch procedure

4.11.12.8.4.4 Signal channels for triggering latch procedure

Name:
CfO_LatchComparator

This register defines the signal channels and their level for triggering the latch procedure.

- This mainly configures which channels are linked to generate the latch event. All three signals from the encoder and digital input 1 can be used for the "AND" operation.
- The "active voltage level" needed for the latch procedure can now be used according to the physical signals.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Defines signal level for encoder signal A	0	Low
		1	High
1	Defines signal level for encoder signal B	0	Low
		1	High
2	Defines signal level for encoder signal R	0	Low
		1	High
3	Defines signal level for digital input 1	0	Low
		1	High
4	Use encoder signal A to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal A
5	Use encoder signal B to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal B
6	Use encoder signal R to trigger latch procedure	0	Disabled
		1	Latch function linked to encoder signal R
7	Use digital input 1 to trigger latch procedure	0	Disabled
		1	Latch function linked to digital input 1

4.11.12.8.4.5 Physical configuration

The following registers must be set to the specified constant value for correct physical configuration:

Constant register "CfO_SIframeGenID"

Name:
CfO_SIframeGenID

Data type	Value	Information
USINT	9	Only default in the bus controller module

Constant register "CfO_SystemCycleTime"

Name:
CfO_SystemCycleTime

Cycle time of encoder acquisition in 1/8 µs steps. 1 encoder value is acquired as the counter value per cycle.

Data type	Value	Information
UINT	800	800 = 100 µs; only default in the bus controller module

Constant register "CfO_PhyIOConfigCh01"

Name:
CfO_PhyIOConfigCh01

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh02"

Name:
CfO_PhyIOConfigCh02

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh03"

Name:
CfO_PhyIOConfigCh03

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh04"

Name:
CfO_PhyIOConfigCh04

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_PhyIOConfigCh05"

Name:
CfO_PhyIOConfigCh05

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_BWQuitTimeSelChannel7_0"

Name:
CfO_BWQuitTimeSelChannel7_0

Data type	Value	Information
USINT	0	Only default in the bus controller module

Constant register "CfO_CounterCycleSelect"

Name:
CfO_CounterCycleSelect

Data type	Value	Information
USINT	2	Only default in the bus controller module

Constant register "CfO_CounterMode"

Name:
CfO_CounterMode

Data type	Value	Information
USINT	3	Only default in the bus controller module

4.11.12.8.5 Encoder - Communication

4.11.12.8.5.1 Counter for verifying the data frame

Name:
SDCLifeCount

The 8-bit counter register is needed for the SDC software package. It is incremented with the system clock to allow the SDC to check the validity of the data frame.

Data type	Value
SINT	-128 to 127

4.11.12.8.5.2 Display of the counter state

Name:
Encoder01

The counter state of the incremental encoder is displayed as a 16 or 32-bit counter value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.12.8.5.3 Net time of the last valid counter value

Name:
Encoder01TimeValid

The net time of the last valid counter value is the time of the last valid counter value (see "Cfo_SystemCycleTime" register) recorded on the module. The user is able to determine the validity of the counter value by evaluating its age in the program. This means that the module and error status bits do not have to be checked additionally to determine the validity of the value.

The net time of the last valid counter value that was read is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in milliseconds.
DINT[1)]	-2.147.483.648 to 2.147.483.647	

1) Can only be configured in the standard function model

4.11.12.8.5.4 Net time of the last counter value change

Name:
Encoder01TimeChanged

For slow X2X Link cycles, the net time of the last counter value change can be used to more accurately determine the speed.

The net time of the last counter value change is displayed as 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value	Information
INT	-32768 to 32767	NetTime in µsec.
DINT[1)]	-2.147.483.648 bis 2.147.483.647	

1) Can only be configured in the standard function model

4.11.12.8.5.5 Counter value at the time of the last latch

Name:
Encoder01Latch

The counter value at the time of the last latch is displayed as a 16 or 32-bit value. Only the 16-bit value is available in the bus controller function model.

Data type	Value
INT	-32768 to 32767
DINT[1)]	-2.147.483.648 bis 2.147.483.647

1) Can only be configured in the standard function model

4.11.12.8.5.6 Counter value of latch event

Name:
Encoder01LatchCount

The latch events are counted and stored in a cyclic 8-bit counter. This counter is incremented with each latch event, thereby indicating a new occurrence. The new latched counter value is stored in the respective latch register.

Data type	Value
SINT	-128 to 127

4.11.12.8.5.7 Encoder commands

Name:
Encoder01Command

This register can be used to

1 reset the counter value. The counter is kept at zero until this command is reset.
2 enable the latch procedure. If the latch configuration is valid and matches the hardware signals, then this activation causes the counter value to be saved in the latch register.

The two different latch configurations that are possible (see section 4.11.3.8.4.3 "Setting the latch mode") must be handled as follows:

- Single shot latch mode:
  After successful latching, indicated by the latch event counter, activation must be reset before any more latching is possible. The activation must be set again if additional latching is needed.
- Continuous latch mode:
  The latch function only has to be enabled/set as long as latching is desired. The latch event counter is incremented with each event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01Reset	0	Do not reset
		1	Set encoder value to 0
1	Encoder01LatchEnable	0	Do not activate latch
		1	Latching
2 - 7	Reserved	0	

4.11.12.8.5.8 Input status of signal lines

Name:
Encoder01_A
Encoder01_B
Encoder01_R
DigitalInput01 to DigitalInput02

This register displays the input status of the signal lines from the encoder and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder01_A	0/1	Input state of encoder signal A
1	Encoder01_B	0/1	Input state of encoder signal B
2	Encoder01_R	0/1	Input state of encoder signal R
3	Reserved	0	
4	DigitalInput01	0/1	Input state - Digital input 1
5	DigitalInput02	0/1	Input state - Digital input 2
6 - 7	Reserved	0	

4.11.12.8.5.9 Error status of signal lines

The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Status of signal lines

Name:
BW_Channel_A
BW_Channel_B
BW_Channel_R

This register displays the error states of the signal lines from the encoder. The error states are latched when they occur and are maintained until acknowledged. The counter and time registers are not updated if there are pending or unacknowledged errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_Channel_A	0	No error in encoder signal A
		1	Open line, short circuit or voltage level too low
1	BW_Channel_B	0	No error in encoder signal B
		1	Open line, short circuit or voltage level too low
2	BW_Channel_R	0	No error in encoder signal R
		1	Open line, short circuit or voltage level too low
3 - 7	Reserved	0	

Acknowledging error status of signal lines

Name:
BW_QuitChannel_A
BW_QuitChannel_B
BW_QuitChannel_R

This register can be used to acknowledge the latched error states of the signal lines from the encoder. However, if there are still pending errors remaining, then the error status remains active. After acknowledging the errors, the bits must also be reset or else any repetition of the error would be undetected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	BW_QuitChannel_A	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal A
1	BW_QuitChannel_B	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal B
2	BW_QuitChannel_R	0	No acknowledgment
		1	Acknowledgment of error status - Encoder signal R
3 - 7	Reserved	0	

Manual acknowledgment of latched error states

The latched error states of the signal lines from the encoder can be acknowledged manually. However, if there are still pending errors remaining, then the error status remains active. After successfully acknowledging the errors (latched error status = 0), the acknowledge bits must still be reset by the user or else a re-occurrence of an error could be overlooked by the user.

Example 1: **Cause of error corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user after the cause of error has been corrected. The latched error status changes to zero.

The manual acknowledge must now be reset so that any new errors will be recognized by the user.

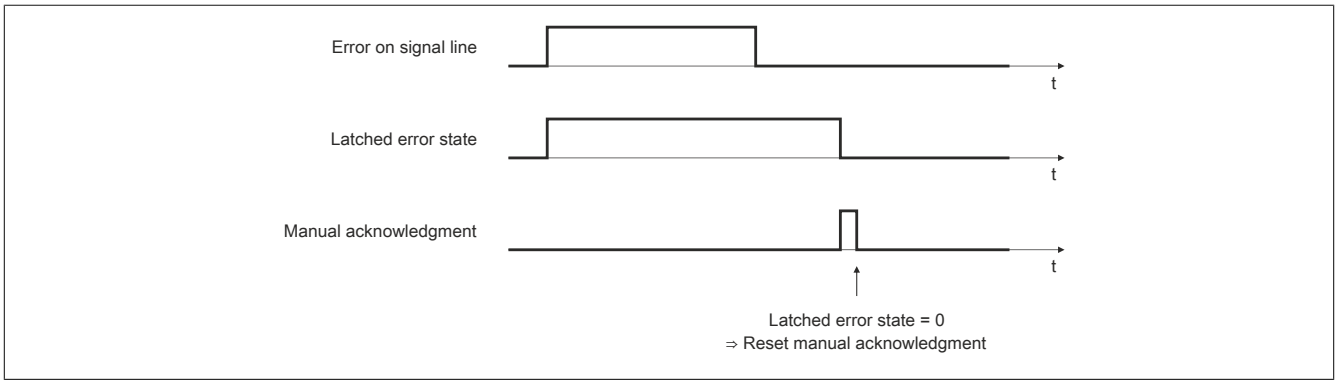

Figure 191: Cause of error corrected before being acknowledged

Example 2: **Cause of error not yet corrected before being acknowledged**

An error has occurred on a signal line. The error state is detected and latched by the module. The error is acknowledged by the user before the cause of error has been corrected. The latched error status remains set because the error is still remaining.

Acknowledgment is only successful after the cause of error has been corrected. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

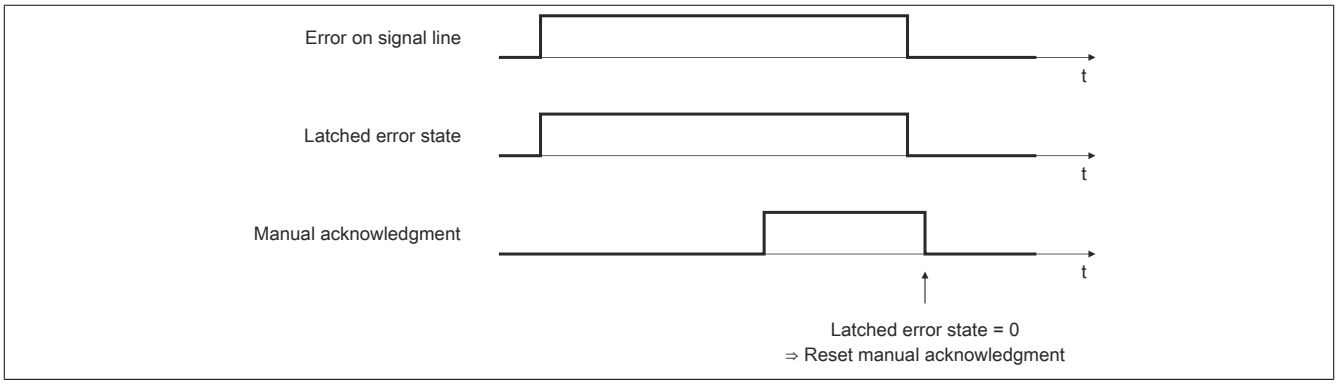

Figure 192: Cause of error not yet corrected before being acknowledged

Automatic acknowledgment of latched error states

In addition to manual acknowledgment, automatic acknowledgment of the latched error states after a specified amount of time can also be enabled. Make sure that the time is set long enough for the higher-level system to reliably detect the status messages and for the validity of the counter value to be determined using its age.

If the time specification = 0, then only manual acknowledgment is possible.

Example 1: An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged as soon as the time expires. The latched error status changes to zero.

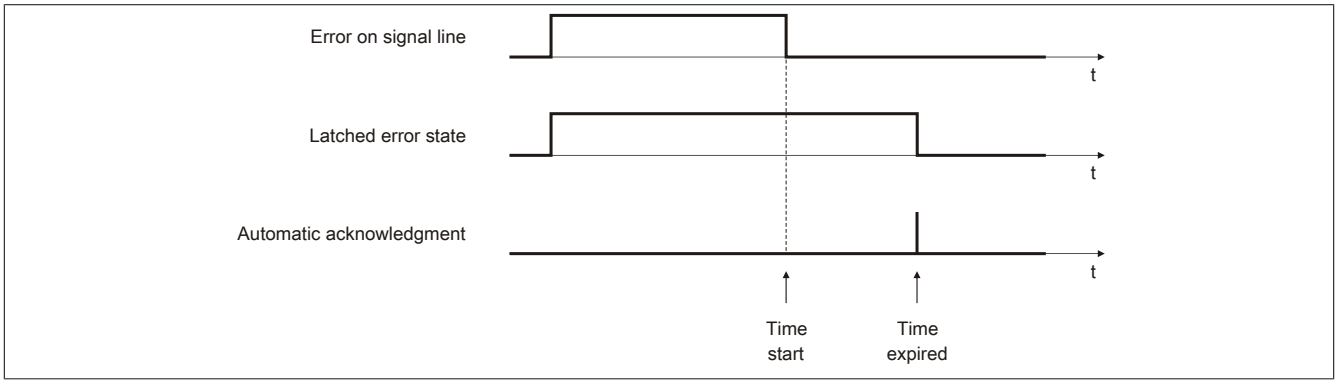

Figure 193: Latched error state acknowledged automatically

Example 2: Automatic and manual acknowledge used

An error has occurred on a signal line. The error state is detected and latched by the module. The time for automatic acknowledgment starts counting after the cause of error has been corrected. The error is acknowledged manually by the user before the time expires. The latched error status changes to zero. The manual acknowledge must now be reset so that any new errors will be recognized by the user.

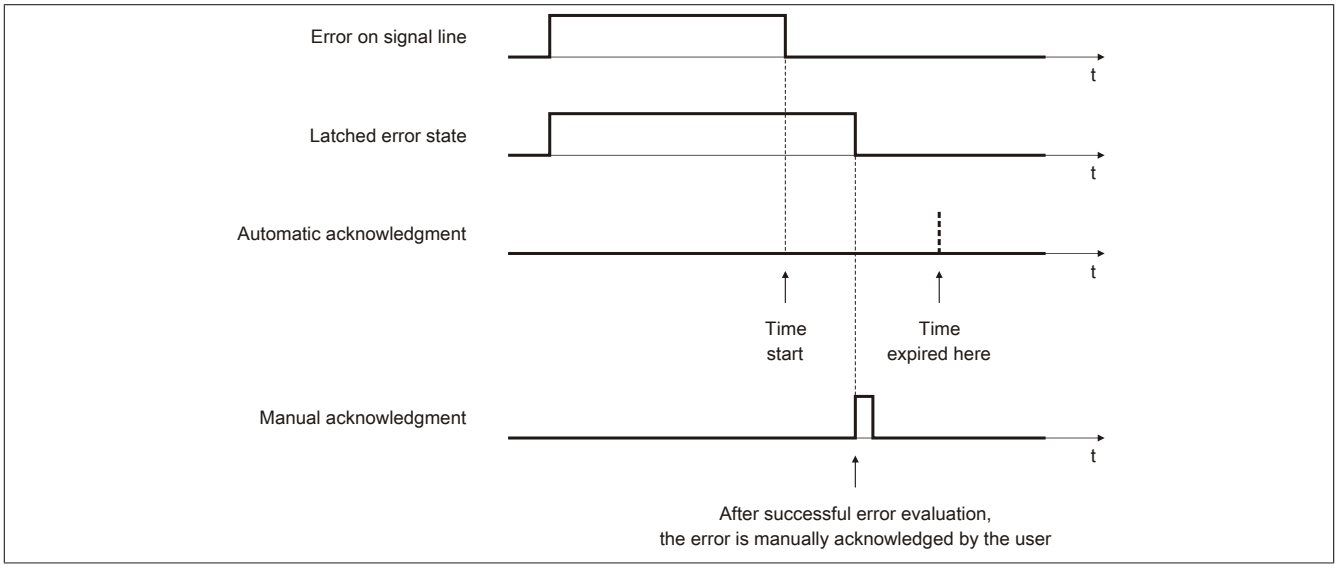

Figure 194: Automatic and manual acknowledge used

4.11.12.8.5.10 Status of encoder supplies

Name:
PowerSupply01 to PowerSupply02

This register shows the status of the integrated encoder supplies. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1	PowerSupply02	0	5 VDC encoder power supply OK
		1	5 VDC encoder power supply faulty
2 - 7	Reserved	-	

4.11.12.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.11.12.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
150 µs

4.11.13 X20DC2190

4.11.13.1 General information

This module can be used to determine paths and to calculate speeds at the same time. The ultrasonic transducer rods are connected directly to the RS422 interface. Communication to the transducer rod takes place using start/stop signals. With the DPI/IP protocol, it is also possible, for example, to read operational properties directly from the transducer. During service (when a transducer is being exchanged) the machine can be started again quickly without additional configuration work.

The module is designed for connecting 2 transducer rods with a total of up to 4 paths. That means, for example, that 2 ultrasonic transducers with 2 magnets each or one with 4 magnets can be used. The combination 3/1 is also possible. The module provides 24 VDC as an external supply for the sensor.

- Ultrasonic transducer module
- Path measurement (resolution 10 µm)
- Speed measurement (resolution 100 µm/s)
- 1, 2, 3 and 4 magnetic rod measurements possible
- DPI/IP protocol supported

4.11.13.2 Order data

Model number	Short description	Figure
	Counter functions

4.11.13.3 Technical data

Product ID	X20DC2190
Short description	
I/O module	Ultrasonic transducer module, 2 transducer rods, 4 position detection, speed measurement
General information	
B&R ID code	0x2188
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	1.1 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Channels for path and speed measurements	
Quantity	2
Supported encoder types	Start/Stop interface EP start/stop interface DPI/IP interface
Encoder supply	
Voltage	24 VDC, module-internal, max. 150 mA
Monitoring	Configurable overvoltage/undervoltage monitoring (±10%, ±15%, ±20%, ±25%)
Short circuit protection	Rev. D0 and higher
Input and output level	RS422 differential level
Multi-magnet measurement	Yes, in combination per rod, max. 4 magnets total
Outputs	1.6 µs durational initialization pulse
Inputs	
Path measurement	Resolution = 0.01mm, measurement range = ±5.2m
Speed measurement	Resolution = 0.1 mm/s, measurement range = ±3.2 m/s
Precision	±50 ppm ±5 ppm/year
Short circuit protection	No
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	0 to 55°C
Vertical installation	0 to 50°C
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 193: X20DC2190 - Technical data

Ta max.: See environmental conditions

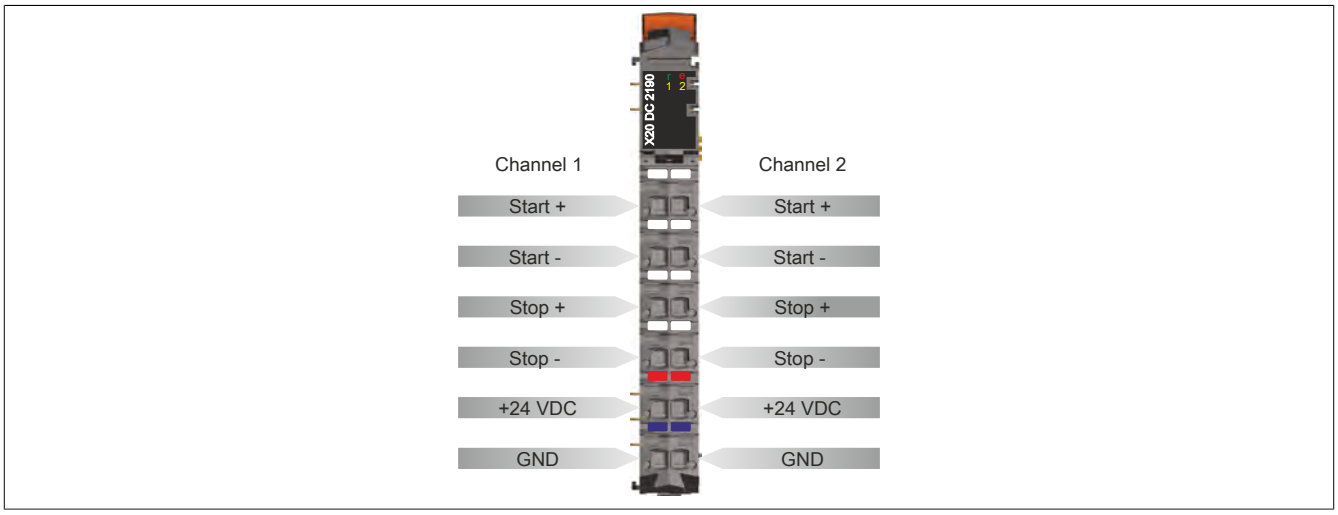
4.11.13.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	Reset mode
			Double flash	Boot mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	1 - 2	Yellow	Off	No transducer rod connected
			On	No transducer rod is connected to the respective measurement channel

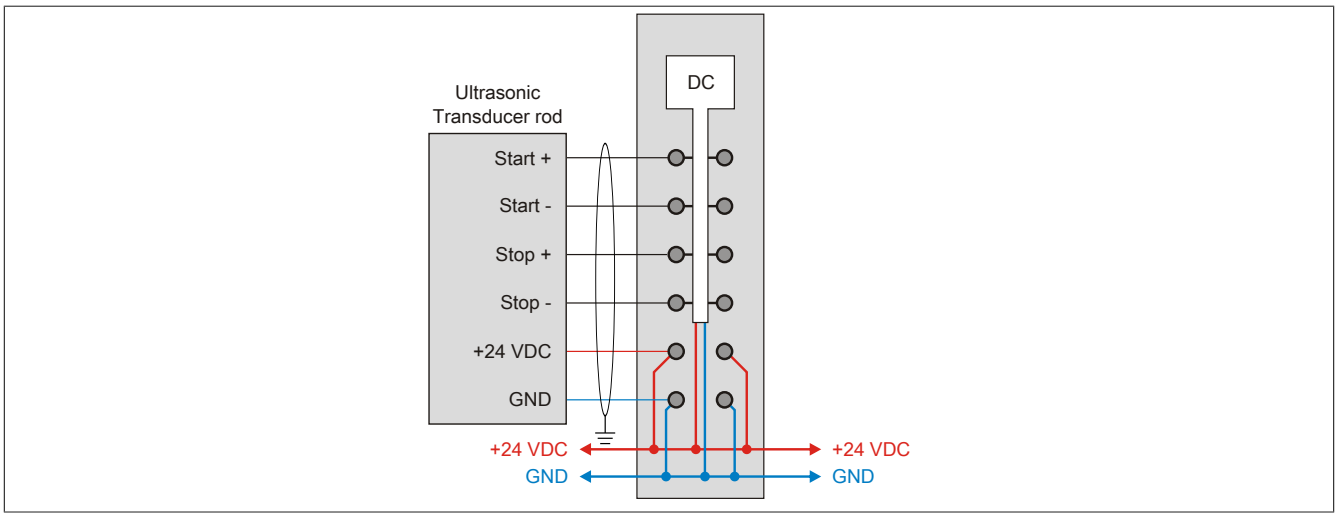
1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.13.5 Pinout



The ultrasonic transducers should be connected using a shielded cable. The shield of the encoder cable is connected to the ground via the shield connection on the X20 bus module.

4.11.13.6 Connection example



4.11.13.7 Register description

4.11.13.7.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

In the bus controller function model, the measurements made from the module are not synchronized with the X2X Link. The time between two measurements is defined by the configured recovery time for the rod (see section 4.11.13.7.12 "Channel configuration" on page 1003) unlike on the X2X where it is the smallest multiple of the X2X cycle time that is larger than the configured recovery time.

4.11.13.7.3.1 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN-I/O.

4.11.13.7.4 Commissioning a transducer rod

Two registers need to be configured to initialize an ultrasonic transducer rod and receive valid measurements. The first step is to enter the length of the rod (see section 4.11.13.7.13 "Rod length 1 and 2" on page 1003). The wave propagation speed for the rod must then be defined (see section 4.11.13.7.9 "Ultrasonic speed specification" on page 1001). This information can usually be found directly on the transducer rod itself or in its data sheet.

If the plausibility limits remain set to 0 (default value), one of the respective ErrorStatus registers will now indicate faulty readings or plausibility errors. If this is the case, plausibility mode can be disabled using the "ConfigOutput01" register (see section 4.11.13.7.11 "Module configuration" on page 1002). This will cause the positions of the magnets to be displayed on the rod.

4.11.13.7.5 Reading the magnet position

Name:
Position01 - Position04

These registers contain the position of the individual magnets on the transducer rods.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647: Resolution 1 µm

4.11.13.7.6 Reading the magnet speed

Name:
Speed01 to Speed04

These registers contain the speed of the individual magnets on the transducer rods. A resolution of 0.1 mm/s is achieved by calculating the speed from 2 position values within a 100 ms interval.

Data type	Value
INT	-32768 to 32767: Resolution 0.1 mm/s

4.11.13.7.7 Error status

Name:
ErrorStatus01 to ErrorStatus04

These registers can be used to indicate the error status for individual channels.

Data type	Value
USINT	See bit structure.

Bit structure

Bit	Description
0 - 3	Counter for plausibility errors (cyclic)
4 - 7	Counter for mis-measurements (cyclic)

Possible reasons for plausibility errors:

- Configured max. or min. path of a magnet was exceeded
- Configured max. speed was exceeded

Possible reasons for faulty measurements:

- Configured rod length was exceeded
- Rod failure
- Missing measurement magnet

Information:

If the registers "USSpeed01" and "USSpeed02" are unequal to 0 after the module starts up, the respective error counters on slower fieldbus systems (e.g. CAN I/O) may continue to count until the module configuration is completed. In some cases, this is due problems between the respective rod and the default configuration.

4.11.13.7.8 Status information about the transducer rods

Name:
StatusInput01

This register displays the status information for the transducer rods.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Supply voltage too low	0	Supply voltage OK
		1	Supply voltage too low
1	Supply voltage too high	0	Supply voltage OK
		1	Supply voltage too high
2	Transducer Rod 1	0	Ok
		1	Deactivated or not initialized
3	Transducer Rod 2	0	Ok
		1	Deactivated or not initialized
4	Transducer Rod 1	0	Protocol error (invalid data)
		1	Protocol OK (valid data)
5	Transducer Rod 2	0	Protocol error (invalid data)
		1	Protocol OK (valid data)
6 - 7	Reserved		

Comment concerning bits 4 + 5

If this bit is set to "1", configuration data was successfully read from the measurement rod using DPI/IP or EP protocol. This data can now be read into the application using asynchronous access.

4.11.13.7.9 Ultrasonic speed specification

Name:
USSpeed01 to USSpeed02

The module does not perform any measurements on the respective rod while these registers have the value 0. Also disabled:

- Automatic check to determine whether a rod is connected
- Parameter upload via DPI/IP or EP protocol

If a value >0 but <1000cm/s is specified here, the module freezes all measurements and error counters of the corresponding rod, regardless of whether plausibility mode is enabled or not. Based on the default ultrasonic speed of 280,000 cm/s, however, periodic measurement start pulses continue to be generated according to the formula in section 4.11.13.7.12 "Channel configuration" on page 1003. In this case the rod check (inserted/not inserted and parameter upload) continues to be active.

As soon as a valid value (≥1000) is specified, the module recalculates the measurement rate (see section 4.11.13.7.12 "Channel configuration" on page 1003) and begins the position/speed measurement.

Data type	Value
UDINT	0 to 4,294,967,296: Resolution 1 cm/s

4.11.13.7.10 Applying new magnet offsets

Name:
StatusOutput01

This register makes it easier to more quickly determine new offsets (= zero positions) for the individual magnets. This approach is an alternative or additional method to determining an offset via configuration registers (see section 4.11.13.7.14 "Offset position on the transducer" on page 1004).

If the respective bit changes from 0 to 1 in "StatusOutput01" (see following table) then the current mechanical position of the respective magnet becomes the calculated zero position (register "Position0x" = 0).
From that moment, the current mechanical position will be subtracted from all future measured positions. This is essentially a type of referencing. The max. and min. magnet paths (see section 4.11.13.7.15 "Plausibility check configuration" on page 1004) are now based on the new zero position.
This process can be repeated at any time by setting the bit again.

Information:

An offset position determined in this manner *CANNOT* be read out. The registers "ConfigOutput07Read", "ConfigOutput08Read", "ConfigOutput15Read" and "ConfigOutput16Read" can only be used to read the current contents of "ConfigOutput07", "ConfigOutput08", "ConfigOutput15" and "ConfigOutput16".

Data type	Value
USINT	See bit structure.

Bit	Name	Value	Information
0	Magnet 1	0	No effect
		1	Apply offset magnet 1
...		...	
3	Magnet 4	0	No effect
		1	Apply offset magnet 4
4 - 7	Reserved		

4.11.13.7.11 Module configuration

Name:
ConfigOutput01

This register configures the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Plausibility mode	0	The plausibility error counter is incremented with each implausible measurement and the last plausible measurement value is "frozen" (default)
		1	The plausibility error counter is incremented with each implausible measurement and the implausible measurement value is forwarded to the controller
1	Reserved		
2 - 3	Tolerance for monitoring the supply voltage	00	25%
		01	20%
		10	15%
		11	10%
4 - 7	Magnet number	0000	4 magnets on channel 1, channel 2 not available
		0001	3 magnets on channel 1, 1 magnet on channel 2
		0010	2 magnets on channel 1, 2 magnets on channel 2
		0011	1 magnet on channel 1, 0 magnets on channel 2
		0100	2 magnets on channel 1, 0 magnets on channel 2
		0101	3 magnets on channel 1, 0 magnets on channel 2
		0110	2 magnets on channel 1, 1 magnet on channel 2
		0111	1 magnet on channel 1, 1 magnet on channel 2
		1xxx	Reserved

4.11.13.7.12 Channel configuration

Name:
ConfigOutput02

This register can be used to configure the individual channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Transducer Rod 1	000	User parameter
		001	DPI/IP (Balluf)
		010	EP Start/Stop (MTS)
		011	Reserved
		1xx	Reserved
3 - 4	Rod 1: Start/Stop IF type	00	Start/Stop Signal: Rising edge - rising edge
		01	Start/Stop Signal: Falling edge - falling edge
		10	Start/Stop Signal: Rising edge - falling edge (gate time)
		11	Only Stop Signal: Start when signal is triggered (initialization pulses)
5	Rod 1: Recovery time factor, minimum time between two measurements	0	3 x USW runtime for rod (default)
		1	2 x USW runtime for rod
6 - 7	Reserved		
8 - 10	Transducer Rod 2	000	User parameter
		001	DPI/IP (Balluf)
		010	EP Start/Stop (MTS)
		011	Reserved
		1xx	Reserved
11 - 12	Rod 2: Start/Stop IF type	00	Start/Stop Signal: Rising edge - rising edge
		01	Start/Stop Signal: Falling edge - falling edge
		10	Start/Stop Signal: Rising edge - falling edge (gate time)
		11	Only Stop Signal: Start when signal is triggered (initialization pulses)
13	Rod 2: Recovery time factor, minimum time between two measurements	0	3 x USW runtime for rod (default)
		1	2 x USW runtime for rod
14 - 15	Reserved		

Comment concerning bits 5 + 13

USW transducer rods require a certain recovery time between two measurements to allow the ultrasonic wave to fade. Otherwise there is a risk of interfering with the next measurement (especially when the rod has more than 1 magnet).

Depending on the setting, the module waits at least 2 or 3 times the runtime of the ultrasonic wave for the measurement rod (default = 3x). In the standard function module, the next measurement is then triggered synchronously with the next X2XLink cycle.

The runtime measurement is based on the settings for the rod length (plus a safety margin of 100mm) and the ultrasonic speed:

- USW runtime = (rod length + 100mm) / ultrasonic speed.

For their rods, BALLUFF recommends a recovery time equal to 3 times the maximum runtime of the ultrasonic wave for the measurement rod. This is the default setting for the module.

The setting can be switched to 2 times the runtime if the measurement rate is otherwise too slow. This may only be done after consulting the manufacturer of the transducer rods!

4.11.13.7.13 Rod length 1 and 2

Name:
ConfigOutput03 to ConfigOutput04

These registers are used to configure the length of the respective rod.

- Rod length 1: ConfigOutput03
- Rod length 2: ConfigOutput04

Data type	Value
UDINT	0 to 4,294,967,296: Resolution 1 mm

4.11.13.7.14 Offset position on the transducer

Name:
ConfigOutput07 to ConfigOutput08
ConfigOutput15 to ConfigOutput16

These registers are used to assign the respective magnet an offset position (= zero position) on the transducer. The max. and min. magnet paths refer to these specified offsets (see 4.11.13.7.15 "Plausibility check configuration" on page 1004). If the offset is changed using the StatusOutput01 register, this becomes the new zero position. This does not affect the contents of the offset register.

- Offset magnet 1: ConfigOutput07
- Offset magnet 2: ConfigOutput08
- Offset magnet 3: ConfigOutput15
- Offset magnet 4: ConfigOutput16

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647: Resolution 1 µm

4.11.13.7.15 Plausibility check configuration

These registers are used to configure the plausibility check (also see section 4.11.13.7.7 "Error status" on page 1000).

4.11.13.7.15.1 Min. plausible magnet position

Name:
ConfigOutput09 to ConfigOutput10
ConfigOutput17 to ConfigOutput18

These registers are used to assign the min. plausible magnet position based on the applicable offset.

- Min. path - magnet 1: ConfigOutput09
- Min. path - magnet 2: ConfigOutput10
- Min. path - magnet 3: ConfigOutput17
- Min. path - magnet 4: ConfigOutput18

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647: Resolution 1 µm

4.11.13.7.15.2 Max. plausible magnet position

Name:
ConfigOutput11 to ConfigOutput12
ConfigOutput19 to ConfigOutput20

These registers are used to assign the max. plausible magnet position based on the applicable offset.

- Max. path - magnet 1: ConfigOutput11
- Max. path - magnet 2: ConfigOutput12
- Max. path - magnet 3: ConfigOutput19
- Max. path - magnet 4: ConfigOutput20

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647: Resolution 1 µm

4.11.13.7.15.3 Max. plausible magnet speed

Name:
ConfigOutput13 to ConfigOutput14
ConfigOutput21 to ConfigOutput22

These registers are used to assign the max. plausible magnet speed.

- Max. speed - magnet 1: ConfigOutput13
- Max. speed - magnet 2: ConfigOutput14
- Max. speed - magnet 3: ConfigOutput21
- Max. speed - magnet 4: ConfigOutput22

Data type	Value
UDINT	0 to 4,294,967,296: Resolution 0.1 mm/s

4.11.13.7.16 Dead time for rods 1 and 2

Name:
ConfigOutput23 to ConfigOutput24

These registers are used to configure the dead time of the respective rod.

- Dead time for rod 1: ConfigOutput23
- Dead time for rod 2: ConfigOutput24

To prevent the multiple pulses that occur with some encoders from affecting the measurement, all pulses received within a configurable timespan from the beginning of the measurement are not evaluated. The range for the dead time lies between 0 and 255 µs. The following figure illustrates the effects of defining a dead time:

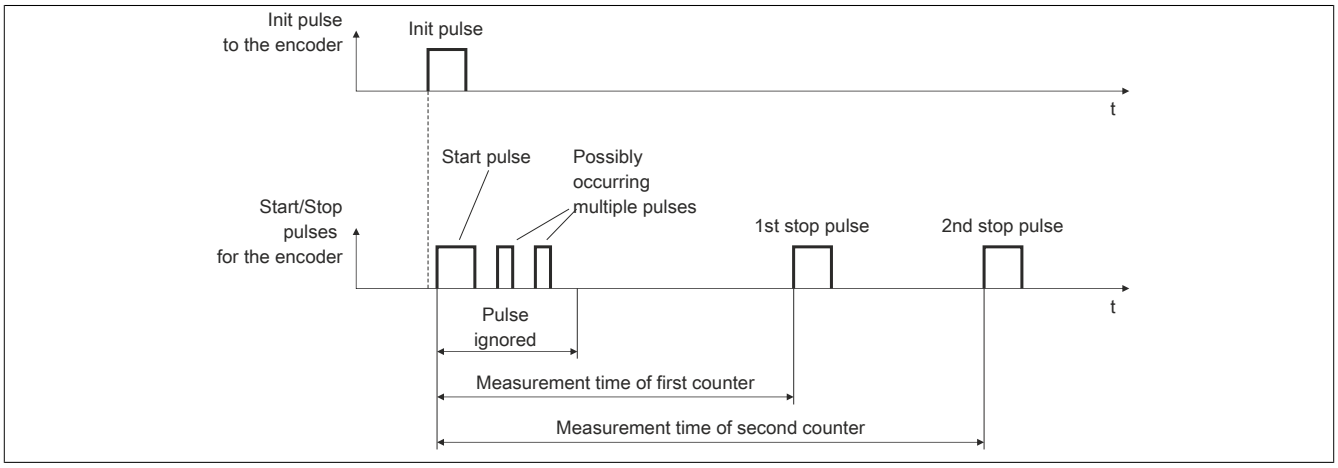

Figure 195: Pulse Ignored after Start Pulse

Data type	Value
USINT	0 to 255: Resolution 1 µs (default: 0 µs)

4.11.13.7.17 Read configuration register

Name:
ConfigOutput01Read to ConfigOutput04Read
ConfigOutput07Read to ConfigOutput24Read

These registers are used to read the states of the corresponding configuration registers.

4.11.13.7.18 Status register

Name:
StatusInput09 to StatusInput36

These registers are used to store the data read after a parameter upload from transducer rods with DPI/IP protocol or EP protocol. The registers "StatusInput19" to "StatusInput36" remain empty (0x0000) on transducer rods with EP protocol.

4.11.13.7.18.1 Parameter overview

The following parameters are stored in the status registers:

Register	Description	Supported by the protocol	
		DP/IP	EP
StatusInput09	Rod length 1 [mm]	●	●
StatusInput10	Rod length 2 [mm]	●	●
StatusInput11	Ultrasonic speed 1	●	●
StatusInput12	Ultrasonic speed 2	●	●
StatusInput13	Rod 1: Zero point offset [µm]	●	●
StatusInput14	Rod 2: Zero point offset [µm]	●	●
StatusInput15	Rod 1: Vendor ID (see transducer rod data sheet)	●	●
StatusInput16	Rod 2: Vendor ID (see transducer rod data sheet)	●	●
StatusInput17	Rod 1: Serial number (Hex coded)	●	●
StatusInput18	Rod 2: Serial number (Hex coded)	●	●
StatusInput19	Rod 1: Type ID 1 (MSB = letter 1)	●	0x0000
StatusInput20	Rod 1: Type ID 2 (MSB = letter 5)	●	0x0000
StatusInput21	Rod 1: Type ID 3 (MSB = letter 9)	●	0x0000
StatusInput22	Rod 1: Type ID 4 (MSB = letter 13)	●	0x0000
StatusInput23	Rod 1: Type ID 5 (MSB = letter 17)	●	0x0000
StatusInput24	Rod 1: Type ID 6 (MSB = letter 21)	●	0x0000
StatusInput25	Rod 2: Type ID 1 (MSB = letter 1)	●	0x0000
StatusInput26	Rod 2: Type ID 2 (MSB = letter 5)	●	0x0000
StatusInput27	Rod 2: Type ID 3 (MSB = letter 9)	●	0x0000
StatusInput28	Rod 2: Type ID 4 (MSB = letter 13)	●	0x0000
StatusInput29	Rod 2: Type ID 5 (MSB = letter 17)	●	0x0000
StatusInput30	Rod 2: Type ID 6 (MSB = letter 21)	●	0x0000
StatusInput31	Rod 1: Serial number ASCII 1 (MSB = letter 1)	●	0x0000
StatusInput32	Rod 1: Serial number ASCII 2 (MSB = letter 5)	●	0x0000
StatusInput33	Rod 1: Serial number ASCII 3 (MSB = letter 9)	●	0x0000
StatusInput34	Rod 2: Serial number ASCII 1 (MSB = letter 1)	●	0x0000
StatusInput35	Rod 2: Serial number ASCII 2 (MSB = letter 5)	●	0x0000
StatusInput36	Rod 2: Serial number ASCII 3 (MSB = letter 9)	●	0x0000

4.11.13.7.18.2 DPI/IP protocol (BALLUFF) / EP protocol (MTS)

Requirements for a successful upload of the transducer rod parameters to the module:

1. Selection of the communication protocol (DPI/IP or EP). See section . 4.11.13.7.12 "Channel configuration" on page 1003
2. Transducer rod must support the respective protocol.
3. If the transducer rod does not support the selected protocol, the module will detect this after a timeout of approx. 300 ms and will treat the rod as a "normal" transducer rod.

After the module is started or after a transducer rod is connected, the parameter upload should be complete within 200 to 400 ms.

A communication error causes the data upload to cancel. A new upload attempt can be initiated by the user by deactivating and reactivating the communication protocol using asynchronous access.

All rod parameters can be read to the controller using asynchronous access. The read parameters "rod length" and "ultrasonic speed" are **NOT** automatically uploaded to the module.

It is left up to the application whether the upload values for rod length 1 and rod length 2 or for ultrasonic speed 1 and ultrasonic speed 2 are uploaded.

Information:

Keep in mind that no position measurements can be performed on a rod while parameters are being uploaded. The module freezes all existing position/speed data for all magnets on the rod while the parameters are uploading. Parameters should therefore only be uploaded with the machine stopped, and this should be ensured by the application.

4.11.13.7.19 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.11.14 X20(c)DC2395

4.11.14.1 General information

This module is a multifunctional counter module. It can be connected to one SSI encoder, one ABR encoder, two AB encoders or four event counters. Two outputs are available for pulse width modulation. The functions can also be mixed.

- 24 VDC encoder inputs
- SSI, ABR, AB or event counters for inputs
- Pulse width modulation for outputs
- 24 VDC and GND for encoder supply

Information:

This module is a multifunctional module. Some bus controllers only support the default function model.

Default function model:

- **2x event counter (24 V)**
- **2x PWM output (24 V)**

4.11.14.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

2) Dead time when switching between push and pull: max. 1.5 µs.

4.11.14.5 LED status indicators

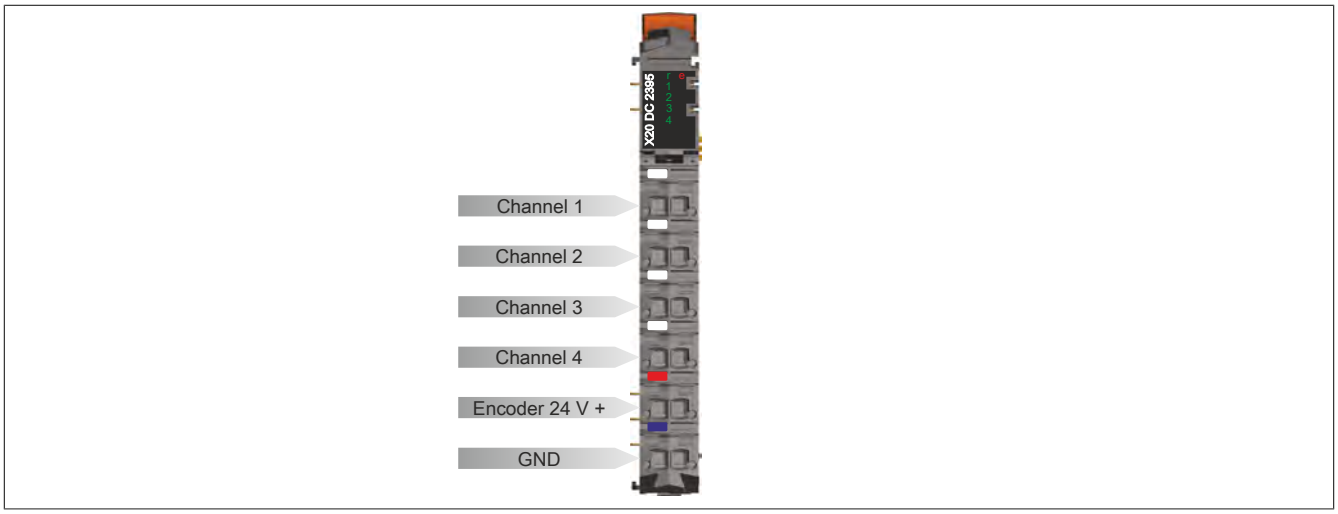
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	1 - 4	Green		Status of the corresponding digital signal

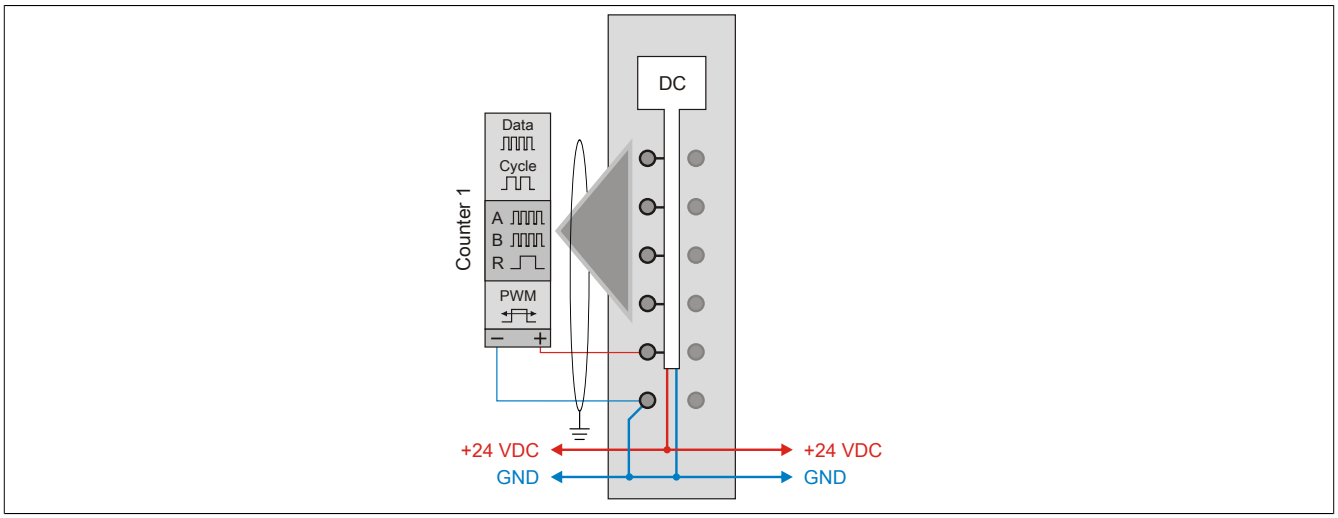
1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.14.6 Pinout

Shielded cables must be used for all signal lines.



4.11.14.7 Connection example



4.11.14.8 Function overview

The following functions can be configured on the module. They cannot all be used at the same time due to the multiple use of the hardware channels and the limited cyclic data length.

- 4 digital channels, 2 of which can be configured as outputs
- 4 event counters with configurable counting direction and optional referencing via digital input
- 2 PWM outputs
- 2 up/down counters, each with optional latch inputs and comparator output
- 2 AB counters, each with optional latch inputs and comparator output
- 1 ABR encoder with configurable reference pulse edge and reference position, optional reference enable input, latch input and comparator output
- 1 SSI counter with optional latch input and comparator output
- 2 edge-triggered time measurement functions with configurable start edge based on current configuration settings

4.11.14.8.1 Description of channel assignments

The functions listed here are directly assigned to the respective hardware channels and cannot be changed:

Channel	Signal connections
1	• Digital input 1 • Event counter 1 • AB encoder 1 - signal line A • Up/down counter 1 - frequency • SSI encoder 1 - data line • ABR encoder 1 - signal line A
2	• Digital input 2 • Digital output 2 • Event counter 2 • PWM output 2 • AB encoder 1 - signal line B • Up/down counter 1 - direction • SSI encoder 1 - clock line • ABR encoder 1 - signal line B
3	• Digital input 3 • Event counter 3 • AB encoder 2 - signal line A • Up/down counter 2 - frequency • ABR encoder 1 - signal line R
4	• Digital input 4 • Digital output 4 • Event counter 4 • PWM output 4 • AB encoder 2 - signal line B • Up/down counter 2 - direction • ABR encoder 1 - reference enable input

Options available in addition to these basic functions, such as comparator outputs or latch inputs, can be configured freely to unused input/output channels.

4.11.14.8.2 Connection options

Channels 1 to 4 can be connected as follows:

Channel	Function					
1	I	Event counter	A	A	SSI data	
2	I/O	Event counter	B	B	SSI cycle	PWM
3	I	Event counter	A	R		
4	I/O	Event counter	B	Enable reference		PWM

The functions can also be mixed. For example:

Example 1	
Channel	**Function**
1	SSI data
2	SSI cycle
3	Event counter
4	PWM

Example 2	
Channel	**Function**
1	SSI data
2	SSI cycle
3	A
4	B

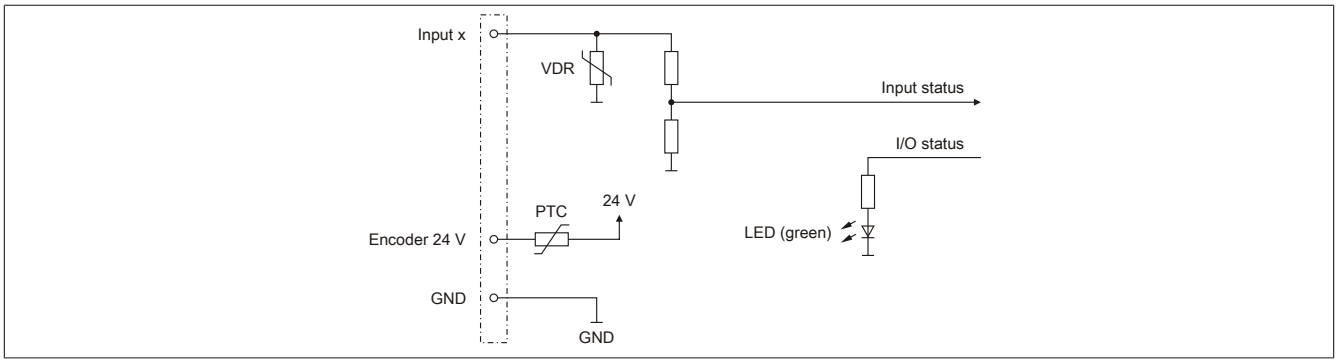
Example 3	
Channel	**Function**
1	Event counter
2	PWM
3	Event counter
4	PWM

Example 4	
Channel	**Function**
1	A
2	B
3	R
4	Enable reference

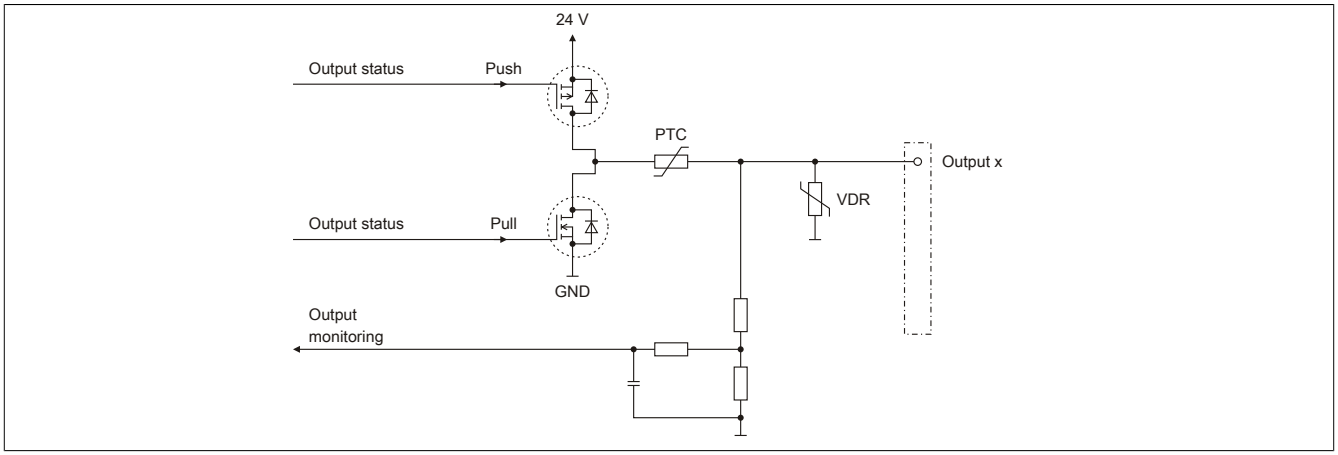
Example 5	
Channel	**Function**
1	A
2	B
3	Event counter
4	PWM

Example 6	
Channel	**Function**
1	Event counter
2	PWM
3	A
4	B

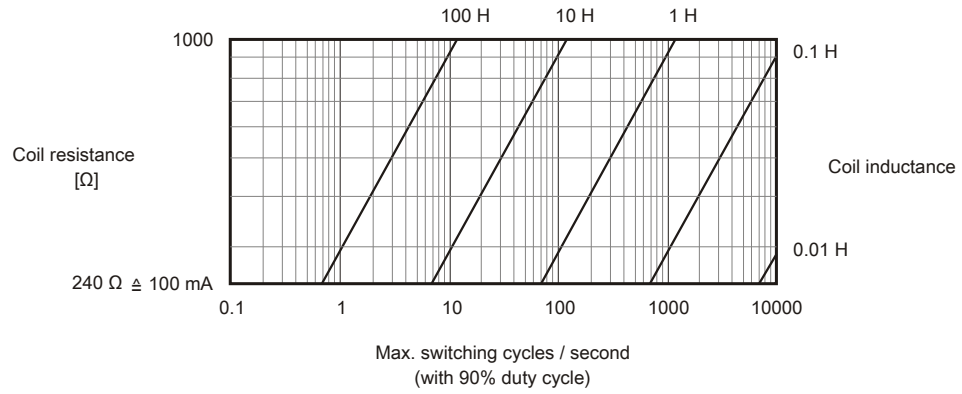
4.11.14.9 Input circuit diagram



4.11.14.10 Output circuit diagram



4.11.14.11 Switching inductive loads



4.11.14.12 Calculating the period duration

The outputs of the module can be operated as PWM outputs. The period duration is calculated using the following formula:

$$\text{Period duration} = \frac{n}{48000}\ \text{s}$$

A value of 2 to 65535 can be defined for n.

Example

n	Period duration	Frequency
2	416 µs	24 kHz
24000	500 ms	2 Hz
48000	1 s	1 Hz
65535	1.36 s	0.73 Hz

4.11.14.13 Register description

4.11.14.13.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.14.13.2 Function model 0 - Standard and Function model 1 - 32-bit counter

The following 2 models can be selected:

- 16-bit counter, Function model 0
- 32-bit counter, Function model 1 (identified in the table with a "(D)" in the data type and "(_32Bit)" in the name.)

The only difference between these two models is that they use either 16-bit or 32-bit registers for incremental counter functions. These include:

- ABR encoders
- AB encoders
- Up/down counters
- Event counters

All other module functions e.g. SSI, PWM and time measurement, as well as their data types, are identical for the two models.

4.11.14.13.3 Function model 254 - Bus controller

Unlike the function models 0 and 1, this model only offers a selection of functions with a limited scope of configuration on the module.

The following functions are provided and can be run at the same time:

- 2 event counter with configurable counting direction
- 2 PWM outputs

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
(N-1) * 2	-	CfO_CFGchannel0N (Index N = 1 to 4)	USINT				●
64 + N * 2	-	CfO_LEDNsource (Index N = 0 to 3)	USINT				●
2,056	-	CfO_Counter1configReg0	USINT				●
2,312	-	CfO_Counter2configReg0	USINT				●
Communication							
2,080	0	EventCounter01	UINT	●			
2,336	2	EventCounter03	UINT	●			
6,146	0	PWMOutput02	UINT			●	
6,162	2	PWMOutput04	UINT			●	
40	4	Status of encoder supply	USINT	●			
		PowerSupply01	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.11.14.13.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.14.13.4 General module registers

4.11.14.13.4.1 Configuring LED status indicators

Name:
CfO_LED0source to CfO_LED3source

These registers can be used to define how the module's LED status indicators are used. Blinking patterns can be generated from the application, and the status of the physical inputs and outputs can be indicated.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	MODE = 0	0	LED off
		1	Blinking quickly
		2	Blinking
		3	Blinking slowly
		4	Single flash
		5	Double flash
		6 to 15	Reserved
	MODE = 1 (inverted)	0	LED on
		1	Blinking quickly
		2	Blinking
		3	Blinking slowly
		4	Single flash
		5	Double flash
		6 to 15	Reserved
	MODE = 2	0 to 3	Number of the physical input channel
		4 to 15	Reserved
	MODE = 3	0 to 3	Number of the physical output channel
		4 to 15	Reserved
4 - 7	Selection of the mode for the LED status indicator	0	LED blinking pattern
		1	Inverted LED blinking pattern
		2	Displays a channel's physical input status
		3	Displays a channel's physical output status
		4 to 15	Reserved

4.11.14.13.4.2 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.14.13.5 Digital inputs and outputs

4.11.14.13.5.1 Configure physical channels

Name:
CfO_CFGchannel01 to CfO_CFGchannel04

This register can be used to configure physical I/O channels 1 to 4.

Information:

Except for bit 2 (inverted input), all other bits are only available for channels 2 and 4.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Push[1)]	0	Disabled
		1	Enabled
1	Pull[1)]	0	Disabled
		1	Enabled
2	Inverted input	0	Disabled
		1	Enabled
3	Inverted output	0	Disabled
		1	Enabled
4 - 7	Output type	0	Direct I/O
		1 to 5	Reserved
		6	PWM (channel-specific)
		7	SSI clock (channel-specific)

1) To configure a channel as an output, Push and/or Pull must be enabled.

4.11.14.13.5.2 Reset mask of the digital channels

Name:
CfO_OutClearMask

The settings in this register only affect the values written to registers 4.11.14.13.5.5 "DigitalOutput02 and 04".

- 0 allows manual reset of digital outputs using registers DigitalOutput02 and 04
- 1 prevents manual reset of digital outputs using registers DigitalOutput02 and 04

When "1" is used, the "output event function" can be used to reset the outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0	Writing 0 to the DigitalOutput02 register resets the output
		1	Writing 0 from the DigitalOutput02 register does not reset the output
2	Reserved	-	
3	DigitalOutput04	0	Writing 0 to the DigitalOutput04 register resets the output
		1	Writing 0 from the DigitalOutput04 register does not reset the output
4 - 7	Reserved	-	

4.11.14.13.5.3 Set mask of the digital channels

Name:
CfO_OutSetMask

The settings in this register only affect the values written to registers 4.11.14.13.5.5 "DigitalOutput02 and 04".

- 0 allows manual setting of digital outputs using registers DigitalOutput02 and 04
- 1 prevents manual setting of digital outputs using registers DigitalOutput02 and 04

When "1" is used, the "output event function" can be used to set the outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0	Writing 1 to the DigitalOutput02 register sets the output
		1	Writing 1 from the DigitalOutput02 register does not set the output
2	Reserved	-	
3	DigitalOutput04	0	Writing 1 to the DigitalOutput04 register sets the output
		1	Writing 1 from the DigitalOutput04 register does not set the output
4 - 7	Reserved	-	

4.11.14.13.5.4 Input states of the channels

Name:
see "Name in the AS I/O configuration"

This register reads the input status of a physical channel. The polarity settings are accounted for in the value (bit 2 in 4.11.14.13.5.1 "CfO_CFGchannel[x]" register).

The bits in this register are shown in the AS I/O mapping table under different names based on the function used in order to improve readability.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Physical input channel	Value	Name in the AS I/O configuration
0	Channel 1	0 or 1	DigitalInput01
1	Channel 2	0 or 1	DigitalInput02 StatusDigitalOutput02
2	Channel 3	0 or 1	DigitalInput03
3	Channel 4	0 or 1	DigitalInput04 StatusDigitalOutput04 ReferenceEnableSwitch01 ComparatorActualValue01
4 - 7	Reserved	-	

4.11.14.13.5.5 Output states of the channels

Name:
DigitalOutput02 and DigitalOutput04

The output status of a physical channel can be written using this register. In order to configure a channel as an output:

1 Bit 0 "Push" and/or bit 1 "Pull" must be enabled in the 4.11.14.13.5.1 "CfO_CFGchannel[x]" register.
2 Bits 4 to 7 in the 4.11.14.13.5.1 "CfO_CFGchannel[x]" register must be set to Direct I/O.
3 0 must be set for the respective channel in the 4.11.14.13.5.2 "CfO_OutClearMask" and 4.11.14.13.5.3 "CfO_OutSetMask" registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0 or 1	Output status of channel 2
2	Reserved	-	
3	DigitalOutput04	0 or 1	Output status of channel 4
4 - 7	Reserved	-	

4.11.14.13.6 Event functions

The module provides configurable event functions. An event function can be connected to physical I/O and the values derived from them (e.g. counters) or be purely used for internal processing.

Every event function has event inputs and outputs. Event functions can also have only inputs or only outputs. Each event output has a unique event ID. It is possible to configure when an event should be generated on an event output. The effect of an event is determined by the respective event function.

Event functions can also be linked to one another. The link takes place using the event input. Every event input has a 16-bit register to which the event number of the linked event output is written.

Information:

The module functions that can be configured in the AS I/O configuration are primarily based on these event functions and their links. Changes in the AS I/O configuration have multiple effects on event functions and their links.

4.11.14.13.6.1 List of event IDs

Various hardware and software functions send event IDs or require event IDs in order to start. The following table shows all of the IDs available to configure the module.

Event ID	Description	
Direct event inputs		
512	Comparator condition	FALSE
513	Comparator condition	TRUE
Counter comparator function		
2,112	Counter function 1	Event function 1; FALSE
2,113		Event function 1; TRUE
2,144		Event function 2; FALSE
2,145		Event function 2; TRUE
2,368	Counter function 2	Event function 1; FALSE
2,369		Event function 1; TRUE
2,400		Event function 2; FALSE
2,401		Event function 2; TRUE
Edge events		
4,096	Falling edge on I/O channel	Channel 1
...		...
4,099		Channel 4
4,112	Rising edge on I/O channel	Channel 1
...		...
4,115		Channel 4
4,128	Rising or falling edge on I/O channel	Channel 1
...		...
4,131		Channel 4
SSI counter events		
7,168	SSI valid	
7,169	SSI ready	
SSI comparator events		
7,232	SSI 1 comparator condition	FALSE
7,233		TRUE
Timerevents		
208	Timer1	50 µs
209	Timer2	100 µs
210	Timer3	200 µs
211	Timer4	400 µs
212	Timer5	800 µs
213	Timer6	1600 µs
214	Timer7	3200 µs
215	Timer8	3200 µs (time offset to timer 7)
Network functions		
224	SOAISOP (**s**ynchronous **o**ut **a**synchronous **i**n **s**tart of **p**rotocol)	
225	AOSISOP (**a**synchronous **o**ut **s**ynchronous **i**n **st**art of **p**rotocol)	
226	SOAIEOP (**s**ynchronous **o**ut **a**synchronous **i**n **e**nd of **p**rotocol)	
227	AOSIEOP (**a**synchronous **o**ut synchronous **i**n **e**nd of **p**rotocol)	
Idle event		
192	No-load operation	

Timer

There are 8 timer events that the module can generate.

Information:

The timers have the highest event priority. All other system functions are interrupted when a timer event occurs, and jitter for the amount of time it takes to process the event.

Idle event

Idle time is the time that remains after the system has processed all higher priority events and operations. The module performs the following functions during idle time:

- Handling of the asynchronous protocol
- Mechanism for (re-)linking events
- Operation of LEDs
- Execution of event event functions linked to the idle function

4.11.14.13.6.2 Edge events

For each physical input channel there are 3 event functions

- Falling edge
- Rising edge
- Falling and rising edge

The respective event is triggered when an edge is detected on the hardware input and the "CfO_EdgeDetectRising" and/or "CfO_EdgeDetectFalling" register has been configured for the respective channel.

Edges are detected by the hardware and processed for each interrupt. The interrupt handler uses an event distributor, which requires a specific amount of time for each edge to operate the hardware and execute linked event functions. To reduce this time, edge detection can be enabled/disabled individually for each channel. To optimize system load and I/O jitter, it is important to only enable edge detection where it is actually needed.

Information:

Edge detection can also be used for channels that are configured as outputs.

Event frequency limitation

To stabilize the system, there is a mechanism that limits the number of events created through edge recognition. At least one idle event must occur between two edge events for the same edge.

The "CfO_FallingDisProtection" and "CfO_RisingDisProtection" registers can be used to disable this limitation for each edge, and then an event will be generated for every edge. However, this can cause a system overload, i.e. I/O operation can fail for up to 100 ms before the module changes to the reset state.

Generate event on falling edge

Name:
CfO_EdgeDetectFalling

This register defines whether an event is generated on a falling edge.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	No event generated on falling edge.
		1	Events 4096 and 4128 are generated on falling edge.
...		...	
3	Channel 4	0	No event generated on falling edge.
		1	Events 4099 and 4131 are generated on falling edge.
4 - 7	Reserved	-	

Generate event on rising edge

Name:
CfO_EdgeDetectRising

This register defines whether an event is generated on a rising edge.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	No event generated on rising edge.
		1	Events 4112 and 4128 are generated on rising edge.
...		...	
3	Channel 4	0	No event generated on rising edge.
		1	Events 4115 and 4131 are generated on rising edge.
4 - 7	Reserved	-	

Enable limit for falling edges

Name:
CfO_FallingDisProtection

This register can be used to enable/disable the event frequency limit for falling edges on the respective channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
...		...	
3	Channel 4	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
4 - 7	Reserved	-	

Enable limit for rising edges

Name:
CfO_RisingDisProtection

This register can be used to enable/disable the event frequency limit for rising edges on the respective channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
...		...	
3	Channel 4	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
4 - 7	Reserved	-	

4.11.14.13.6.3 Direct input function

The module features a direct input function.

This event function is based on comparator functionality. If the event configured in the "CfO_DIREKTIOevent0IDwr" register occurs, the event function compares the status of all Direct I/O channels enabled in the "CfO_EvComp-Mask" register to a status defined in the "CfO_DIREKTIOeventcompState" register. The event that is generated depends on the results of this comparison.

- If the respective bits are the same, then event number 513 is generated
- If the respective bits are different, then event number 512 is generated

Configure event ID for input function

Name:
CfO_DIREKTIOevent0IDwr

This register holds the event ID generated by the direct input function. For a list of all possible event IDs, see 4.11.14.13.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,233	ID of event function

Configure the mode of the input function

Name:
CfO_DIREKTIOevent0mode

The mode in which the direct input function operates can be set in this register.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 7	Reserved	-	

Comparator status for comparator mask

Name:
CfO_DIREKTIOevent0compState

This register contains the status bits that are compared with the bits specified in the "CfO_Ev0CompMask" register, which contain the I/O input status, when an event is received.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator status of channel 1	0 or 1	
...		...	
3	Comparator status of channel 4	0 or 1	
4 - 7	Reserved	-	

Configure the comparator mask for the input function

Name:
CfO_Ev0CompMask

If a bit is set, then the input status of the respective channel is compared with that bit in the "CfO_DIREKTIOeventcompState" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Do not compare bit
		1	Compare bit in register
...		...	
3	Channel 4	0	Do not compare bit
		1	Compare bit in register
4 - 7	Reserved	0	

4.11.14.13.6.4 Direct output functions

The module has 2 of these event functions

The effect of executing this event function is similar to writing to the 4.11.14.13.5.5 "DigitalOutput02 and 04" registers. When this event function is triggered, however, the changed output states are passed on to the hardware immediately, regardless of the X2X cycle.

When this event function is used, the masks of the respective outputs (see 4.11.14.13.5.2 "CfO_OutClearMask" and 4.11.14.13.5.3 "CfO_OutSetMask" registers) must be set to 1. Otherwise the output status would constantly be overwritten by the values in the 4.11.14.13.5.5 "DigitalOutput02 and 04" registers.

Configure event ID for output function

Name:
CfO_DIREKTIOevent0IDwr to CfO_DIREKTIOevent1IDwr

These registers hold the event IDs that trigger the direct output function. For a list of all possible event IDs, see 4.11.14.13.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,233	ID of event function

Configure channels for resetting

Name:
CfO_DIREKTIOoutclearmask0 to CfO_DIREKTIOoutclearmask1

Writing "1" to the bit position that corresponds to a channel resets the output if the output event function is being executed. This corresponds to writing "0" to the 4.11.14.13.5.5 "DigitalOutput 02 and 04" registers.

The bit that corresponds to channels that should be reset should be set to "1" in the 4.11.14.13.5.2 "CfO_OutClearMask" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	Channel 2	0	Reset channel 2
		1	Do not reset channel 2
2	Reserved	-	
3	Channel 4	0	Reset channel 4
		1	Do not reset channel 4
4 - 7	Reserved	-	

Configure channels for setting

Name:
CfO_DIREKTIOoutsetmask0 to CfO_DIREKTIOoutsetmask1

Writing "1" to the bit position that corresponds to a channel sets the output if the output event function is being executed. This corresponds to writing "1" to the 4.11.14.13.5.5 "DigitalOutput 02 and 04" registers.

The bit that corresponds to channels that should be reset should be set to "1" in the 4.11.14.13.5.3 "CfO_OutSet-Mask" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	Channel 2	0	Set channel 2
		1	Do not set channel 2
2	Reserved	-	
3	Channel 4	0	Set channel 4
		1	Do not set channel 4
4	Reserved	-	

4.11.14.13.7 Counters and encoders

The module has 2 internal counter functions, each with 2 event counter registers. Each of these 2 counters is permanently assigned to 2 physical inputs. This assignment cannot be changed.

The counter registers perform different functions based on how the event functions are connected. The counter registers can be configured in the following ways:

- ABR counter
- AB counter
- Up/down counters
- Event counters

Different names are used for them in Automation Studio and in the register description to improve clarity.

Channel	Counter function	Counter register	Name in AS
1	1	1	ABEncoder01 ABREncoder01 Counter01 EventCounter01
2		2	EventCounter02
3	2	1	ABEncoder02 Counter02 EventCounter03
4		2	EventCounter04

4.11.14.13.7.1 Counter value calculation

There are 3 steps for calculating the state of any counter function

1. The counter value is based on the 2 absolute value counters "abs1" and "abs2". They are only used internally in the module and cannot be read. Depending on the mode, these registers show the respective physical input signals.

	Mode		
	Edge counters	AB encoders	Up/down counter
abs1	Edges of counter channel 1	Increments in positive direction	Counter channel 2 = 0: Edges of counter channel 1 in up direction
abs2	Edges of counter channel 2	Increments in negative direction	Counter channel 2 = 1 Edges of counter channel 1 in down direction

2. From the absolute value registers "abs1" and "abs2", 2 more counters are formed: "counter 1" and "counter 2". These are only used internally in the module and cannot be read. The following values are used for the calculation:

- Absolute value registers "abs1" and "abs2"
- SW_reference_counter 1 and 2: This reference value can be defined by the "CfO_CounterPresetValue" register to allow referencing <> 0.
- HW_reference_counter 1 and 2: In the "CfO_CounterEventMode" register, you can configure whether latched values should be copied to these registers when counter events occur.

counter1 = abs1 + SW_reference_counter1 - HW_reference_counter1
counter2 = abs2 + SW_reference_counter2 - HW_reference_counter2

3. The counter registers contain the sum of the two internal counters "counter 1" and "counter 2". The "CfO_CounterConfigReg" register allows you to define a sign for each "counter" register and define whether or not it should be used.

Counter register = counter1 + counter2

4.11.14.13.7.2 Sample configurations

All of the settings available in Automation Studio for AB encoders, ABR encoders, up/down counters and event counters are based on the two counter functions.
The following configuration examples show the values with which Automation Studio initializes the module registers in order to implement these functions.

I/O configuration - AB encoder

The following table shows how the module's various event functions can be linked in order to configure an AB encoder.

[x] stands for the respective counter function, either 1 or 2

Register	Value	Comment
For the function		
CfO_Counter[x]config	0x01	Mode = Up/down counter
CfO_Counter[x]configReg0	0x0D	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.14.13.7.1 "Counter value calculation" and "Examples of calculation configurations")
For the latch		
CfO_Counter[x]event0config	0x000D	Configuration of the calculation of the first value used for the latch
CfO_Counter[x]event0mode	0x03	Mode of the first counter event function - Continuous
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger Latch 1 ("Latch 01 - Channel" in the AS I/O configuration).
CfO_Counter[x]event1config	0x0D	Configuration of the calculation of the second value used for the latch
CfO_Counter[x]event1mode	0x03	Mode of the second counter event function - Continuous
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger Latch 2
For the comparator		
CfO_Counter1event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config	0x900D or 0xA00D	Configuration of the comparator for the second counter event
CfO_Counter1event1mode	0x03	Mode of the second counter event function - Continuous
CfO_DIREKTIOoutevent0IDwr	0x0861	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0	0x08, 0x20, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr	0x0860	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1	0x08, 0x20, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - ABR encoder

The following table shows how the module's various event functions can be linked in order to configure an ABR encoder.

Register	Value	Comment
For the function		
CfO_Counter1PresetValue1	(any)	Desired offset value for referencing
CfO_Counter1event0IDwr	0x0201	Link between the first counter event and the "direct input" comparator condition TRUE
CfO_Counter1config	0x01	Mode = AB encoder
CfO_Counter1configReg0	0x0D	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.14.13.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_DIREKTIOevent0IDwr	0x1002 or 0x1012	Selection of the desired input edge as trigger for the ABR encoder function
CfO_Counter1event0config	0x0000	Configuration of the first counter event (for referencing)
CfO_DIREKTIOevent0mode	0x03	Mode of the "direct input function" - Continuous
CfO_DIREKTIOevent0compState	0x00 or 0x08	Comparator status for the "direct input function"
CfO_Ev0CompMask	0x08	Comparator mask for the "direct input function"
For the latch		
CfO_Counter1event0config	0x000D	Configuration of the calculation of the value used for the latch
CfO_Counter1event0mode	0x03	Mode of the first counter event function - Continuous
CfO_Counter1event0IDwr	(any)	Number of the event that should trigger the latch
For the comparator		
CfO_Counter1event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config	0x900D or 0xA00D	Configuration of the comparator for the second counter event
CfO_Counter1event1mode	0x03	Mode of the second counter event function - Continuous
CfO_DIREKTIOoutevent0IDwr	0x0861	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0	0x08, 0x20, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr	0x0860	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1	0x08, 0x20, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - Up/down counter

The following table shows how the module's various event functions can be linked in order to configure an up/down counter.

[x] stands for the respective counter function, either 1 or 2

Register	Value	Comment
For the function		
CfO_Counter[x]config	0x03	Counter mode = Up/down counter
CfO_Counter[x]configReg0	0x0D, 0x07	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.14.13.7.1 "Counter value calculation" and "Examples of calculation configurations")
For the latch		
CfO_Counter[x]event0config	0x0D, 0x07	Configuration of the calculation of the first value used for the latch
CfO_Counter[x]event0mode	0x03	Mode of the first counter function - Continuous
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger Latch 1
CfO_Counter[x]event1config	0x0D, 0x07	Configuration of the calculation of the second value used for the latch
CfO_Counter[x]event1mode	0x03	Mode of the second counter function - Continuous
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger Latch 2
For the comparator		
CfO_Counter1event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config	0x900D, 0xA00D or 0x9007, 0xA007	Configuration of the comparator for the second counter event
CfO_Counter1event1mode	0x03	Mode of the second counter event function - Continuous
CfO_DIREKTIOoutevent0IDwr	0x0861	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0	0x08, 0x20, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr	0x0860	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1	0x08, 0x20, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - Event counter

The following table shows how the module's various event functions can be linked in order to configure an event counter.

[x] stands for the respective counter function, either 1 or 2

Register	Value	Comment
For event counters on channels 1 and 3		
CfO_Counter[x]configReg0	0x01 or 0x03	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.14.13.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_Counter[x]event0mode	0x43	Mode of the first counter event function and referencing configuration
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger referencing
For event counters on channels 2 and 4		
CfO_Counter[x]configReg1	0x04 or 0x08	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.14.13.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_Counter[x]event1mode	0x83	Mode of the second counter event function and referencing configuration
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger referencing

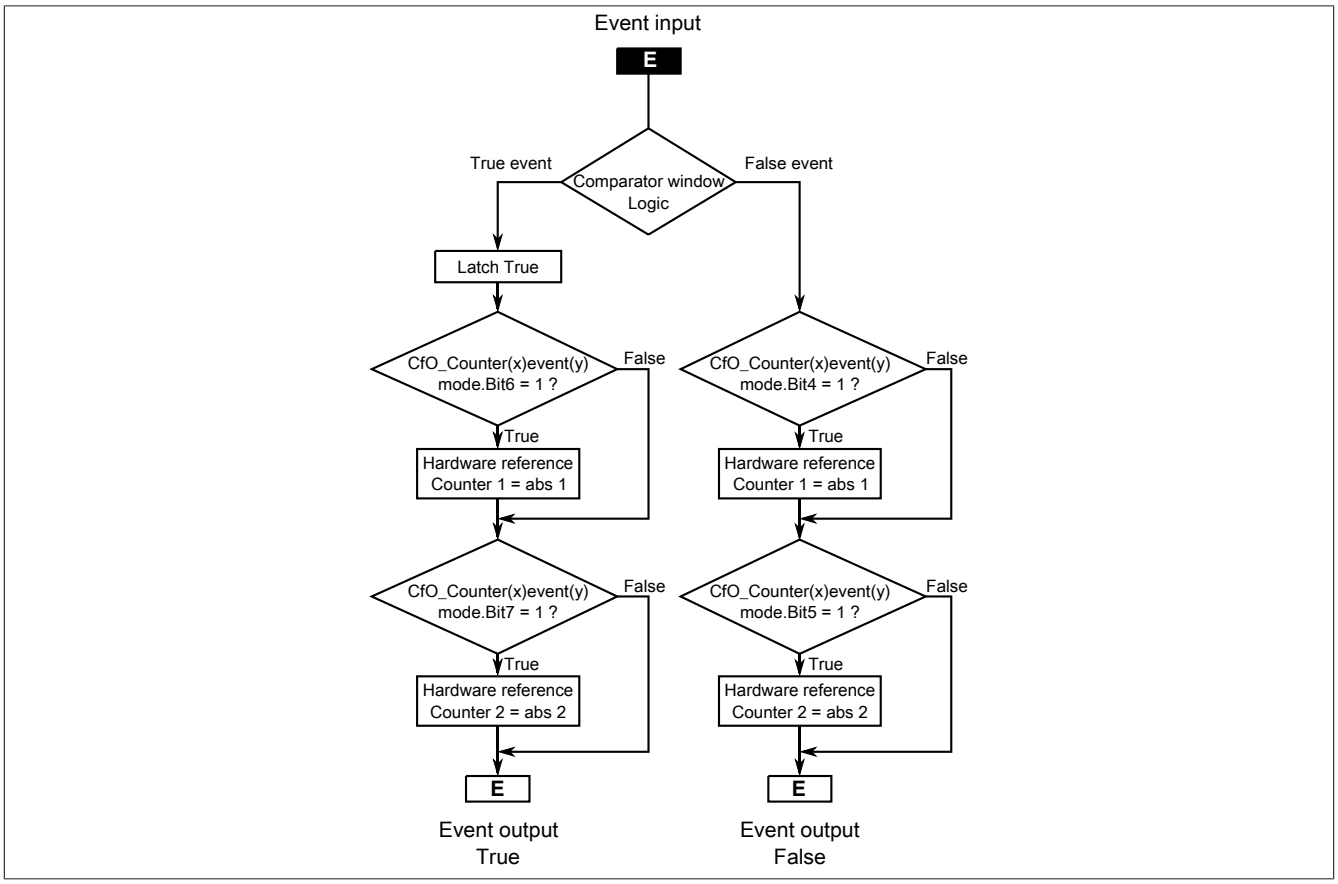
4.11.14.13.7.3 General event functions

Each of the 2 counter functions has 2 counter event functions. These consist of:

- Event ID that triggers the counter event function
- A window comparator
- Latch register for saving the counter value

When the counter event function is complete, a combined event ID in the range 2112 to 2401 (see 4.11.14.13.6.1 "List of event IDs") is sent.

Each counter event function also has the option to copy the current counter value to the "HW reference counter" when an event occurs (see 4.11.14.13.7.1 "Counter value calculation").



Configure counter mode

Name:
Counter function 1: CfO_Counter1config
Counter function 2: CfO_Counter2config

These registers are used to configure the mode of the counter function. Each counter function can be operated in 3 different modes.

	Counter function mode		
	Edge counters	**AB encoder**	**Up/down counter**
Counter channel 1[1)]	Counting pulses, edge counter 1	A	Metering pulses
Counter channel 2[1)]	Counting pulses, edge counter 2	B	Counting direction (0 = positive, 1 = negative)
Counter register 1	Counter value 1	Position	Counter value
Counter register 2	Counter value 2		

1) Corresponds to the physical channels of the counter functions. See 4.11.14.8.1 "Description of channel assignments".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Counter mode	00	Edge counters
		01	AB encoder
		11	Up/down counter
2 - 7	Reserved	-	

Configure calculation of internal counters

Name:
Counter function 1: CfO_Counter1configReg0 to CfO_Counter2configReg0
Counter function 2: CfO_Counter1configReg1 to CfO_Counter2configReg1

The calculation of the internal "counter1" and "counter2" registers can be configured in these registers. For information on using these internal registers, see 4.11.14.13.7.1 "Counter value calculation".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	counter 1 - use	0	0 is added instead of "counter 1"
		1	"counter 1" is used for addition
1	counter 1 - sign	0	The sign of the "counter 1" register is not changed for addition
		1	The sign of the "counter 1" register is reversed for addition
2	counter 2 - use	0	0 is added instead of "counter 2"
		1	"counter 2" is used for addition
3	counter 2 - sign	0	The sign of the "counter 2" register is not changed for addition
		1	The sign of the "counter 2" register is reversed for addition
4 - 7	Reserved	-	

Examples of calculation configurations

0b00000001	= 0x01	Only the "counter1 - use" bit is set, entering the contents of the "counter" (edge of counter event channel 1) directly in the counter register.
0b00000011	= 0x03	"counter 1 - use" and "counter1 - sign" bits are set. The sign is changed so that the counter register counts in the negative direction.
0b00001101	= 0x0d	Edges on counter input channel 1 increase the value in the counter register. Edges on counter input channel 2 decrease the value in the counter register. This value is the best setting for the modes "AB encoder" and "Up/down counter".

Offset value for referencing

Name:

Counter function 1: CfO_Counter1PresetValue1 to CfO_Counter2PresetValue1
Counter function 1: CfO_Counter1PresetValue1_32Bit to CfO_Counter2PresetValue1_32Bit

Counter function 2: CfO_Counter1PresetValue2 to CfO_Counter1PresetValue2
Counter function 2: CfO_Counter1PresetValue2_32Bit to CfO_Counter1PresetValue2_32Bit

"Preset value" in the AS I/O configuration.

These registers can be used to define an offset value for referencing. This value is copied to the internal SW_reference_counter register of the respective counter register.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

Counter register

Name:
Different names are used for these 4 registers depending on their function.

These 4 registers show the results of the counter value calculation for the respective register. Depending on the function, this corresponds to either the encoder position or the counter value.

For information on the relationship between physical channels and counter registers, see 4.11.14.13.7 "Counters and encoders" and 4.11.14.8.1 "Description of channel assignments"

Counter function 1		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder01
	ABR encoders	ABREncoder01
	Up/down counters	Counter01
	Event counters	EventCounter01
2	**Event counters**	EventCounter02

Counter function 2		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder02
	Up/down counters	Counter02
	Event counters	EventCounter03
2	**Event counters**	EventCounter04

Data type	Value	Information
INT	-32,768 to 32,767	Encoder position or counter value
DINT[1)]	-2,147,483,648 to 2,147,483,647	Encoder position or counter value

1) Only in function model 1

Status of the ABR encoder

Name:
StatusABR01

The referencing status of the ABR encoder is shown in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	0	
2	Bit is always 1 after the first reference pulse.	0	No reference pulses have occurred since the start of referencing.
		1	The first reference pulse has occurred.
3	State change when referencing is complete	0 or 1	
4	Bit is always 1 after the first reference pulse.	0	No reference pulses have occurred since the start of referencing.
		1	The first reference pulse has occurred.
5 - 7	Continuous counter	xxx	Increased with each reference pulse

Examples of possible values

0b00000000	= 0x00	Referencing OFF or homing procedure already active
0b00111100	= 0x3C	First reference complete, reference value applied in the "ABREncoder0" register
0bxxx11100	= 0xxB	Bits 5 to 7 are changed with each reference pulse
0bxxx1x100	= 0xxx	Bits changed continuously with the setting continuous referencing. With every reference pulse, the reference value is applied to the "ABREncoder0" register

Configure ABR referencing mode

Name:
ReferenceModeABR01

The bits in this register are used to configure the reaction to the configured reference pulse.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Sets the referencing mode	00	Referencing OFF
		01	Single shot referencing
		10	Reserved
		11	Continuous referencing
2 - 5	Reserved	-	
6 - 7	Reserved	11	Must always be 11!

This results in the following values:

0b00000000	= 0x00	Referencing OFF
0b11000001	= 0xC1	Single shot referencing → When starting over after the referencing process is complete, the value 0x00 must be written to start again. Wait until the "StatusABR" register also takes on the value 0x00, then the value 0xC1 can be written again.
0b11000011	= 0xC3	Continuous referencing → Referencing takes place automatically with every reference pulse

4.11.14.13.7.4 Comparator functions

The ABR and AB encoders and the up/down counter have a comparator function. It always works the same and is described here globally for all three.

The comparators are implemented in software form. They do not work actively but rather passively, i.e. the comparison is only carried out when an event is received. The event received is forwarded along the TRUE or FALSE branch depending on the status of the comparator condition. An event function like this generally also offers a latch for the TRUE and FALSE branch to save the value used for the comparator at the time of the event.

Comparator modes

Comparator functions can be operated in 4 different modes.

- **Off**
  Events are ignored.
- **Single**
  The event function is executed once and then disables itself automatically. To re-enable it, the "event function mode" must be changed, preferably to "off" and then to the desired mode. This setting allows a hardware latch to be simulated.
- **State change**
  The event function only responds when the comparator status has changed, i.e. from false to true (or vice versa). Only the first event for each status is processed, e.g. the first "true" of a sequence of events with the comparator condition "true". After the event function is enabled, the first incoming event is used to determine the starting status and therefore not forwarded. This setting allows a hardware comparator to be simulated.
- **Continuous**
  Each incoming event is forwarded to the true or false branch depending on the comparator condition. This setting allows event filters to be created.

Configure event ID for comparator

Name:
Counter function 1: CfO_Counter1event0IDwr to CfO_Counter1event1IDwr
Counter function 2: CfO_Counter2event0IDwr to CfO_Counter2event1IDwr

This register holds the event ID that should trigger the counter event function. For a list of all possible event IDs, see 4.11.14.13.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,233	ID of counter event function

Configure calculation of comparator

Name:
Counter function 1: CfO_Counter1event0config to CfO_Counter1event1config
Counter function 2: CfO_Counter2event0config to CfO_Counter2event1config

These registers are used to configure the counter event function for the respective counter function.

Bits 0 to 3 configure the calculation of the comparison or to latch the value. This calculation is similar to the calculation of the counter register (see 4.11.14.13.7.1 "Counter value calculation")

Bits 8 to 13 can be used to limit the number of bits used for the comparison. A mask is calculated as 2^n - 1 and linked with an "AND" operation. This makes it possible to generate a comparator pulse every 2^n increments.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	counter 1 - use	0	0 is added instead of "counter 1"
		1	"counter 1" is used for addition
1	counter 1 - sign	0	The sign of the "counter 1" register is not changed for addition
		1	The sign of the "counter 1" register is reversed for addition
2	counter 2 - use	0	0 is added instead of "counter 2"
		1	"counter 2" is used for addition
3	counter 1 - sign	0	The sign of the "counter 2" register is not changed for addition
		1	The sign of the "counter 2" register is reversed for addition
4 - 7	Reserved	-	
8 - 13	Number of bits for comparator mask	x	The mask value is calculated as 2^n-1, where n is value set in these bits. Default: 0
14	Reserved	-	
15	Margin comparator mode	0	MarginComparator01 >= (Current position - OriginComparator01)
		1	MarginComparator01 > (Current position - OriginComparator01)

Configure mode and latching of comparator function

Name:
Counter function 1: CfO_Counter1event0mode to CfO_Counter1event1mode
Counter function 2: CfO_Counter2event0mode to CfO_Counter2event1mode

In these registers you can set the mode for the comparator function and optional copying of the latched registers.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Bits 4 to 7 can be used to define hardware referencing actions.

Based on these bits, the values of the internal absolute value counters "abs1" and "abs2" can be copied to the respective "HW_reference_counter" register at every counter event (see 4.11.14.13.7.1 "Counter value calculation"). This function can be used to reference the counter values directly in the hardware.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 3	Reserved	-	
4	Copy abs1 counter value	0	No action
		1	When event is FALSE → hardware reference counter 1 = abs1
5	Copy abs2 counter value	0	No action
		1	When event is FALSE → hardware reference counter 2 = abs2
6	Copy abs1 counter value	0	No action
		1	When event is TRUE → hardware reference counter 1 = abs1
7	Copy abs2 counter value	0	No action
		1	When event is TRUE → hardware reference counter 2 = abs2

Comparator origin

Name:
OriginComparator01

This register is available for the AB and ABR encoders and the up/down counters.

It defines the position value at which the respective configured comparator output channel is set.

Data type	Value	Information
INT	-32,768 to 32,767	Comparator window origin, 16-bit
DINT	-2,147,483,648 to 2,147,483,647	Comparator window origin, 32-bit

Width of the comparator

Name:
MarginComparator01

This register is available for the AB and ABR encoders and the up/down counters.

It defines the width of the comparator window in the positive direction.

Data type	Value	Information
INT	-32,768 to 32,767	Width of comparator window, 16-bit
DINT	-2,147,483,648 to 2,147,483,647	Width of comparator window, 32-bit

Read latch position or counter value

Name:
Different names are used for these 4 registers depending on their function.

If the comparator returns "TRUE", then the current counter value is latched and copied to these registers. The calculation of the comparator value used for the latch can be configured in the "Configure calculation of comparator" register.

Counter function 1		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB01
	Up/down counters	Latch01Counter01
2	**ABR encoders**	Latch01ABR01
	AB encoders	Latch02AB01
	Up/down counters	Latch02Counter01

Counter function 2		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB02
	Up/down counters	Latch01Counter02
	Event counters	Latch02AB02
2	**Event counters**	Latch02Counter02

Data type	Value	Information
INT	-32,768 to 32,767	Latched encoder position or counter value
DINT[1)]	-2,147,483,648 to 2,147,483,647	Latched encoder position or counter value

1) Only in function model 1

4.11.14.13.8 SSI encoder interface

The module has 1 SSI encoders available, supported directly in the hardware. Two 24 V output channels are set for the SSI encoder and cannot be changed. (See also 4.11.14.8.1 "Description of channel assignments")

When using the SSI encoder, the corresponding clock channel can be configured in the 4.11.14.13.5.1 "CfO_CFGchannel" register as "Channel-specific" and "Push/Pull".

SSI encoders	Channel number
Data channel	1
Clock channel	2

4.11.14.13.8.1 SSI event functions

The SSI encoder consists of an event function and an event input. The SSI cycle is started when an event is received on this input.

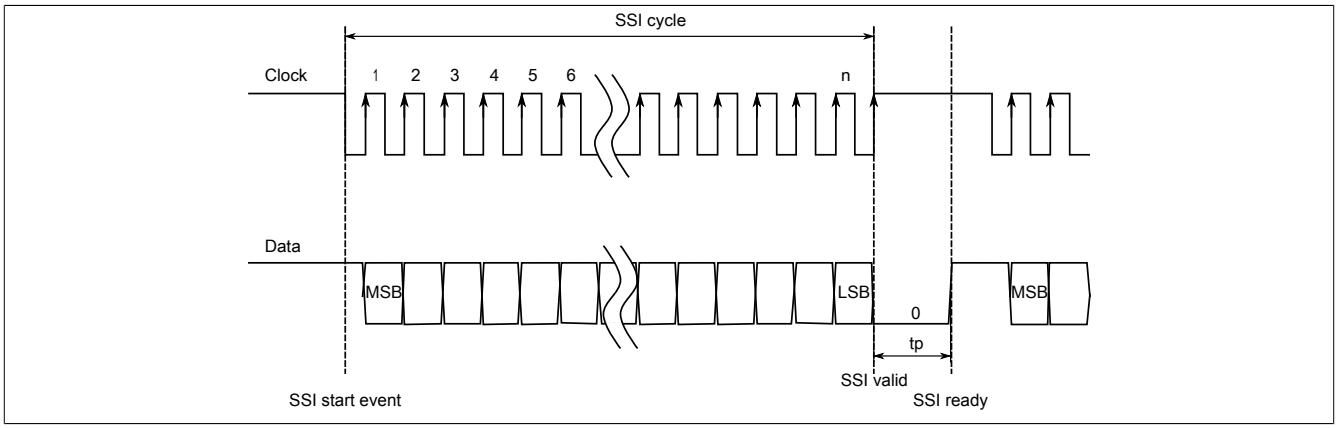
Information:

The SSI event function is not linked to an event by default, i.e. SSI functions are disabled.

Two events are sent from the SSI encoder interface..

- An "SSI valid" event is triggered immediately after the end of the SSI cycle if a new counter value is available.
- The "SSI ready" event then shows when the monoflop time has expired (tp in SSI encoder timing diagram). This is the earliest that the next SSI cycle can be started.

SSI encoder - Timing diagram



Configure event ID for SSI

Name:
CfO_SSI1eventIDwr

This register holds the event ID that should start the SSI cycle. For a list of all possible event IDs, see 4.11.14.13.6.1 "List of event IDs"

Normally this register is set to network event 225 "AOSISOP"- This ensures that the new encoder position is available at the next "I/O → Synchronous Frame" transfer. Check the SSI transfer time and the X2X cycle time, because the SSI cycle must be completed within this time.

Data type	Value	Information
INT	192 to 7,233	ID of event function

Configure SSI

Name:
CfO_SSI1cfg

This configuration register is used to set the coding, the clock rate and the number of bits. Default = 0. This must be set once using an acyclic write command.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding

SSI advanced configuration

Name:
ConfigAdvanced

This configuration register is used to set the coding, the clock rate, the number of bits and the monostable multivibrator settings. Default = 0. This must be set once using an acyclic write command.

It only differs from "CfO_SSI1cfg" by data length and additional monostable multivibrator testing.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding
16 - 17	Monostable multivibrator check	00	Check OFF, no additional clock bit
		01	Check set to High level
		10	Check set to Low level
		11	Level is clocked but ignored
18 - 31	Reserved	0	

Enable SSI event function

Name:
CfO_SSI1control

The two SSI encoder events can be enabled/disabled using this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Event: SSI valid	0	Not sent
		1	Sent
1	Event: SSI ready	0	Not sent
		1	Sent
2 - 7	Reserved	-	

Read SSI position

Name:
SSIEncoder01

The last transferred SSI position can be read out from this register. The SSI encoder value is displayed as a 32-bit position value. This position value is generated synchronously with the X2X cycle.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Last SSI position transferred

4.11.14.13.8.2 SSI comparator condition

The module has an assigned comparator function for the SSI function. These consist of:

- Event ID that triggers the comparator function
- The window comparator
- Latch register for saving the counter value

When the comparator function is complete, event ID 7232 or 7233 (see 4.11.14.13.6.1 "List of event IDs") is sent.

Configure event ID for SSI comparator

Name:
CfO_SSI1event0IDwr

This register holds the event ID that should start the SSI comparator function. For a list of all possible event IDs, see 4.11.14.13.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,233	ID of comparator function

Configure the mode of the SSI comparator function

Name:
CfO_SSI1event0mode

This register can be used to configure the mode of the comparator function.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 7	Reserved	-	

Configure calculation of SSI comparator

Name:
CfO_SSI1event0config

The calculation of the position value used for the comparator can be configured in this register.

The window comparator condition is calculated as follows:

```
counter_window_value = ssi_counter & (2^ssi_data_bits - 1)
diff = counter_window_value – origin_comparator
if ((diff & (2^(comparator_mask)-1)) <= margin_comparator)
condition = True;
else
condition = False;
```

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 5	SSI data bits	x	Number of data bits used for masking
6 - 7	Reserved	-	
8 - 13	Comparator mask	x	The mask value is calculated from 2^n-1, where n is the value configured in SSI data bits. Default: 0
14	Comparator mode	0	MarginComparator >= SSI position - OriginComparator
		1	MarginComparator > SSI position - OriginComparator

Origin of the SSI comparator

Name:
OriginComparator01_SSI

This register contains the origin of the window comparator.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Origin of the window comparator.

Width of the SSI comparator

Name:
MarginComparator01_SSI

This register provides the width of the window comparator.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Width of the SSI window comparator

Read SSI latch position

Name:
Latch01SSI01

If the SSI window comparator returns "True", then the current SSI position is latched and saved in this register.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Latched SSI position

4.11.14.13.9 PWM - Pulse width modulation

The module has 2 PWM functions available, supported directly by the hardware. A 24 V output channel is set for each PWM encoder and cannot be changed. (See also 4.11.14.8.1 "Description of channel assignments")

When using the PWM function, the corresponding channel can be configured in the 4.11.14.13.5.1 "CfO_CFGchannel" register as "Channel-specific".

PWM function	Channel
PWM1	2
PWM2	4

4.11.14.13.9.1 Configure PWM prescaler

Name:
CfO_PWM0prescaler to CfO_PWM1prescaler

The length of the PWM cycle is configured using this register. The base is a 48 MHz clock, which can be changed (divided) using the setting in this register. One PWM cycle consists of 1,000 of the resulting clocks after they have been divided. The period length of the PWM cycle is calculated as follows:

$$PWM\_cycle = 1000 \frac{prescale}{48000000} [s]$$

Data type	Value	Information
UINT	2 to 65,535	Prescaler for PWM cycle

4.11.14.13.9.2 Output PWM values

Name:
PWMOutput02 and PWMOutput04

In this register, a configuration is made for the percentage of the PWM cycle (in 1/10 % steps) that the PWM output is logical 1, i.e. ON.

Data type	Value	Information
UINT	0 to 1,000	PWM output always off
	2 to 999	Turn on time in 1/10% steps
	1,000	PWM output always on

4.11.14.13.10 Time measurement function

The module has a time measurement function for each I/O channel. It can be configured separately for rising and falling edges on each channel.
A starting edge can be configured for each time measurement function. When a configured starting edge occurs, the value of the internal timer is saved in a FIFO. This FIFO holds up to 16 elements. When the actual trigger edge occurs, the difference in time between the starting edge and the triggered edge is copied to the respective register.
Bits 8 to 11 "Previous start edge" of the 4.11.14.13.10.2 "CfO_EdgeTimeFallingMode" and 4.11.14.13.10.3 "CfO_EdgeTimeRisingMode" registers can be used to define which detected starting edge from the FIFO should be used to calculate the difference. Additionally, when the trigger edge occurs, the counter clocked internally using bits 12 to 15 "Time measurement resolution are copied to the 4.11.14.13.10.10 "TimeStampFallingCH" and 4.11.14.13.10.11 "TimeStampRisingCH" registers.

Information:

The time measurement function is an extension of edge detection, so all of the channels used must be configured there.

4.11.14.13.10.1 Enable time measurement function

Name:
CfO_EdgeTimeglobalenable

This register enables/disables the time measurement function for the entire module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Time measurement function	0	Disabled for entire module
		1	Enabled for entire module
1 - 7	Reserved	-	

4.11.14.13.10.2 Configure time measurement function for the falling edge

Name:
CfO_EdgeTimeFallingMode01 to CfO_EdgeTimeFallingMode04

These registers can be used to configure the time measurement function for the falling edge of the respective channel.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Selects the channel for the starting edge	0	Channel 1
		...	
		3	Channel 4
4	Selects the edge for the starting edge	0	The falling edge of the channel configured in bits 0 to 3 serves as the starting edge.
		1	The rising edge of the channel configured in bits 0 to 3 serves as the starting edge.
5 - 6	Reserved	-	
7	Trigger	0	Triggered[1)]
		1	Continuous[2)]
8 - 11	Previous start edge	0 to 15	The value determines which entry in the starting edge FIFO should be used to calculate the time difference.
12 - 15	Time measurement resolution	0	8 Mhz
		1	4 Mhz
		2	2 Mhz
		3	1 Mhz
		4	500 kHz
		5	250 kHz
		6	125 kHz
		7	625 kHz

1) The time measurement is triggered by the corresponding bit in the 4.11.14.13.10.5 "TriggerRisingCH" register.
2) Time measurement runs continuously and is triggered at every edge.

4.11.14.13.10.3 Configure time measurement function for the rising edge

Name:
CfO_EdgeTimeRisingMode01 to CfO_EdgeTimeRisingMode04

These registers can be used to configure the time measurement function for the rising edge of the respective channel.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Selects the channel for the starting edge	0	Channel 1
		...	
		3	Channel 4
4	Selects the edge for the starting edge	0	The falling edge of the channel configured in bits 0 to 3 serves as the starting edge.
		1	The rising edge of the channel configured in bits 0 to 3 serves as the starting edge.
5 - 6	Reserved	-	
7	Trigger	0	Triggered[1)]
		1	Continuous[2)]
8 - 11	Previous start edge	0 to 15	The value determines which entry in the starting edge FIFO should be used to calculate the time difference.
12 - 15	Time measurement resolution	0	8 Mhz
		1	4 Mhz
		2	2 Mhz
		3	1 Mhz
		4	500 kHz
		5	250 kHz
		6	125 kHz
		7	625 kHz

1) The time measurement is triggered by the corresponding bit in the 4.11.14.13.10.4 "TriggerRisingCH" register.
2) Time measurement runs continuously and is triggered at every edge.

4.11.14.13.10.4 Trigger falling edge detection

Name:
TriggerFallingCH01 to TriggerFallingCH04

If bit 7 "Trigger" is cleared in the 4.11.14.13.10.2 "CfO_EdgeTimeFallingMode" register, then detection of a falling edge on the respective input can be triggered using the respective bit in this register. After a bit has been set, the next falling edge on the corresponding channel is detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TriggerFallingCH01	0	Falling edges on channel 1 are not detected
		1	The next falling edge on channel 1 will be detected
...		...	
3	TriggerFallingCH04	0	Falling edges on channel 4 are not detected
		1	The next falling edge on channel 4 will be detected
4 - 7	Reserved	-	

4.11.14.13.10.5 Trigger rising edge detection

Name:
TriggerRisingCH01 to TriggerRisingCH04

If bit 7 "Trigger" is cleared in the 4.11.14.13.10.3 "CfO_EdgeTimeRisingMode" register, then detection of a rising edge on the respective input can be triggered using the respective bit in this register. After a bit has been set, the next rising edge on the corresponding channel is detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TriggerRisingCH01	0	Rising edges on channel 1 are not detected
		1	The next rising edge on channel 1 will be detected
...		...	
3	TriggerRisingCH04	0	Rising edges on channel 4 are not detected
		1	The next rising edge on channel 4 will be detected
4 - 7	Reserved	-	

4.11.14.13.10.6 Show first falling trigger edge

Name:
BusyTriggerFallingCH01 to BusyTriggerFallingCH04

If edges are triggered via the bits in the 4.11.14.13.10.4 "TriggerFallingCH" register, then a set bit in this register indicates that no falling edges have been detected on the respective channel since the corresponding bit was set in the "TriggerFallingCH" register. If a falling edge occurs on the respective channel, then the corresponding BusyTriggerFalling bit is cleared.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	BusyTriggerFallingCH01	0	Falling edge detected on channel 1
		1	Module waiting for a falling edge on channel 1
...		...	
3	BusyTriggerFallingCH04	0	Falling edge detected on channel 4
		1	Module waiting for a falling edge on channel 4
4 - 7	Reserved	-	

4.11.14.13.10.7 Show first rising trigger edge

Name:
BusyTriggerRisingCH01 to BusyTriggerRisingCH04

If edges are triggered via the bits in the 4.11.14.13.10.5 "TriggerRisingCH" register, then a set bit in this register indicates that no rising edges have been detected on the respective channel since the corresponding bit was set in the "TriggerRisingCH" register. If a rising edge occurs on the respective channel, then the corresponding BusyTriggerRising bit is cleared.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	BusyTriggerRisingCH01	0	Rising edge detected on channel 1
		1	Module waiting for a rising edge on channel 1
...		...	
3	BusyTriggerRisingCH04	0	Rising edge detected on channel 4
		1	Module waiting for a rising edge on channel 4
4 - 7	Reserved	-	

4.11.14.13.10.8 Count falling trigger edges

Name:
CountFallingCH01 to CountFallingCH04

These registers contain cyclic counters that are incremented with every detected falling edge on the respective channel.

Data type	Value	Information
USINT	0 to 255	Counter for falling edges

4.11.14.13.10.9 Count rising trigger edges

Name:
CountRisingCH01 to CountRisingCH04

These registers contain cyclic counters that are incremented with every detected rising edge on the respective channel.

Data type	Value	Information
USINT	0 to 255	Counter for rising edges

4.11.14.13.10.10 Time stamp of falling edge

Name:
TimeStampFallingCH01 to TimeStampFallingCH04

When a falling edge occurs on the respective channel, the current counter value of the module timer is copied to these registers.

Data type	Value	Information
UINT	0 to 65,535	Time stamp for rising edges

4.11.14.13.10.11 Time stamp of the rising edge

Name:
TimeStampRisingCH01 to TimeStampRisingCH04

When a rising edge occurs on the respective channel, the current counter value of the module timer is copied to these registers.

Data type	Value	Information
UINT	0 to 65,535	Time stamp for rising edges

4.11.14.13.10.12 Time difference of falling edge

Name:
TimeDiffFallingCH01 to TimeDiffFallingCH04

When a falling edge occurs on the respective channel, the time difference compared to the starting edge configured in bit 4 of the 4.11.14.13.10.2 "CfO_EdgeTimeFallingMode" register is copied to this register.

Data type	Value	Information
UINT	0 to 65,535	Time difference from starting edge

4.11.14.13.10.13 Time difference of rising edge

Name:
TimeDiffRisingCH01 to TimeDiffRisingCH04

When a rising edge occurs on the respective channel, the time difference compared to the starting edge configured in bit 4 of the 4.11.14.13.10.3 "CfO_EdgeTimeRisingMode" register is copied to this register.

Data type	Value	Information
UINT	0 to 65,535	Time difference from starting edge

4.11.14.13.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.14.13.12 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.14.13.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.15 X20DC2396

4.11.15.1 General information

The module is equipped with two inputs for an ABR incremental encoder with 24 V encoder signal.

- 2 ABR incremental encoder 24 V
- 2 additional inputs e.g. for home enable switch
- 24 VDC and GND for encoder supply

4.11.15.2 Order data

4.11.15.8 Register description

4.11.15.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.15.8.2 Function model 0 - Standard and Function model 1 - Standard with 32-bit encoder counter value

The difference between function model 0 and function model 1 is the size of the data type for some registers.

- Function model 0 uses data type INT
- Function model 1 uses data type DINT (specified in parentheses)

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
4104	CfO_EdgeDetectFalling	USINT				•
4106	CfO_EdgeDetectRising	USINT				•

1) The offset specifies the position of the register within the CAN object.

4.11.15.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.11.15.8.4 ABR encoder - Configuration registers

4.11.15.8.4.1 Reference pulse

The following registers must be configured by a single acyclic write with the listed values so that the homing procedure is completed on the edge of the reference pulse.

The homing procedure can take place on:

- Rising edge
- Falling edge (default configuration)

Constant register "CfO_EdgeDetectFalling"

Name:

CfO_EdgeDetectFalling

Data type	Value	Filter
USINT	0x00	Configuration value for rising edge
	0x04	Encoder 1 - Configuration value for falling edge
	0x40	Encoder 2 - Configuration value for falling edge
	0x44	Encoders 1 and 2 - Configuration value for falling edge

Constant register "CfO_EdgeDetectRising"

Name:

CfO_EdgeDetectRising

Data type	Value	Filter
USINT	0x00	Configuration value for falling edge (default 0x00)
	0x04	Encoder 1 - Configuration value for rising edge
	0x40	Encoder 2 - Configuration value for rising edge
	0x44	Encoders 1 and 2 - Configuration value for rising edge

Constant register "ConfigOutput24"

Name:

ConfigOutput24

This register contains the value for ABR encoder 1.

Data type	Value	Filter
UINT	0x1012	Configuration value for rising edge
	0x1002	Configuration value for falling edge

Constant register "ConfigOutput32"

Name:
ConfigOutput32

This register contains the value for ABR encoder 2.

Data type	Value	Filter
UINT	0x1016	Configuration value for rising edge
	0x1006	Configuration value for falling edge

4.11.15.8.4.2 Setting the home position

Name:
CfO_PresetABR01_1 to CfO_PresetABR01_2
CfO_PresetABR02_1 to CfO_PresetABR02_2

CfO_PresetABR01_1_32Bit to CfO_PresetABR01_2_32Bit
CfO_PresetABR02_1_32Bit to CfO_PresetABR02_2_32Bit (only in function model 1)

It is possible to specify two home positions for each encoder with these registers through a one-off acyclic write, for example (default = 0). The configured values are applied to the counter values after a completed homing procedure.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.15.8.4.3 Homing with reference enable input

Regardless of the referencing mode, it is possible using this register to prevent the home position from being applied when the corresponding reference input voltage level occurs (see 4.11.15.8.5.2 "Input state of digital inputs 1 to 2": bit 7). The desired setting can be configured by a one-off acyclic write.

Voltage level for reference enable activation - ABR encoder 1

Name:

ConfigOutput26

The voltage level of the digital input 1 to activate reference enable is configured with this register.

Data type	Value	Filter
USINT	0x00	Reference enable is active at 0 VDC
	0x08	Reference enable is active at 24 VDC

Reference enable of the input - ABR encoder 1

Name:
ConfigOutput27

This register can be used to define whether the reference enable is activated.

Data type	Value	Filter
USINT	0x00	Reference enable input OFF (default)
	0x08	Reference enable input activated

Voltage level for reference enable activation - ABR encoder 2

Name:

ConfigOutput34

The voltage level of the digital input 2 to activate reference enable is configured with this register.

Data type	Value	Filter
USINT	0x00	Reference enable is active at 0 VDC
	0x80	Reference enable is active at 24 VDC

Reference enable of the input - ABR encoder 2

Name:
ConfigOutput35

This register can be used to define whether the reference enable is activated.

Data type	Value	Filter
USINT	0x00	Reference enable input OFF (default)
	0x80	Reference enable input activated

4.11.15.8.5 ABR encoder - Configuration registers

4.11.15.8.5.1 Counter state of the encoders

Name:
Encoder01 to Encoder02

The encoder values are displayed in this register.

Data type	Value
INT	-32,768 to 32,767
DINT[1)]	-2,147,483,648 to 2,147,483,647

1) Only in function model 1

4.11.15.8.5.2 Input state of digital inputs 1 to 2

Name:
DigitalInput01 to DigitalInput02.

This register displays the input status of the encoders and the digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Encoder 1	0 or 1	Input state - Signal A
1		0 or 1	Input state - Signal B
2		0 or 1	Input state of reference pulse
3	DigitalInput01	0 or 1	Input state - Digital input 1
4	Encoder 2	0 or 1	Input state - Signal A
5		0 or 1	Input state - Signal B
6		0 or 1	Input state of reference pulse
7	DigitalInput02	0 or 1	Input state - Digital input 2

4.11.15.8.5.3 Reading the referencing mode

Name:
ReferenceModeEncoder01 to ReferenceModeEncoder02

This register determines the referencing mode.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1		00	Referencing OFF
		01	Single shot referencing
		11	Continuous referencing
2 - 5		0	Bits permanently set = 0
6 - 7		00	Referencing OFF
		11	Bits permanently set = 1

This results in the following values:

Binary	Hex	Function
00000000	0x00	Referencing OFF
11000001	0xC1	Single shot referencing For a new start after the completed homing procedure: • Write value 0x00 • Wait until bit 0 to bit 3 of the StatusInput01 register takes on the value 0. Counter bits 4 to 7 are not erased • Switch homing procedure on again
11000011	0xC3	Continuous referencing Referencing occurs at every reference pulse.

4.11.15.8.5.4 Status of the homing procedure

Name:
StatusInput01 (for encoder 1) to StatusInput02 (for encoder 2)

This register contains information regarding whether the referencing process is off, active or complete.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Reference pulse without homing[1)]	0	No reference impulse without homing has occurred yet
		1	At least a reference impulse without homing has occurred
1	State change	0 or 1	Changes with each reference pulse without homing
2	Reference pulse with homing[1)]	0	No homing has occurred yet
		1	At least one homing procedure has occurred
3	State change	0 or 1	Changes with each homing procedure that has taken place
4	Reference pulse	0	The last reference pulse didn't bring about a homing procedure
		1	The last reference pulse brought about a homing procedure
5 - 7	Counter	x	Free-running counter, increased with each reference pulse

1) Always 1 after the first reference pulse that has occurred

Examples of possible values:

Binary	Hex	Function
0x00000000	0x00	Referencing OFF or homing procedure already active
0x00111100	0x3CE	First homing procedure complete Reference value applied in the Encoder01 register
0xxxx11100	0xxB	Bits 5 to 7 are changed with each reference pulse
0xxxx1x100	0xxx	Continuously changing the bits with the "Continuous referencing" setting. The reference value is applied to the Encoder01 register on each reference pulse.

4.11.15.8.5.5 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.15.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.15.8.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.15.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.16 X20DC2398

4.11.16.1 General information

This module is equipped with two inputs for SSI absolute encoders with 24 V encoder signal.

- 2 SSI absolute encoder 24 V
- 2 additional inputs
- 24 VDC and GND for encoder supply

4.11.16.2 Order data

4.11.16.9 Register description

4.11.16.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.16.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
7176	ConfigOutput15	UINT				•
7432	ConfigOutput16	UINT				•
7172	ConfigAdvanced01	UDINT				•
7428	ConfigAdvanced02	UDINT				•
Communication						
7184	Encoder01	UDINT	•			
7440	Encoder02	UDINT	•			
264	Input state of digital inputs 1 to 2	USINT	•			
	DigitalInput01	Bit 3				
	DigitalInput02	Bit 7				
40	Status of encoder supply	USINT	•			
	PowerSupply01	Bit 0				

4.11.16.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
7176	-	ConfigOutput15	UINT				•
7432	-	ConfigOutput16	UINT				•
7172	-	ConfigAdvanced01	UDINT				•
7428	-	ConfigAdvanced02	UDINT				•
Communication							
7184	0	Encoder01	UDINT	•			
7440	8	Encoder02	UDINT	•			
264	4	Input state of digital inputs 1 to 2	USINT	•			
		DigitalInput01	Bit 3				
		DigitalInput02	Bit 7				
40	5	Status of encoder supply	USINT	•			
		PowerSupply01	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.11.16.9.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.11.16.9.4 SSI encoder configuration register

4.11.16.9.4.1 Standard configuration

Name:
ConfigOutput15 to ConfigOutput 16

This configuration register is used to set the coding, the clock rate and the number of bits. Default = 0. This must be set once using an acyclic write command.

"ConfigOutput15": Configuration register for SSI encoder01 and
"ConfigOutput16": Configuration register for SSI encoder02

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits		
6 - 7	Clock rate	11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding

4.11.16.9.4.2 Extended configuration

Name:
ConfigAdvanced01 to ConfigAdvanced02

This configuration register is used to set the coding, the clock rate, the number of bits and the monostable multivibrator settings. Default = 0. This must be set once using an acyclic write command.

It only differs from register ConfigOutput15 + 16 by data length and additional monostable multivibrator testing.

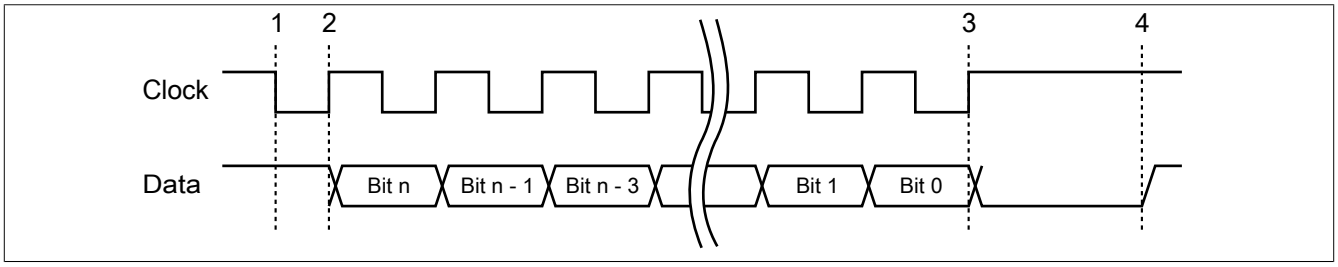
"ConfigAdvanced01": Configuration register for SSI encoder01 and
"ConfigAdvanced02": Configuration register for SSI encoder02

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding
16 - 17	Monostable multivibrator	00	Check OFF, no additional clock bit
		01	Check set to High level
		10	Check set to Low level
		11	Level is clocked but ignored
18 - 31	Reserved	0	

Transfer to synchronous serial interface



Measurement value processing

1 Starting bit ... Stores the measurement value
2 Output of first data bit
3 All data bits are transferred, monostable multivibrator time starts counting down.
4 Monostable multivibrator returns to its initial state. A new transfer can be started.

4.11.16.9.5 SSI encoder - Configuration registers

4.11.16.9.5.1 SSI position values

Name:
Encoder01 to Encoder02

The two SSI encoder values are displayed as 32-bit position values. The SSI position values are generated synchronously with the X2X cycle.

Data type	Value	Filter
UDINT	0 to 4,294,967,729	SSI position

4.11.16.9.5.2 Input state of digital inputs 1 to 2

Name:
DigitalInput01 to DigitalInput02

This register is used to indicate the input state of digital inputs 1 to 2.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
3	DigitalInput01	0 or 1	Input state - Digital input 1
7	DigitalInput02	0 or 1	Input state - Digital input 2

4.11.16.9.5.3 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.16.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.16.9.7 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.16.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.11.17 X20DC4395

4.11.17.1 General information

This module is a multifunctional counter module. It can be connected to two SSI encoders, two ABR encoders, four AB encoders or eight event counters. Four outputs are available for pulse width modulation. The functions can also be mixed.

- 24 VDC encoder inputs
- SSI, ABR, AB or event counters for inputs
- Pulse width modulation for outputs
- 24 VDC and GND for encoder supply

Information:

This module is a multifunctional module. Some bus controllers only support the default function model.

Default function model:

- **1x ABR incremental encoder (24 V)**
- **1x SSI absolute encoder (24 V)**
- **1x event counter (24 V)**
- **2x PWM output (24 V)**

4.11.17.2 Order data

4.11.17.4 LED status indicators

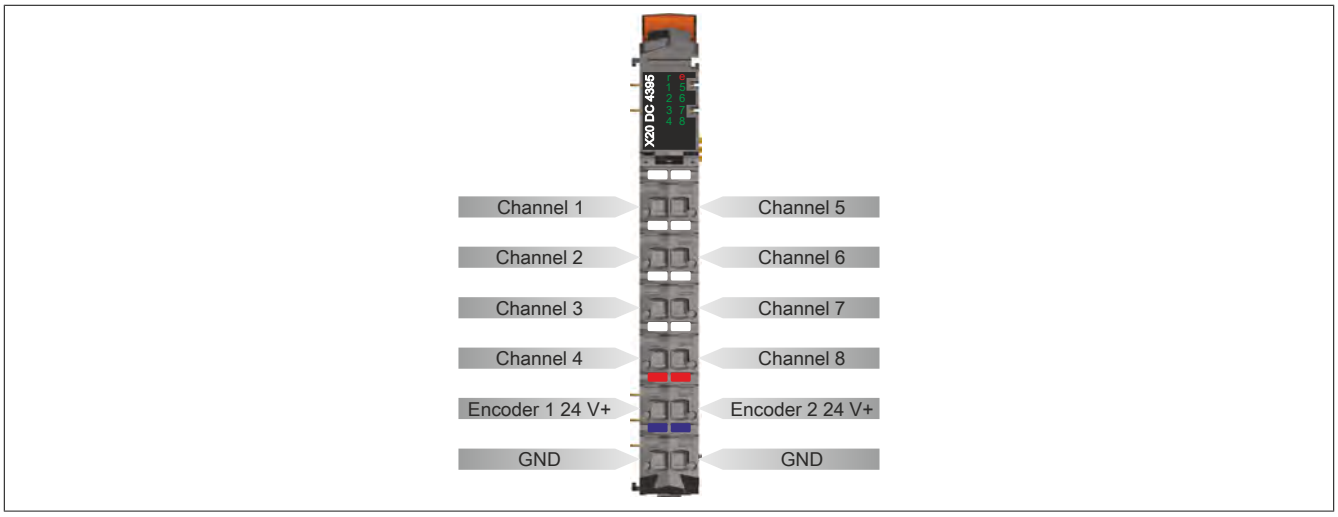
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	1 - 8	Green		Status of the corresponding digital signal

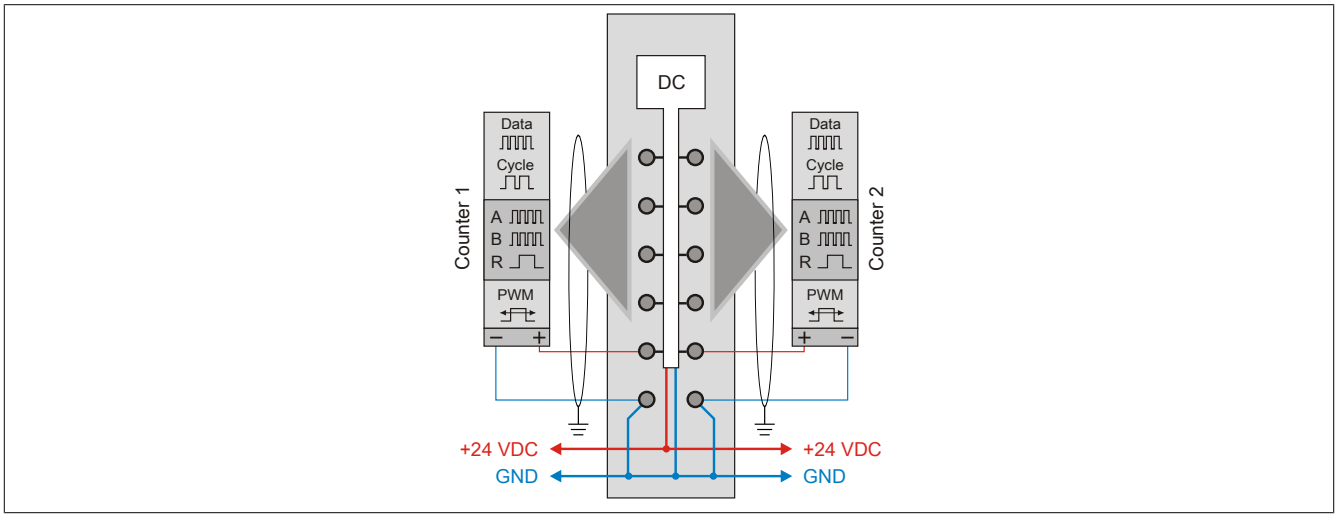
1) Depending on the configuration, a firmware update can take up to several minutes.

4.11.17.5 Pinout

Shielded cables must be used for all signal lines.



4.11.17.6 Connection example



4.11.17.7 Function overview

The following functions can be configured on the module. They cannot all be used at the same time due to the multiple use of the hardware channels and the limited cyclic data length.

- 8 digital channels, 4 of which can be configured as outputs
- 8 event counters with configurable counting direction and optional referencing via digital input
- 4 PWM outputs
- 4 up/down counters, each with optional latch inputs and comparator output
- 4 AB counters, each with optional latch inputs and comparator output
- 2 ABR encoder with configurable reference pulse edge and reference position, optional reference enable input, latch input and comparator output
- 2 SSI counter with optional latch input and comparator output
- 2 edge-triggered time measurement functions with configurable start edge based on current configuration settings

4.11.17.7.1 Description of channel assignments

The functions listed here are directly assigned to the respective hardware channels and cannot be changed:

Channel	Signal connections
1	• Digital input 1 • Event counter 1 • AB encoder 1 - signal line A • Up/down counter 1 - frequency • SSI encoder 1 - data line • ABR encoder 1 - signal line A
2	• Digital input 2 • Digital output 2 • Event counter 2 • PWM output 2 • AB encoder 1 - signal line B • Up/down counter 1 - direction • SSI encoder 1 - clock line • ABR encoder 1 - signal line B
3	• Digital input 3 • Event counter 3 • AB encoder 2 - signal line A • Up/down counter 2 - frequency • ABR encoder 1 - signal line R
4	• Digital input 4 • Digital output 4 • Event counter 4 • PWM output 4 • AB encoder 2 - signal line B • Up/down counter 2 - direction • ABR encoder 1 - reference enable input
5	• Digital input 5 • Event counter 5 • AB encoder 3 - signal line A • Up/down counter 3 - frequency • SSI encoder 2 - data line • ABR encoder 2 - signal line A
6	• Digital input 6 • Digital output 6 • Event counter 6 • PWM output 6 • AB encoder 3 - signal line B • Up/down counter 3 - direction • SSI encoder 2 - clock line • ABR encoder 2 - signal line B
7	• Digital input 7 • Event counter 7 • AB encoder 4 - signal line A • Up/down counter 4 - frequency • ABR encoder 2 - signal line R
8	• Digital input 8 • Digital output 8 • Event counter 8 • PWM output 8 • AB encoder 4 - signal line B • Up/down counter 4 - direction • ABR encoder 2 - reference enable input

Options available in addition to these basic functions, such as comparator outputs or latch inputs, can be configured freely to unused input/output channels.

4.11.17.7.2 Connection options

Channels 1 to 8 can be connected as follows:

Channel	Function					
1	I	Event counter	A	A	SSI data	
2	I/O	Event counter	B	B	SSI cycle	PWM
3	I	Event counter	A	R		
4	I/O	Event counter	B	Enable reference		PWM
5	I	Event counter	A	A	SSI data	
6	I/O	Event counter	B	B	SSI cycle	PWM
7	I	Event counter	A	R		
8	I/O	Event counter	B	Enable reference		PWM

The functions can also be mixed. For example:

Example 1	
Channel	Function
1	SSI data
2	SSI cycle
3	Event counter
4	PWM
5	A
6	B
7	Event counter
8	PWM

Example 2

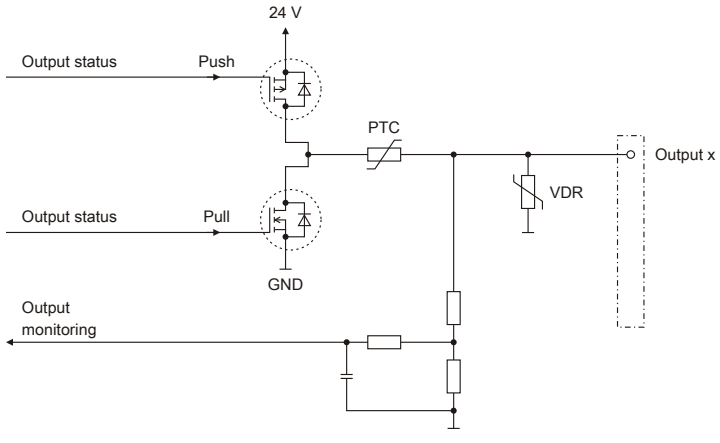
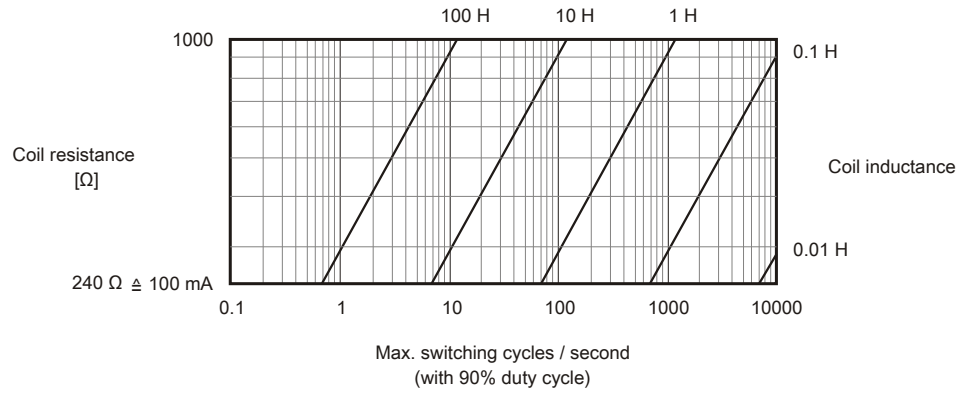
4.11.17.9 Output circuit diagram



4.11.17.10 Switching inductive loads



4.11.17.11 Calculating the period duration

The outputs of the module can be operated as PWM outputs. The period duration is calculated using the following formula:

$$\text{Period duration} = \frac{n}{48000}\ \text{s}$$

A value of 2 to 65535 can be defined for n.

Example

n	Period duration	Frequency
2	416 µs	24 kHz
24000	500 ms	2 Hz
48000	1 s	1 Hz
65535	1.36 s	0.73 Hz

4.11.17.12 Register description

4.11.17.12.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.11.17.12.2 Function model 0 - Standard and Function model 1 - 32-bit counter

The following 2 models can be selected:

- 16-bit counter, Function model 0
- 32-bit counter, Function model 1 (identified in the table with a "(D)" in the data type and "(_32Bit)" in the name.)

The only difference between these two models is that they use either 16-bit or 32-bit registers for incremental counter functions. These include:

- ABR encoders
- AB encoders
- Up/down counters
- Event counters

All other module functions e.g. SSI, PWM and time measurement, as well as their data types, are identical for the two models.

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Module configuration - General

4.11.17.12.3 Function model 254 - Bus controller

Unlike the function models 0 and 1, this model only offers a selection of functions with a limited scope of configuration on the module.

The following functions are provided and can be run at the same time:

- SSI encoders
- ABR encoder with configurable reference pulse edge and reference position
- 1 event counter with configurable counting direction
- 2 PWM outputs

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Module configuration - General							
N * 2 - 2	-	CfO_CFGchannel0N (Index N = 1 to 8)	USINT				●
N * 2 + 64	-	CfO_LEDNsource (Index N = 0 to 7)	USINT				●
Configuration - ABR encoder

6,194	8	PWMOutput08	UINT			●	

1) The offset specifies the position of the register within the CAN object.

4.11.17.12.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.11.17.12.4 General module registers

4.11.17.12.4.1 Configuring LED status indicators

Name:
CfO_LED0source to CfO_LED7source

These registers can be used to define how the module's LED status indicators are used. Blinking patterns can be generated from the application, and the status of the physical inputs and outputs can be indicated.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	MODE = 0	0	LED off
		1	Blinking quickly
		2	Blinking
		3	Blinking slowly
		4	Single flash
		5	Double flash
		6 to 15	Reserved
	MODE = 1 (inverted)	0	LED on
		1	Blinking quickly
		2	Blinking
		3	Blinking slowly
		4	Single flash
		5	Double flash
		6 to 15	Reserved
	MODE = 2	0 to 7	Number of the physical input channel
		8 to 15	Reserved
	MODE = 3	0 to 7	Number of the physical output channel
		8 to 15	Reserved
4 - 7	Selection of the mode for the LED status indicator	0	LED blinking pattern
		1	Inverted LED blinking pattern
		2	Displays a channel's physical input status
		3	Displays a channel's physical output status
		4 to 15	Reserved

4.11.17.12.4.2 Status of encoder supply

Name:
PowerSupply01

This register shows the status of the integrated encoder supply. A faulty encoder power supply is displayed as a warning.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	PowerSupply01	0	24 VDC encoder power supply OK
		1	24 VDC encoder power supply faulty
1 - 7	Reserved	-	

4.11.17.12.5 Digital inputs and outputs

4.11.17.12.5.1 Configure physical channels

Name:
CfO_CFGchannel01 to CfO_CFGchannel08

This register can be used to configure physical I/O channels 1 to 8.

Information:

Except for bit 2 (inverted input), all other bits are only available for channels 2, 4, 6 and 8.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Push[1)]	0	Disabled
		1	Enabled
1	Pull[1)]	0	Disabled
		1	Enabled
2	Inverted input	0	Disabled
		1	Enabled
3	Inverted output	0	Disabled
		1	Enabled
4 - 7	Output type	0	Direct I/O
		1 to 5	Reserved
		6	PWM (channel-specific)
		7	SSI clock (channel-specific)

1) To configure a channel as an output, Push and/or Pull must be enabled.

4.11.17.12.5.2 Reset mask of the digital channels

Name:
CfO_OutClearMask

The settings in this register only affect the values written to registers 4.11.17.12.5.5 "DigitalOutput02 to 08".

- 0 allows manual reset of digital outputs using registers DigitalOutput02 to 08
- 1 prevents manual reset of digital outputs using registers DigitalOutput02 to 08

When "1" is used, the "output event function" can be used to reset the outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0	Writing 0 to the DigitalOutput02 register resets the output
		1	Writing 0 from the DigitalOutput02 register does not reset the output
2	Reserved	-	
3	DigitalOutput04	0	Writing 0 to the DigitalOutput04 register resets the output
		1	Writing 0 from the DigitalOutput04 register does not reset the output
4	Reserved	-	
5	DigitalOutput06	0	Writing 0 to the DigitalOutput06 register resets the output
		1	Writing 0 from the DigitalOutput06 register does not reset the output
6	Reserved	-	
7	DigitalOutput08	0	Writing 0 to the DigitalOutput08 register resets the output
		1	Writing 0 from the DigitalOutput08 register does not reset the output

4.11.17.12.5.3 Set mask of the digital channels

Name:
CfO_OutSetMask

The settings in this register only affect the values written to registers 4.11.17.12.5.5 "DigitalOutput02 to 08".

- 0 allows manual setting of digital outputs using registers DigitalOutput02 to 04
- 1 prevents manual setting of digital outputs using registers DigitalOutput02 to 04

When "1" is used, the "output event function" can be used to reset the outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0	Writing 1 to the DigitalOutput02 register sets the output
		1	Writing 1 from the DigitalOutput02 register does not set the output
2	Reserved	-	
3	DigitalOutput04	0	Writing 1 to the DigitalOutput04 register sets the output
		1	Writing 1 from the DigitalOutput04 register does not set the output
4	Reserved	-	
5	DigitalOutput06	0	Writing 1 to the DigitalOutput06 register sets the output
		1	Writing 1 from the DigitalOutput06 register does not set the output
6	Reserved	-	
7	DigitalOutput08	0	Writing 1 to the DigitalOutput08 register sets the output
		1	Writing 1 from the DigitalOutput08 register does not set the output

4.11.17.12.5.4 Input states of the channels

Name:
see "Name in the AS I/O configuration"

This register reads the input status of a physical channel. The polarity settings are accounted for in the value (bit 2 in 4.11.17.12.5.1 "CfO_CFGchannel[x]" register).

The bits in this register are shown in the AS I/O mapping table under different names based on the function used in order to improve readability.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Physical input channel	Value	Name in the AS I/O configuration
0	Channel 1	0 or 1	DigitalInput01
1	Channel 2	0 or 1	DigitalInput02 StatusDigitalOutput02 ComparatorActualValue02 ComparatorActualValue03
2	Channel 3	0 or 1	DigitalInput03
3	Channel 4	0 or 1	DigitalInput04 StatusDigitalOutput04 ReferenceEnableSwitch01 ComparatorActualValue01 ComparatorActualValue02 ComparatorActualValue03
4	Channel 5	0 or 1	DigitalInput05
5	Channel 6	0 or 1	DigitalInput06 StatusDigitalOutput06 ComparatorActualValue01
6	Channel 7	0 or 1	DigitalInput07
7	Channel 8	0 or 1	DigitalInput08 StatusDigitalOutput08 ReferenceEnableSwitch02 ComparatorActualValue01 ComparatorActualValue02 ComparatorActualValue03

4.11.17.12.5.5 Output states of the channels

Name:
DigitalOutput02 to DigitalOutput08

The output status of a physical channel can be written using this register. In order to configure a channel as an output:

1 Bit 0 "Push" and/or bit 1 "Pull" must be enabled in the 4.11.17.12.5.1 "CfO_CFGchannel[x]" register.
2 Bits 4 to 7 in the 4.11.17.12.5.1 "CfO_CFGchannel[x]" register must be set to Direct I/O.
3 0 must be set for the respective channel in the 4.11.17.12.5.2 "CfO_OutClearMask" and 4.11.17.12.5.3 "CfO_OutSetMask" registers.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	DigitalOutput02	0 or 1	Output status of channel 2
2	Reserved	-	
3	DigitalOutput04	0 or 1	Output status of channel 4
4	Reserved	-	
5	DigitalOutput06	0 or 1	Output status of channel 6
6	Reserved	-	
7	DigitalOutput08	0 or 1	Output status of channel 8

4.11.17.12.6 Event functions

The module provides configurable event functions. An event function can be connected to physical I/O and the values derived from them (e.g. counters) or be purely used for internal processing.

Every event function has event inputs and outputs. Event functions can also have only inputs or only outputs. Each event output has a unique event ID. It is possible to configure when an event should be generated on an event output. The effect of an event is determined by the respective event function.

Event functions can also be linked to one another. The link takes place using the event input. Every event input has a 16-bit register to which the event number of the linked event output is written.

Information:

The module functions that can be configured in the AS I/O configuration are primarily based on these event functions and their links. Changes in the AS I/O configuration have multiple effects on event functions and their links.

4.11.17.12.6.1 List of event IDs

Various hardware and software functions send event IDs or require event IDs in order to start. The following table shows all of the IDs available to configure the module.

Event ID	Description	
Direct event inputs		
512	Comparator condition 1	FALSE
513		TRUE
544	Comparator condition 2	FALSE
545		TRUE
576	Comparator condition 3	FALSE
577		TRUE
608	Comparator condition 4	FALSE
609		TRUE
Counter comparator function		
2,112	Counter function 1	Event function 1; FALSE
2,113		Event function 1; TRUE
2,144		Event function 2; FALSE
2,145		Event function 2; TRUE
2,368	Counter function 2	Event function 1; FALSE
2,369		Event function 1; TRUE
2,400		Event function 2; FALSE
2,401		Event function 2; TRUE
2,624	Counter function 3	Event function 1; FALSE
2,625		Event function 1; TRUE
2,656		Event function 2; FALSE
2,657		Event function 2; TRUE
2,880	Counter function 4	Event function 1; FALSE
2,881		Event function 1; TRUE
2,912		Event function 2; FALSE
2,913		Event function 2; TRUE
Edge events		
4,096	Falling edge on I/O channel	Channel 1
...		...
4,103		Channel 8
4,112	Rising edge on I/O channel	Channel 1
...		...
4,119		Channel 8
4,128	Rising or falling edge on I/O channel	Channel 1
...		...
4,135		Channel 8
SSI counter events		
7,168	SSI 1	SSI valid
7,169		SSI ready
7,424	SSI 2	SSI valid
7,425		SSI ready
SSI comparator events		
7,232	SSI 1 comparator condition	FALSE
7,233		TRUE
7,488	SSI 2 comparator condition	FALSE
7,489		TRUE
Timerevents		
208	Timer1	50 µs
209	Timer2	100 µs
210	Timer3	200 µs
211	Timer4	400 µs
212	Timer5	800 µs
213	Timer6	1600 µs
214	Timer7	3200 µs
215	Timer8	3200 µs (time offset to timer 7)
Network functions		
224	SOAISOP (**s**ynchronous **o**ut **a**synchronous **i**n **s**tart of **p**rotocol)	
225	AOSISOP (**a**synchronous **o**ut **s**ynchronous **i**n **st**art of **p**rotocol)	
226	SOAIEOP (**s**ynchronous **o**ut **a**synchronous **i**n **e**nd of **p**rotocol)	
227	AOSIEOP (**a**synchronous **o**ut synchronous **i**n **e**nd of **p**rotocol)	
Idle event		
192	No-load operation	

Timer

There are 8 timer events that the module can generate.

Information:

The timers have the highest event priority. All other system functions are interrupted when a timer event occurs, and jitter for the amount of time it takes to process the event.

Idle event

Idle time is the time that remains after the system has processed all higher priority events and operations. The module performs the following functions during idle time:

- Handling of the asynchronous protocol
- Mechanism for (re-)linking events
- Operation of LEDs
- Execution of event event functions linked to the idle function

4.11.17.12.6.2 Edge events

For each physical channel there are 3 event functions

- Falling edge
- Rising edge
- Falling and rising edge

The respective event is triggered when an edge is detected on the hardware input and the "CfO_EdgeDetectRising" and/or "CfO_EdgeDetectFalling" register has been configured for the respective channel.

Edges are detected by the hardware and processed for each interrupt. The interrupt handler uses an event distributor, which requires a specific amount of time for each edge to operate the hardware and execute linked event functions. To reduce this time, edge detection can be enabled/disabled individually for each channel. To optimize system load and I/O jitter, it is important to only enable edge detection where it is actually needed.

Information:

Edge detection can also be used for channels that are configured as outputs.

Event frequency limitation

To stabilize the system, there is a mechanism that limits the number of events created through edge recognition. At least one idle event must occur between two edge events for the same edge.

The "CfO_FallingDisProtection" and "CfO_RisingDisProtection" registers can be used to disable this limitation for each edge, and then an event will be generated for every edge. However, this can cause a system overload, i.e. I/O operation can fail for up to 100 ms before the module changes to the reset state.

Generate event on falling edge

Name:
CfO_EdgeDetectFalling

This register defines whether an event is generated on a falling edge.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	No event generated on falling edge.
		1	Events 4096 and 4128 are generated on falling edge.
...		...	
7	Channel 8	0	No event generated on falling edge.
		1	Events 4103 and 4135 are generated on falling edge.

Generate event on rising edge

Name:
CfO_EdgeDetectRising

This register defines whether an event is generated on a rising edge.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	No event generated on rising edge.
		1	Events 4112 and 4128 are generated on rising edge.
...		...	
7	Channel 8	0	No event generated on rising edge.
		1	Events 4119 and 4135 are generated on rising edge.

Enable limit for falling edges

Name:
CfO_FallingDisProtection

This register can be used to enable/disable the event frequency limit for falling edges on the respective channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
...		...	
7	Channel 7	0	Event frequency limit enabled.
		1	Event frequency limit disabled.

Enable limit for rising edges

Name:
CfO_RisingDisProtection

This register can be used to enable/disable the event frequency limit for rising edges on the respective channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Event frequency limit enabled.
		1	Event frequency limit disabled.
...		...	
7	Channel 8	0	Event frequency limit enabled.
		1	Event frequency limit disabled.

4.11.17.12.6.3 Direct input functions

The module has 2 "direct input functions"

These event functions are based on comparator functionality. If the event configured in the "CfO_DIREKTIO-event0IDwr" register occurs, the event function compares the status of all Direct I/O channels enabled in the "CfO_EvCompMask" register to a status defined in the "CfO_DIREKTIOeventcompState" register. The event that is generated depends on the results of this comparison.

- If the respective bits are the same, then event number 513 or 545 is generated
- If the respective bits are different, then event number 512 or 544 is generated

Configure event ID for input function

Name:
CfO_DIREKTIOevent0IDwr to CfO_DIREKTIOevent1IDwr

This register holds the event ID generated by the direct input function. For a list of all possible event IDs, see 4.11.17.12.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,289	ID of event function

Configure the mode of the input function

Name:
CfO_DIREKTIOevent0mode to CfO_DIREKTIOevent1mode

The mode in which the direct input function operates can be set in this register.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 7	Reserved	-	

Comparator status for comparator mask

Name:
CfO_DIREKTIOevent0compState to CfO_DIREKTIOevent1compState

This register contains the status bits that are compared with the bits specified in the "CfO_Ev0CompMask" register, which contain the I/O input status, when an event is received.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Comparator status of channel 1	0 or 1	
...		...	
7	Comparator status of channel 8	0 or 1	

Configure the comparator mask for the input function

Name:
CfO_Ev0CompMask to CfO_Ev1CompMask

If a bit is set, then the input status of the respective channel is compared with that bit in the "CfO_DIREKTIOevent-compState" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Do not compare bit
		1	Compare bit in register
...		...	
7	Channel 8	0	Do not compare bit
		1	Compare bit in register

4.11.17.12.6.4 Direct output functions

The module has 4 of these event functions

The effect of executing this event function is similar to writing to the 4.11.17.12.5.5 "DigitalOutput02 to 08" registers. When this event function is triggered, however, the changed output states are passed on to the hardware immediately, regardless of the X2X cycle.

When this event function is used, the masks of the respective outputs (see 4.11.17.12.5.2 "CfO_OutClearMask" and 4.11.17.12.5.3 "CfO_OutSetMask" registers) must be set to 1. Otherwise the output status would constantly be overwritten by the values in the 4.11.17.12.5.5 "DigitalOutput02 to 08" registers.

Configure event ID for output function

Name:
CfO_DIREKTIOevent0IDwr to CfO_DIREKTIOevent3IDwr

These registers hold the event IDs that trigger the direct output function. For a list of all possible event IDs, see 4.11.17.12.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,489	ID of event function

Configure channels for resetting

Name:
CfO_DIREKTIOoutclearmask0 to CfO_DIREKTIOoutclearmask3

Writing "1" to the bit position that corresponds to a channel resets the output if the output event function is being executed. This corresponds to writing "0" to the 4.11.17.12.5.5 "DigitalOutput 02 to 08" registers.

The bit that corresponds to channels that should be reset should be set to "1" in the 4.11.17.12.5.2 "CfO_OutClearMask" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	Channel 2	0	Reset channel 2
		1	Do not reset channel 2
2	Reserved	-	
3	Channel 4	0	Reset channel 4
		1	Do not reset channel 4
4	Reserved	-	
5	Channel 6	0	Reset channel 6
		1	Do not reset channel 6
6	Reserved	-	
7	Channel 8	0	Reset channel 8
		1	Do not reset channel 8

Configure channels for setting

Name:
CfO_DIREKTIOoutsetmask0 to CfO_DIREKTIOoutsetmask3

Writing "1" to the bit position that corresponds to a channel sets the output if the output event function is being executed. This corresponds to writing "1" to the 4.11.17.12.5.5 "DigitalOutput 02 to 08" registers.

The bit that corresponds to channels that should be reset should be set to "1" in the 4.11.17.12.5.3 "CfO_OutSet-Mask" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Reserved	-	
1	Channel 2	0	Set channel 2
		1	Do not set channel 2
2	Reserved	-	
3	Channel 4	0	Set channel 4
		1	Do not set channel 4
4	Reserved	-	
5	Channel 6	0	Set channel 6
		1	Do not set channel 6
6	Reserved	-	
7	Channel 8	0	Set channel 8
		1	Do not set channel 8

4.11.17.12.7 Counters and encoders

The module has 4 internal counter functions, each with 2 event counter registers. Each of these 4 counters is permanently assigned to 2 physical inputs. This assignment cannot be changed.

The counter registers perform different functions based on how the event functions are connected. The counter registers can be configured in the following ways:

- ABR counter
- AB counter
- Up/down counters
- Event counters

Different names are used for them in Automation Studio and in the register description to improve clarity.

Channel	Counter function	Counter register	Name in AS
1	1	1	ABEncoder01 ABREncoder01 Counter01 EventCounter01
2		2	EventCounter02
3	2	1	ABEncoder02 Counter02 EventCounter03
4		2	EventCounter04
5	3	1	ABEncoder03 ABREncoder02 Counter03 EventCounter05
6		2	EventCounter06
7	4	1	ABEncoder04 Counter04 EventCounter07
8		2	EventCounter08

4.11.17.12.7.1 Counter value calculation

There are 3 steps for calculating the state of any counter function

1. The counter value is based on the 2 absolute value counters "abs1" and "abs2". These are only used internally in the module and cannot be read. Depending on the mode, these registers show the respective physical input signals.

	Mode		
	Edge counters	AB encoders	Up/down counter
abs1	Edges of counter channel 1	Increments in positive direction	Counter channel 2 = 0: Edges of counter channel 1 in up direction
abs2	Edges of counter channel 2	Increments in negative direction	Counter channel 2 = 1 Edges of counter channel 1 in down direction

2. From the absolute value registers "abs1" and "abs2", 2 more counters are formed: "counter 1" and "counter 2". They are only used internally in the module and cannot be read. The following values are used for the calculation:

- Absolute value registers "abs1" and "abs2"
- SW_reference_counter 1 and 2: This reference value can be defined by the "CfO_CounterPresetValue" register to allow referencing <> 0.
- HW_reference_counter 1 and 2: In the "CfO_CounterEventMode" register, you can configure whether latched values should be copied to these registers when counter events occur.

counter1 = abs1 + SW_reference_counter1 - HW_reference_counter1
counter2 = abs2 + SW_reference_counter2 - HW_reference_counter2

3. The counter registers contain the sum of the two internal counters "counter 1" and "counter 2". The "CfO_CounterConfigReg" register allows you to define a sign for each "counter" register and define whether or not it should be used.

Counter register = counter1 + counter2

4.11.17.12.7.2 Sample configurations

All of the settings available in Automation Studio for AB encoders, ABR encoders, up/down counters and event counters are based on the two counter functions.
The following configuration examples show the values with which Automation Studio initializes the module registers in order to implement these functions.

I/O configuration - AB encoder

The following table shows how the module's various event functions can be linked in order to configure an AB encoder.

[x] stands for the respective counter function, from 1 to 4

Register	Value	Comment
For the function		
CfO_Counter[x]config	0x01	Mode = Up/down counter
CfO_Counter[x]configReg0	0x0D	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.17.12.7.1 "Counter value calculation" and "Examples of calculation configurations")
For the latch		
CfO_Counter[x]event0config	0x000D	Configuration of the calculation of the first value used for the latch
CfO_Counter[x]event0mode	0x03	Mode of the first counter event function - Continuous
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger Latch 1 ("Latch 01 - Channel" in the AS I/O configuration).
CfO_Counter[x]event1config	0x0D	Configuration of the calculation of the second value used for the latch
CfO_Counter[x]event1mode	0x03	Mode of the second counter event function - Continuous
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger Latch 2
For the comparator		
CfO_Counter1event1IDwr CfO_Counter3event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config CfO_Counter3event1config	0x900D or 0xA00D	Configuration of the comparator for the second counter event
CfO_Counter1event1mode CfO_Counter3event1mode	0x03	Mode of the second counter event function - Continuous
CfO_DIREKTIOoutevent0IDwr CfO_DIREKTIOoutevent2IDwr	0x0861 0x0A61	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0 CfO_DIREKTIOoutsetmask2	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr CfO_DIREKTIOoutevent3IDwr	0x0860 0x0A60	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1 CfO_DIREKTIOoutclearmask3	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - ABR encoder

The following table shows how the module's various event functions can be linked in order to configure an ABR encoder.

Register	Value	Comment
For the function		
CfO_Counter1PresetValue1 CfO_Counter3PresetValue1	(any)	Desired offset value for referencing
CfO_Counter1event0IDwr CfO_Counter3event0IDwr	0x0201	Link between the first counter event and the "direct input" comparator condition TRUE
CfO_Counter1config CfO_Counter3config	0x01	Mode = AB encoder
CfO_Counter1configReg0 CfO_Counter3configReg0	0x0D	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.17.12.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_DIREKTIOevent0IDwr CfO_DIREKTIOevent1IDwr	0x1002 or 0x1012	Selection of the desired input edge as trigger for the ABR encoder function
CfO_Counter1event0config CfO_Counter3event0config	0x0000	Configuration of the first counter event (for referencing)
CfO_DIREKTIOevent0mode CfO_DIREKTIOevent1mode	0x03	Mode of the "direct input function" - Continuous
CfO_DIREKTIOevent0compState CfO_DIREKTIOevent1compState	0x00 or 0x08	Comparator status for the "direct input function"
CfO_Ev0CompMask CfO_Ev1CompMask	0x08	Comparator mask for the "direct input function"
For the latch		
CfO_Counter1event0config CfO_Counter3event1config	0x000D	Configuration of the calculation of the value used for the latch
CfO_Counter1event0mode CfO_Counter3event1mode	0x03	Mode of the first counter event function - Continuous
CfO_Counter1event0IDwr CfO_Counter3event1IDwr	(any)	Number of the event that should trigger the latch
For the comparator		
CfO_Counter1event1IDwr CfO_Counter3event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config CfO_Counter3event1config	0x900D or 0xA00D	Configuration of the comparator for the second counter event
CfO_DIREKTIOoutevent0IDwr CfO_DIREKTIOoutevent2IDwr	0x0861 0x0A61	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0 CfO_DIREKTIOoutsetmask2	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr CfO_DIREKTIOoutevent3IDwr	0x0860 0x0A60	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1 CfO_DIREKTIOoutclearmask3	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - Up/down counter

The following table shows how the module's various event functions can be linked in order to configure an up/down counter.

[x] stands for the respective counter function, from 1 to 4

Register	Value	Comment
For the function		
CfO_Counter[x]config	0x03	Counter mode = Up/down counter
CfO_Counter[x]configReg0	0x0D, 0x07	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.17.12.7.1 "Counter value calculation" and "Examples of calculation configurations")
For the latch		
CfO_Counter[x]event0config	0x0D, 0x07	Configuration of the calculation of the first value used for the latch
CfO_Counter[x]event0mode	0x03	Mode of the first counter function - Continuous
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger Latch 1
CfO_Counter[x]event1config	0x0D, 0x07	Configuration of the calculation of the second value used for the latch
CfO_Counter[x]event1mode	0x03	Mode of the second counter function - Continuous
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger Latch 2
For the comparator		
CfO_Counter1event1IDwr CfO_Counter3event1IDwr	0x00D0	Event number of Timer 1 (50 µs) **Information:** **The latch and comparator must not have the same event number!**
CfO_Counter1event1config CfO_Counter3event1config	0x900D, 0xA00d or 0x9007, 0xA007	Configuration of the comparator for the second counter event
CfO_Counter1event1mode CfO_Counter3event1Imode	0x03	Mode of the second counter event function - Continuous
CfO_DIREKTIOoutevent0IDwr CfO_DIREKTIOoutevent2IDwr	0x0861	TRUE event output of the second counter to trigger the direct output function (set outputs).
CfO_DIREKTIOoutsetmask0 CfO_DIREKTIOoutsetmask2	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be set when comparator condition = TRUE
CfO_DIREKTIOoutevent1IDwr CfO_DIREKTIOoutevent3IDwr	0x0860 0x0A60	FALSE event output of the second counter to trigger the direct output function (reset outputs).
CfO_DIREKTIOoutclearmask1 CfO_DIREKTIOoutclearmask3	0x08, 0x20, 0x80 0x02, 0x08, 0x80	Outputs that should be reset when comparator condition = FALSE

I/O configuration - Event counter

The following table shows how the module's various event functions can be linked in order to configure an event counter.

[x] stands for the respective counter function, from 1 to 4

Register	Value	Comment
For event counters on channels 1, 3, 5 and 7		
CfO_Counter[x]configReg0	0x01 or 0x03	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.17.12.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_Counter[x]event0mode	0x43	Mode of the first counter event function and referencing configuration
CfO_Counter[x]event0IDwr	(any)	Number of the event that should trigger referencing
For event counters on channels 2, 4, 6 and 8		
CfO_Counter[x]configReg1	0x04 or 0x08	Configure the calculation of the internal "counter1" and "counter2" registers (see 4.11.17.12.7.1 "Counter value calculation" and "Examples of calculation configurations")
CfO_Counter[x]event1mode	0x83	Mode of the second counter event function and referencing configuration
CfO_Counter[x]event1IDwr	(any)	Number of the event that should trigger referencing

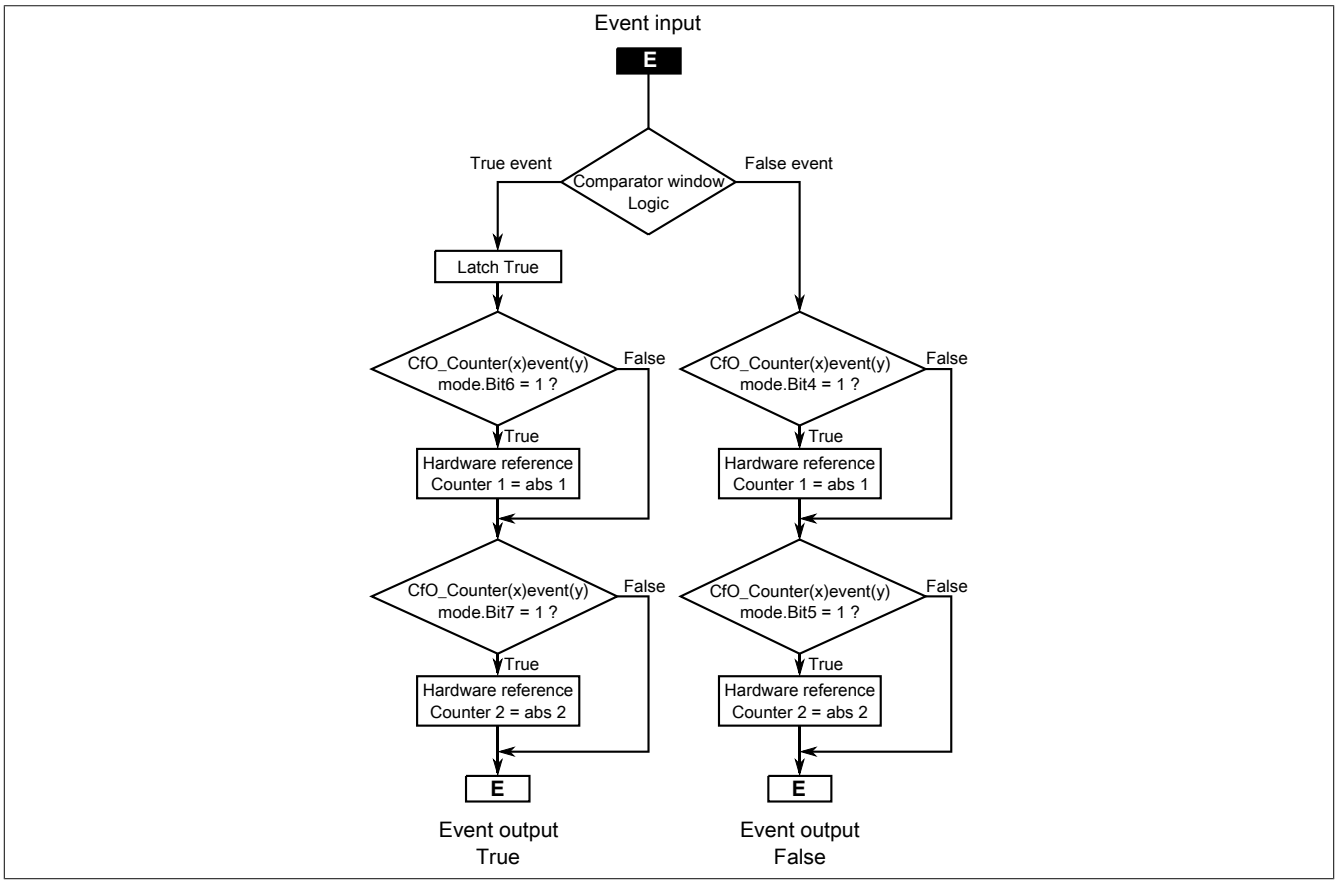
4.11.17.12.7.3 General event functions

Each of the 4 counter functions has 2 counter event functions. These consist of:

- Event ID that triggers the counter event function
- A window comparator
- Latch register for saving the counter value

When the counter event function is complete, a combined event ID in the range 2112 to 2913 (see 4.11.17.12.6.1 "List of event IDs") is sent.

Each counter event function also has the option to copy the current counter value to the "HW reference counter" when an event occurs (see 4.11.17.12.7.1 "Counter value calculation").



Configure counter mode

Name:
CfO_Counter1config to CfO_Counter4config

These registers are used to configure the mode of the counter function. Each counter function can be operated in 3 different modes.

	Counter function mode		
	Edge counters	**AB encoder**	**Up/down counter**
Counter channel 1[1)]	Counting pulses, edge counter 1	A	Metering pulses
Counter channel 2[1)]	Counting pulses, edge counter 2	B	Counting direction (0 = positive, 1 = negative)
Counter register 1	Counter value 1	Position	Counter value
Counter register 2	Counter value 2		

1) Corresponds to the physical channels of the counter functions. See 4.11.17.7.1 "Description of channel assignments".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Counter mode	00	Edge counters
		01	AB encoder
		11	Up/down counter
2 - 7	Reserved	-	

Configure calculation of internal counters

Name:
CfO_Counter1configReg0 to CfO_Counter4configReg0 ("counter 1")
CfO_Counter1configReg1 to CfO_Counter4configReg1 ("counter 2")

The calculation of the internal "counter1" and "counter2" registers can be configured in these registers. For information on using these internal registers, see 4.11.17.12.7.1 "Counter value calculation".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	counter 1 - use	0	0 is added instead of "counter 1"
		1	"counter 1" is used for addition
1	counter 1 - sign	0	The sign of the "counter 1" register is not changed for addition
		1	The sign of the "counter 1" register is reversed for addition
2	counter 2 - use	0	0 is added instead of "counter 2"
		1	"counter 2" is used for addition
3	counter 2 - sign	0	The sign of the "counter 2" register is not changed for addition
		1	The sign of the "counter 2" register is reversed for addition
4 - 7	Reserved	-	

Examples of calculation configurations

0b00000001	= 0x01	Only the "counter1 - use" bit is set, entering the contents of the "counter" (edge of counter event channel 1) directly in the counter register.
0b00000011	= 0x03	"counter 1 - use" and "counter1 - sign" bits are set. The sign is changed so that the counter register counts in the negative direction.
0b00001101	= 0x0d	Edges on counter input channel 1 increase the value in the counter register. Edges on counter input channel 2 decrease the value in the counter register. This value is the best setting for the modes "AB encoder" and "Up/down counter".

Offset value for referencing

Name:
CfO_Counter1PresetValue1 to CfO_Counter4PresetValue1
CfO_Counter1PresetValue1_32Bit to CfO_Counter4PresetValue1_32Bit (SW_reference_counter1)

CfO_Counter1PresetValue2 to CfO_Counter4PresetValue2
CfO_Counter1PresetValue2_32Bit to CfO_Counter4PresetValue2_32Bit (SW_reference_counter2)

These registers can be used to define an offset value for referencing. This value is copied to the internal SW_reference_counter register of the respective counter register.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

Counter register

Name:
Different names are used for these 8 registers depending on their function.

These 8 registers show the results of the counter value calculation for the respective register. Depending on the function, this corresponds to either the encoder position or the counter value.

For information on the relationship between physical channels and counter registers, see 4.11.17.12.7 "Counters and encoders" and 4.11.17.7.1 "Description of channel assignments"

Counter 1 - Counter channel 1		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder01
	ABR encoders	ABREncoder01
	Up/down counters	Counter01
	Event counters	EventCounter01
2	**Event counters**	EventCounter02

Counter 1 - Counter channel 2		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder02
	Up/down counters	Counter02
	Event counters	EventCounter03
2	**Event counters**	EventCounter04

Counter 2 - Counter channel 1		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder03
	ABR encoders	ABREncoder02
	Up/down counters	Counter03
	Event counters	EventCounter05
2	**Event counters**	EventCounter06

Counter 2 - Counter channel 2		
Counter register	**Function**	**Name**
1	**AB encoders**	ABEncoder04
	Up/down counters	Counter04
	Event counters	EventCounter07
2	**Event counters**	EventCounter08

Data type	Value	Information
INT	-32,768 to 32,767	Encoder position or counter value
DINT[1)]	-2,147,483,648 to 2,147,483,647	Encoder position or counter value

1) Only in function model 1

Status of the ABR encoder

Name:
StatusABR01 to StatusABR02

The referencing status of the ABR encoder is shown in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Reserved	0	
2	Bit is always 1 after the first reference pulse.	0	No reference pulses have occurred since the start of referencing.
		1	The first reference pulse has occurred.
3	State change when referencing is complete	0 or 1	State change when referencing is complete
4	Bit is always 1 after the first reference pulse.	0	No reference pulses have occurred since the start of referencing.
		1	The first reference pulse has occurred.
5 - 7	Continuous counter	xxx	Increased with each reference pulse

Examples of possible values

0b00000000	= 0x00	Referencing OFF or homing procedure already active
0b00111100	= 0x3C	First reference complete, reference value applied in the "ABREncoder0" register
0bxxx11100	= 0xxB	Bits 5 to 7 are changed with each reference pulse
0bxxx1x100	= 0xxx	Bits changed continuously with the setting continuous referencing. With every reference pulse, the reference value is applied to the "ABREncoder0" register

Configure ABR referencing mode

Name:
ReferenceModeABR01 to ReferenceModeABR02

The bits in this register are used to configure the reaction to the configured reference pulse.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Sets the referencing mode	00	Referencing OFF
		01	Single shot referencing
		10	Reserved
		11	Continuous referencing
2 - 5	Reserved	-	
6 - 7	Reserved	11	Must always be 11!

This results in the following values:

0b00000000	= 0x00	Referencing OFF
0b11000001	= 0xC1	Single shot referencing → When starting over after the referencing process is complete, the value 0x00 must be written to start again. Wait until the "StatusABR" register also takes on the value 0x00, then the value 0xC1 can be written again.
0b11000011	= 0xC3	Continuous referencing → Referencing takes place automatically with every reference pulse

4.11.17.12.7.4 Comparator functions

The ABR and AB encoders and the up/down counter have a comparator function. It always works the same and is described here globally for all three.

The comparators are implemented in software form. They do not work actively but rather passively, i.e. the comparison is only carried out when an event is received. The event received is forwarded along the TRUE or FALSE branch depending on the status of the comparator condition. An event function like this generally also offers a latch for the TRUE and FALSE branch to save the value used for the comparator at the time of the event.

Comparator modes

Comparator functions can be operated in 4 different modes.

- **Off**
  Events are ignored.
- **Single**
  The event function is executed once and then disables itself automatically. To re-enable it, the "event function mode" must be changed, preferably to "off" and then to the desired mode. This setting allows a hardware latch to be simulated.
- **State change**
  The event function only responds when the comparator status has changed, i.e. from false to true (or vice versa). Only the first event for each status is processed, e.g. the first "true" of a sequence of events with the comparator condition "true". After the event function is enabled, the first incoming event is used to determine the starting status and therefore not forwarded. This setting allows a hardware comparator to be simulated.
- **Continuous**
  Each incoming event is forwarded to the true or false branch depending on the comparator condition. This setting allows event filters to be created.

Configure event ID for comparator

Name:
CfO_Counter1event0IDwr to CfO_Counter4event0IDwr (event function 1)
CfO_Counter1event1IDwr to CfO_Counter4event1IDwr (event function 2)

This register holds the event ID that should trigger the counter event function. For a list of all possible event IDs, see 4.11.17.12.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,489	ID of counter event function

Configure calculation of comparator

Name:
CfO_Counter1event0config to CfO_Counter4event0config (event function 1)
CfO_Counter1event1config to CfO_Counter4event1config (event function 2)

These registers are used to configure the counter event function for the respective counter function.

Bits 0 to 3 configure the calculation of the comparison or to latch the value. This calculation is similar to the calculation of the counter register (see 4.11.17.12.7.1 "Counter value calculation")

Bits 8 to 13 can be used to limit the number of bits used for the comparison. A mask is calculated as 2^n - 1 and linked with an "AND" operation. This makes it possible to generate a comparator pulse every 2^n increments.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	counter 1 - use	0	0 is added instead of "counter 1"
		1	"counter 1" is used for addition
1	counter 1 - sign	0	The sign of the "counter 1" register is not changed for addition
		1	The sign of the "counter 1" register is reversed for addition
2	counter 2 - use	0	0 is added instead of "counter 2"
		1	"counter 2" is used for addition
3	counter 1 - sign	0	The sign of the "counter 2" register is not changed for addition
		1	The sign of the "counter 2" register is reversed for addition
4 - 7	Reserved	-	
8 - 13	Number of bits for comparator mask	x	The mask value is calculated as 2^n-1, where n is value set in these bits. Default: 0
14	Reserved	-	
15	Margin comparator mode	0	MarginComparator >= (Current position - OriginComparator)
		1	MarginComparator > (Current position - OriginComparator)

Configure mode and latching of comparator function

Name:
CfO_Counter1event0mode to CfO_Counter4event0mode (event function 1)
CfO_Counter1event1mode to CfO_Counter4event1mode (event function 2)

In these registers you can set the mode for the comparator function and optional copying of the latched registers.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Bits 4 to 7 can be used to define hardware referencing actions.

Based on these bits, the values of the internal absolute value counters "abs1" and "abs2" can be copied to the respective "HW_reference_counter" register at every counter event (see 4.11.17.12.7.1 "Counter value calculation"). This function can be used to reference the counter values directly in the hardware.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 3	Reserved	-	
4	Copy abs1 counter value	0	No action
		1	When event is FALSE → hardware reference counter 1 = abs1
5	Copy abs2 counter value	0	No action
		1	When event is FALSE → hardware reference counter 2 = abs2
6	Copy abs1 counter value	0	No action
		1	When event is TRUE → hardware reference counter 1 = abs1
7	Copy abs2 counter value	0	No action
		1	When event is TRUE → hardware reference counter 2 = abs2

Comparator origin

Name:
OriginComparator01 to OriginComparator02 (ABR encoder)
OriginComparator01 and OriginComparator03 (AB encoder and up/down counter)

This register is available for the AB and ABR encoders and the up/down counters.

It defines the position value at which the respective configured comparator output channel is set.

Data type	Value	Information
INT	-32,768 to 32,767	Comparator window origin, 16-bit
DINT	-2,147,483,648 to 2,147,483,647	Comparator window origin, 32-bit

Width of the comparator

Name:
MarginComparator01 to MarginComparator02 (ABR encoder)
MarginComparator01 and MarginComparator03 (AB encoder and up/down counter)

This register is available for the AB and ABR encoders and the up/down counters.

It defines the width of the comparator window in the positive direction.

Data type	Value	Information
INT	-32,768 to 32,767	Width of comparator window, 16-bit
DINT	-2,147,483,648 to 2,147,483,647	Width of comparator window, 32-bit

Read latch position or counter value

Name:
Different names are used for these 4 registers depending on their function.

If the comparator returns "TRUE", then the current counter value is latched and copied to these registers. The calculation of the comparator value used for the latch can be configured in the "CfO_Counter[x]event[y]config" register.

Counter 1 - Latch 1		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB01
	Up/down counters	Latch01Counter01
2	**AB encoders**	Latch02AB01
	ABR encoders	Latch01ABR01
	Up/down counters	Latch02Counter01

Counter 1 - Latch 2		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB02
	Up/down counters	Latch01Counter02
2	**AB encoders**	Latch02AB02
	Up/down counters	Latch02Counter02

Counter 2 - Latch 1		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB03
	Up/down counters	Latch01Counter03
2	**AB encoders**	Latch02AB03
	ABR encoders	Latch01ABR02
	Up/down counters	Latch02Counter03

Counter 2 - Latch 2		
Event function	**Function**	**Name**
1	**AB encoders**	Latch01AB04
	Up/down counters	Latch01Counter04
2	**AB encoders**	Latch02AB04
	Up/down counters	Latch02Counter04

Data type	Value	Information
INT	-32,768 to 32,767	Latched encoder position or counter value
DINT[1)]	-2,147,483,648 to 2,147,483,647	Latched encoder position or counter value

1) Only in function model 1

4.11.17.12.8 SSI encoder interface

The module has 2 SSI encoders available, supported directly in the hardware. Two 24 V output channels are set for each SSI encoder and cannot be changed. (See also 4.11.17.7.1 "Description of channel assignments")

When using the SSI encoder, the corresponding clock channel can be configured in the 4.11.17.12.5.1 "CfO_CFGchannel" register as "Channel-specific" and "Push/Pull".

Encoder	Data channel	Clock channel
SSI1	1	2
SSI2	5	6

4.11.17.12.8.1 SSI event functions

Each of the two SSI encoders consists of an event function and an event input. The SSI cycle is started when an event is received on this input.

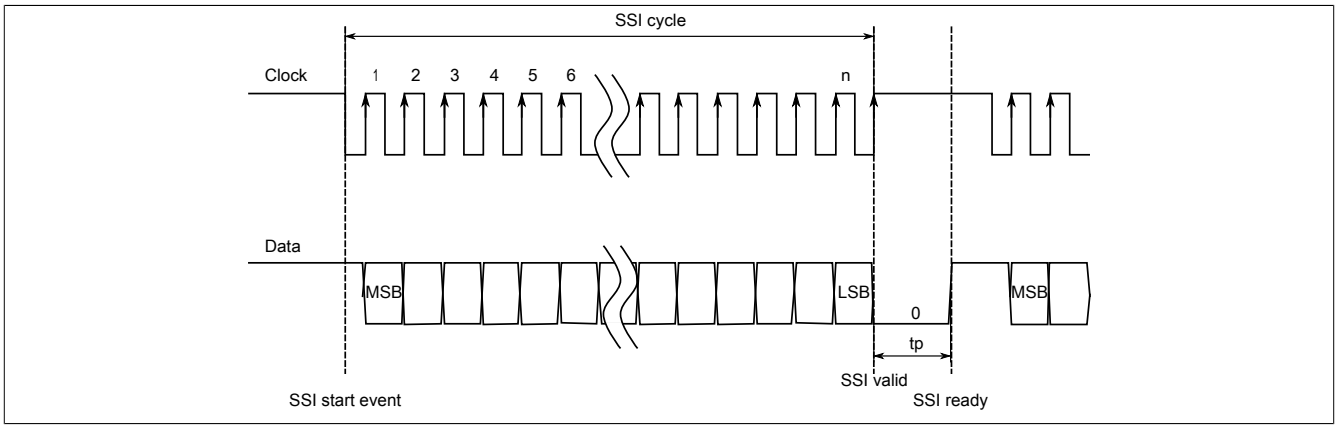
Information:

The SSI event function is not linked to an event by default, i.e. SSI functions are disabled.

Two events are sent from the SSI encoder interface..

- An "SSI valid" event is triggered immediately after the end of the SSI cycle if a new counter value is available.
- The "SSI ready" event then shows when the monoflop time has expired (tp in SSI encoder timing diagram). This is the earliest that the next SSI cycle can be started.

SSI encoder - Timing diagram



Configure event ID for SSI

Name:
CfO_SSI1event0IDwr to CfO_SSI2event0IDwr

This register holds the event ID that should start the SSI cycle. For a list of all possible event IDs, see 4.11.17.12.6.1 "List of event IDs"

Normally this register is set to network event 225 "AOSISOP"- This ensures that the new encoder position is available at the next "I/O → Synchronous Frame" transfer. Check the SSI transfer time and the X2X cycle time, because the SSI cycle must be completed within this time.

Data type	Value	Information
INT	192 to 7,233	ID of event function

Configure SSI

Name:
CfO_SSI1cfg to CfO_SSI2cfg

This configuration register is used to set the coding, the clock rate and the number of bits. Default = 0. This must be set once using an acyclic write command.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding

SSI advanced configuration

Name:
ConfigAdvanced01 to ConfigAdvanced02

This configuration register is used to set the coding, the clock rate, the number of bits and the monostable multivibrator settings. Default = 0. This must be set once using an acyclic write command.

It only differs from "CfO_SSI1cfg" by data length and additional monostable multivibrator testing.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 5	SSI value valid bits	x	
6 - 7	Clock rate	00	1 MHz
		01	500 kHz
		10	250 kHz
		11	125 kHz
8 - 13	SSI number of bits	x	Number of bits including leading zeros
14	Reserved	0	
15	Keying	0	Binary coding
		1	Gray coding
16 - 17	Monostable multivibrator check	00	Check OFF, no additional clock bit
		01	Check set to High level
		10	Check set to Low level
		11	Level is clocked but ignored
18 - 31	Reserved	0	

Enable SSI event function

Name:
CfO_SSI1control to CfO_SSI2control

The two SSI encoder events can be enabled/disabled using this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Event: SSI valid	0	Not sent
		1	Sent
1	Event: SSI ready	0	Not sent
		1	Sent
2 - 7	Reserved	-	

Read SSI position

Name:
SSIEncoder01 to SSIEncoder02

The last transferred SSI position can be read out from this register. The SSI encoder value is displayed as a 32-bit position value. This position value is generated synchronously with the X2X cycle.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Last SSI position transferred

4.11.17.12.8.2 SSI comparator condition

The module has an assigned comparator function for the SSI function. These consist of:

- Event ID that triggers the comparator function
- The window comparator
- Latch register for saving the counter value

When the comparator function is complete, event ID 7232 to7489 (see 4.11.17.12.6.1 "List of event IDs") is sent.

Configure event ID for SSI comparator

Name:
CfO_SSI1eventIDwr to CfO_SSI2eventIDwr

This register holds the event ID that should start the SSI comparator function. For a list of all possible event IDs, see 4.11.17.12.6.1 "List of event IDs"

Data type	Value	Information
INT	192 to 7,233	ID of comparator function

Configure the mode of the SSI comparator function

Name:
CfO_SSI1event0mode to CfO_SSI2event0mode

This register can be used to configure the mode of the comparator function.

Comparator functions can be operated in 4 different modes. For a description, see "Comparator modes".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Comparator mode	0	Off
		1	Single
		2	State change
		3	Continuous
2 - 7	Reserved	-	

Configure calculation of SSI comparator

Name:
CfO_SSI1event0config and CfO_SSI2event0config

The calculation of the position value used for the comparator can be configured in this register.

The window comparator condition is calculated as follows:

```
counter_window_value = ssi_counter & (2^ssi_data_bits - 1)
diff = counter_window_value – origin_comparator
if ((diff & (2^(comparator_mask)-1)) <= margin_comparator)
condition = True;
else
condition = False;
```

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 5	SSI data bits	x	Number of data bits used for masking
6 - 7	Reserved	-	
8 - 13	Comparator mask	x	The mask value is calculated from 2^n-1, where n is the value configured in SSI data bits. Default: 0
14	Comparator mode	0	MarginComparator >= SSI position - OriginComparator
		1	MarginComparator > SSI position - OriginComparator

Origin of the SSI comparator

Name:
OriginComparator01_SSI to OriginComparator02_SSI

This register contains the origin of the window comparator.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Origin of the window comparator.

Width of the SSI comparator

Name:
MarginComparator01_SSI to MarginComparator02_SSI

This register provides the width of the window comparator.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Width of the SSI window comparator

Read SSI latch position

Name:
Latch01SSI01 to Latch01SSI02

If the SSI window comparator returns "True", then the current SSI position is latched and saved in this register.

Data type	Value	Information
UDINT	0 to 4,294,967,295	Latched SSI position

4.11.17.12.9 PWM - Pulse width modulation

The module has 4 PWM functions available, supported directly by the hardware. A 24 V output channel is set for each PWM encoder and cannot be changed. (See also 4.11.17.7.1 "Description of channel assignments")

When using the PWM function, the corresponding channel can be configured in the 4.11.17.12.5.1 "CfO_CFGchannel" register as "Channel-specific".

PWM function	Channel
PWM1	2
PWM2	4
PWM3	6
PWM4	8

4.11.17.12.9.1 Configure PWM prescaler

Name:
CfO_PWM0prescaler to CfO_PWM3prescaler

The length of the PWM cycle is configured using this register. The base is a 48 MHz clock, which can be changed (divided) using the setting in this register. One PWM cycle consists of 1,000 of the resulting clocks after they have been divided. The period length of the PWM cycle is calculated as follows:

$$PWM\_cycle = 1000 \frac{prescale}{48000000} [s]$$

Data type	Value	Information
UINT	2 to 65,535	Prescaler for PWM cycle

4.11.17.12.9.2 Output PWM values

Name:
PWMOutput02, PWMOutput04, PWMOutput06, PWMOutput08

In this register, a configuration is made for the percentage of the PWM cycle (in 1/10 % steps) that the PWM output is logical 1, i.e. ON.

Data type	Value	Information
UINT	0 to 1,000	PWM output always off
	2 to 999	Turn on time in 1/10% steps
	1,000	PWM output always on

4.11.17.12.10 Time measurement function

The module has a time measurement function for each I/O channel. It can be configured separately for rising and falling edges on each channel.
A starting edge can be configured for each time measurement function. When a configured starting edge occurs, the value of the internal timer is saved in a FIFO. This FIFO holds up to 16 elements. When the actual trigger edge occurs, the difference in time between the starting edge and the triggered edge is copied to the respective register.
Bits 8 to 11 "Previous start edge" of the 4.11.17.12.10.2 "CfO_EdgeTimeFallingMode" and 4.11.17.12.10.3 "CfO_EdgeTimeRisingMode" registers can be used to define which detected starting edge from the FIFO should be used to calculate the difference. Additionally, when the trigger edge occurs, the counter clocked internally using bits 12 to 15 "Time measurement resolution are copied to the 4.11.17.12.10.10 "TimeStampFallingCH" and 4.11.17.12.10.11 "TimeStampRisingCH" registers.

Information:

The time measurement function is an extension of edge detection, so all of the channels used must be configured there.

4.11.17.12.10.1 Enable time measurement function

Name:
CfO_EdgeTimeglobalenable

This register enables/disables the time measurement function for the entire module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Time measurement function	0	Disabled for entire module
		1	Enabled for entire module
1 - 7	Reserved	-	

4.11.17.12.10.2 Configure time measurement function for the falling edge

Name:
CfO_EdgeTimeFallingMode01 to CfO_EdgeTimeFallingMode08

These registers can be used to configure the time measurement function for the falling edge of the respective channel.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Selects the channel for the starting edge	0	Channel 1
		...	
		7	Channel 8
4	Selects the edge for the starting edge	0	The falling edge of the channel configured in bits 0 to 3 serves as the starting edge.
		1	The rising edge of the channel configured in bits 0 to 3 serves as the starting edge.
5 - 6	Reserved	-	
7	Trigger	0	Triggered[1)]
		1	Continuous[2)]
8 - 11	Previous start edge	0 to 15	The value determines which entry in the starting edge FIFO should be used to calculate the time difference.
12 - 15	Time measurement resolution	0	8 Mhz
		1	4 Mhz
		2	2 Mhz
		3	1 Mhz
		4	500 kHz
		5	250 kHz
		6	125 kHz
		7	625 kHz

1) The time measurement is triggered by the corresponding bit in the 4.11.17.12.10.5 "TriggerRisingCH" register.
2) Time measurement runs continuously and is triggered at every edge.

4.11.17.12.10.3 Configure time measurement function for the rising edge

Name:
CfO_EdgeTimeRisingMode01 to CfO_EdgeTimeRisingMode08

These registers can be used to configure the time measurement function for the rising edge of the respective channel.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Selects the channel for the starting edge	0	Channel 1
		...	
		7	Channel 8
4	Selects the edge for the starting edge	0	The falling edge of the channel configured in bits 0 to 3 serves as the starting edge.
		1	The rising edge of the channel configured in bits 0 to 3 serves as the starting edge.
5 - 6	Reserved	-	
7	Trigger	0	Triggered[1)]
		1	Continuous[2)]
8 - 11	Previous start edge	0 to 15	The value determines which entry in the starting edge FIFO should be used to calculate the time difference.
12 - 15	Time measurement resolution	0	8 Mhz
		1	4 Mhz
		2	2 Mhz
		3	1 Mhz
		4	500 kHz
		5	250 kHz
		6	125 kHz
		7	625 kHz

1) The time measurement is triggered by the corresponding bit in the 4.11.17.12.10.5 "TriggerRisingCH" register.
2) Time measurement runs continuously and is triggered at every edge.

4.11.17.12.10.4 Trigger falling edge detection

Name:
TriggerFallingCH01 to TriggerFallingCH08

If bit 7 "Trigger" is cleared in the 4.11.17.12.10.2 "CfO_EdgeTimeFallingMode" register, then detection of a falling edge on the respective input can be triggered using the respective bit in this register. After a bit has been set, the next falling edge on the corresponding channel is detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TriggerFallingCH01	0	Falling edges on channel 1 are not detected
		1	The next falling edge on channel 1 will be detected
...		...	
7	TriggerFallingCH08	0	Falling edges on channel 8 are not detected
		1	The next falling edge on channel 8 will be detected

4.11.17.12.10.5 Trigger rising edge detection

Name:
TriggerRisingCH01 to TriggerRisingCH08

If the "Continued/triggered" bit is cleared in the 4.11.17.12.10.3 "CfO_EdgeTimeRisingMode" register, then detection of a rising edge on the respective input can be triggered using the respective bit in this register. After a bit has been set, the next rising edge on the corresponding channel is detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Trigger rising edge - Channel 1	0	Rising edges on channel 1 are not detected
		1	The next rising edge on channel 1 will be detected
...		-	
7	Trigger rising edge - Channel 8	0	Rising edges on channel 8 are not detected
		1	The next rising edge on channel 8 will be detected

4.11.17.12.10.6 Show first falling trigger edge

Name:
BusyTriggerFallingCH01 to BusyTriggerFallingCH08

If edges are triggered via the bits in the 4.11.17.12.10.4 "TriggerFallingCH" register, then a set bit in this register indicates that no falling edges have been detected on the respective channel since the corresponding bit was set in the "TriggerFallingCH" register. If a falling edge occurs on the respective channel, then the corresponding BusyTriggerFalling bit is cleared.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	BusyTriggerFallingCH01	0	Falling edge detected on channel 1
		1	Module waiting for a falling edge on channel 1
...		...	
7	BusyTriggerFallingCH08	0	Falling edge detected on channel 8
		1	Module waiting for a falling edge on channel 8

4.11.17.12.10.7 Show first rising trigger edge

Name:
BusyTriggerRisingCH01 to BusyTriggerRisingCH08

If edges are triggered via the bits in the 4.11.17.12.10.5 "TriggerRisingCH" register, then a set bit in this register indicates that no rising edges have been detected on the respective channel since the corresponding bit was set in the "TriggerRisingCH" register. If a rising edge occurs on the respective channel, then the corresponding BusyTriggerRising bit is cleared.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	BusyTriggerRisingCH01	0	Rising edge detected on channel 1
		1	Module waiting for a rising edge on channel 1
...		...	
7	BusyTriggerRisingCH08	0	Rising edge detected on channel 8
		1	Module waiting for a rising edge on channel 8

4.11.17.12.10.8 Count falling trigger edges

Name:
CountFallingCH01 to CountFallingCH08

These registers contain cyclic counters that are incremented with every detected falling edge on the respective channel.

Data type	Value	Information
USINT	0 to 255	Counter for falling edges

4.11.17.12.10.9 Count rising trigger edges

Name:
CountRisingCH01 to CountRisingCH08

These registers contain cyclic counters that are incremented with every detected rising edge on the respective channel.

Data type	Value	Information
USINT	0 to 255	Counter for rising edges

4.11.17.12.10.10 Time stamp of falling edge

Name:
TimeStampFallingCH01 to TimeStampFallingCH08

When a falling edge occurs on the respective channel, the current counter value of the module timer is copied to these registers.

Data type	Value	Information
UINT	0 to 65,535	Time stamp for rising edges

4.11.17.12.10.11 Time stamp of the rising edge

Name:
TimeStampRisingCH01 to TimeStampRisingCH08

When a rising edge occurs on the respective channel, the current counter value of the module timer is copied to these registers.

Data type	Value	Information
UINT	0 to 65,535	Time stamp for rising edges

4.11.17.12.10.12 Time difference of falling edge

Name:
TimeDiffFallingCH01 to TimeDiffFallingCH08

When a falling edge occurs on the respective channel, the time difference compared to the starting edge configured in bit 4 of the 4.11.17.12.10.2 "CfO_EdgeTimeFallingMode" register is copied to this register.

Data type	Value	Information
UINT	0 to 65,535	Time difference from starting edge

4.11.17.12.10.13 Time difference of rising edge

Name:
TimeD-iffRisingCH01 to TimeDiffRisingCH08

When a rising edge occurs on the respective channel, the time difference compared to the starting edge configured in bit 4 of the 4.11.17.12.10.3 "CfO_EdgeTimeRisingMode" register is copied to this register.

Data type	Value	Information
UINT	0 to 65,535	Time difference from starting edge

4.11.17.12.11 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
128 µs

4.11.17.12.12 Maximum cycle time

The maximum cycle time defines how far the bus cycle can be increased without internal counter overflows causing module malfunctions.

Minimum cycle time
16 ms

4.11.17.12.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
128 µs

4.12 CPUs

The X20 CPUs are a powerful addition to the X20 system. With the exception of the entry level model, all CPUs are based on Intel ATOM™ processors, which are available in various performance classes. Each CPU is available with either one or three slots for interface modules.

Flexible communication options onboard

In addition to one CompactFlash, two USB and two RS232 interfaces, there are also two independent Ethernet interfaces. One of them is a standard gigabit Ethernet interface for TCP/IP data traffic.

Behind the second female RJ45 connector, there is a pure Fast Ethernet interface (100 Mbit/s) that serves as a POWERLINK interface. This means that no additional POWERLINK interface is needed to operate a POWERLINK network.

Easy maintenance

A special feature of the CPU modules is that they are operated fan-free. The CPU can be operated throughout the full temperature range of the X20 system (-25 to 60°C). Depending on the model, derating may be required over 55°C.

The built-in SRAM buffer battery can be exchanged during operation as long as local regulations allow it. When the battery is exchanged with the power off, the SRAM is buffered for approximately 1 minute. This makes maintenance work very simple.

4.12.1 Brief information

Product ID	Short description	on page
X20CP1301	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 1 GB flash drive onboard, 1 insert slot for X20 interface modules, 1 USB interface, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including power supply module, 3x X20TB1F terminal blocks, slot cover and X20 locking plate X20AC0SR1 (right) included	1112
X20CP1381	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included	1112
X20CP1382	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included	1112
X20CP1483	X20 CPU, x86 100 MHz Intel compatible, 32 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1168
X20CP1483-1	X20 CPU, x86 100 MHz Intel compatible, 64 MB DRAM, 128 kB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1168
X20CP1583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20CP1584	X20 CPU, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20CP1585	X20 CPU, ATOM 1.0 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20CP1586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20CP3583	X20 CPU, ATOM 333 MHz compatible, 128 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1189
X20CP3584	X20 CPU, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.	1189
X20CP3585	X20 CPU, ATOM 1.0 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.	1189
X20CP3586	X20 CPU, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000BASE-T, 1 POWERLINK interface, incl. supply module, 1 terminal block, slot cover and X20 locking plate (right) included, order application memory separately.	1189
X20cCP1584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20cCP1586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1185
X20cCP3584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1189
X20cCP3586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.	1189

4.12.2 X20CP1301, X20CP1381 and X20CP1382

4.12.2.1 General information

Compact CPUs are available with processor speeds of 200 MHz and 400 MHz. Depending on the variant, up to 256 MB RAM and up to 32 kB nonvolatile onboard RAM is available. A built-in flash drive is available to store up to 2 GB of application and other data.

All CPUs come equipped with Ethernet, USB and one RS232 interface. In both performance classes, integrated POWERLINK and CAN bus interfaces are also available. If additional fieldbus connections are needed, all CPUs can be upgraded with an interface module from the standard X20 product range. These CPUs do not require fans or batteries and are therefore maintenance-free. 30 different digital inputs and outputs and two analog inputs are integrated in the devices. One analog input can be used for PT1000 resistance temperature measurement.

- CPU is Intel® ATOM™ 400 MHz compatible with integrated I/O processor
- Ethernet, POWERLINK with poll-response chaining and USB onboard
- 1 slot for modular interface expansion
- 30 digital inputs/outputs and two analog inputs integrated in the device
- 1/2 GB flash drive onboard
- 128/256 MB DDR3 SDRAM
- Fanless
- No battery
- Battery-backed real-time clock

4.12.2.2 Order data

Model number	Short description
	X20 CPUs
X20CP1301	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 1 GB flash drive onboard, 1 insert slot for X20 interface modules, 1 USB interface, 1 RS232 interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including power supply module, 3x X20TB1F terminal blocks, slot cover and X20 locking plate X20AC0SR1 (right) included
X20CP1381	X20 CPU, with integrated I/O, x86-200, 128 MB DDR3 RAM, 16 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included
X20CP1382	X20 CPU, with integrated I/O, x86-400, 256 MB DDR3 RAM, 32 kB FRAM, 2 GB flash drive on board, 1 insert slot for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 CAN bus interface, 1 POWERLINK interface, 1 Ethernet interface 10/100 Base-T, 14 digital inputs, 24 VDC, sink, 4 digital inputs, 2 µs, 24 VDC, sink, 4 digital outputs, 24 VDC, 0.5 A, source, 4 digital outputs, 2 µs, 24 VDC, 0.2 A, 4 digital inputs/outputs, 24 VDC, 0.5 A, 2 analog inputs ±10 V or 0 to 20 mA / 4 to 20 mA, 1 PT1000 instead of an analog input, including supply module, 3x X20TB1F terminal blocks, slot cover and X20AC0SR1 locking plate (right) included

Terminating resistor	-	Integrated in the module	
Controller	-	SJA 1000	
Digital inputs			
Quantity	14 standard inputs, 4 high-speed inputs and 4 mixed channels, configurable as inputs or outputs using software		
Nominal voltage	24 VDC		
Input voltage	24 VDC -15 % / +20 %		
Input current at 24 VDC	X1 - Standard inputs: Typ. 3.5 mA X2 - Standard inputs: Typ. 2.68 mA X2 - High-speed inputs: Typ. 3.5 mA X3 - Mixed channels: Typ. 2.68 mA		
Input filter			
Hardware	Standard inputs and mixed channels: ≤200 µs High-speed inputs: ≤2 µs, when used as standard inputs: ≤200 µs		
Software	Default 1 ms, configurable between 0 and 25 ms in 0.1 ms intervals		
Connection type	1-wire connections		
Input circuit	Sink		
Additional functions	X2 - High-speed digital inputs: 2x 250 kHz event counting, 2x AB counter, ABR incremental encoder, direction/frequency, period measurement, gate measurement, differential time measurement, edge counters, edge times		
Input resistance	X1 - Standard inputs: 6.8 kΩ X2 - Standard inputs: 8.9 kΩ X2 - High-speed inputs: 6.8 kΩ X3 - Mixed channels: 8.9 kΩ		
Switching threshold			
Low	<5 VDC		
High	>15 VDC		
AB incremental encoder			
Quantity	2		
Encoder inputs	24 V, asymmetrical		
Counter size	32-bit		
Input frequency	Max. 100 kHz		
Evaluation	4x		
Encoder supply	Module-internal, max. 300 mA		
Overload behavior of the encoder supply	Short circuit protection, overload protection		
ABR incremental encoder			
Quantity	1		
Encoder inputs	24 V, asymmetrical		
Counter size	32-bit		
Input frequency	Max. 100 kHz		
Evaluation	4x		
Encoder supply	Module-internal, max. 300 mA		
Overload behavior of the encoder supply	Short circuit protection, overload protection		
Event counter			
Quantity	2		
Signal form	Square wave pulse		
Evaluation	1x		
Input frequency	Max. 250 kHz		
Counter frequency	250 kHz		
Counter size	32-bit		
Time measurement			
Possible measurements	Period measurement, gate measurement, differential time measurement, edge counter, edge times		
Measurements per module	Each function up to 4x		
Counter size	32-bit		
Timestamp	1 µs resolution		
Signal form	Square wave pulse		
Analog inputs			
Quantity	2 [8)]		
Input	±10 V or 0 to 20 mA / 4 to 20 mA, via different terminal connections		
Input type	Differential input		

Table 204: Technical data

Product ID	X20CP1301	X20CP1381	X20CP1382
Digital converter resolution

Gain	0.18% (Rev. <C0: 0.37%) [9]		
Offset	0.04% (Rev. <C0: 0.25%) [10]		
Current			
Gain	0 to 20 mA = 0.15% (Rev. <C0: 0.52%) / 4 to 20 mA = 0.25% [9]		
Offset	0 to 20 mA = 0.1% (Rev. <C0: 0.4%) / 4 to 20 mA = 0.15% [11]		
Max. gain drift			
Voltage	0.017 %/°C [9]		
Current	0 to 20 mA = 0.015 %/°C / 4 to 20 mA = 0.023 %/°C [9]		
Max. offset drift			
Voltage	0.008 %/°C [10]		
Current	0 to 20 mA = 0.008 %/°C / 4 to 20 mA = 0.012 %/°C [11]		
Common-mode rejection			
DC	70 dB		
50 Hz	70 dB		
Common-mode range	±12 V		
Crosstalk between channels	<-70 dB		
Nonlinearity			
Voltage	<0.025% [10]		
Current	<0.05% [11]		
Temperature inputs resistance measurement			
Quantity	1		
Input	Resistance measurement with constant current supply for 2-wire connections		
Digital converter resolution	13-bit		
Conversion time	Only temperature input enabled: 200 µs Temperature and analog input enabled: 400 µs		
Conversion procedure	SAR		
Output format	INT or UINT for resistance measurement		
Sensor			
PT1000	-200 to 850°C		
Resistance measurement range	0.1 to 4000 Ω		
Temperature sensor resolution	1 LSB = 0x0005 = 0.16°C		
Resistance measurement resolution	1 LSB = 0x0005 = 0.49 Ω		
Input filter	1st-order low pass / cutoff frequency 7 Hz		
Sensor standard	IEC/EN 60751		
Common-mode range	1 V		
Linearization method	Internal		
Measuring current	1 mA		
Permitted input signal	Short-term max. ±30 V		
Max. error at 25°C			
Gain	0.3% (Rev. <C0: 1.93%) [12]		
Offset	0.15% (Rev. <C0: 0.32%) [13]		
Max. gain drift	0.023 %/°C [12]		
Max. offset drift	0.012 %/°C [13]		
Nonlinearity	<0.05% [13]		
Standardized value range for resistance measurement	0.1 Ω to 4000 Ω	0.1 Ω to 4000.0 Ω	0.1 Ω to 4000 Ω
Crosstalk between channels	<-70 dB		
Common-mode rejection			
50 Hz	>60 dB		

Table 204: Technical data

Product ID	X20CP1301	X20CP1381	X20CP1382
Temperature sensor standardization			
PT1000	-200 to 850°C		
Digital outputs			
Design	Standard outputs and mixed channels: FET positive switching High-speed outputs: Push-Pull		
Quantity	4 standard outputs, 4 high-speed outputs and 4 mixed channels, configurable as inputs or outputs using software		
Nominal voltage	24 VDC		
Switching voltage	24 VDC -15 % / +20 %		
Nominal output current	Standard outputs and mixed channels: 0.5 A High-speed outputs: 0.2 A		
Total nominal current	Standard outputs and mixed channels: 4 A High-speed outputs: 0.8 A		
Connection type	1-wire connections		
Output circuit	Standard outputs and mixed channels: Source High-speed outputs: Sink or source		
Output protection [14]	Thermal cutoff if overcurrent or short circuit occurs (see value "Peak short circuit current") Internal inverse diode for switching inductive loads (see section "Switching inductive loads")		
Pulse width modulation [15]			
Period duration	5 to 65535 µs corresponds to 200 kHz to 15 Hz		
Pulse duration	0.0 to 100.0%, minimum 2.5 µs		
Resolution for pulse duration	0.1% of the configured frequency		
Diagnostic status	Standard outputs and mixed channels: Output monitoring with 10 ms delay High-speed outputs: Output monitoring with 10 µs delay		
Leakage current when switched off	Standard outputs and mixed channels: 5 µA High-speed outputs: 25 µA		
$R_{DS(on)}$	140 mΩ [16]		
Residual voltage	Standard outputs and mixed channels: <0.1 V at 0.5 A rated current High-speed outputs: <0.9 V at 0.1 A rated current		
Peak short circuit current	Standard outputs and mixed channels: <3 A High-speed outputs: <20 A		
Switching on after overload or short circuit cutoff	Standard outputs and mixed channels: Approx. 10 ms (depends on the module temperature) High-speed outputs: No switch on		
Switching delay			
0 -> 1	Standard outputs and mixed channels: <300 µs High-speed outputs: <3 µs		
1 -> 0	Standard outputs and mixed channels: <300 µs High-speed outputs: <3 µs		
Switching frequency			
Resistive load [17]	Standard outputs and mixed channels: Max. 500 Hz High-speed outputs: 50 kHz, max. 200 kHz (see section "Switching frequency derating for high-speed digital outputs")		
Inductive load	See section "Switching inductive loads"		
Braking voltage when switching off inductive loads	Standard outputs and mixed channels: Typ. 45 VDC		
Operating conditions			
Mounting orientation

Table 204: Technical data

Product ID	X20CP1301	X20CP1381	X20CP1382
Dimensions			
Width		164 mm	
Height		99 mm	
Depth		75 mm	
Weight	300 g	310 g	

Table 204: Technical data

1) The specified values are maximum values. The exact calculation is available with the other module documentation for download from the B&R website.
2) See section "X20 shielding brackets".
3) Ta min.: 0°C
   Ta max.: See environmental conditions
4) When operated in parallel, the nominal power of 2 W is not permitted to be added to the total power.
5) Up to 2 W bus load.
6) Can be set in Automation Studio.
7) See the POWERLINK section of the AS help system under "General information, Hardware - IF/LS".
8) To reduce power dissipation, B&R recommends bridging unused inputs on the terminals or configuring them as current signals.
9) Based on the current measured value.
10) Based on the 20 V measurement range.
11) Based on the 20 mA measurement range.
12) Based on the current resistance value.
13) Based on the entire resistance measurement range.
14) For high-speed digital outputs, derating must be applied at switching frequencies >50 kHz (see section "Switching frequency derating for high-speed digital outputs"). Overtemperature protection is not provided.
15) The high-speed digital outputs can be used for pulse width modulation.
16) Only for standard outputs and mixed channels.
17) Standard outputs and mixed channels: At loads ≤1 kΩ.

4.12.2.4 LED status indicators on the integrated X1 I/O slot

Figure	LED	Color	Status	Description
	E	Red	On	SERVICE mode
			Blinking	The "E" LED blinks red and the "RF" LED blinks yellow when there is a license violation.
			Double flash	BOOT mode (during firmware update)[1)]
	R	Green	On	Application running
			Blinking	Boot mode system start: CPU initializing the application, all bus systems and I/O modules[1)]
		Red	On	Reset in progress
	RF	Yellow	On	SERVICE or BOOT mode
			Blinking	The "RF" LED blinks yellow and the "E" LED blinks red when there is a license violation.
	SE	Green/Red		Status/Error LED. The statuses of this LED are described in section 4.12.2.4.1 ""S/E" LED".
	ET	Green	On	A link to the peer station has been established.
			Blinking	A link to the peer station has been established. The LED blinks when Ethernet activity is taking place on the bus.
	PL	Green	On	A link to the POWERLINK peer station has been established.
			Blinking	A link to the POWERLINK peer station has been established. The LED blinks when Ethernet activity is taking place on the bus.
	A1 - A2	Green	Off	Open line or disconnected sensor
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK
	1 - 4	Green		Input state of the corresponding digital input
	C	Yellow	On	CPU transmitting or receiving data via the CAN bus interface
	S	Yellow	On	CPU transmitting or receiving data via the RS232 interface
	T	Yellow	On	The terminating resistor integrated in the CPU is switched on.
	DC	Yellow	On	CPU power supply OK

Table 205: LED status indicators on the integrated X1 I/O slot

1) The process can take several minutes depending on the configuration.

4.12.2.4.1 "S/E" LED

The Status/Error LED is a green/red dual LED. The LED status can have different meanings depending on the operating mode.

4.12.2.4.1.1 Ethernet mode

In this mode, the interface is operated as an Ethernet interface.

Green - Status	Description
On	Interface being operated as an Ethernet interface

Table 206: Status/Error LED - Ethernet operating mode

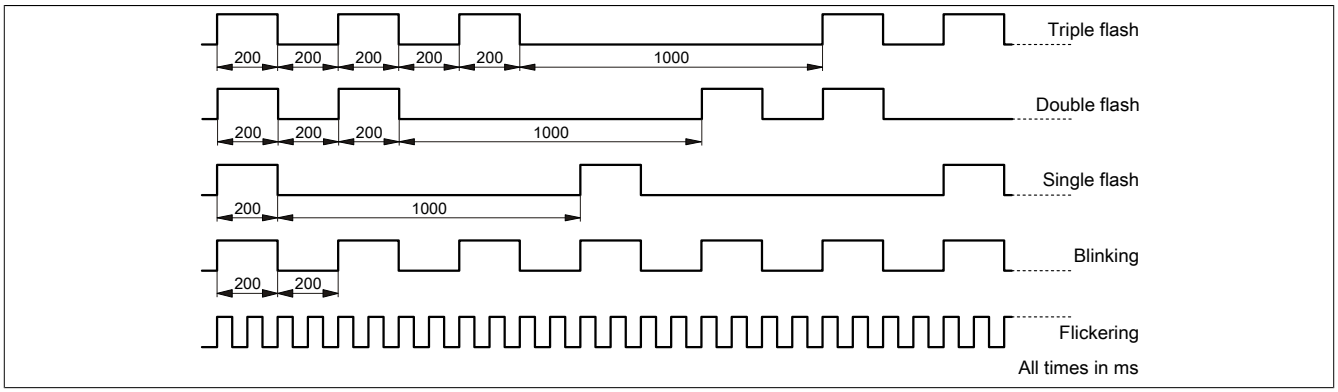
4.12.2.4.1.2 POWERLINK

Red - Error	Description
On	The module is in an error mode (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: The LED blinks red several times immediately after startup. This is not an error.

Table 207: Status/Error LED as Error LED - POWERLINK operating mode

Green - Status	Description
Off	**Mode** The module is in NOT_ACTIVE mode or: • Switched off • Starting up • Not configured correctly in Automation Studio • Defective **Managing node (MN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to PRE_OPERATIONAL_1 mode. If POWERLINK communication is detected before the time expires, however, then the MN will not be started. **Controlled node (CN)** The bus is being monitored for POWERLINK frames. If a corresponding frame is not received within the defined time frame (timeout), then the module switches immediately to BASIC_ETHERNET mode. If POWERLINK communication is detected before this time expires, however, the module switches immediately to PRE_OPERATIONAL_1 mode.
Green flickering (approx. 10 Hz)	**Mode** The module is in BASIC_ETHERNET mode. The interface is being operated as an Ethernet TCP/IP interface. **Managing node (MN)** This state can only be changed by resetting the module. **Controlled node (CN)** If POWERLINK communication is detected while in this state, the module will transition to the PRE_OPERATIONAL_1 state.
Single flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_1 mode. **Managing node (MN)** The MN starts "reduced cycle" operation. Cyclic communication is not yet taking place. **Controlled node (CN)** The module can be configured by the MN in this state. The CN waits until it receives an SoC frame and then switches to the PRE_OPERATIONAL_2 mode. An LED lit red in this state indicates failure of the MN.
Double flash (approx. 1 Hz)	**Mode** The module is in PRE_OPERATIONAL_2 mode. **Managing node (MN)** The MN begins cyclic communication (cyclic input data is not yet being evaluated). The CNs are configured in this state. **Controlled node (CN)** The module can be configured by the MN in this state. A command then switches the module to READY_TO_OPERATE mode. An LED lit red in this mode indicates failure of the MN.
Triple flash (approx. 1 Hz)	**Mode** The module is in the READY_TO_OPERATE state. **Managing node (MN)** Cyclic and asynchronous communication is taking place. Any received PDO data is ignored. **Controlled node (CN)** The configuration of the module is completed. Normal cyclic and asynchronous communication is taking place. The PDO data sent corresponds to the PDO mapping. Cyclic data is not yet being evaluated, however. An LED lit red in this mode indicates failure of the MN.
On	**Mode** The module is in PRE_OPERATIONAL_2 mode. PDO mapping is active and cyclic data is being evaluated.
Blinking (approx. 2.5 Hz)	**Mode** The module is in STOPPED mode. **Managing node (MN)** This status is not possible for the MN. **Controlled node (CN)** No output data is produced or input data supplied. It is only possible to enter or leave this mode after the MN has given the appropriate command.

Table 208: Status/Error LED as Status LED - POWERLINK operating mode



4.12.2.4.2 System failure error codes

Incorrect configuration or defective hardware can cause a system stop error.

The error code is indicated by the red Error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. The error code is output cyclically every 2 seconds.

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	●	●	●	-	Pause	●	●	●	-	Pause
Hardware error: The module or a system component is defective and must be replaced.	-	●	●	-	Pause	-	●	●	-	Pause

Table 209: Status/Error ("S/E") LED - System failure error codes

Key: ● ... 150 ms
- ... 600 ms
Pause ... 2 second delay

4.12.2.5 LED status indicators on the integrated X2 I/O slot

Figure	LED	Color	Status	Description
	1 - 14	Green		Input state of the corresponding digital input

Table 210: LED status indicators on the integrated X2 I/O slot

4.12.2.6 LED status indicators on the integrated X3 I/O slot

Figure	LED	Color	Status	Description
	DC	Yellow	On	I/O supply OK
	E	Red	Off	Everything OK
			Double flash	No power to module
	1 - 4	Yellow		Output status of the corresponding digital output
	5 - 8	Yellow		Input or output status of the corresponding digital input or output
	9 - 12	Yellow		Output status of the corresponding high-speed digital output

Table 211: LED status indicators on the integrated X3 I/O slot

4.12.2.7 Operating and connection elements

X20CP1301

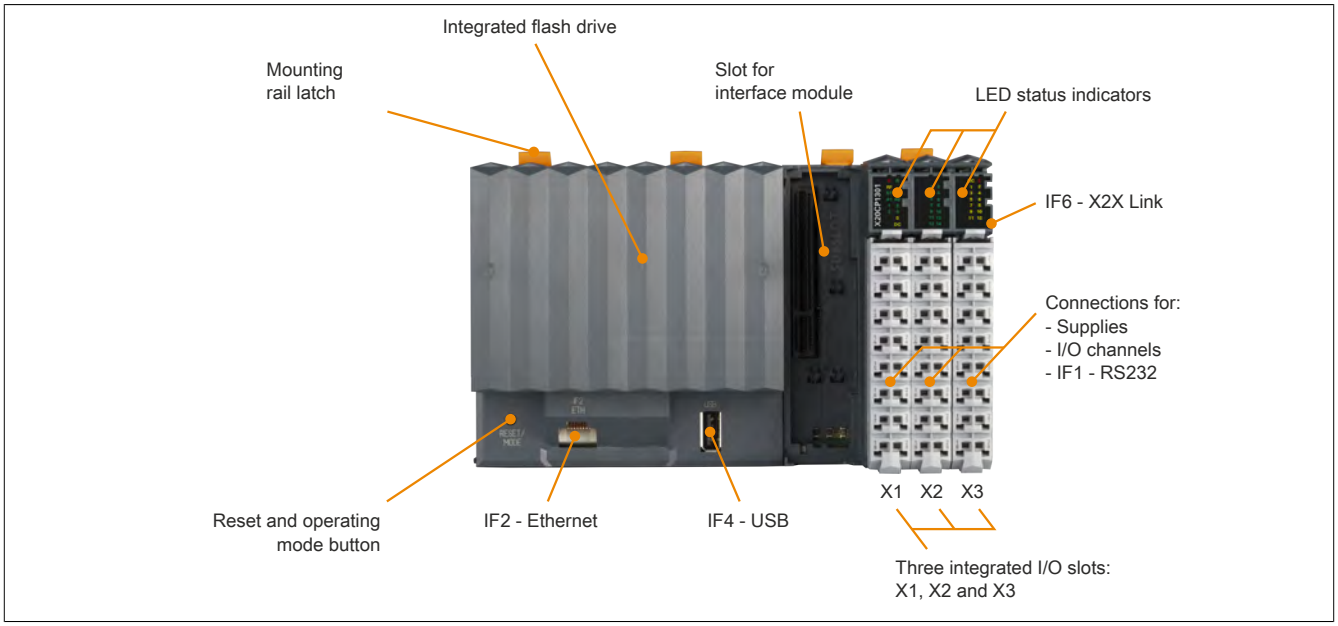


Figure 196: Operating elements for X20CP1301

X20CP1381 and X20CP1382

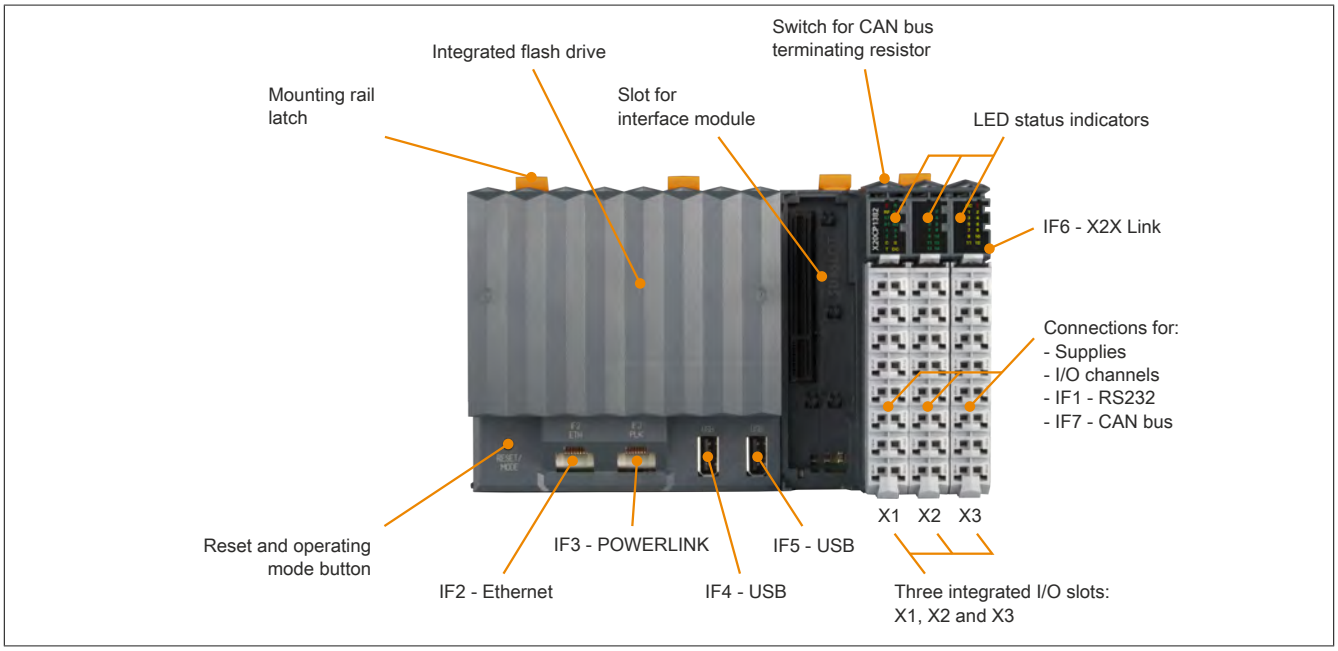

Figure 197: Operating elements for X20CP1381 and X20CP1382

4.12.2.8 Flash drive

These CPUs require application memory in order to operate. This application memory is integrated on a flash drive.

4.12.2.9 Reset and operating mode button

Figure 198: Reset and operating mode button

4.12.2.9.1 Reset

The button must be pressed for less than 2 seconds to trigger a reset. This triggers a hardware reset on the CPU, which means that:

- All application programs are stopped.
- All outputs are set to zero.

The PLC then boots into service mode by default. The boot mode that follows after pressing the reset button can be defined in Automation Studio.

- Service mode (default)
- Warm restart
- Cold restart
- Diagnostic mode

4.12.2.9.2 Operating mode

Three operating modes can be configured using different button sequences:

Operating mode	Button sequence	Description
BOOT	Boot mode is enabled by the following button sequence: • Press the button for less than two seconds. As soon as the "R" LED on the X1 I/O slot is lit **RED**, the button can be released. • Then press the button within two seconds for longer than two seconds. As soon as the "R" LED is no longer lit, the button can be released.	The default Automation Runtime system is started and the runtime system can be installed via the online interface (Automation Studio). User flash memory is deleted only after the download begins.
RUN	Press the button for less than two seconds. As soon as the "R" LED on the X1 I/O slot is lit **RED**, the button can be released.	RUN mode: The triggering and boot behavior are the same as what happens when a hardware reset is triggered (see section 4.12.2.9.1 "Reset" on page 1123).
DIAGNOSE	Press the button for more than 2 seconds. The "R" LED on the X1 I/O slot lights up **RED** and then goes out. As soon as the "R" LED is no longer lit, the button can be released.	Boots the CPU in diagnostic mode. Program sections in User RAM and User FlashPROM are not initialized. After diagnostic mode, the CPU always boots with a cold restart.

Table 212: Operating mode description

4.12.2.10 CPU supply

A power supply is integrated in these compact CPUs. It has a feed for the CPU, X2X Link and the internal I/O supply. The supply for the CPU and X2X Link is electrically isolated.

The connections are located on the X3 I/O slot.

4.12.2.10.1 Compact CPU supply concept

To ensure proper operation of compact CPUs, the following items must be taken into consideration:

The supply concept	Description
CPU and I/O GND	The GND contact is provided five times on the terminal blocks of the integrated I/O slots. All GND contacts are connected to one another. The GND contacts of the CPU and I/O supply therefore use the same voltage.
Plug-in X20 I/O modules	Supply of X20 I/O modules that can be connected to the compact CPU: • X2X Link: Supplied by the CPU supply • I/O channels: Supplied by the I/O supply
Integrated X1 I/O slot	All digital and analog signals as well as the RS232 and CAN bus interface are supplied by the CPU supply. Their operation is therefore guaranteed even if there is no I/O supply.
Integrated X2 I/O slot	• All digital signals are supplied by the CPU supply. Their operation is therefore guaranteed even if there is no I/O supply. • The encoder supply is supplied by the I/O supply. If the encoder is not to be connected to the E-stop chain, then it must be connected to an external power supply or it will be supplied by the CPU supply.
Integrated X3 I/O slot	• All 12 digital signals are supplied by the I/O supply. • The status messages for each channel also work without an I/O supply. This guarantees that status messages will continue to be transferred during an E-stop. • The status of the I/O supply is indicated by a separate status message. **Caution!** **Channels 5 to 8 are designed as mixed channels. If one of these channels is being used, it is absolutely essential to ensure that there is no external voltage present on the I/O channel when the I/O supply is cut off. Otherwise, power will be regenerated back to the plus terminal of the I/O supply via the I/O channel. This will result in defective components.** **The following solutions are available for preventing power regeneration from occurring:** • **The I/O supply of the CPU is not permitted to be switched off, which allows the reference potential to be maintained.** • **If the I/O supply is switched off anyway (e.g. as part of the E-stop chain), then the sensor/actuator supplies must also be switched off. This prevents potential power regeneration and protects components from being destroyed.**

Table 213: Compact CPU supply concept

4.12.2.10.2 Pinout

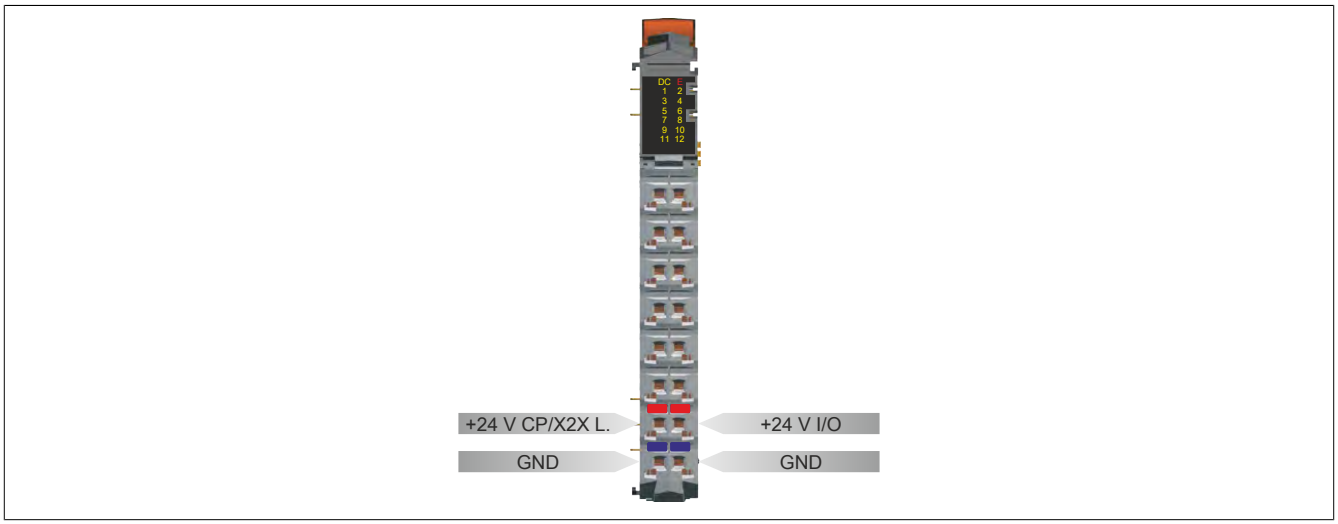

Figure 199: Integrated power supply - Pinout

4.12.2.10.3 Connection example

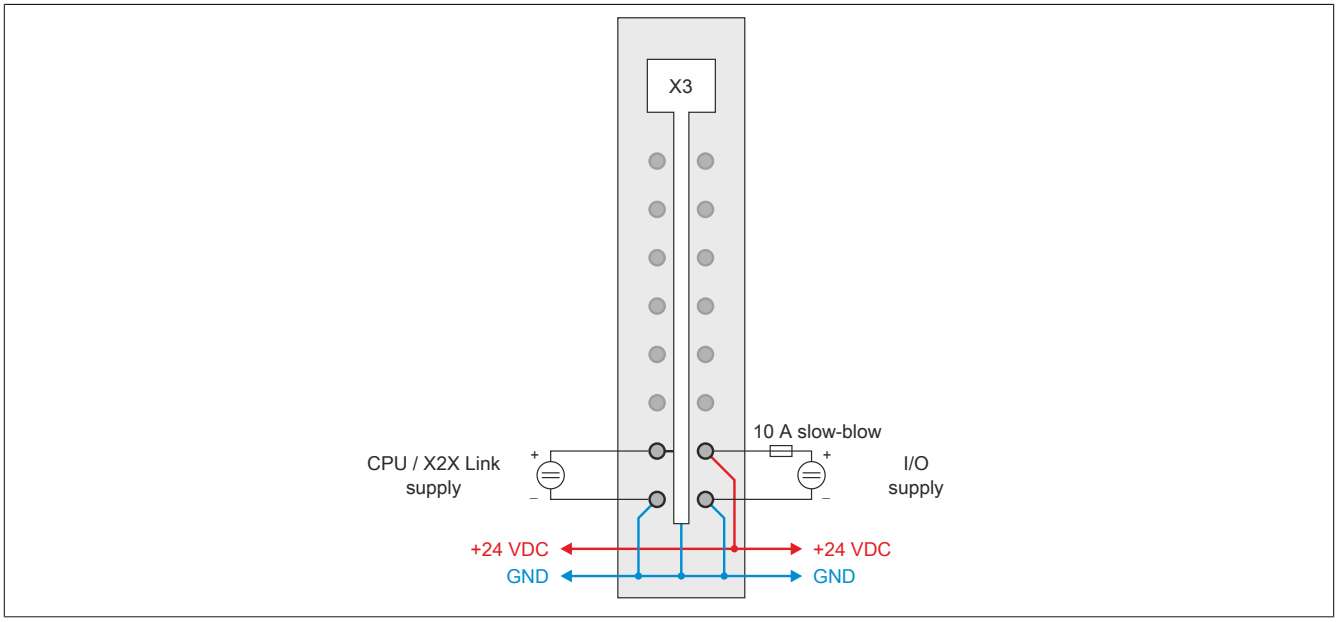

Figure 200: CPU supply - Connection example

4.12.2.11 RS232 interface (IF1)

The non-electrically isolated RS232 interface is primarily intended to serve as an online interface for communication with the programming device. It is located on the X1 I/O slot.

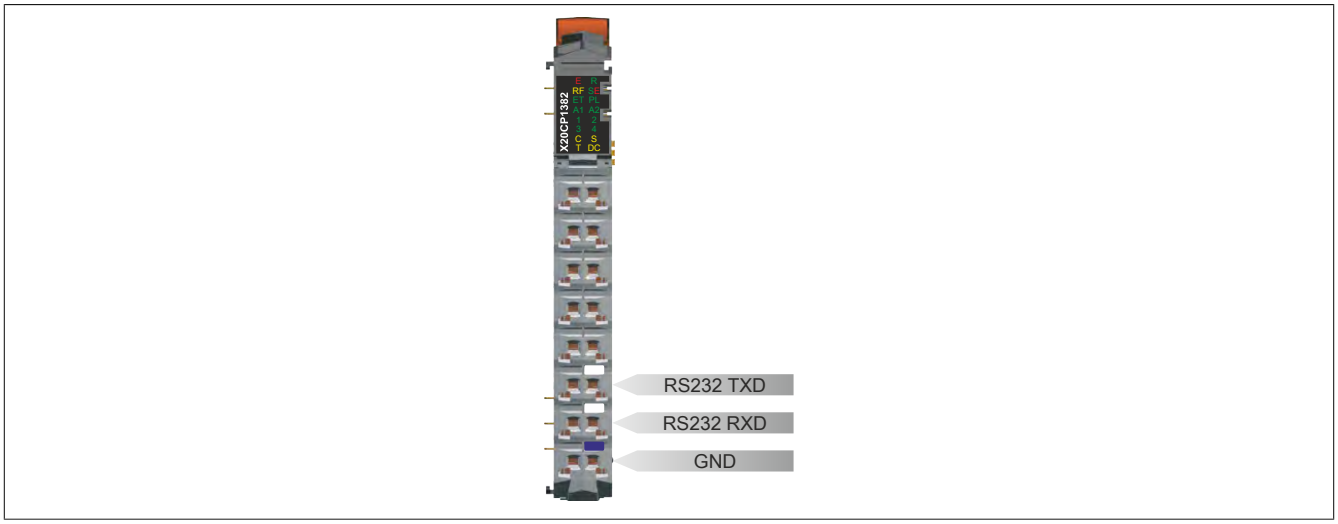

Figure 201: RS232 interface (IF1) on the X1 I/O slot - Pinout

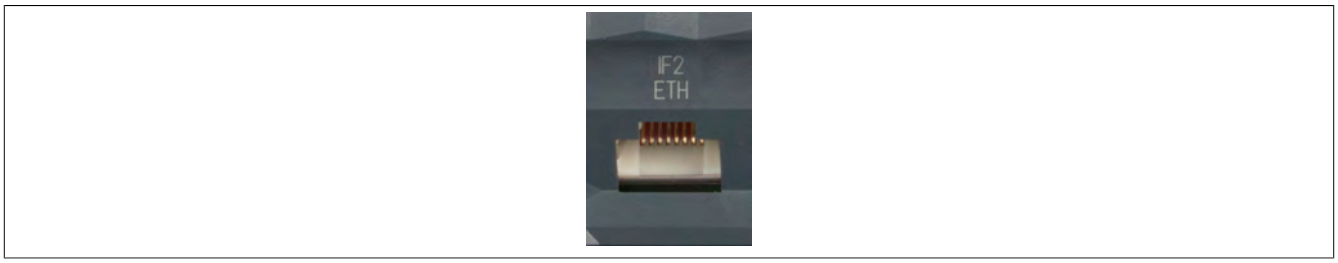
4.12.2.12 Ethernet interface (IF2)



The IF2 interface is designed for 10BASE-T / 100BASE-TX transmission.

The INA2000 station number can be set using the Automation Studio software.

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section at www.br-automation.com.

Information:

The Ethernet interface (IF2) is not suited for POWERLINK (see section 4.12.2.13 "POWERLINK interface (IF3)" on page 1127).

Pinout

Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	TXD	Transmit data
	2	TXD\	Transmit data\
	3	RXD	Receive data
	4	Termination	
	5	Termination	
	6	RXD\	Receive data\
	7	Termination	
	8	Termination	

Table 214: Pinout

4.12.2.13 POWERLINK interface (IF3)

Compact CPUs X20CP1381 and X20CP1382 are equipped with a POWERLINK interface.

POWERLINK

Node numbers between 0x01 and 0xF0 are permitted. The node number can be configured using software.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as a controlled node.
0xF0	Operation as a managing node.
0xF1 - 0xFF	Reserved, switch position not permitted

Table 215: POWERLINK node number

Ethernet mode

In this mode, the interface is operated as an Ethernet interface. The INA2000 station number can be set using the Automation Studio software.

Pinout

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section at www.br-automation.com.

Pin	Assignment	
1	RxD	Receive data
2	RxD\	Receive data\
3	TxD	Transmit data
4	Termination	
5	Termination	
6	TxD\	Transmit data\
7	Termination	
8	Termination	

Table 216: POWERLINK interface (IF3) - Pinout

4.12.2.14 USB interfaces (IF4 and IF5)

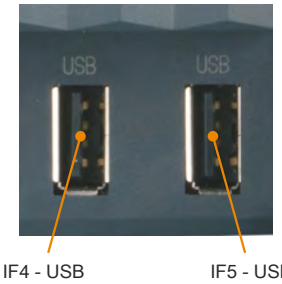


Figure 202: USB interfaces (IF4 and IF5)

IF4 and IF5 are non-electrically isolated USB interfaces. The connection is made using a USB 2.0 interface. Only IF4 is available on the entry level CPU.

The USB interfaces can only be used for devices approved by B&R (e.g. floppy disk drive, DiskOnKey or dongle).

Information:

- **USB interfaces cannot be used for online communication with a programming device.**
- **Only devices isolated from GND can be connected to the USB interfaces.**
- **The USB interfaces can handle up to the following current:**
  - **IF4: Max. 0.5 A**
  - **IF5: Max. 0.1 A**

4.12.2.15 CAN bus interface (IF7)

With the exception of the entry level CPU, all compact CPUs are equipped with a non-electrically isolated CAN bus interface. It is located on the X1 I/O slot.

4.12.2.15.1 Pinout

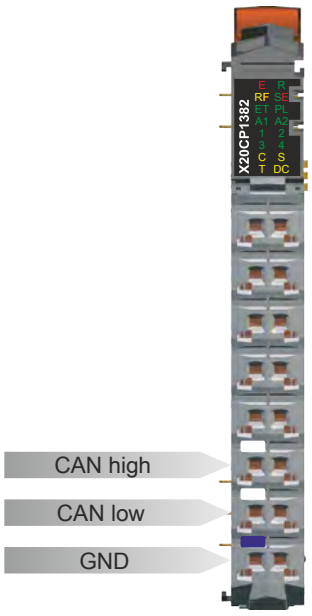

Figure 203: CAN bus interface (IF7) on the X1 I/O slot - Pinout

4.12.2.15.2 Terminating resistor

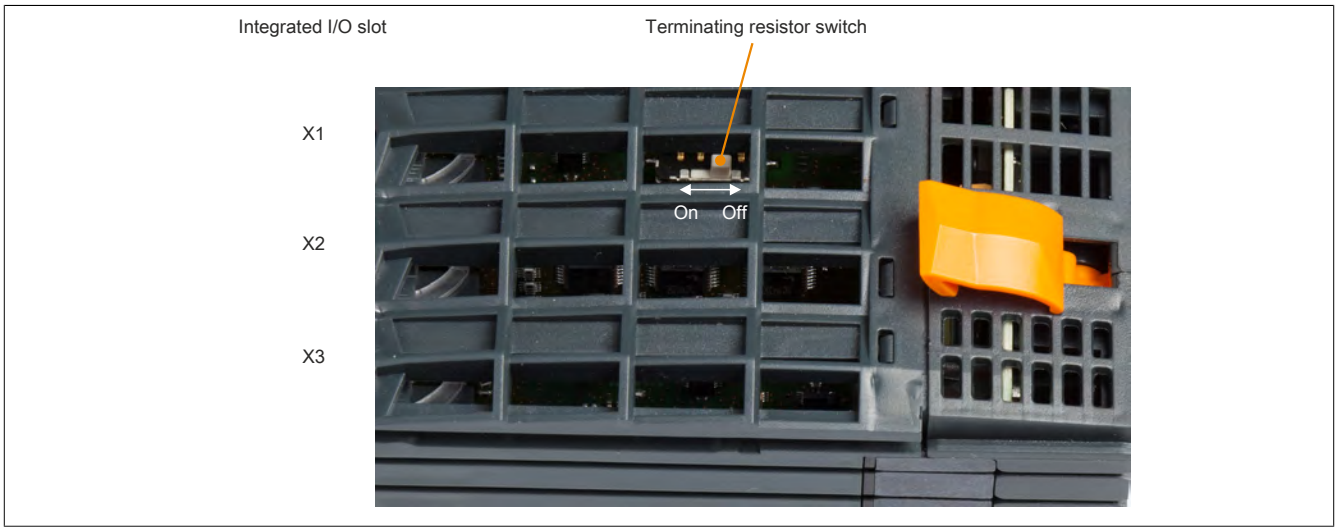

Figure 204: Switch positions for the CAN bus terminating resistor

A terminating resistor is already installed on the X1 I/O slot. It can be turned on and off with a switch on top of the housing. An active terminating resistor is indicated by the "T" LED.

4.12.2.16 Slot for interface modules

These CPUs are equipped with one slot for interface modules.

Various bus and network systems can easily be integrated into the X20 system by selecting the corresponding interface module.

4.12.2.17 Overtemperature cutoff

To prevent damage, a shutdown/reset is triggered on the CPU when the processor reaches 95°C.

The following errors are entered in the logbook:

Error number	Error description
9204	WARNING: System halted because of temperature check
9210	WARNING: Boot by watchdog or manual reset

Table 217: Logbook entries after overtemperature cutoff

4.12.2.18 Data and real-time clock buffering

Compact CPUs are not designed for use with batteries. This makes them completely maintenance-free. The following features make operation without a backup battery possible.

Data and real-time clock buffering	Type of buffering	Note
Remanent variables	FRAM	This FRAM stores its contents ferroelectrically. Unlike normal SRAM, this does not require a battery.
Real-time clock	Gold foil capacitor	The real-time clock is buffered for approx. 1000 hours by a gold foil capacitor. The gold foil capacitor is completely charged after 3 continuous hours of operation.

4.12.2.19 Programming the system flash memory

General information

In order for the application project to be executed on the CPU, the Automation Runtime operating system, system components and application project must be installed on the flash drive.

Installation over an online connection

These CPUs come standard with an Automation Runtime system (with limited functionality) already installed. This runtime system is started in boot mode (see section 4.12.2.9 "Reset and operating mode button" on page 1123 or an invalid flash drive). Some of its tasks include initializing the Ethernet and integrated serial RS232 interfaces so that it is possible to download a runtime system.

1. Switch on the supply voltage for the CPU. The CPU starts with the default Automation Runtime in boot mode (see section 4.12.2.9 "Reset and operating mode button" on page 1123 or an invalid flash drive).
2. Establish a physical online connection between the programming device (PC or industrial PC) and the CPU (e.g. over an Ethernet network or the RS232 interface).
3. Before you can establish an online connection via Ethernet, the CPU must be assigned an IP address. Search for available B&R target system in the local network by selecting **Online / Settings** from the Automation Studio menu and then clicking the **Browse targets** button. The CPU should appear in the list. If the CPU has not already received an IP address from a DHCP server, right-click on it and select **Set IP parameters** from the shortcut menu. All necessary network configurations can be made on a temporary basis in this dialog box (should be identical to the settings defined in the project).
4. Configure an online connection in Automation Studio. For details about the configuration: See AS help system under "Automation Software / Communication / Online communication"
5. Start the download procedure by selecting **Services** from the **Project** menu. Then select **Transfer Automation Runtime** from the pop-up menu. Now follow the instructions provided by Automation Studio.

4.12.2.20 I/O channels

Compact CPUs are equipped with three integrated I/O slots. These devices have 30 digital inputs/outputs and two analog inputs. One analog input can also be used for PT1000 resistance temperature measurement.

Information about the functions of the high-speed digital inputs and outputs can be found in the section 4.12.2.24 "Functions of the high-speed digital inputs/outputs" on page 1138.

Overview of available I/O channels:

Integrated I/O	Quantity	I/O slot	Description
Digital inputs	14	X1: DI 1 to DI 4 X2: DI 1 to DI 10	24 VDC, sink, ≥0.5 ms, configurable software filter
High-speed digital inputs	4	X2: DI 11 to DI 14	24 VDC, sink, 2 µs, configurable software filter
Digital outputs	4	X3: DO 1 to DO 4	24 VDC, 0.5 A, source
Fast digital outputs	4	X3: DO 9 to DO 12	24 VDC, 0.2 A, 2 µs
Digital inputs/outputs	4	X3: DI 5 / DO 5 to DI 8 / DO 8	24 VDC, 0.5 A, configurable software filter
Analog inputs	2	X1: AI 1 to AI 2	±10 V / 0 to 20 mA or 4 to 20 mA, 12-bit, 1 ms
Temperature inputs	1	X1: AI 1 (Sensor + and Sense -)	PT1000 resistance temperature measurement Measurement takes place using the AI 1 analog input.

4.12.2.24 Functions of the high-speed digital inputs/outputs

4.12.2.24.1 Functions of the high-speed digital inputs

Possible functions

The high-speed digital inputs DI 11 to DI 14 can be configured for the following functions:

Channel	Counter function				Edge detection	
DI 11	Event counter 1	A	A	D - Direction	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times
DI 12		B	B	F - Frequency	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times
DI 13	Event counter 2	A	R	R	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times
DI 14		B	E - Reference enable	E - Reference enable	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times

Table 220: Possible functions of the high-speed digital inputs DI 11 to DI 14

Please note

The following points must be taken into account to correctly configure the high-speed digital inputs:

- The counter functions are mutually exclusive. Only one type of counter function can be selected at a time. It is not possible to select two event counters (DI 11 and DI 13) at the same time together with an AB or DF counter (each on DI 13 and DI 14)!
- It is possible to select a counter function and edge detection at the same time.
- A position or counter latch is possible when configuring the high-speed inputs as a 2x event counter, ABR incremental encoder or DF function.

Examples of possible configurations

Channel	Configuration 1	Configuration 2	Configuration 3	Configuration 4
DI 11	Event counter 1	• Edge counters • Edge times	A	D
DI 12	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times	B	F
DI 13	Event counter 2	A	R	R
DI 14	• Period measurement • Gate measurement • Differential time measurement	B	E - Reference enable	E - Reference enable

Channel	Configuration 5	Configuration 6	Configuration 7	Configuration 8
DI 11	Event counter 1	A	• Period measurement • Gate measurement • Differential time measurement	D - Direction
DI 12	• Edge counters • Edge times	B	• Period measurement • Gate measurement • Differential time measurement	F - Frequency
DI 13	Event counter 2	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times	• Edge counters • Edge times
DI 14	• Period measurement • Gate measurement • Differential time measurement	• Edge counters • Edge times	• Edge counters • Edge times	• Period measurement • Gate measurement • Differential time measurement

4.12.2.24.2 Functions of the high-speed digital outputs

Possible functions

The high-speed digital outputs DO 9 to DO 12 can be configured for the following functions:

Channel	Function	
DO 9	PWM - Pulse width modulation	D - Direction
DO 10	PWM - Pulse width modulation	F - Frequency
DO 11	PWM - Pulse width modulation	D - Direction
DO 12	PWM - Pulse width modulation	F - Frequency

Table 221: Possible functions of the high-speed digital inputs DO 9 to DO 12

Examples of possible configurations

Channel	Configuration 1	Configuration 2	Configuration 3	Configuration 4
DO 9	PWM - Pulse width modulation	D - Direction	PWM - Pulse width modulation	D - Direction
DO 10	PWM - Pulse width modulation	F - Frequency	PWM - Pulse width modulation	F - Frequency
DO 11	D - Direction	PWM - Pulse width modulation	PWM - Pulse width modulation	D - Direction
DO 12	F - Frequency	PWM - Pulse width modulation	PWM - Pulse width modulation	F - Frequency

80	StatusInput01	USINT	•			

4.12.2.28.1.1 Digital inputs

Unfiltered

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:
X1CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

Data type	Value	Filter
USINT	0	No SW filter
	1	0.1 ms
	...	...
	250	25 ms - Higher values are limited to this value

Input state of digital inputs 1 to 4

Name:
DigitalInput01 to DigitalInput04

This register is used to indicate the input state of digital inputs 1 to 4.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status of digital input 1
...		...	
3	DigitalInput04	0 or 1	Input status of digital input 4

4.12.2.28.1.2 Analog inputs

Analog input values are recorded in a fixed interval. The time required for conversion/updating depends on the number of analog inputs and on the input signal:

Input signal	Time required for conversion/updating
1 current/voltage input	100 µs
1 temperature/resistance input	200 µs
2 current/voltage inputs	200 µs
1 current/voltage input and 1 temperature/resistance input	400 µs

Analog input values

Name:
AnalogInput01

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal
INT	-32,768 to 32,767	Voltage signal -10 to 10 VDC
	0 to 32,767	Current signal 0 to 20 mA (with 0 to 20 mA configuration)
	-8,192 to 32,767	Current signal 0 to 20 mA (with 4 to 20 mA configuration)
	-2,000 to 8,500	PT1000 signal -200.0 to 850.0°C
UINT	0 to 40,000	Resistance signal 0 to 4000.0 Ω

Name:
AnalogInput02

The analog input value is mapped in this register depending on the configured operating mode.

Data type	Value	Input signal
INT	-32,768 to 32,767	Voltage signal -10 to 10 VDC
	0 to 32,767	Current signal 0 to 20 mA (with 0 to 20 mA configuration)
	-8,192 to 32,767	Current signal 0 to 20 mA (with 4 to 20 mA configuration)

Input status

Name:
StatusInput01

This register holds the status of the analog inputs. A change in the monitoring status generates an error message. The following states are monitored depending on the settings:

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

Limiting the analog value

In addition to the status information, the analog value is set to the limit values listed below by default when an error occurs (see "Limit values"). The analog value is limited to the new values if the limit values were changed.

Input filter

The analog inputs are equipped with a configurable input filter.

Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

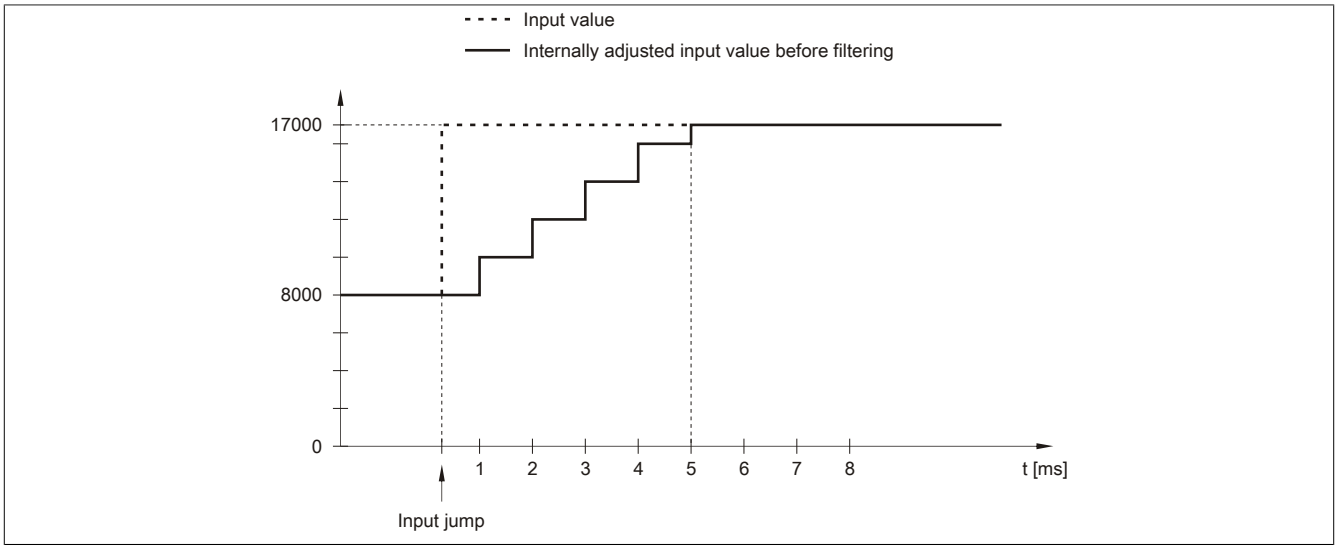

Figure 223: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

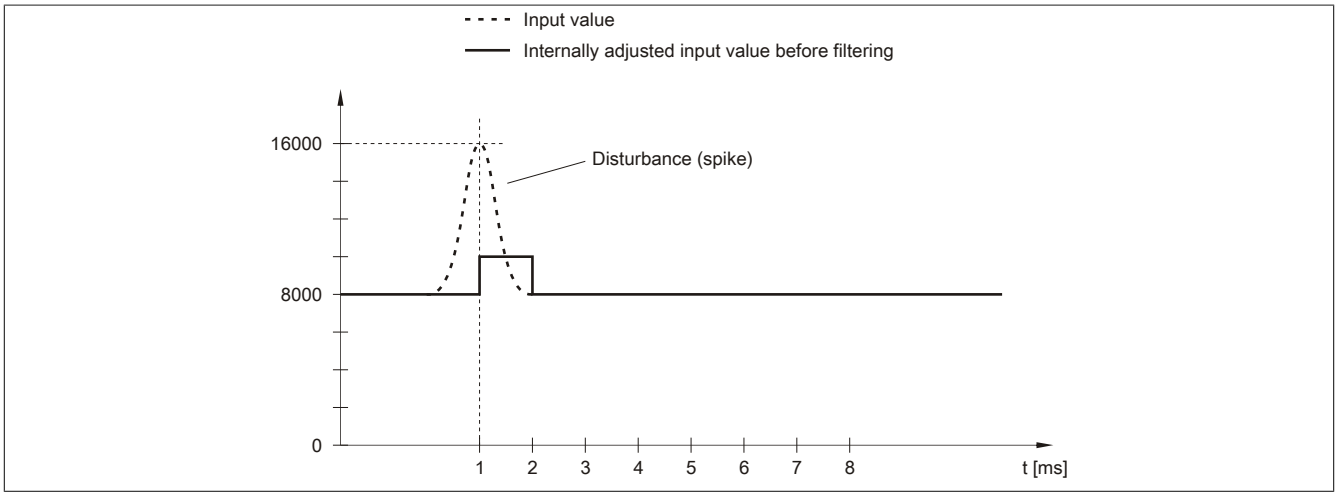

Figure 224: Adjusted input value for disturbance

Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several bus cycles.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

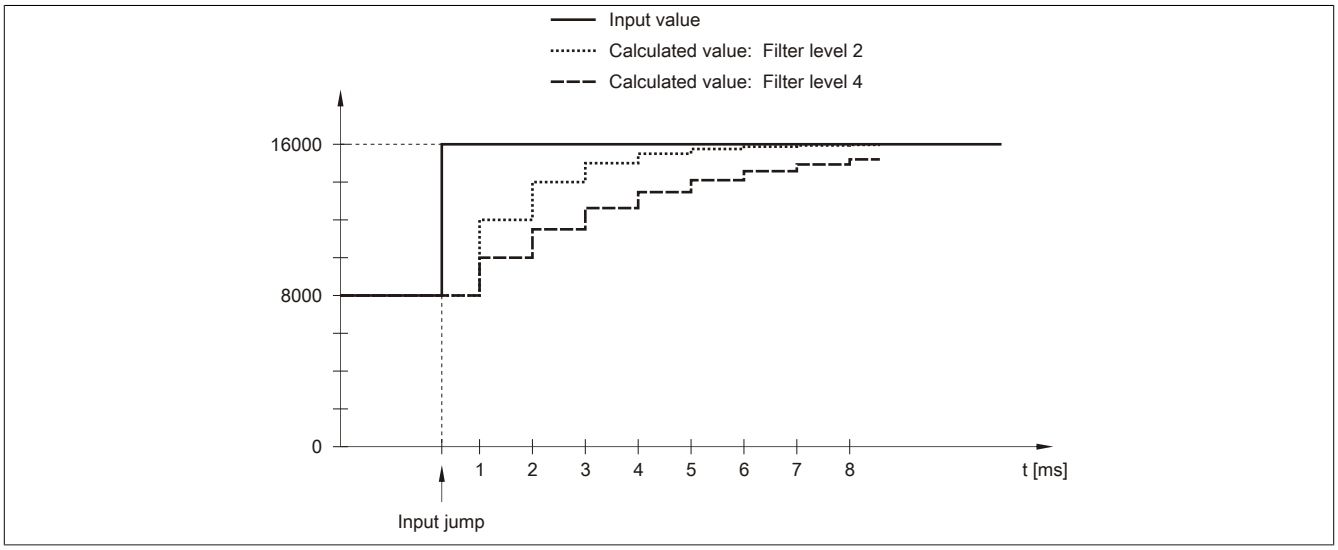

Figure 225: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

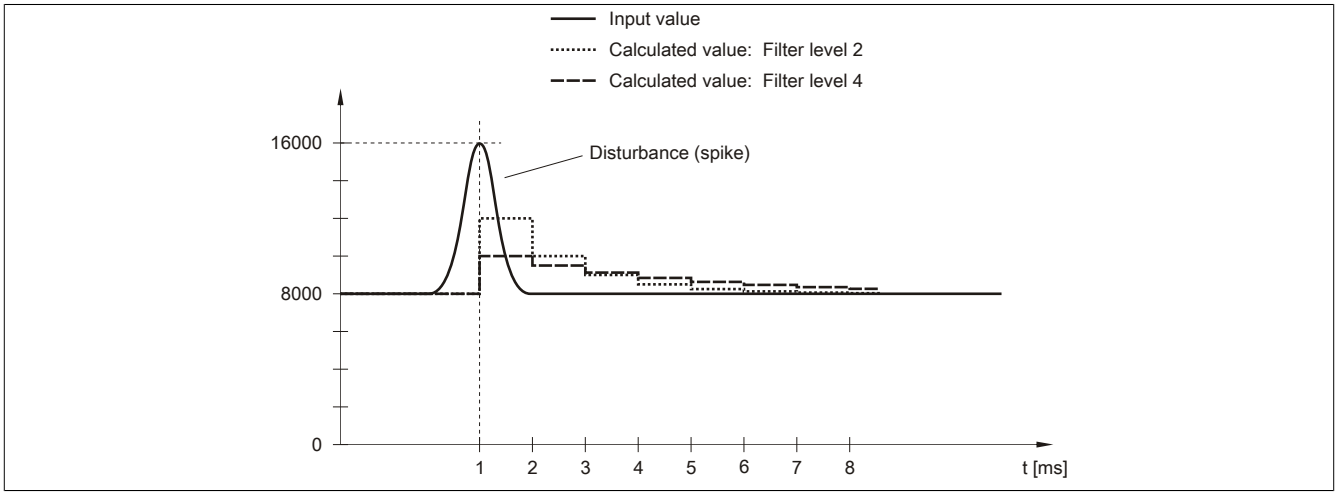

Figure 226: Calculated value during disturbance

Configuring the input filter

Name:
X1CfO_AI1_Filter

X1CfO_AI2_Filter

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limit	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

Channel type

Name:
X1CfO_AI_Mode

This register can be used to define the type and range of signal measurement.

Each channel is capable of handling current, voltage or resistance signals. This differentiation is made using multiple connection terminal points and an integrated switch. The switch is automatically activated depending on the specified configuration. The following input signals can be set:

Input signal	On channel
±10 V voltage signal (default)	1 and 2
0 to 20 mA current signal	1 and 2
4 to 20 mA current signal	1 and 2
PT1000 measurement	1
Resistance measurement	1

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Analog input - Channel 1	000	Channel disabled
		001	±10 V voltage signal
		010	0 to 20 mA current signal
		011	4 to 20 mA current signal
		100	PT1000 measurement
		101	Resistance measurement
3	Reserved	0	
4 - 5	Analog input - Channel 2	00	Channel disabled
		01	±10 V voltage signal
		10	0 to 20 mA current signal
		11	4 to 20 mA current signal
6 - 7	Reserved	0	

Limit values

The input signal is monitored at the upper and lower limit values. By default the following limits are set for each mode:

Limit value (default)	Voltage signal ±10 V		Current signal 0 to 20 mA		Current signal 4 to 20 mA	
Upper maximum limit value	10 V	32767 (0x7FFF)	20 mA	32767 (0x7FFF)	20 mA	32767 (0x7FFF)
Lower minimum limit value	-10 V	-32767 (0x8001)	0 mA	0[1)]	4 mA	0[2)]

Table 222: Limit values for voltage and current signals

1) The analog value is limited down to 0.
2) Due to the default limit value, the analog value is limited to a minimum of 0 at currents <4 mA.

Limit value (default)	Temperature measurement		Resistance measurement	
Upper maximum limit value	800.0°C	8000 (0x1F40)	4000.0 Ω	32767 (0x7FFF)
Lower minimum limit value	-200.0°C	-2000 (0xF830)	0 Ω	0

Table 223: Limit values for temperature and resistance measurement

Other limit values can be defined if necessary. These are activated automatically by writing the limit value register (see "Lower limit value" and "Upper limit value"). From this point on, the analog values will be monitored and limited according to the new limits. The results of monitoring are displayed in the status register (see "Input status").

Application example of setting limit values

A negative limit value must be configured in order to measure values <4 mA with a current signal of 4 to 20 mA: 0 mA corresponds to the value -8192 (0xE000).

Lower limit value

Name:
X1CfO_AI1_LowerLim
X1CfO_AI2_LowerLim

These registers can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set (see "Input status").

Data type	Value
INT	-32,768 to 32,767
UINT	0 to 65535

Information:

When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.

Upper limit value

Name:
X1CfO_AI1_UpperLim
X1CfO_AI2_UpperLim

These registers can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set (see "Input status").

Data type	Value
INT	0 to 32,767
UINT	0 to 65535

4.12.2.28.2.1 Digital inputs

Unfiltered

The input status is recorded in a 100 µs cycle.

Filtered

The filtered status is transferred in a 100 µs cycle.

Filtering takes place asynchronously in an interval of 100 µs.

Digital input filter

Name:
X2CfO_DI_Filter

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs.

Data type	Value	Filter
USINT	0	No SW filter
	1	0.1 ms
	...	...
	250	25 ms - Higher values are limited to this value

Input state of digital inputs 1 to 14

Name:
DigitalInput01 to DigitalInput14

These registers are used to indicate the input state of digital inputs 1 to 14.

Data type	Value
USINT	See bit structure.

Bit structure of register 4096:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input status of digital input 1
...		...	
7	DigitalInput08	0 or 1	Input status of digital input 8

Bit structure of register 4097:

Bit	Name	Value	Information
0	DigitalInput09	0 or 1	Input status of digital input 9
...		...	
5	DigitalInput14	0 or 1	Input status of digital input 14

4.12.2.28.2.2 Edge detection

Digital inputs 11 to 14 can be used for fast edge detection. This runs parallel to all other functions such as counters, etc. This function does not use the digital input filter.

The edge detection function measures edges with µs precision. 2 units are available. A master and a slave edge can be configured for each unit. At each master edge, the timestamp of the master edge and the differential time to the previous slave edge (if present) are logged. A "Master count" can always be utilized to determine how many edges have been detected since the last task class cycle. The timestamp is based on the system time of the CPU.

The combination of rising/falling edges of each channel can be used to configure the following functions for each unit:

Function	Description
Edge time	Measure an edge time
Period duration	Measure the master and differential time
Gate time	Measure the master and differential time
Time offset	Measure the master and differential time of edges on different channels

Edge detection unit - Mode settings

The edge detection unit needs to be configured according to the desired function.

Function	Description
Basic timestamp, master edge mode	The current system time is saved as the master time at the time of the edge.
Timestamp and/or differential time, master and slave edge mode	The slave edge starts the measurement and the system time is saved temporarily. When the master edge occurs, the current system time is saved as the master time and the difference between the master and slave edges is calculated.

Name:
X2CfO_EdgeDetectUnit01Mode
X2CfO_EdgeDetectUnit02Mode

These registers are used to configure the mode of the basic function for either just the master edge or both master and slave edges.

Data type	Value	Information
USINT	0x00	Edge detection disabled on Unit0x: Time measurement not possible
	0x80	Edge detection enabled on Unit0x: Reaction only possible for master edge, no differential measurement possible
	0xC0	Edge detection enabled on Unit0x: Reaction possible for configured master and slave edges

Edge detection unit - Selection of master edge

Name:
X2CfO_EdgeDetectUnit01Master
X2CfO_EdgeDetectUnit02Master

These registers are used to select the source of the master edge for the respective unit. Either the rising or falling edge of one of the 4 fast digital input channels can be selected. Only one edge can be selected for each unit.

Data type	Value	Information
USINT	0	Digital input channel 11: Rising edge
	2	Digital input channel 12: Rising edge
	4	Digital input channel 13: Rising edge
	6	Digital input channel 14: Rising edge
	1	Digital input channel 11: Falling edge
	3	Digital input channel 12: Falling edge
	5	Digital input channel 13: Falling edge
	7	Digital input channel 14: Falling edge

Edge detection unit - Selection of slave edge

Name:
X2CfO_EdgeDetectUnit01Slave
X2CfO_EdgeDetectUnit02Slave

These registers are used to select the source of the slave edge for the respective unit. Either the rising or falling edge of one of the 4 fast digital input channels can be selected. Only one edge can be selected for each unit.

Data type	Value	Information
USINT	0	Digital input channel 11: Rising edge
	2	Digital input channel 12: Rising edge
	4	Digital input channel 13: Rising edge
	6	Digital input channel 14: Rising edge
	1	Digital input channel 11: Falling edge
	3	Digital input channel 12: Falling edge
	5	Digital input channel 13: Falling edge
	7	Digital input channel 14: Falling edge

Edge detection unit - Master edge counter

Name:
EdgeDetect01Mastercount
EdgeDetect02Mastercount

These registers hold the counter values of the detected master edges. The counter value is used to detect new measurements.

Data type	Value	Information
INT	-32,768 to 32,767	Running counter: Number of detected master edges

Edge detection unit - Master edge timestamp

Name:
EdgeDetect01Mastertime
EdgeDetect02Mastertime

The exact CPU system time of the respective unit is saved to these registers when a master edge occurs. If multiple master edges occur within a single cycle (task class), then the time of the last edge is shown.

Data type	Value	Information
DINT	-2,147,483,648 to 2,147,483,647	CPU system time of master edge [µs]
