Table 537: X20ET8819 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions

2) Spacing is based on the width of the X20BB80 bus base. Up to two X20HB2880 or X20HB2881 hub expansion modules and one X20PS9400 power supply module are also always required for the Ethernet analysis tool.

4.24.2.4 LED status indicators

Figure	LED	Color	Status	Description
	S/E[1]	Green/red		Status/Error LED. The statuses of this LED are described in section 4.24.2.5 "S/E LED".
	L/A IF1	Green	On	A link to the remote station has been established.
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus
	L/A IF2	Green	On	A link to the remote station has been established.
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus

1) The Status/Error LED is a green/red dual LED.

4.24.2.5 S/E LED

The Status/Error LED is a green and red dual LED.

Red - Error	Description
On	This error can occur only in Analysis mode. If packets are lost when in Analysis mode, the red Status LED lights up. Remedy: Use the "MODE" switch to reduce the number of bytes in the received packets (see 4.24.2.14 "Analysis mode" on page 2297). As soon as no packets are lost for longer than 1 s, it switches back to green.

Table 538: Status/error LED is red: LED indicates error

Green - Status	Description
Off	The Ethernet analysis tool is either booting or not receiving power.
Green flickering (approx. 10 Hz)	The analysis tool is in Service mode: Analysis tool disabled, go to website to update firmware (see 4.24.2.13 "Firmware update" on page 2296)
Single flash (approx. 1 Hz)	The external trigger is active. No data is currently being recorded. No data has been recorded since turned on.
Double flash (approx. 1 Hz)	The external trigger is active. No data is currently being recorded. However, the analysis tool has recorded data at least once. This means that the trigger has been triggered at least once.
On	The analysis tool is active, and is recording all received packets.

Table 539: Status/error LED is green: LED indicates operation

System failure error codes

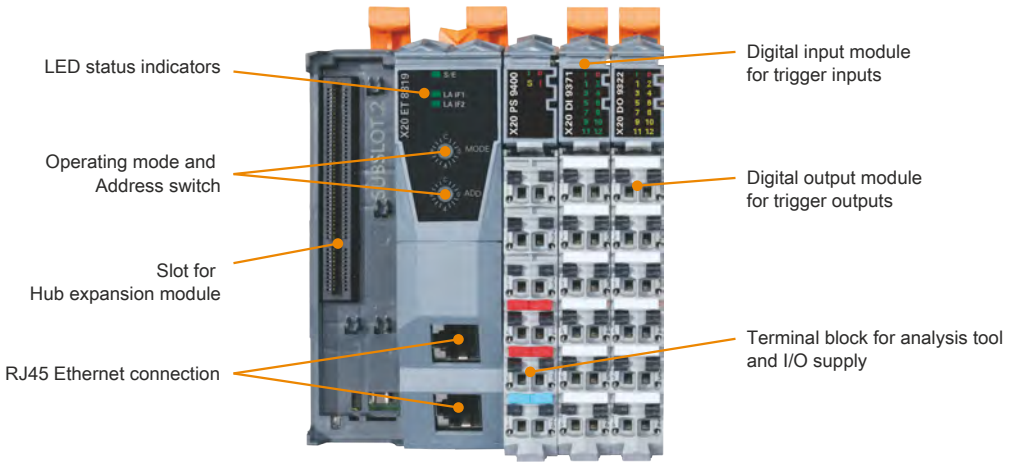
Incorrect node number or defective hardware can cause a system failure error. The error code is indicated by the red error LED using four switch-on phases. The switch-on phases have a duration of either 150 ms or 600 ms. Error code output is repeated cyclically after 2 seconds.

Key: • ... 150 ms
− ... 600 ms
Delay ... 2 sec. delay

Error description	Error code indicated by red status LED									
RAM error: The module is defective and must be replaced.	•	•	•	−	Pause	•	•	•	−	Pause
Wrong node number	•	−	−	−	Pause	•	−	−	−	Pause
Hardware errors: The module or a system component is defective and must be replaced.	−	•	•	−	Pause	−	•	•	−	Pause

Table 540: Status/Error LED as Error LED - System failure error codes

4.24.2.6 Operating and connection elements

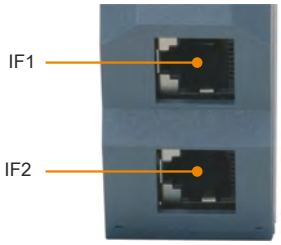


4.24.2.7 Operating mode and address switch

switches	Description
MODE	Specifies the mode in which the analysis tool is run (see 4.24.2.14 "Analysis mode" on page 2297)
ADD	The following addresses are derived from the position of the ADD switch: • Own IP address (192.168.0.ADD) • Analysis mode: Destination MAC (01:00:5 e: 00:00: ADD) • Analysis mode: MulticastIP 239.0.0.ADD Note: Position 0 is not permitted

4.24.2.8 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.24.2.9 Hardware configuration 1

If the Ethernet analysis tool is run without additional hub expansion modules, then recording is only possible on port T0. The analysis tool must be connected to an available hub port in the system.

Information:

An X20HB288x module is not permitted in this hardware configuration.

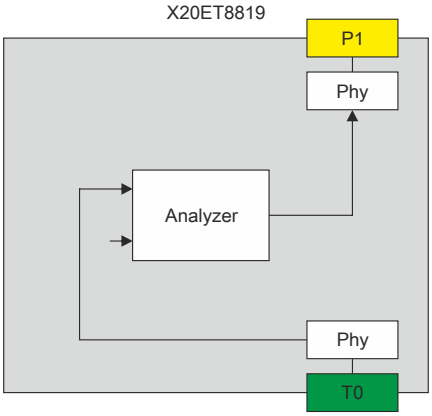


Figure 371: Diagram of hardware configuration 1

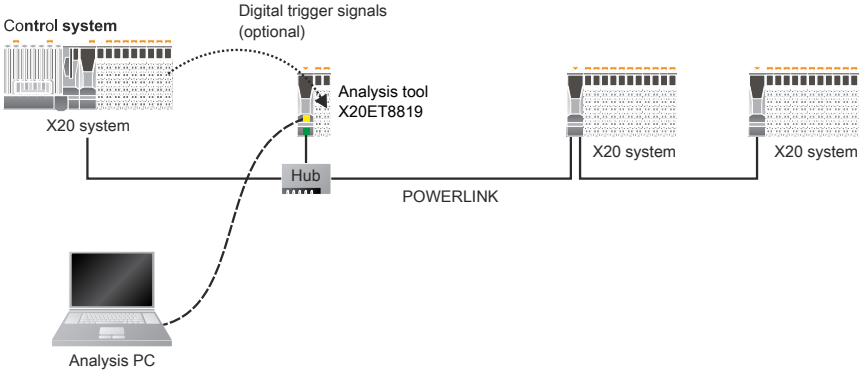

Figure 372: Example application of hardware configuration 1

4.24.2.10 Hardware configuration 2

Extending the Ethernet analysis tool with an X20HB2880 or X20HB2881 allows even full-duplex lines to be recorded as well. In this case ports T1 and T2 are analyzed.

Information:

Only the required X20HB288x module is permitted in this hardware configuration. A second X20HB288x module would produce different behavior (see Hardware configuration 3).

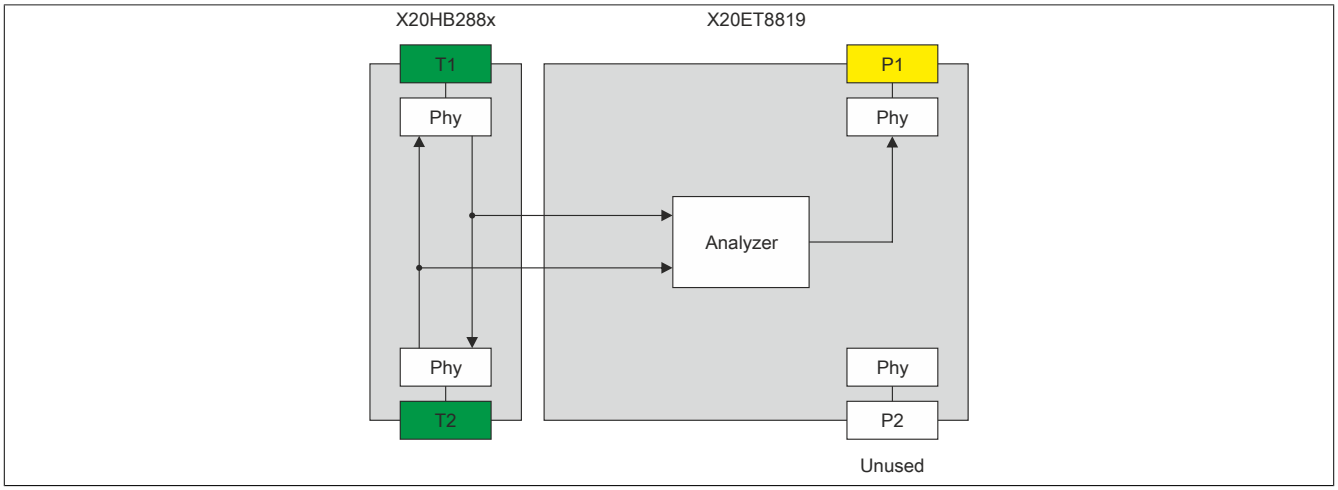

Figure 373: Diagram of hardware configuration 2

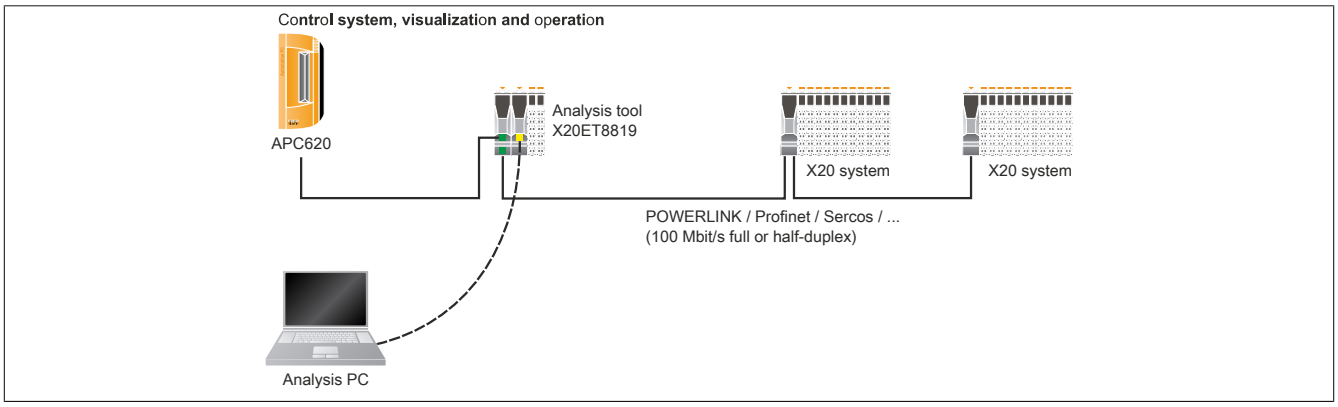

Figure 374: Example application of hardware configuration 2

4.24.2.11 Hardware configuration 3a

Simultaneous data recording at two locations in the network is possible by using two X20HB2880 or X20HB2881. **Only** data from T1 and T3 is analyzed.

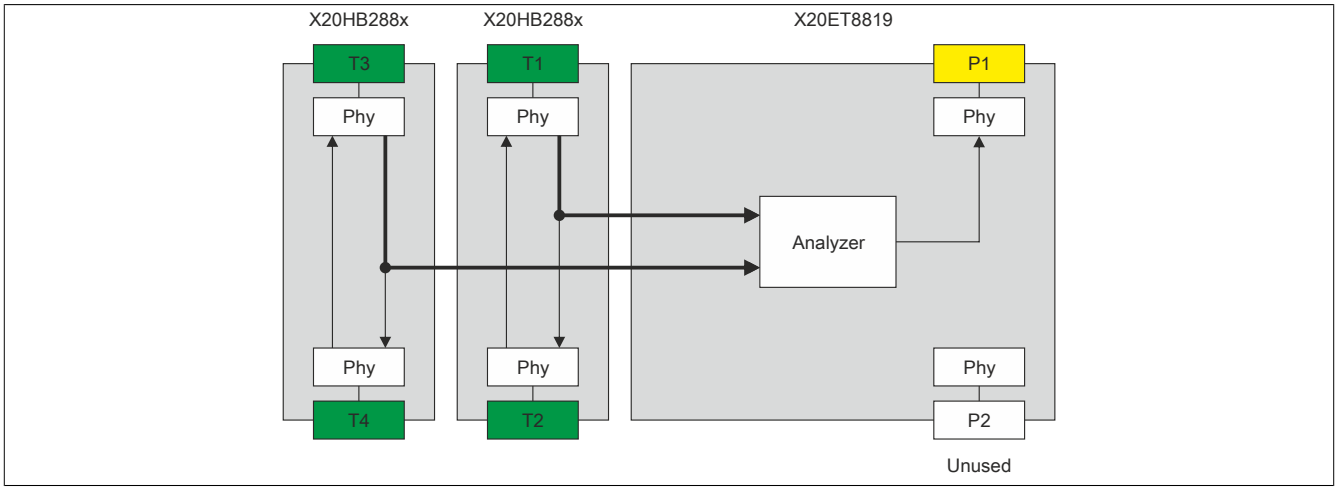

Figure 375: Diagram of hardware configuration 3a

Example application 1 shows data being recorded simultaneously from two hubs.

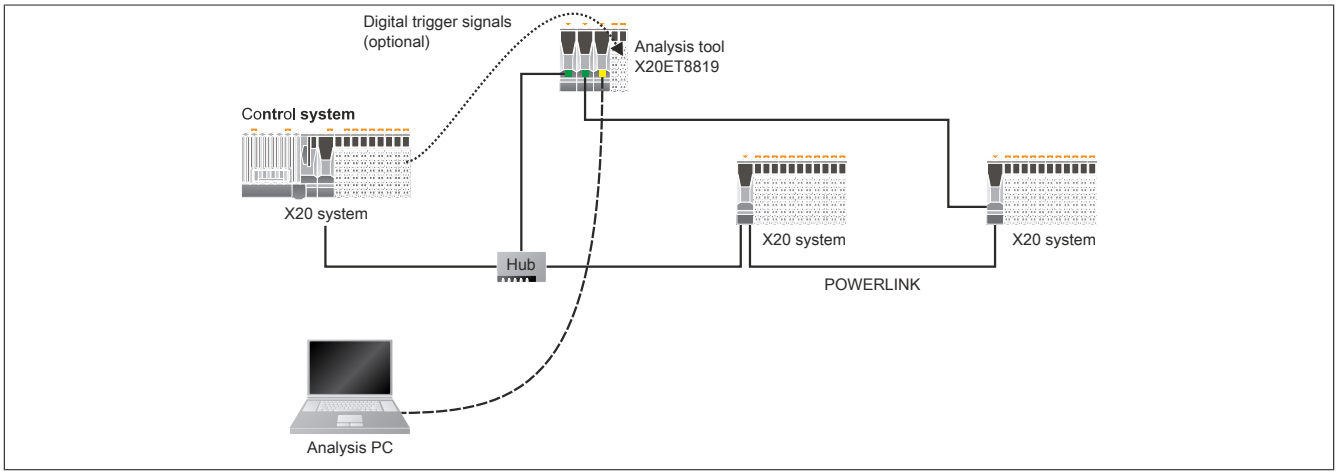

Figure 376: Example application 1 of hardware configuration 3, connection via hubs

The two hub expansion modules can also be inserted in series in the network. It should be noted that in this case data recording is only possible in one direction at a time.

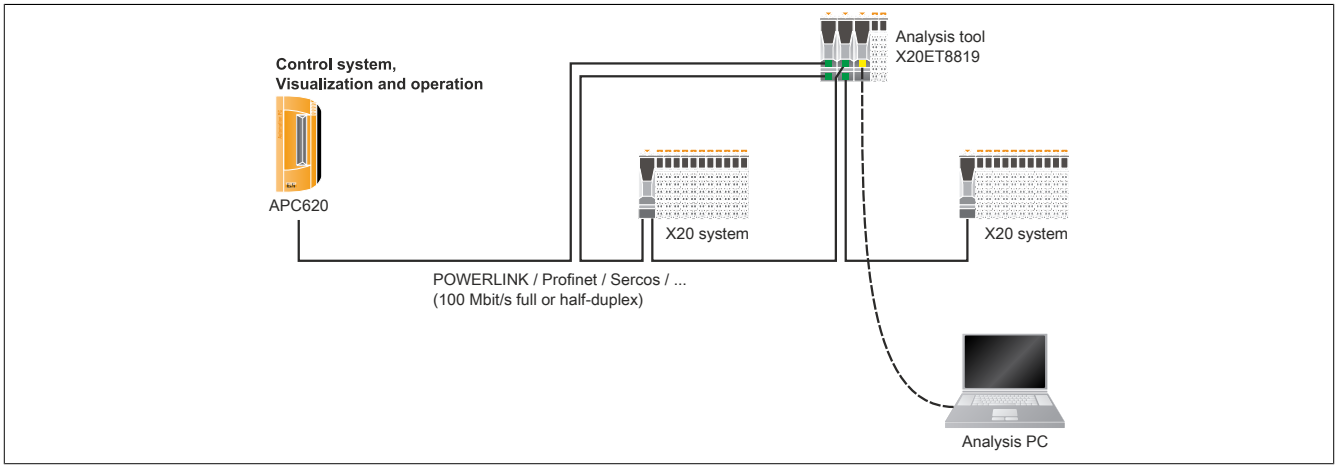

Figure 377: Example application 2 of hardware configuration 3, connection in line

4.24.2.12 Hardware configuration 3b

With firmware V 1.03 and higher, data traffic in half-duplex networks (e.g. POWERLINK) is recorded in both directions.

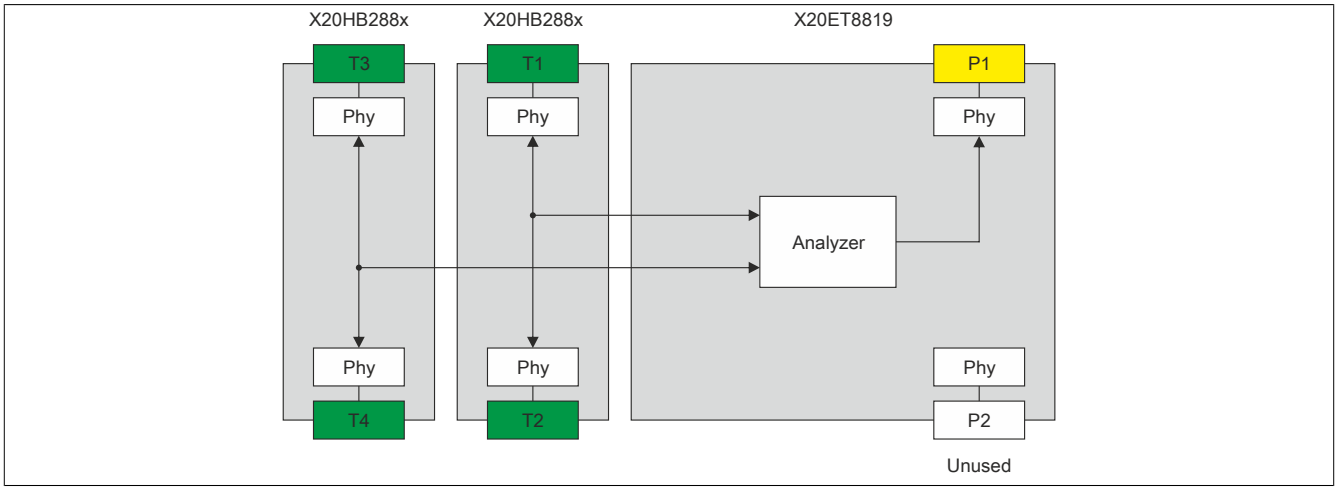

Figure 378: Diagram of hardware configuration 3b

4.24.2.13 Firmware update

To update the firmware, the webpage of the X20ET8819 module must be opened when in service mode. To do this, set the MODE switch to 0 and ADD to a value between 0x1 and 0xF. When the hardware is restarted now, the module will enter service mode. A connection can be established to the webpage using a web browser via the interface IF1 (P1) and the IP address 192.168.0.ADD. The update is started by selecting "Firmware Download".

Figure 379: Start firmware update

4.24.2.13.1 Firmware history

Version	Comment
1.05	Continuous product improvement for analysis mode A with frame lengths >1016 bytes.
1.04	• New analysis mode: In this mode, every package is recorded in its original size. • If two X20HB288x modules are used, data traffic on half-duplex networks can be recorded in both directions.
1.02	Support for trigger outputs: The X20DO9322 can now be used as the second I/O module.
1.00	First version

4.24.2.14 Analysis mode

Each time an incoming packet is analyzed, (see hardware configurations 1 to 3), the analysis tool saves the reception timestamp, various flags and the first 'n' bytes of data from the received packet in capture frames. These frames are sent via IF 1 (P1).

The number of recorded data bytes, 'n', is set with the operating mode switch MODE. This defines the number of packets that are sent for each capture frame.

MODE	n	p/s	Description
0	-	-	Service mode
1	24	148800	45 packets fit in a capture frame: (1514-64) / (24+8) = 45 packets 2	40	148800	3	64	148800	This is the first setting at which complete packets fit in the capture frame (minimum packet with 60 byte payload). 20 packets can fit in one capture frame, however this setting could cause problems on the analysis PC because there is not much idle time between the capture frames. 4	80	128000	
5	120	88000	
6	196	56000	
7	280	40000	
8	716	16000	2 packets fit in a capture frame: (716+8)*2 + 64 = 1512 bytes A setting 'n' > 716 has the disadvantage that a network with full capacity would not be able to be analyzed.
9	24 to 1440	-	The analysis tool selects the largest possible value for 'n' itself due to the packet volume of the last capture frame that was sent. This means that each capture frame can be assigned a different 'n' value. 'n' is always a multiple of 4 and can assume values between 24 and 1440.
A	-	-	Up to a size of 1440 bytes every packet is recorded in its original size.
B - F	-	-	Reserved

Note:

- A change in the position of the MODE switch from 1 to A will be applied online during operation.
- If the S/E LED is red, then the number of bytes to be recorded should be reduced.

4.24.2.15 Using trigger inputs

The Ethernet analysis tool launches the first connected I/O module in the standard function model. The X2X link is configured with a fixed cycle of 1 ms. If this configuration contains digital input data (digital input module X20DI9371), the first 4 digital inputs will be included in the packet header.

4.24.2.15.1 Background

When looking for very complicated errors, it is usually not possible to find a trigger condition on the network. It is often difficult to discern whether the cause of the problem is even associated with the Ethernet communication or somewhere else. The fact that such errors are extremely rare makes finding them that much harder.
A permanent record of network frames through the module X20ET8819 would exceed storage capabilities of the recording software due to the large amount of data. The trigger inputs on the X20ET8819 offer an additional way to circumvent this problem. Analysis of the network can be started or stopped when a specific event occurs.

In most cases, the problem can be indicated using a digital signal. The CPU can detect errors or irregularities (e.g. failure of a network slave), for example, and then set a digital output on the local I/O bus. If this signal is connected to a digital input on the Ethernet analysis tool, then the module is able to evaluate this information and trigger a response such as pausing an active recording.

4.24.2.15.2 Evaluation of the inputs on the analysis tool X20ET8819

Input 1 - 4

The first 4 inputs will be inserted only in the packet header by the X20ET8819. The recording software from B&R (OmniPeek full version and plugin) can determine how the signals are interpreted.

Input 5 - 7

If the recording software is unable to evaluate the first 4 inputs (Wireshark, OmniPeek, various other capture tools), then inputs 5 - 7 are used to control the Ethernet analysis tool X20ET8819 directly.

Input	Name	Description
5	ExternActivate	Recording will not start automatically if this input is set to HIGH when the analysis tool is turned on. The module waits for a positive edge on input 6.
6	ExternStart	Recording begins when a positive edge occurs on this input. The value in 'captureId', offset 49 in the capture frame header is incremented to indicate to the receiving tool that a new recording has been started. When recording using the recording software from B&R, this information can be used to switch to a new ring buffer and to store the last one.
7	ExternStop	Recording stops when a negative edge occurs on this input.
8 - 12	-	Reserved

Table 541: Evaluation of inputs 5 - 7 on the analysis tool

Example 1

A drive is started one time each minute. After 10 to 30 hours, a problem arises on a network station shortly after starting the drive. To analyze the error, the Ethernet communication is recorded between when the start command is issued and when the error occurs.

Problems:

Due to the large amount of data it is not possible to record the entire 30 hours. Someone would have to stay on the analysis PC the whole time to stop recording when the error occurs.

Solution:

Input	Description
ExternActivate	Input permanently wired to 24 VDC = Activates the external trigger function
ExternStart / ExternStop	Connect both inputs to the same digital output that the master uses to notify the X20ET8819 when to start and stop recording. The master can, for example, always set the output before the drive start command and reset it as soon as the startup has been completed. When the master detects an error, it only has stop setting the output. This would mean that after 30 hours the recording is certain to contain the time period in which the error occurred and as well as a few prior recordings of proper startups for comparison.

Table 542: Function of the inputs in Example 1

Example 2

A system containing multiple X20 I/O systems on the POWERLINK network is experiencing sporadic failures. An I/O slave suddenly fails for no apparent reason after running properly for a long time. To analyze whether the failure is network related, the time before the failure must be recorded.

Problems:

The master has no indication as to when and why the problem occurs. That means there is no start condition for the recording. Someone would have to stay on the analysis PC the whole time to stop recording when the error occurs.

Solution:

Input	Description
ExternActivate	Input permanently wired to 24 VDC = Activates the external trigger function
ExternStart	Input permanently wired to 24 VDC = Ensures that the recording starts immediately when the X20ET8819 is turned on
ExternStop	Connect input to a digital output on the affected I/O slave, which is permanently set to 1 by the program. As soon as the slave fails the first time and resets the digital outputs, recording is stopped by the negative edge on ExternStop and is not started again.

Table 543: Function of the inputs in Example 2

4.24.2.16 Using trigger outputs

Output	Name	Description
1	FrameError	As soon as a frame error (CRC, Oversize, Preamble, Noise or Alignment) occurs, this output is set for 10 ms.
2 - 12	-	Reserved

Table 544: Using trigger outputs in the event of an error

4.24.2.17 B&R recording software

The recording plug-in (for WildPackets OmniPeek™) to decode the capture frames is available for download in the Download section on the B&R homepage.

B&R provides the following free recording software for the module in the Downloads section of the B&R website:

- Ethernet Analyzer Plugin for Wildpackets OmniPeek™
- B&R Network Analyzer (stand-alone solution)

4.24.3 X20(c)HB8815

4.24.3.1 General information

The POWERLINK TCP/IP gateway enables the exchange of all types of application data (HMI, diagnostics, parameter data, etc.) between a POWERLINK V2 network and a TCP/IP network. It functions like a layer 2 switch, with the exception that cyclic POWERLINK packets are not routed to the ETH port.

With respect to the functionality of layer 2 switches, it should be mentioned that the gateway uses the store-and-forward principle. Gateway functionality doesn't need to be configured separately.
When the gateway receives a frame, it saves the MAC address of the sender and the corresponding interface in the source address table (SAT). If the destination address is found in the SAT, the gateway routes the frame to the corresponding interface. Frames with a broadcast or multicast address are always routed to all interfaces.

When IP packets are received at the "ETH" port that are larger than the MTU configured for POWERLINK, they are fragmented, if permitted.

- "ETH" port: Interface for TCP/IP network
- "PLK" port: Interface for POWERLINK network

> **Information:**
>
> **I/O modules cannot be operated with the X20HB8815.**
> **POWERLINK V1 is not supported.**

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) (see www.ethernet-powerlink.org).

The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the gateway. This means that a basic device provides up to 2 POWERLINK ports.

- POWERLINK
- Up to 2 slots for hub expansion modules
- 3x / 5x POWERLINK hub

4.24.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

> **For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.**

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.24.3.3 Order data

Model number	Short description	Figure
	X20 hub system	
X20HB8815	X20 POWERLINK - TCP/IP gateway, can be expanded with active hub modules, 2x RJ45	
X20cHB8815	X20 POWERLINK - TCP/IP gateway, coated, can be expanded with active hub modules, 2x RJ45	
	Required accessories	
	System modules for bus controllers	
X20BB80	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included	
X20cBB80	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/X20AC0SR1 included	
	System modules for expandable bus controllers	
X20BB81	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	
X20BB82	X20 bus base, for X20 base module (BC, HB, etc.) and X20 power supply module, with 2 expansion slots for 2 X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	
X20cBB81	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	
X20cBB82	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included	
	System modules for the X20 hub system	
X20PS8002	X20 power supply module for standalone hub and compact link selector	
X20cPS8002	X20 power supply module, coated, for standalone hub and compact link selector	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	
	Optional accessories	
	System modules for the X20 hub system

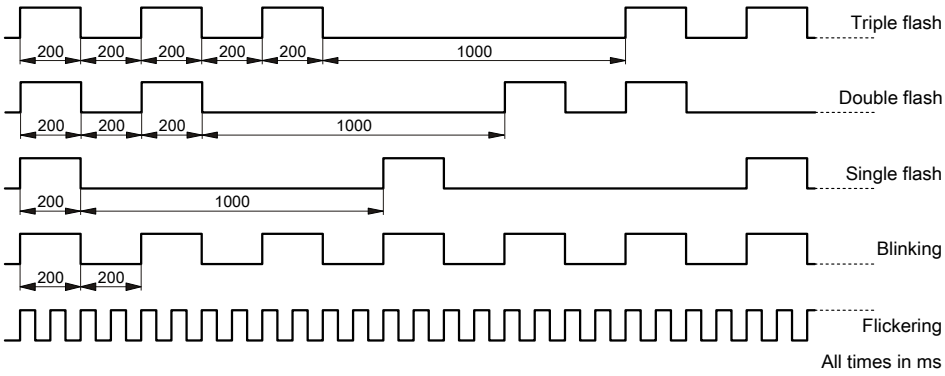
2) Spacing is based on the width of the X20BB80 bus base. Up to two X20HB2880 or X20HB2881 hub expansion modules and one X20PS8002 supply module are also always required for the gateway.

4.24.3.5 LED status indicators

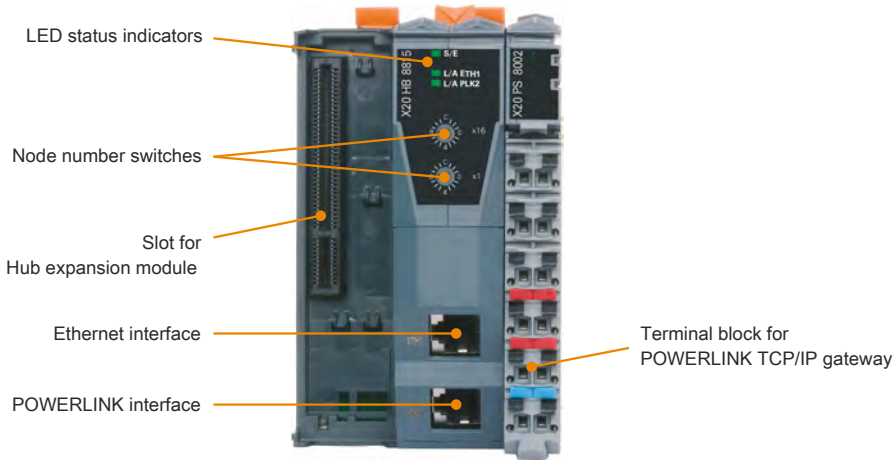
Figure	LED	Color	Status	Description
	S/E[1]	Green	Off	No power supply or mode is NOT_ACTIVE. The controlled node (CN) is either not getting power, or it is in the NOT_ACTIVE state. The CN waits in this state for about 5 seconds after a restart. Communication is not possible with the module. If no POWERLINK communication is detected during these 5 seconds, the CN goes into the BASIC_ETHERNET state (flickering). If POWERLINK communication is detected before this time passes, however, the CN goes directly into the PRE_OPERATIONAL_1 state.
			Flickering	BASIC_ETHERNET mode. The CN has not detected any POWERLINK communication. It is possible to communicate directly with the CN in this state (e.g. with UDP, IP, etc.). If POWERLINK communication is detected while in this state, the CN goes into the PRE_OPERATIONAL_1 state.
			Single flash	PRE_OPERATIONAL_1 mode. When operated on a POWERLINK V1 manager, the CN goes directly into the PRE_OPERATIONAL_2 state. When operated on a POWERLINK V2 manager, the CN waits until an SoC frame is received and then goes into the PRE_OPERATIONAL_2 state.
			Double flash	PRE_OPERATIONAL_2 mode. The CN is normally configured by the manager in this state. Issuing a command (POWERLINK V2) or setting the data valid flag in the output data (POWERLINK V1) then switches to the READY_TO_OPERATE state.
			Triple flash	READY_TO_OPERATE mode. In a POWERLINK V1 network, the CN automatically switches to the OPERATIONAL state as soon as input data is present. In a POWERLINK V2 network, the manager switches to the OPERATIONAL state by issuing a command.
			On	OPERATIONAL mode. PDO mapping is active and cyclic data is being evaluated.
			Blinking	STOPPED mode. No output data is produced or input data supplied. It is only possible to enter or leave this state after the manager has given the appropriate command.
		Red	On	The controlled node (CN) is in an error state (failed Ethernet frames, increased number of collisions on the network, etc.). If an error occurs in the following states, then the green LED blinks over the red LED: • PRE_OPERATIONAL_1 • PRE_OPERATIONAL_2 • READY_TO_OPERATE  Note: • The LED blinks red several times immediately after startup. This is not an error. • The LED is lit red for CNs with configured physical node number 0 but that have not yet been assigned a node number via Dynamic Node Allocation (DNA).
	L/A IFx	Green	On	A link to the peer station has been established (TCP/IP network).
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus
	L/A PLK2	Green	On	A link to the peer station has been established (POWERLINK network).
			Blinking	A link to the remote station has been established. Indicates Ethernet activity is taking place on the bus

1) The Status/Error LED "S/E" is a green/red dual LED.

Status LED - Blinking patterns



4.24.3.6 Operating and connection elements



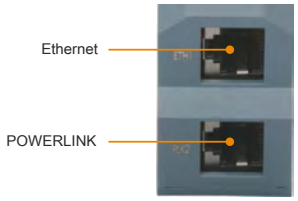
4.24.3.7 POWERLINK node number switches

The node number for a POWERLINK station is set using its two number switches.

Switch position	Description
0x00	Reserved, switch position not permitted
0x01 - 0xEF	Node number of the POWERLINK node. Operation as controlled node.
0xF0 - 0xFF	Reserved, switch position not permitted

4.24.3.8 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

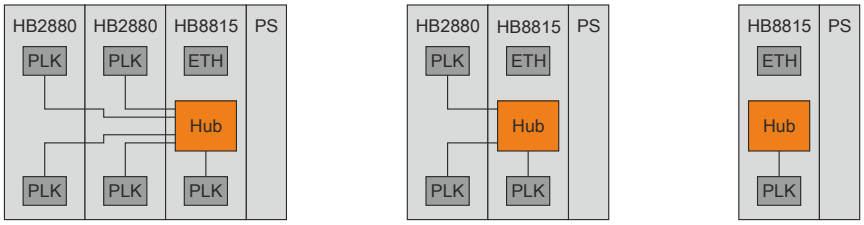
4.24.3.9 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the module:

Bus base	Slots for hub expansion modules
X20BB81	1
X20BB82	2

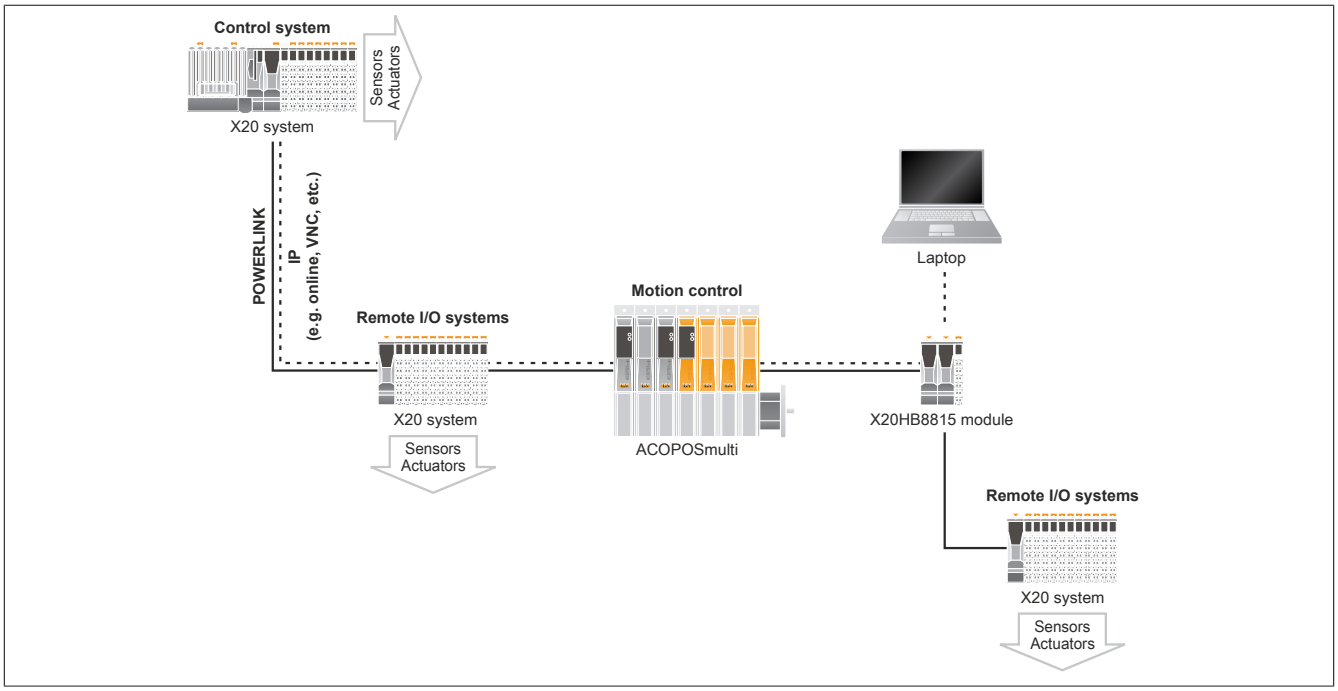
Table 547: Slots for hub expansion modules for various bus bases

The hub expansion module for the gateway is a 2x hub, which allows the gateway to be expanded into a 5x POWERLINK hub.

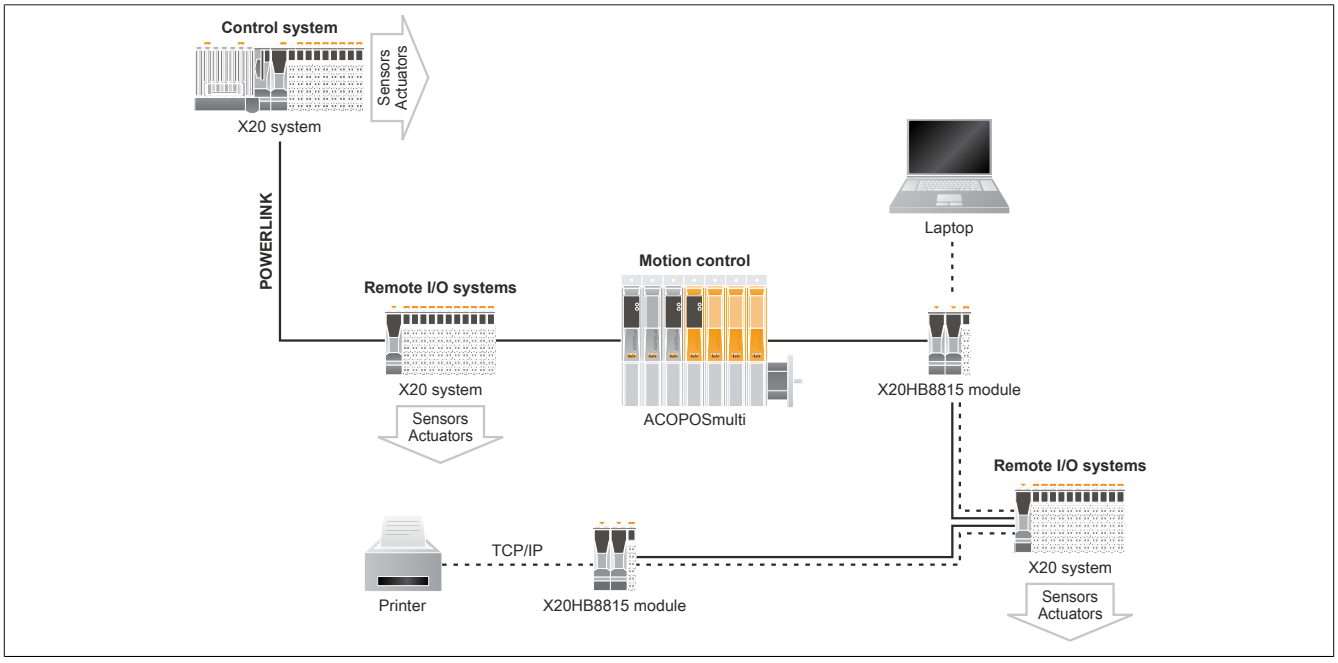


4.24.3.10 Usage examples

Example 1: Online connection with Automation Studio via POWERLINK



Example 2: Use the POWERLINK network for TCP/IP services



4.24.3.11 SG3

This module is not supported on SG3 targets.

4.24.3.12 Firmware

This module comes with preinstalled firmware. The firmware is a component of Automation Studio. The module is automatically updated to this version.

To update the firmware included in Automation Studio, the hardware must be upgraded (see "Project management" / "Automation Studio upgrade" in the help system).

When using a 3rd-party device as a POWERLINK manager, the firmware update can be performed via the integrated Web server.

4.24.3.13 MTU size

Automatic MTU configuration is currently not supported. The MTU size is set to 300 (default value).

The MTU can be set manually under "Asynchronous Optimization" -> "Local ASnd MTU" in the I/O configuration of the module.

4.24.3.14 Asynchronous send priority

If needed, a higher asynchronous send priority can be assigned to the module. The setting for this is made in the I/O configuration of the module under "Asynchronous Optimization" -> "Asynchronous Send Priority".

Information:

If the priority is set too high, it is possible in some circumstances that other POWERLINK stations cannot send their asynchronous data on time.

4.24.4 X20(c)HB8880

4.24.4.1 General information

The X20 hub is a device that can be used universally in standard Ethernet networks or POWERLINK networks. It is suitable for 100 Mbit/s (Fast Ethernet) networks.

The bus modules expanded to the left allow connection of up to 2 hub expansion modules in addition to the hub base module. This means that a single base device provides up to 6 hub interfaces.

- 2x / 4x / 6x Fast Ethernet hub
- Modular construction
- Easily expandable

4.24.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

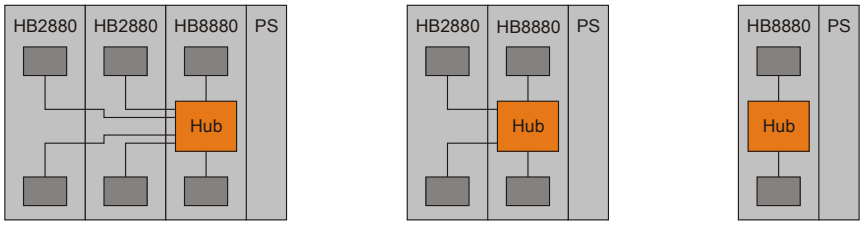
4.24.4.8 Slot for hub expansion modules

Depending on the bus base, up to 2 hub expansion modules can be installed on the left side of the X20 hub:

Bus base	Slots for hub expansion modules
X20BB81	1
X20BB82	2

The hub expansion module is a 2x hub, which allows the hub base module to be expanded into a 6x hub.



6x with X20BB82 4x with X20BB81 2x with X20BB80

4.24.5 X20HB88G0

4.24.5.1 General information

The X20BB81 bus module has an expansion slot on the left side, and therefore the X20HB88G0 junction base module has an additional slot available for an X20HB28G0 EtherCAT junction module. This means that a single base device provides 4 interfaces.

- 4x EtherCAT junction base module

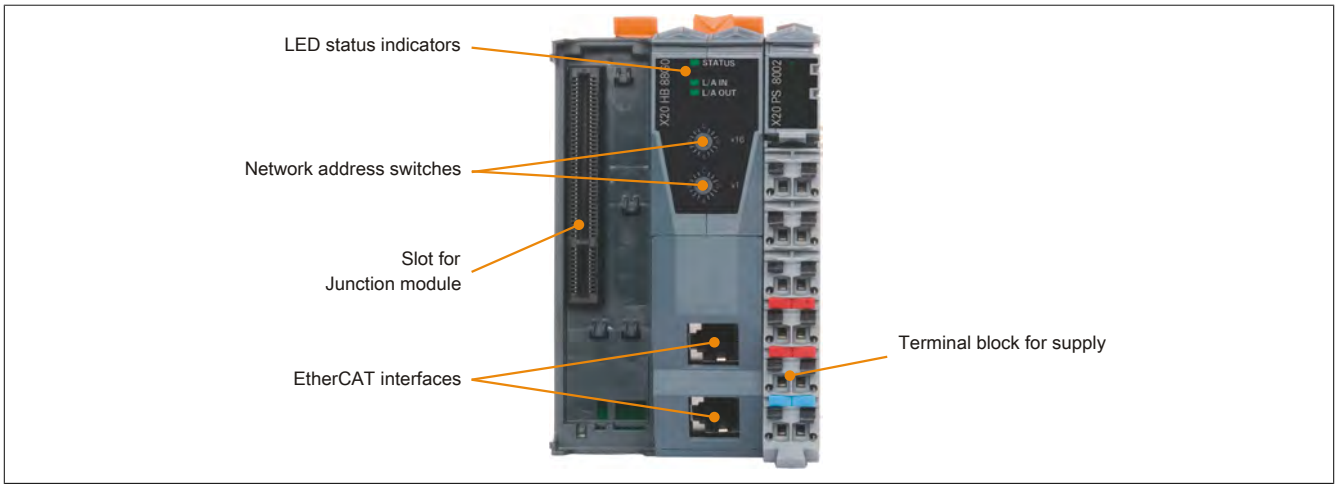
2) For the interfaces on the X20HB28G0 EtherCAT junction module, the hub runtime is 1.1 µs instead of 750 ns.
3) Spacing is based on the width of the X20BB80 bus base. One X20HB28G0 junction module and one X20PS8002 supply module are also always required for the base module.

4.24.5.4 LED status indicators

Figure	LED	Color	Status	Description
	STATUS[1]	Green	On	Junction base module is in OPERATIONAL mode.
			Blinking	PREOPERATIONAL mode
			1 pulse	SAFE OPERATIONAL mode
			Flickering	The junction base module has started and is not yet in INIT mode or it is in BOOTSTRAP mode (e.g. while downloading firmware).
			Off	INIT mode
		Red	On	A critical communication or application error has occurred.
			Blinking	Invalid configuration data
			1 pulse	The junction base module has an internal error and changed the EtherCAT status on its own
			2 pulses	Watchdog timeout (process data watchdog or EtherCAT watchdog)
			Flickering	Error in the start procedure (INIT mode has been achieved, but the error indicator bit in the AL status register is set)
			Off	No error
	L/A IN L/A OUT	Green	Blinking	The respective LED blinks when Ethernet activity is present (PORT OPEN) on the corresponding interface.
			On	Connection (link) established, however no communication (PORT OPEN).
			Off	No physical Ethernet connection exists (PORT CLOSED).

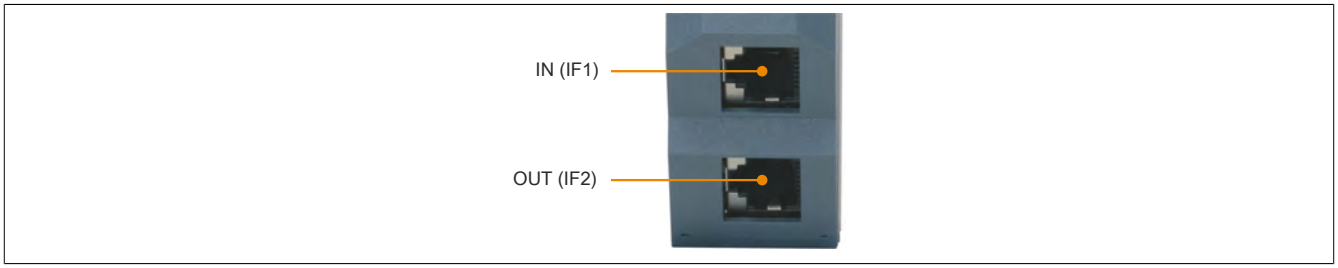
1) The Status LED is a green/red dual LED.

4.24.5.5 Operating and connection elements



4.24.5.6 EtherCAT interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 Shielded RJ45	1	TXD	Transmit data
	2	TXD\	Transmit data\
	3	RXD	Receive data
	4	Termination	
	5	Termination	
	6	RXD\	Receive data\
	7	Termination	
	8	Termination	

4.24.5.7 Network address switch

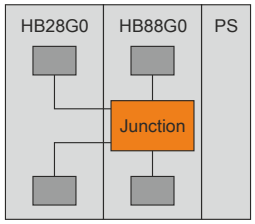
A slave alias address can be set using the two network address switches on the base module. During the initialization phase (during startup), the base module writes the value of the address switch to the ESC register 0x12 or 0x13. However, the value is only accepted in the register if the value of the switch value is between 0x00 and 0xFA (decimal 250).

Switch position	Description
0x00 to 0xFA	Writes the address switch value to the "Station Alias" register.
0xFB to 0xFE	Address switch value not used. ESC Alias registers not changed.
0xFF	Address switch value not used. ESC Alias registers not changed. The base module boots with the default values if the address switch is set to the value "0xFF" before a restart. All set parameters remain unchanged in flash memory.

The master determines whether the alias address is used for the slave addressing by setting the corresponding bit in the ESC DL control register (bit 24).

4.24.5.8 Slot for EtherCAT junction module

The junction base module is equipped with an additional slot. The X20HB28G0 EtherCAT junction module is operated on this slot, providing 4 additional interfaces.



4x with X20BB81

4.25 Motor controllers

The motor controllers offer extensive possibilities for controlling motors, valves or resistive loads and are particularly well suited for controlling brush DC motors. Each output is assigned a status LED.

4.25.1 Brief information

Product ID	Short description	on page
X20MM2436	X20 PWM motor module, 24 to 39 VDC ±25%, 2 PWM motor bridges, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, configurable as incremental encoder	2318
X20MM3332	X20 digital motor module, 24 VDC, 3 digital outputs, full bridge (H bridge), 3 A continuous current, 5 A peak current	2338
X20MM4331	X20 digital motor module, 24 VDC, 4 digital outputs, half bridge, 3 A continuous current, 5 A peak current	2353
X20MM4456	X20 PWM motor module, 24 to 48 VDC ±25%, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 4 digital inputs 24 VDC, sink, configurable as incremental encoder	2366
X20SM1426	X20 stepper motor module, 1 motor connection, 1 A continuous current, 1.2 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder	2387
X20SM1436	X20 stepper motor module, module supply 24-39 VDC ±25%, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder	2432

4.25.2 X20MM2436

4.25.2.1 General information

The motor bridge module is used to control 2 DC motors with a nominal voltage of 24 to 39 VDC ±25% at a nominal current up to 3 A. The module can be reconfigured and used in current controller mode for controlling inductive loads. The module is also equipped with 4 digital inputs, which can be used as incremental counters. Each motor is controlled with a full-bridge (H-bridge). This enables the motors to be moved in both directions.

- 2x outputs (H bridge) with PWM control and 24 to 39 VDC ±25% supply
- 3 A nominal current (3.5 A max current)
- 15 Hz to 50 kHz frequency, 16-bit
- Frequency mode with 10 to 6553.5 Hz or 1 to 655.35 Hz resolution.
- PWM resolution, 15-bit + sign, minimum 10 ns
- Configurable dither
- 2x 2 inputs 24V, can be configured as AB
- Sink connection
- 1-wire connections

4.25.2.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input state of the corresponding digital input
	M1, M2	Orange	On	Output 1 or 2 is active

1) Depending on the configuration, a firmware update can take up to several minutes.

4.25.2.5 Pinout

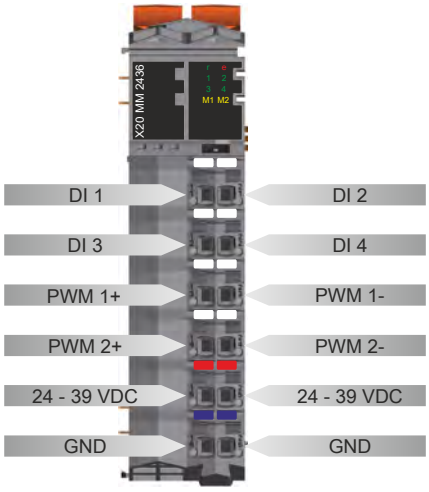
In accordance with the EN60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 3.5 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

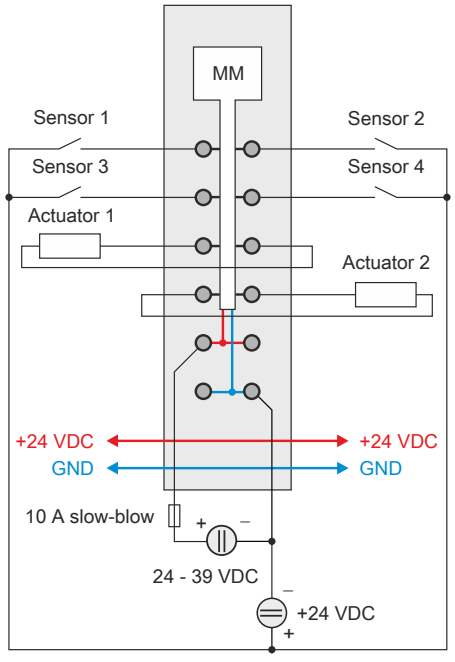
Shielded motor cables must be used in order to meet the limits according to the EN55011 standard (emissions).



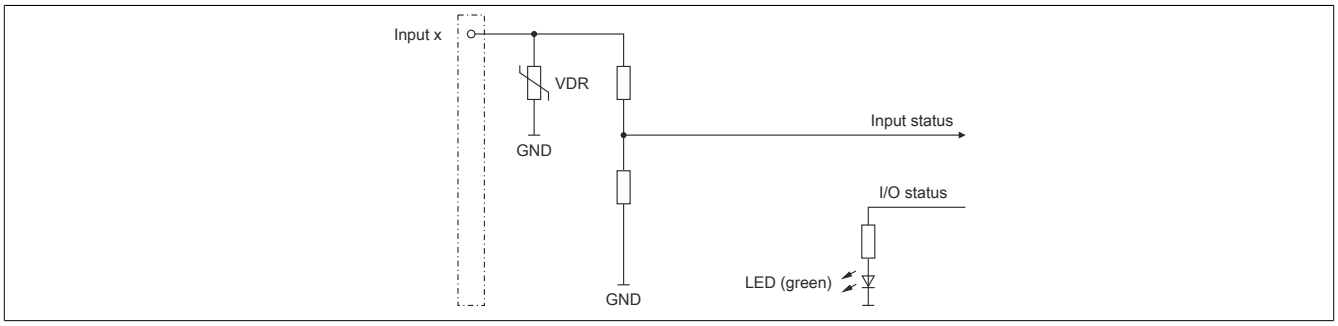
4.25.2.6 Connection example

Information:

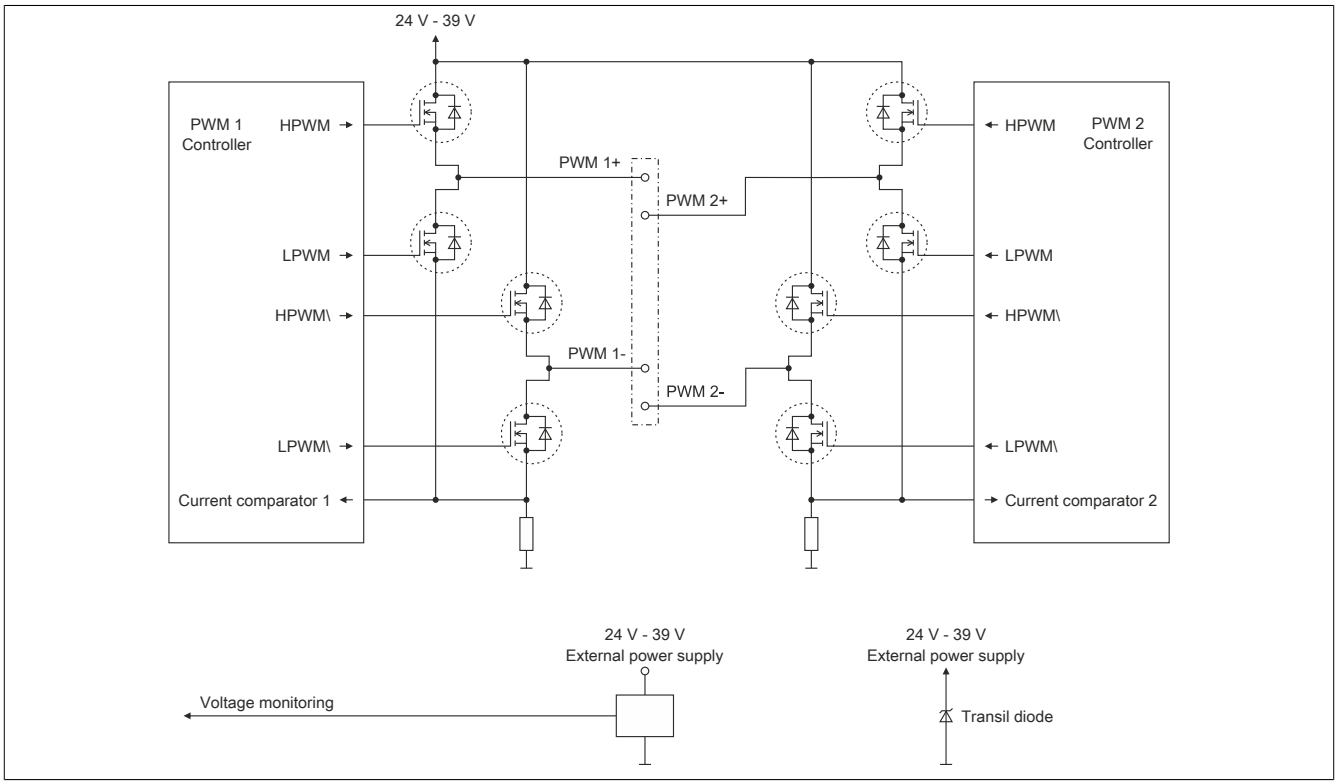
This module can only be operated if supplied with power via the terminal block.



4.25.2.7 Input circuit diagram



4.25.2.8 Output circuit diagram



4.25.2.9 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 7 A is not exceeded on the power supply terminals of the power element.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of wiring, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of wiring, see table):

I_{Mains}	≤	I_b	≤	I_Z
Mains	≤	Fuse	≤	Line/cable

Wire cross section [mm²]	Maximum current load for cable cross section I_Z / rated current for overcurrent protection I_b [A] depending on the type of wiring at an ambient air temperature of 40°C in accordance with IEC 60204-1			
	B1	B2	C	E
1.5	13.5 / 13	13.1 / 10	15.2 / 13	16.1 / 16
2.5	18.3 / 16	16.5 / 16	21 / 20	22 / 20

Table 554: Cable cross section of the mains supply line depending on the type of wiring

The tripping current of the fuse must not exceed the rated current for overcurrent protection I_b.

Type of wiring	Description
B1	Wires in conduit or cable duct
B2	Cables in conduit or cable duct
C	Cables or wires on walls
E	Cables or wires on open-ended cable tray

Table 555: Type of wiring used for the mains supply line

4.25.2.10 Derating

To ensure proper operation, the following items must be taken into consideration:

- The sum of the square of both effective currents (I_N , peak value must not exceed 3 A) must not exceed 9 A². The boost current of 3.5 A for 2 seconds is an exception.
- Modules next to the motor module can have a maximum power consumption of 1.0 W.
- The derating values listed below must be taken into consideration

Example calculations

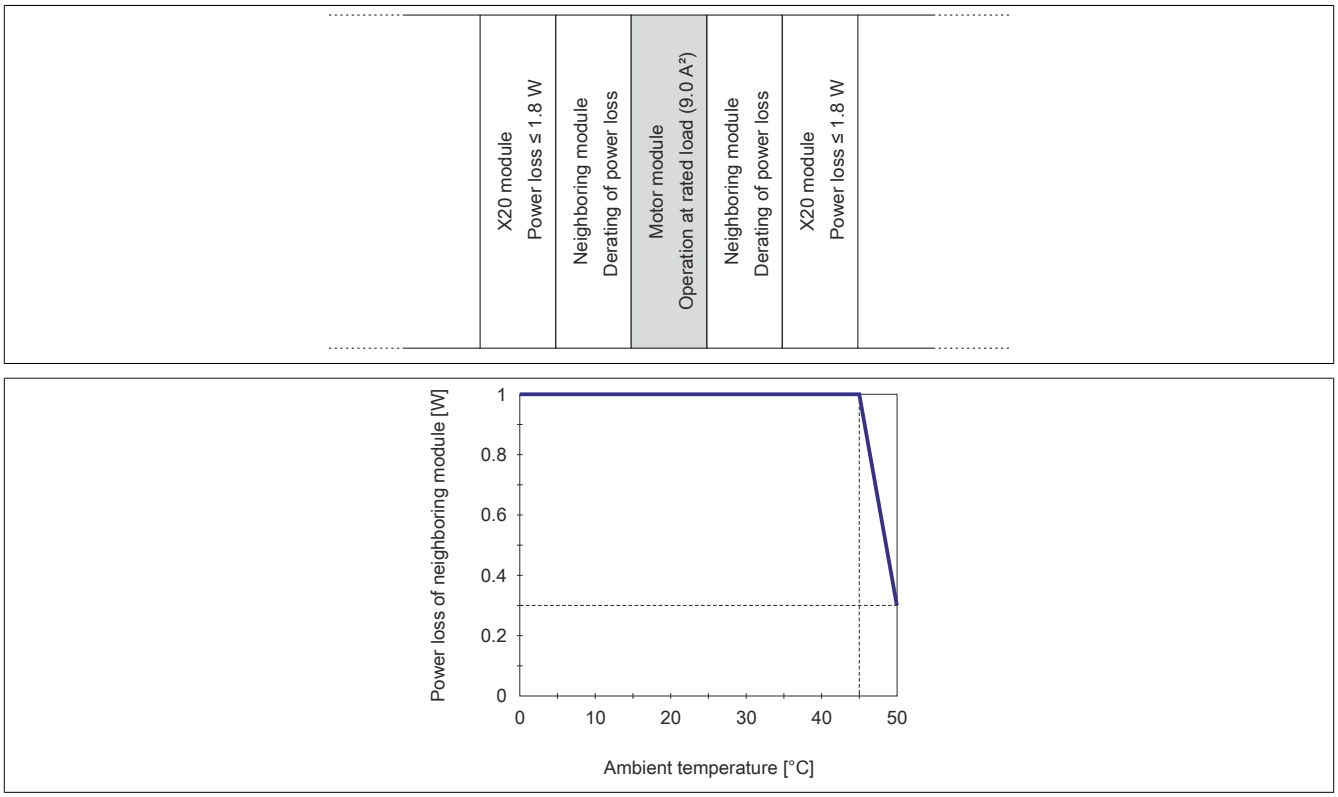
In the following examples, the calculation of I_N^2 is used to check if the current operating state is permitted.

Output current		I_N^2	Operating state permitted
PWM 1	PWM 2		
3.0 A	0 A	$I_N^2 = 3\ A \cdot 3\ A + 0\ A \cdot 0A = 9\ A^2$	Yes
2.1 A	2.1 A	$I_N^2 = 2.1\ A \cdot 2.1\ A + 2.1\ A \cdot 2.1\ A = 8.82\ A^2$	Yes
2.8 A	2.0 A	$I_N^2 = 2.8\ A \cdot 2.8\ A + 2\ A \cdot 2\ A = 11.84\ A^2$	for max. 2 s[1)]

1) The cooling time, which means operation <9 A², must be at least 5 times as long as the time of the overload.

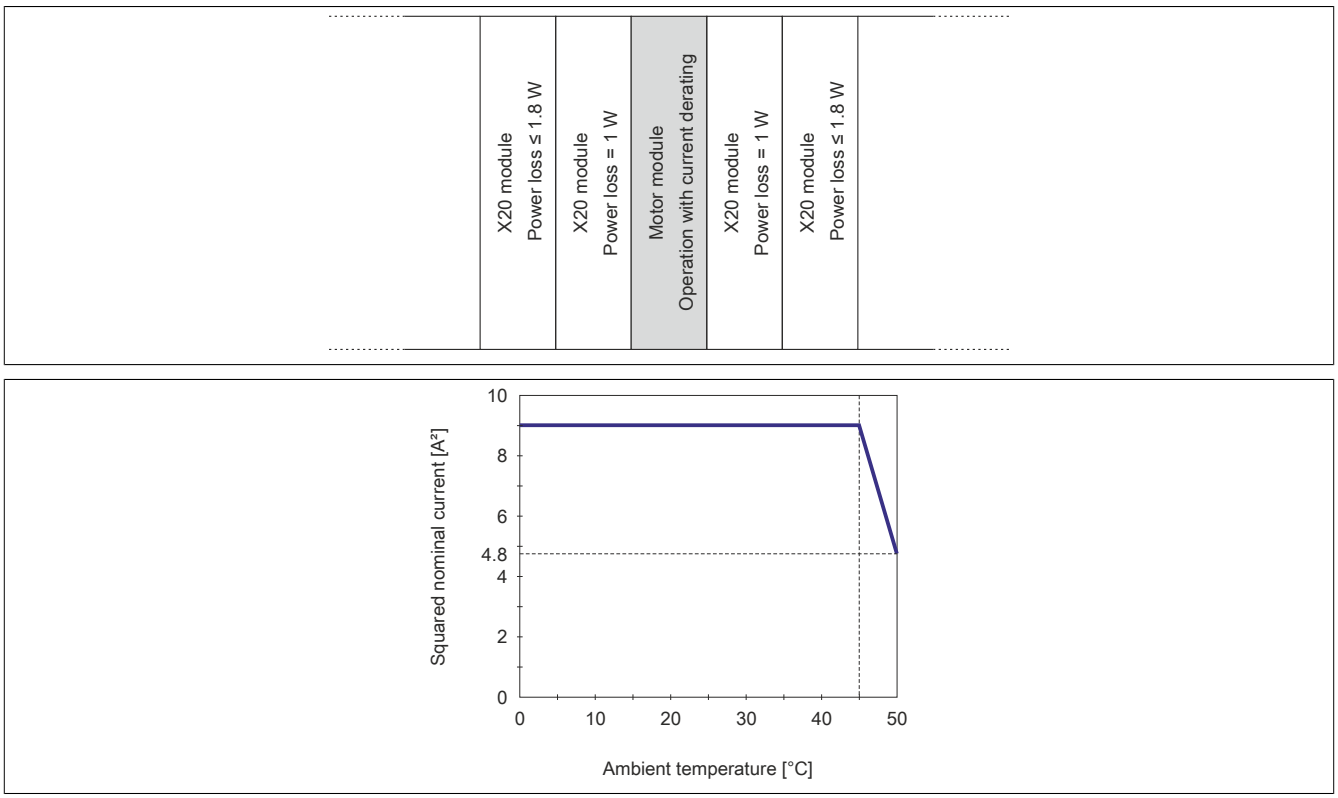
Power loss derating for neighboring modules

Modules directly next to the motor module can have a power loss of 1.0 W. If the motor module is operated with the rated load over the entire temperature range (9.0 A²), a derating for power loss of the neighboring modules must be adhered to starting at 45°C.



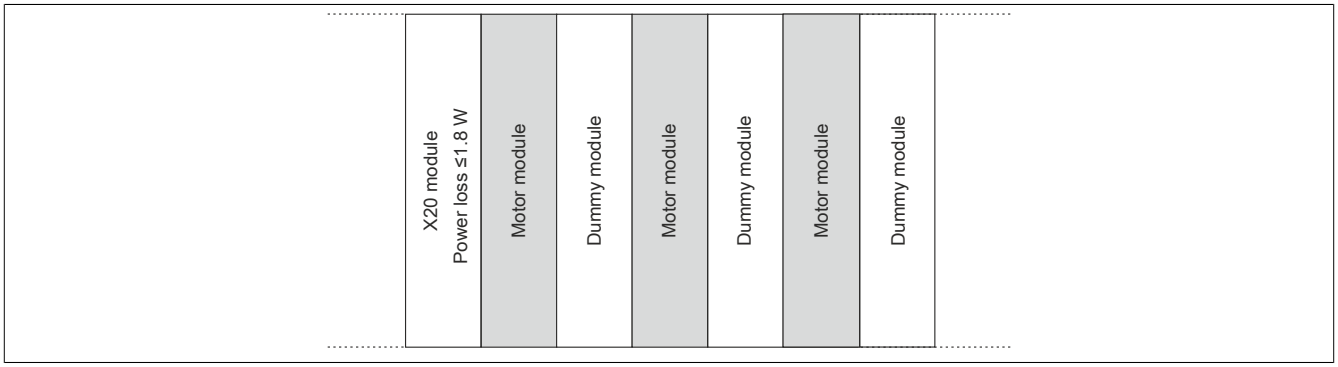
Current derating of the motor module

If the power loss of the neighboring modules to the motor module is 1.0 W, then the current of the motor module must be derated starting at 45°C.



Hardware configuration for multiple motor modules

If three or more motor modules are operated in a cluster, a dummy module must be inserted between the motor modules. There is no derating in this configuration.



4.25.2.11 Monitoring the module supply

The module supply is continually monitored (with firmware Version 3 or higher). If the following limits are exceeded in either direction, an error bit is set.

Upper limit:	>50 V
Lower limit:	<18 V

4.25.2.12 Overvoltage cutoff

If the supply voltage on the module exceeds 50V (e.g. through feedback during generator operation), then both PWM outputs are disabled (PWM output pins are shorted). The outputs are reactivated as soon as the supply voltage is back in the valid range. Switching the outputs on again can cause an open load error in current mode (depending on the current setpoint and load inductance) as well as with any other abrupt change to the current setpoint value.

4.25.2.13 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The PWM outputs are disabled (short-circuited)

Once the module temperature sinks to 83°C, the error bit is automatically cleared by the module and the outputs become operational again.

4.25.2.14 Register description

4.25.2.14.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.25.2.14.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.
2) Firmware version 3 or higher.
3) Firmware version 7.00 or higher.
4) Firmware version 4 or higher.

4.25.2.14.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.25.2.14.4 Operating mode description

Beginning with firmware version 7.00, the module is equipped with the "Frequency mode 1" and "Frequency mode 2" operating modes in addition to "Standard PWM/current mode".
The following table lists the differences between the different operating modes:

	Operating mode		
	Standard PWM/current mode	Frequency mode 1	Frequency mode 2
Frequency setting	1x period duration in µs (see register "PWM period duration")	2x In 1/10 or 1/100 Hz (see register "Frequency")	1x In 1/10 or 1/100 Hz (see register "Frequency")
Duty cycle / Current setting	2x -100 to 100% (see register "PWM pulse width")	1x -100 to 100% (see register "Duty cycle")	2x -100 to 100% (see register "Duty cycle")
Dithering	Yes	No	No
Decay mode setting	Yes	No	No
PWM/current mode selection	Yes	No	No
Other	PWM start from channel 2 offset 180° compared to channel 1	Due to a different frequency, a fixed phase relationship between channel 1 and channel 2 is not possible.	PWM start from channel 2 offset 180° compared to channel 1
	3.5 A per channel	1 A per channel	3.5 A per channel

4.25.2.14.5 Configuration

4.25.2.14.5.1 Counter configuration 1

Name:
CounterConfig01

This register can be used to configure counter 1.

This function is available beginning with firmware Version 4.

Data type	Value
SINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Sets the type of counter.	000	AB counter with 4x evaluation (A = DI 1, B = DI 2)
		001	Event counter (DI 1)
		010	Period measurement (DI 1)
		011	Gate measurement (DI 1)
		100	ABR counter with 4x evaluation (A = DI 1, B = DI 2, R = DI 3, Reference enable = DI 4). Copies counter 1 to counter 2 on a reference pulse. Counter 2 is shown in the I/O map, even if it is disabled in counter configuration 2.
		101 to 111	No counter. Counter is disabled and not shown in the I/O map.
3	Measurement starts	0	At rising edge on DI 1 Referencing at rising edge on DI 3 (only for ABR counters)
		1	At falling edge on DI 1 Referencing at falling edge on DI 3 (only for ABR counters)
4 - 5	Set the counter frequency for gate or period measurement	00	4 MHz
		01	External via DI 2
		10	31.25 kHz
		11	Reserved
6 - 7	Set the reference input	00	Reference input always enabled (DI 3)
		01	Reserved
		10	Enable for reference input (DI 3) if DI 4 = 0
		11	Enable for reference input (DI 3) if DI 4 = 1

4.25.2.14.5.2 Counter configuration 2

Name:
CounterConfig02

This register can be used to configure counter 2. Unlike counter 1, this counter cannot be configured as an ABR counter.

This function is available beginning with firmware Version 4.

Data type	Value
SINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Sets the type of counter.	000	AB counter with 4x evaluation (A = DI 3, B = DI 4)
		001	Event counter (DI 3)
		010	Period measurement (DI 3)
		011	Gate measurement (DI 3)
		100 to 111	No counter. Counter is disabled and not shown in the I/O map.
3	Measurement starts	0	At rising edge on DI 3
		1	At falling edge on DI 3
4 - 5	Set the counter frequency for gate or period measurement	00	4 MHz
		01	External via DI 4
		10	31.25 kHz
		11	Reserved
6 - 7	Reserved	-	

4.25.2.14.5.3 Module configuration

Name:
ConfigOutput03

The output control for each motor can be configured separately in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Output 1	0	PWM control
		1	Current control
1	Output 2	0	PWM control
		1	Current control
2 - 3	Operating mode[1)]	00	Standard PWM/current mode
		01	Frequency mode 1 (bit 0 to 1 ignored)
		10	Frequency mode 2 (bit 0 to 1 ignored)
		11	Reserved
4 - 7	Reserved	-	

1) Firmware version 7.00 or higher.

Information:

After switching on or resetting, only one switchover from the default "Standard PWM/current mode" is allowed after "Frequency mode 1" or "Frequency mode 2". Later reconfigurations into another mode are ignored by the module's firmware.

4.25.2.14.5.4 Registers for "Standard PWM/current mode" operating mode

PWM period duration

Name:
PeriodDurationPWM01PWM02

This register can be used to set the period duration between 20 µs (50 kHz) and 65535 µs (15 Hz).

Data type	Value	Information
UINT	20 to 65535	Time in µs

PWM pulse width

Name:
PulseWidthCurrentPWM01 to PulseWidthCurrentPWM02

The PWM pulse width (PWM mode) or current setting (in current mode) is entered in this register according to the setting in the module configuration register. A negative value changes the output polarity.

Information:

This module uses the same scaling as the X67MM2436 module to maintain software compatibility. Current values larger than 3.5 A are limited to 3.5 A.

Derating must also be taken into consideration when using both channels (see section 4.25.2.10 "Derating").

PWM mode

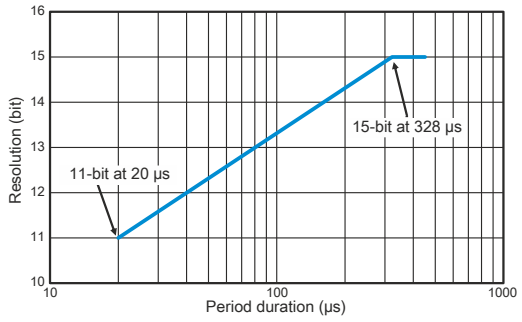
Data type	Value	Output +	Output -
INT	32767	High	Low
	16384	PWM 50/50	Low
	0	Low	Low
	-16384	Low	PWM 50/50
	-32767	Low	High

Current mode

Data type	Value	Current mode	Note
INT	22937 to 32767	+3.5 A (max. 2 s)	Limited internally, check derating
	22936	3.5 A (max. 2 s)	Derating must be taken into consideration.
	19660	+3 A	
	0	0 A	
	-19660	-3 A	
	-22936	-3.5 A (max. 2 s)	Derating must be taken into consideration.
	-22937 to -32767	-3.5 A (max. 2 s)	Limited internally, check derating

Resolution/Derating

As mentioned earlier in the technical data, the PWM resolution is 15-bit (+ sign). This value is derated for a period duration of less than 328 µs because of the minimal PWM timing resolution (10 ns) (see following diagram). With the minimum PWM period duration of 20 µs, the PWM has 11-bit resolution (+ sign):



Decay configuration

Name:
DecayConfig

The decay configuration determines the method and dynamics of current reduction for inductive loads or motors.

"Slow decay" is configured by default. In this mode, the current is automatically reduced relatively slowly with resistance in the load. No energy is regenerated into the module.

"Mixed decay" mode is recommended for applications that require a dynamic and linear reduction of current. In this mode, energy is regenerated into the module during part of the PWM cycle (fast decay).

This function is available beginning with firmware Version 3.

Data type	Value
USINT	See bit structure.

Bit structure:

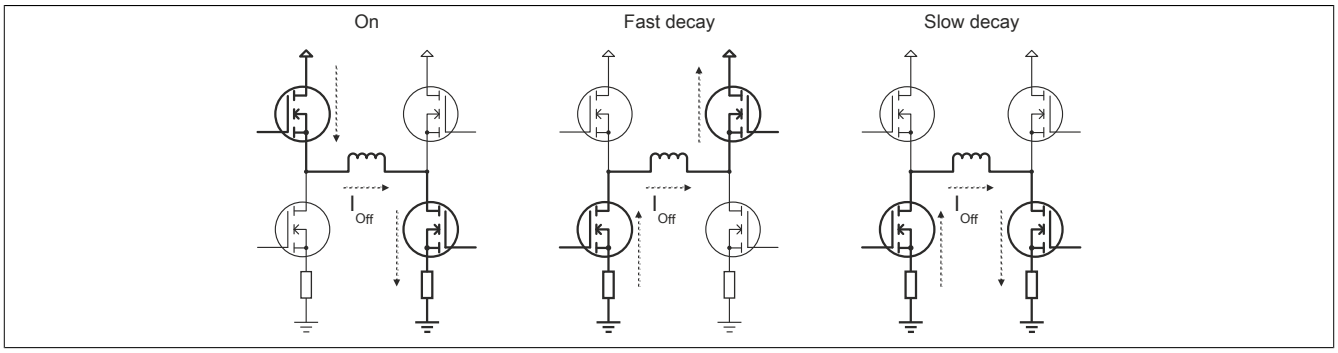
Bit	Description	Value	Information
0 - 1	PWM 1	00	Slow decay (default setting)
		01	Mixed decay
		10 to 11	Reserved
2 - 3	Reserved	0	
4 - 5	PWM 2	00	Slow decay (default setting)
		01	Mixed decay
		10 to 11	Reserved
6 - 7	Reserved	0	

Mixed decay

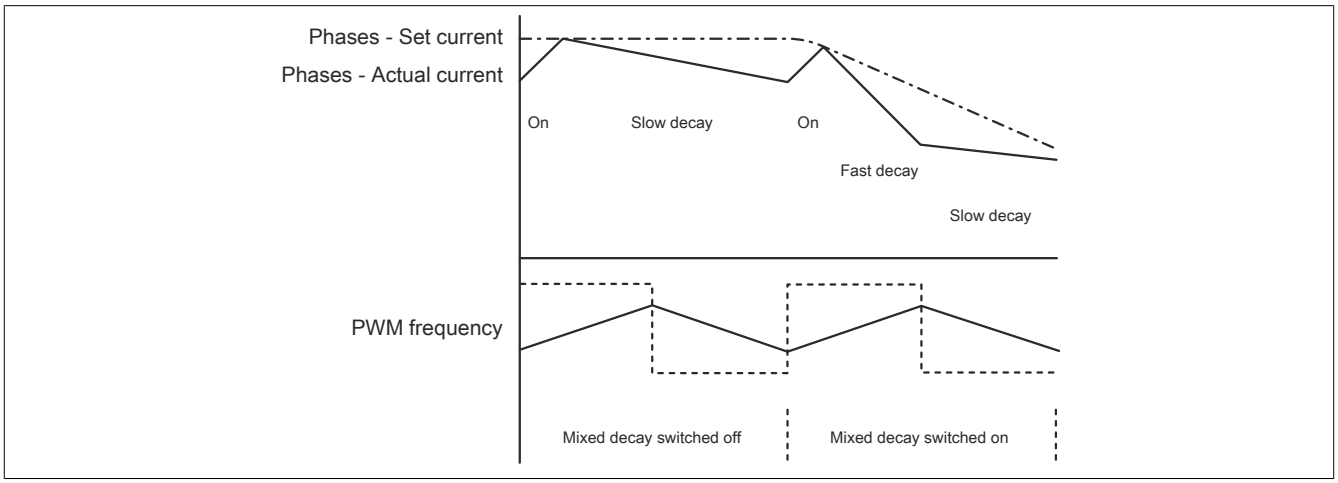
As its name suggests, mixed decay mode is a mix of "slow decay" and "fast decay". This occurs as follows:

A check is made at the beginning of each PWM cycle to determine if the actual current for the phases is below the current setpoint. If this is the case, PWM is enabled (On) until the set current is reached. The system switches to fast decay mode for the rest of the first half of the PWM cycle. If the current setpoint has already been exceeded at the beginning of the PWM cycle (generator operation), the system immediately switches to fast decay mode. The second half of the PWM cycle always takes place in slow decay mode.

This also permits generator operation as long as the valid range for the supply voltage has not been exceeded due to the regeneration into the DC circuit.



Mixed decay - Set / actual current, PWM frequency



Operating DC motors

In PWM mode, the motor current is limited to the maximum current (3.5 A), independent of the supply voltage.

However, the motor switches to generator operation when braking. Because of the counter EMF, which is dependent on the rotary speed, a current is generated in the module that is only limited by the internal resistance of the motor. This is not permitted to exceed 7 A (maximum 2 seconds).

The counter EMF closely corresponds to the voltage needed to achieve this speed. Therefore, the maximum brake current is very easy to calculate with the following formula.

$$I_{Brake} = U_e.Pulse\ width(in\ \%)/100.\frac{1}{R_{Motor}}$$

Example:

Module supply	42 V
Pulse width	16364 (equal to 50%)
Internal resistance of motor	3.5 Ω

$$I_{Brake} = 42V.50/100.\frac{1}{3.5\Omega} = 6A$$

Dither

A dither is used to prevent valves from sticking. This function is supported in both PWM mode and in current mode. The pulse width or current is adjusted according to the dither amplitude and dither frequency.

By default, the dither is active for both outputs as soon as the dither amplitude and dither frequency are set to a value >0. If necessary, the dither can be deactivated for each output individually or simultaneously (see 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale").

Dither amplitude

Name:
ConfigOutput01

This register can be used to configure the amplitude value or pulse width.
0 to 255 corresponds with an amplitude value from 0.0 to 25.5% of the nominal current or the maximum pulse width of 32767.

Data type	Value	Information
USINT	0 to 255	Amplitude value or pulse width

Dither frequency

Name:
ConfigOutput02

This register can be used to set the frequency in 2 Hz steps.

Data type	Value	Information
USINT	0 to 255	Corresponds to 0 to 510 Hz

Dither example

Valve specification	20 to 35% peak to peak of the valve current at 2 A²
	This corresponds to a dither amplitude of ±6.67 to ±11.67% at 3 A. A midrange dither amplitude of 9% at 3 A is selected. This corresponds to a setting of 90.
Dither frequency specification	**40 to 70 Hz**
	A setting of 28 is selected. This corresponds to a frequency of 56 Hz.

4.25.2.14.5.5 Registers for "Frequency mode 1 and 2" operating mode

Frequency

Name:
FrequencyPWM01 to FrequencyPWM02 (frequency mode 1)
FrequencyPWM01PWM02 (frequency mode 2)

The frequency for PWM01 or PWM02 (depends on the frequency mode) can be set individually or together in these registers. The unit is 1/10 or 1/100 Hz depending on how the "FrequencyPrescale" settings are configured. For more information, see the 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale" registers.

Data type	Value	Information
DINT	0	Disabled
	1 to 99	FrequencyPrescale 1/10: 10 Hz FrequencyPrescale 1/100: 1 Hz
	100 to 65535	FrequencyPrescale 1/10: 1/10 * Value = 10 to 6553.5 Hz FrequencyPrescale 1/100: 1/100 * Value = 1 to 655.35 Hz

Duty cycle

Name:
DutyCyclePWM01PWM02 (frequency mode 1)
DutyCyclePWM01 to DutyCyclePWM02 (frequency mode 2)

The duty cycle for the PWM outputs is set individually or separately depending on the frequency mode.

For information about scaling, derating, etc. see the "PWM pulse width" registers (PWM mode).

Important!

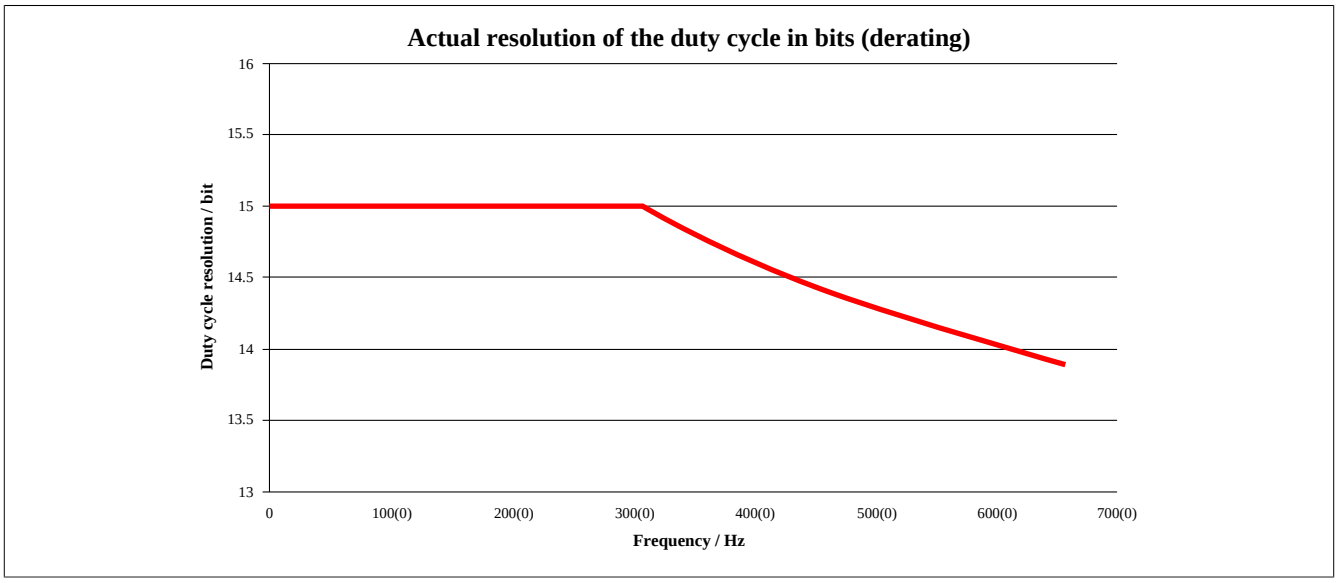
A negative duty cycle can also be configured. In this case, the frequency is output to "PWM1/2" (identical to "Standard PWM/current mode") instead of the "PWM1/2+" output. It is especially important to take this into consideration with actuators that are only able to process positive input values.

Data type	Value
INT	-32768 to 32767

Derating the duty cycle

As with "Standard PWM/current mode", the predefined duty cycle in the frequency modes cannot be implemented over the entire frequency domain with full 15-bit resolution; instead, it is subject to derating.

It is possible to achieve the full 15-bit resolution until about 305 (frequency domain 1) or 3050 Hz (frequency domain 2).



4.25.2.14.6 Communication

4.25.2.14.6.1 Numerator

Name:
Counter01 to Counter02

This register indicates the status of counters 1 and 2. Configuration of the counters is described in sections 4.25.2.14.5.1 "Counter configuration 1" and 4.25.2.14.5.2 "Counter configuration 2". The following counter types or measurements can be configured:

- AB counter
- ABR counter
- Event counter
- Period measurement
- Gate measurement

If counter 1 is configured as an ABR counter, then the register for counter 2 is assigned the current value of counter 1 when the reference pulse occurs.

Data type	Value
INT	-32768 to 32767

Counter function - Assignment of the digital inputs:

Counter function	Counter number	A	B	R	Enable reference	Counter input	Period duration and gate signal	External measuring frequency
Incremental counter	1	DI 1	DI 2	DI 3	DI 4			
	2	DI 3	DI 4					
Event counter	1					DI 1		
	2					DI 3		
Period duration and gate measurement	1						DI 1	DI 2
	2						DI 3	DI 4

4.25.2.14.6.2 Input status

Name:
StatusInput01 to StatusInput04
CounterOverflow01 to CounterOverflow02
RefToggle01

The status of the inputs and counters is mapped in this register.

This function is available beginning with firmware Version 4.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput01	0 or 1	Logical state of input 1
...		...	
3	StatusInput0	0 or 1	Logical state of input 4
4	CounterOverflow01	0	Period duration or gate measurements of counter 1 are within the valid range (0x0 - 0xFFFF). The bit is only valid if overflow detection is enabled (bit 2 = 1 in the 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale" register).
		1	Overflow during period duration or gate measurement (reset with bit 2 = 0 in the 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale" register).
5	CounterOverflow02	0	Period duration or gate measurements of counter 2 are within the valid range (0x0 - 0xFFFF). The bit is only valid if overflow detection is enabled (bit 3 = 1 in the 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale" register).
		1	Overflow during period duration or gate measurement (reset with bit 3 = 0 in the 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale" register).
6	RefToggle01	x	Bit 6 changes value each time the counter state is latched from counter 1 to counter 2. After the module boots, bit 6 = 0.
7	Reserved	-	

4.25.2.14.6.3 Temperature

Name:
Temperature01

The module temperature is displayed in this register.

Data type	Value	Information
SINT	-40 to 125	Module temperature in °C

4.25.2.14.6.4 Error status

Name:
UnderVoltageError
OverVoltageError
OvertemperatureError
OperatingError
CurrentError01 to CurrentError02
OverCurrentError01 to OverCurrentError02

If an error is detected, the corresponding error bit remains set in this register until the error is acknowledged (see 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale").

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	UnderVoltageError	0	No error
		1	Module supply lower limit <18 V
1	OverVoltageError	0	No error
		1	Module supply upper limit >50 V
2	OvertemperatureError	0	No error
		1	Overtemperature
3	OperatingError[1)]	0	No error
		1	Faulty operation
4	CurrentError01	0	No error
		1	Open load error Output 1
5	OverCurrentError01	0	No error
		1	Overcurrent error Output 1
6	CurrentError02	0	No error
		1	Open load error Output 2
7	OverCurrentError02	0	No error
		1	Overcurrent error Output 2

1) Firmware version 7.00 or higher.

Faulty operation

This warning indicates faulty operation of the module. The following table lists possible causes, the module's reaction and how to correct/acknowledge the error.

Cause	Reaction	Correction/Acknowledgment
Default value for "PeriodDuration" or "Frequency" outside of specified range	Default value limited to the specified range	Automatic acknowledgment as soon as the default value is back within specifications
Later reconfiguration of the operating mode (see bits 2 to 3 of the "Module configuration" register)	The new configuration is ignored. The module continues to work in the original operating mode.	The original configuration is restored.

Overcurrent error

An overcurrent error is registered if one of the following conditions is met:

- ≥3.5 or 1 A (frequency mode 1) flow from a PWM output for at least 2 seconds
- ≥5 A flow for 3 consecutive PWM cycles

In both cases, the affected PWM output is deactivated by the firmware (i.e. the pins on the PWM output are short-circuited). The user must acknowledge the error (see 4.25.2.14.6.5 "Error acknowledgment, dither switch-off and FrequencyPrescale") before a PWM output disabled in this manner can be made operational again.

Open load error

An open load error is only registered in current control mode (see 4.25.2.14.5.3 "configuration register") if the current setpoint is not reached. In some cases this can be caused by an open line, although usually the impedance of the load is too high.

4.25.2.14.6.5 Error acknowledgment, dither switch-off and FrequencyPrescale

Name:
ClearError01 to ClearError02
CounterOverflowDetectEnable01 to CounterOverflowDetectEnable02
CounterReset01 to CounterReset02
DitherDisable01 to DitherDisable02
FrequencyPrescale01 to FrequencyPrescale02

This register can be used to acknowledge errors; to enable/disable overflow detection, counters and dither; and to set a prescaler for the frequency domains.

This function is available beginning with firmware Version 4.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ClearError01	0	No effect
		1	Error acknowledgment on output 1 (overcurrent or open load) or acknowledgment from limit switch 1
1	ClearError02	0	No effect
		1	Error acknowledgment on output 2 (overcurrent or open load) or acknowledgment from limit switch 2
2	CounterOverflowDetectEnable01	0	Overflow detection disabled. Bit 4 in the counter status register is reset (see section 4.25.2.14.6.2 "Input status")
		1	Counter 1: Overflow detection enabled.
3	CounterOverflowDetectEnable02	0	Overflow detection disabled. Bit 5 in the counter status register is reset (see section 4.25.2.14.6.2 "Input status")
		1	Counter 2: Overflow detection enabled.
4	CounterReset01	0	Counter 1 is enabled (default).
		1	Counter 1 is set to 0 and disabled. If counter 1 is configured as an ABR counter (see 4.25.2.14.5.1 "Counter configuration 1"), then latch 2 is also set to 0. In this mode, the latched value from counter 1 is stored in counter 2.
5	CounterReset02	0	Counter 2 is enabled (default).
		1	Counter 2 is set to 0 and disabled (no effects if counter 1 is configured as an ABR counter)
6	DitherDisable01	0	Dither for PWM output 1 is enabled (default). The dither frequency and dither amplitude must be >0 (see "Dither").
		1	Dither for PWM output 1 is disabled.
	FrequencyPrescale01[1)]	0	Unit in 1/10 Hz, frequency domain: 10 to 6553.5 Hz
		1	Unit in 1 Hz, frequency domain: 1 to 655.35 Hz
7	DitherDisable02	0	Dither for PWM output 2 is enabled (default). The dither frequency and dither amplitude must be >0 (see "Dither").
		1	Dither for PWM output 2 is disabled.
	FrequencyPrescale02[1)]	0	Unit in 1/10 Hz, frequency domain: 10 to 6553.5 Hz
		1	Unit in 1 Hz, frequency domain: 1 to 655.35 Hz

1) Firmware version 7.00 or higher.

FrequencyPrescale

Beginning with firmware version 7.00, bits 6 to 7 in the "Frequency mode 1 and 2" operating mode have a different meaning.

Instead of enabling/disabling dithering for channel 1 or 2, it toggles the prescaler for the frequency setting between 1/10 and 1/100 Hz.

In "Frequency mode 2" operating mode, only bit 6 (FrequencyPrescale01) is used since both channels are operated with the same frequency.

Information:

The frequency domain can be toggled at any time, but it also results in the frequency jumping by a factor of 10. If this frequency jump is not tolerated in the application, then the value set in the "Frequency" register must be adjusted accordingly.

4.25.2.14.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.25.2.14.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
250 µs

4.25.3 X20MM3332

4.25.3.1 General information

The 3 outputs on the motor module are designed as full-bridge outputs. The continuous current per channel is 3 A at a peak current of up to 5 A. Integrated diagnostics offer the possibility to read back the output current for each channel using the application.

The module offers extensive possibilities for controlling motors, valves or resistive loads and is particularly well suited for controlling brush DC motors. Because the outputs are designed as full-bridge outputs, the motors can be moved in both directions.

- 3 full-bridge outputs (H-bridges)
- High component density
- 3 A continuous current
- 5 A peak current
- Readable current

4.25.3.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

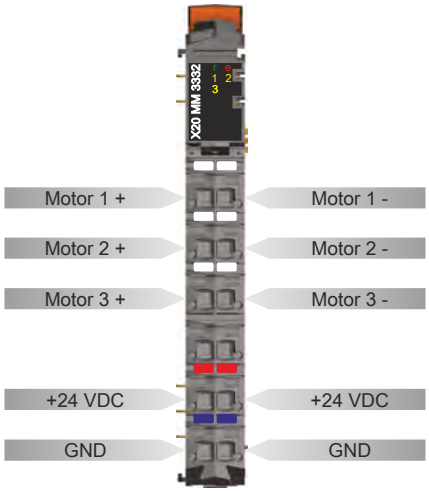
Figure	LED	Color	Color	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 3	Orange	On	The corresponding output is active
			Blinking	Error on the corresponding output
			Off	The corresponding output is switched off

4.25.3.5 Pinout

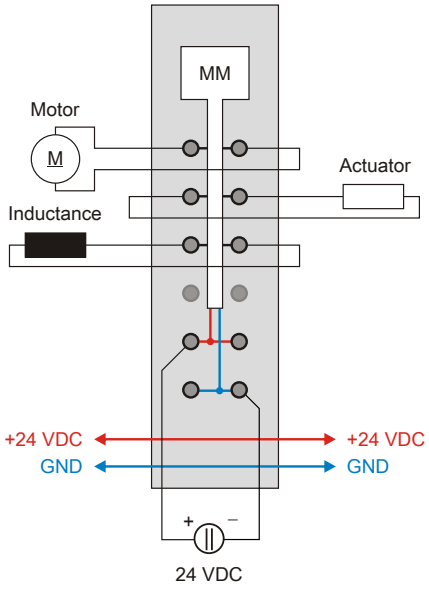
Lines with a cross section between a minimum of 0.75 mm² and a maximum of 2.5 mm² are recommended for the outputs.

Warning!

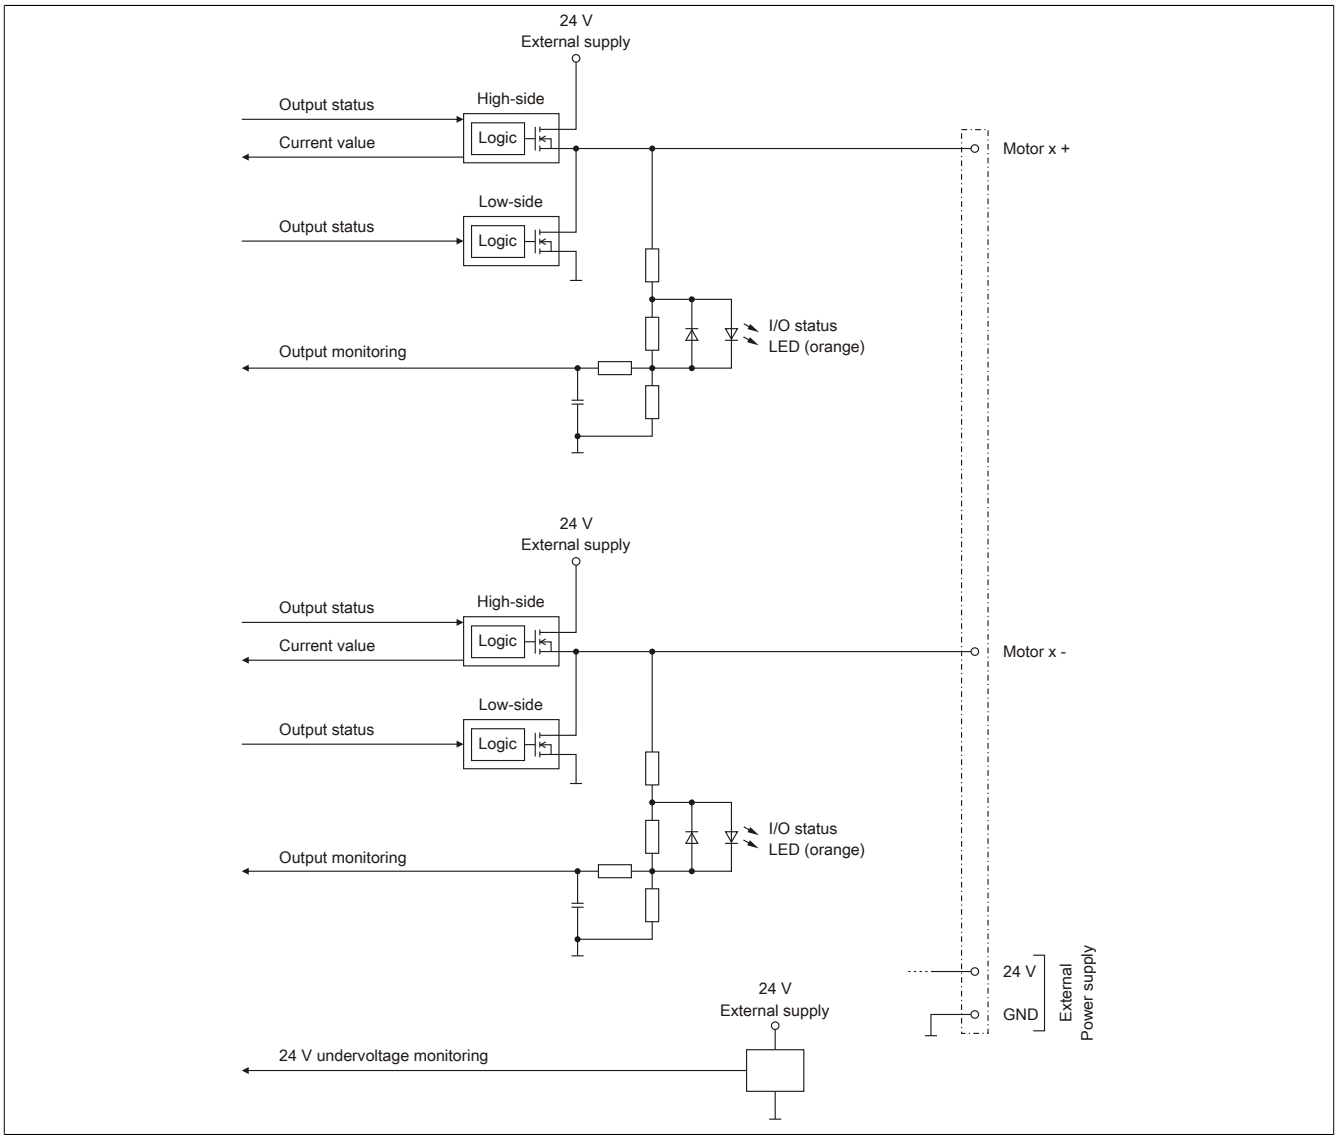
The terminal block is not permitted to be plugged in or unplugged during operation.



4.25.3.6 Connection example

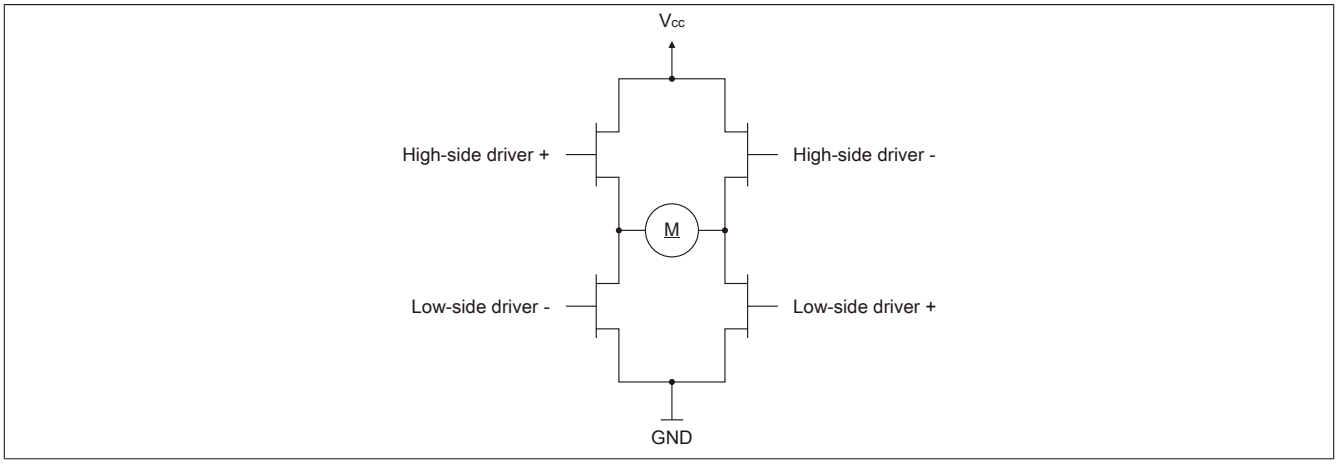


4.25.3.7 Output circuit diagram



4.25.3.8 Function description - Motor operation

Three DC motors can be operated with the module. Each output is designed as a full-bridge output, therefore the motors can be moved in both directions.



Description of the operating modes using the basic circuit diagram shown above:

Operating mode	Description
Rotational direction 1	If the high-side driver + and the low-side driver + are active, the direction of rotation on the motor is from + to -.
Rotational direction 2	If the high-side driver - and the low-side driver - are active, the direction of rotation on the motor is from - to +.
Brakes	If both low-side drivers are active, the motor is short-circuited. This functions as a motor brake.

4.25.3.9 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

I_{Mains}	≤	I_b	≤	I_Z
Mains	≤	Fuse	≤	Line/cable

Wire cross section [mm²]	Current load of the cable cross section I_Z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to IEC 60204-1			
	B1	B2	C	E
1.5	13.5 / 13	13.1 / 10	15.2 / 13	16.1 / 16
2.5	18.3 / 16	16.5 / 16	21 / 20	22 / 20
4.0	24.0 / 24.0	23.0 / 20.0	28.0 / 25.0	30.0 / 25.0
6.0	32.0 / 32.0	29.0 / 25.0	36.0 / 32.0	37.0 / 32.0

Table 558: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b.

Type of layout	Description
B1	Wires in conduit or cable duct
B2	Cables in conduit or cable duct
C	Cables or wires on walls
E	Cables or wires on open cable tray

Table 559: Type of layout for the mains supply line

4.25.3.10 Derating

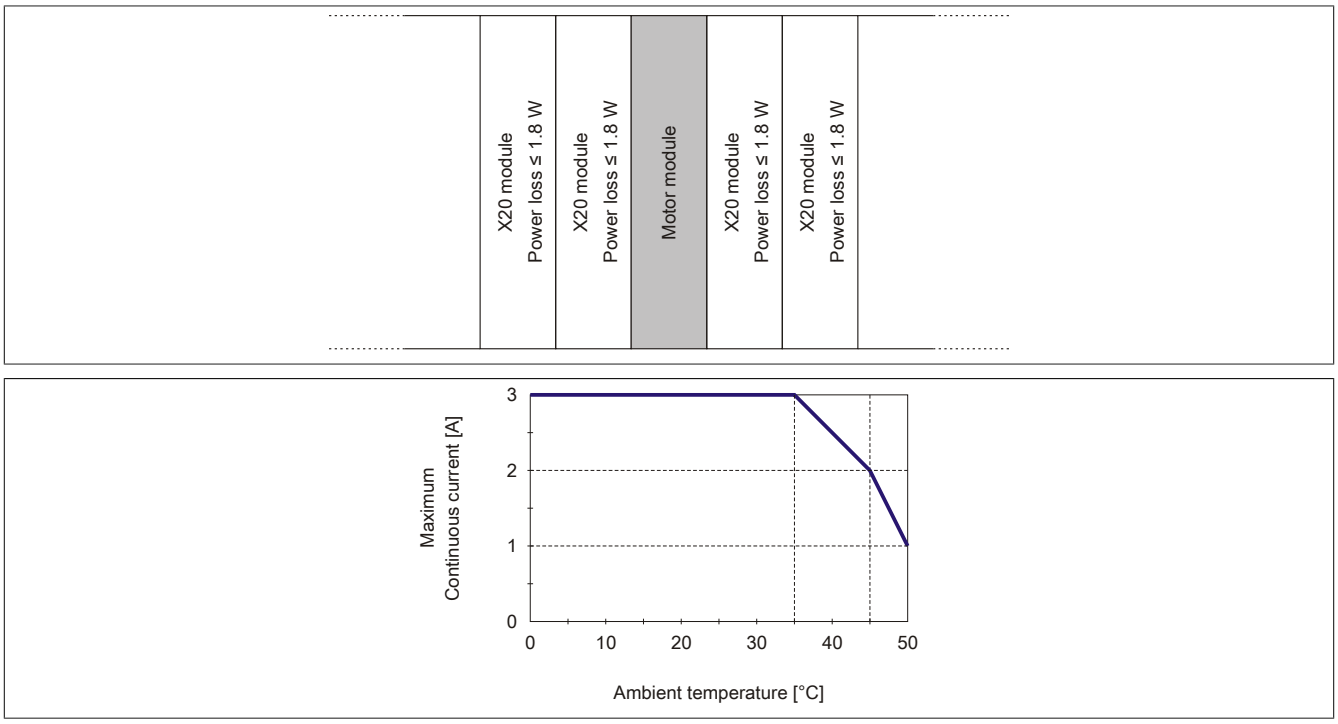
In order to be able to operate the motor module over the entire temperature range, only modules with a maximum power loss of of 0.5 W can be installed next to the motor module or respective turn-off times must be implemented.

If the neighboring modules have a higher power loss and all channels are operated continuously, the motor current must be derated.

When a motor is switched on, the current is increased for a short time. This behavior has no influence on the derating.

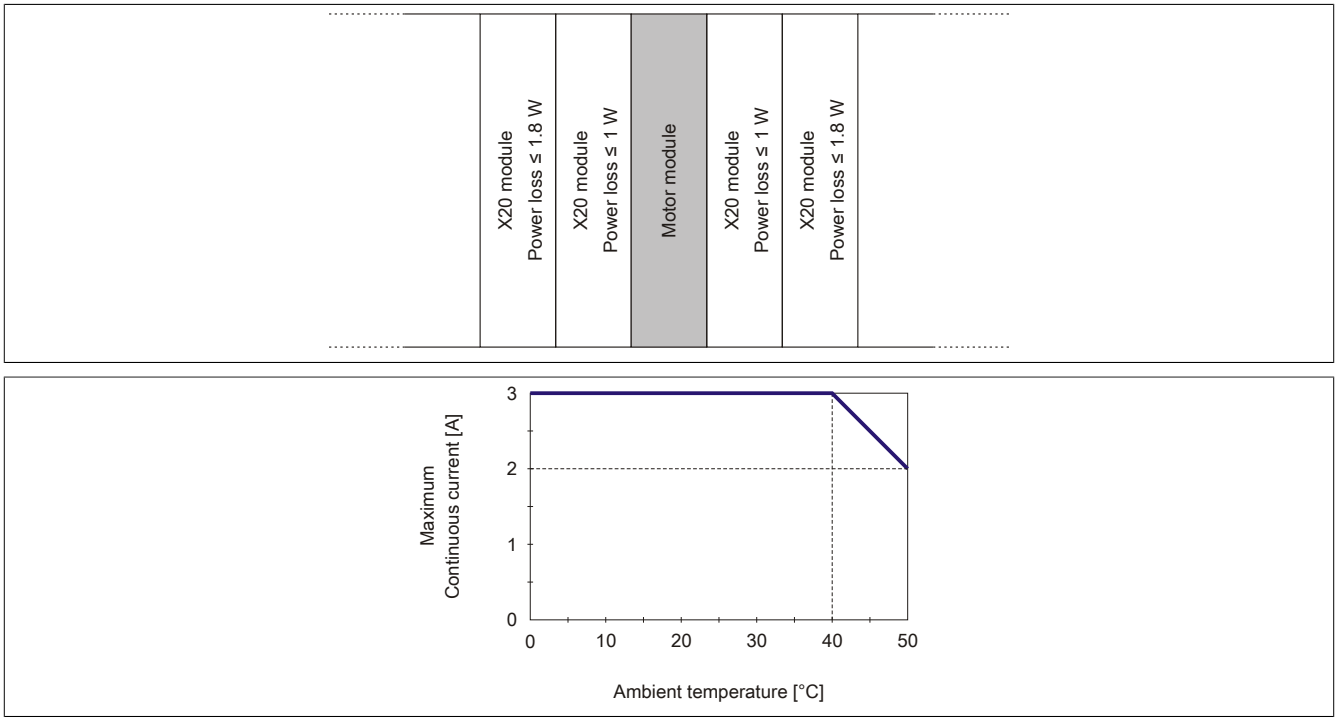
Current derating 1 of the motor module

Current derating for the motor module for neighboring modules with ≤1.8 W thermal power loss.



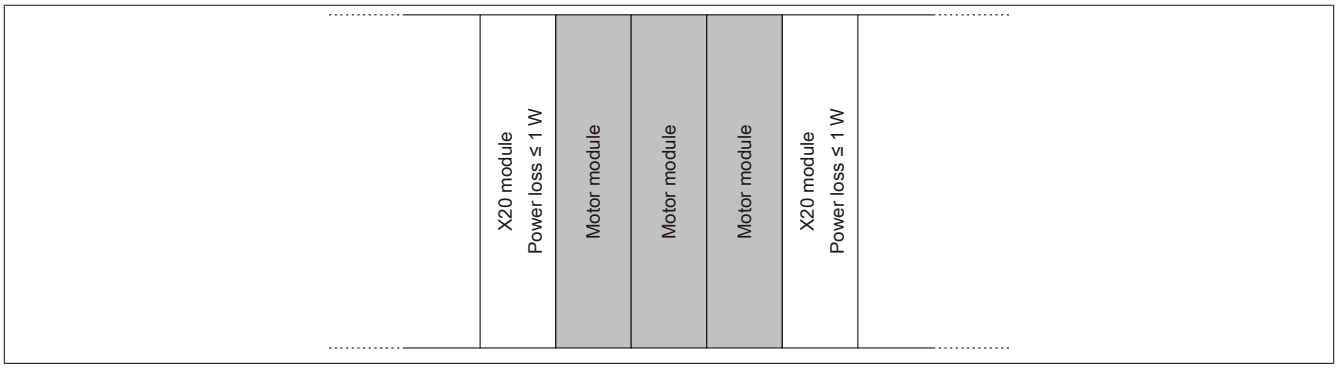
Current derating 2 of the motor module

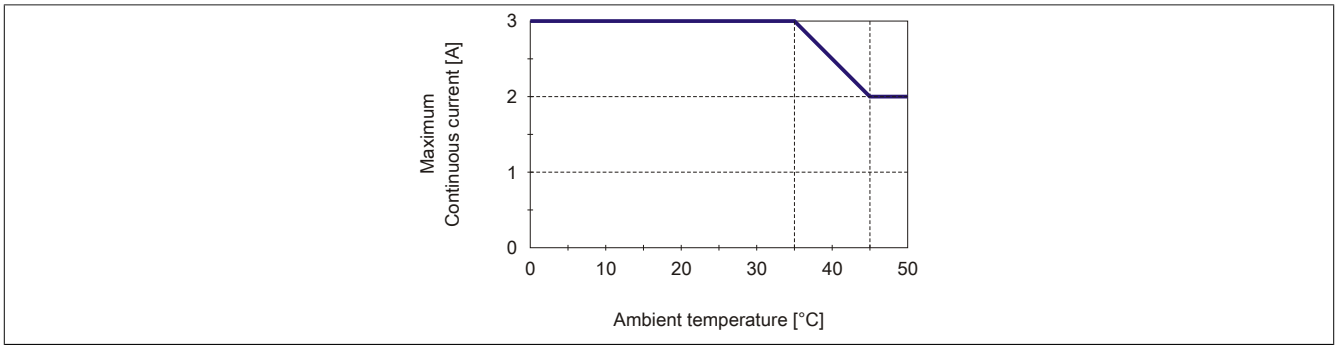
Current derating for the motor module for neighboring modules with ≤1 W thermal power loss.



Current derating 3 of the motor module

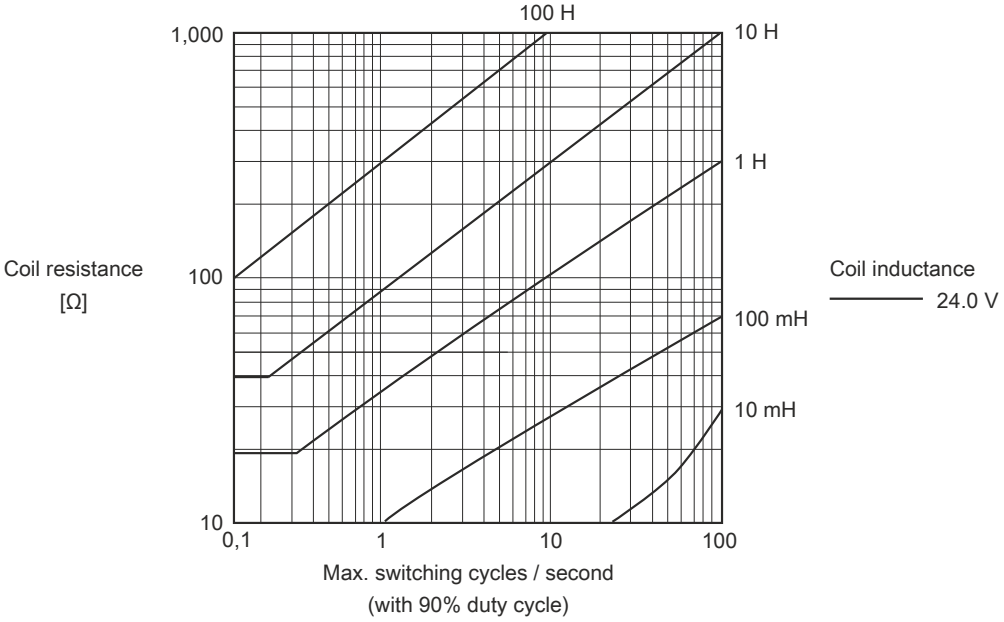
Current derating with multiple motor modules next to each other.



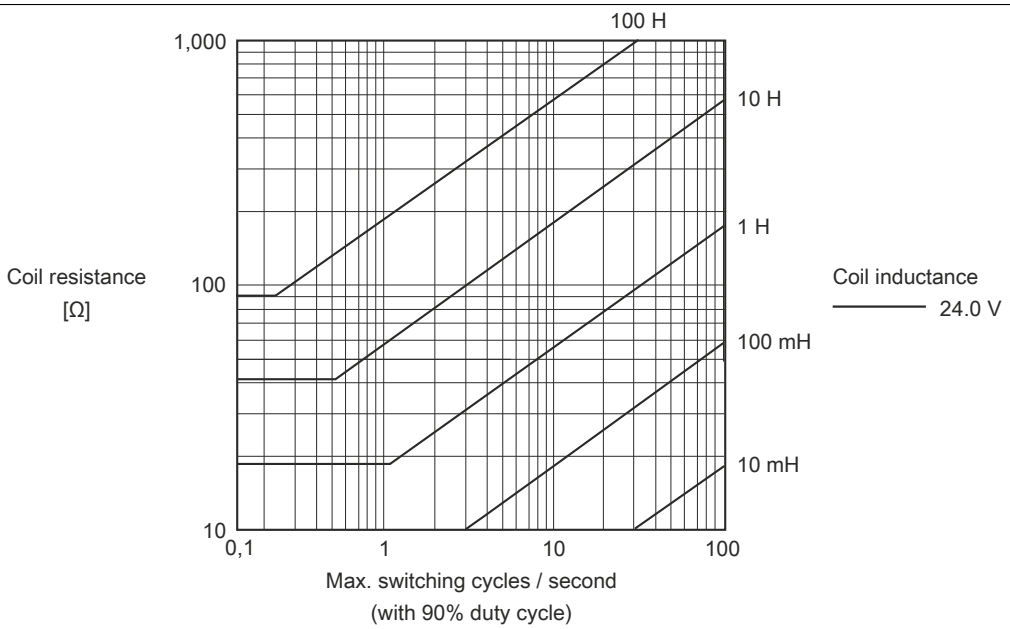


4.25.3.11 Switching inductive loads (e.g. valves)

With enabled short circuit channel - All outputs with same load



With disabled short circuit channel - All outputs with same load



4.25.3.12 Monitoring the module supply

The module supply is continually monitored. If the supply voltage drops below 18V, all channels are switched off and an error bit is set.

Information:

The undervoltage must be present for longer than 250 ms, before all channels are switched off. Power dips can occur when starting motors or capacitive loads!

4.25.3.13 Monitoring the module current

The module current is continually monitored. If an overcurrent occurs, the respective channel is switched off and an error bit is set.

Information:

The overcurrent must be present for longer than 250 ms, before the channel is switched off. High starting currents occur when starting motors or capacitive loads!

4.25.3.14 Channel monitoring

After each switching process, the status inputs are checked with a 2 ms delay to ensure they are correct. This is done so that faulty status signals are not generated when switching motors or capacitive loads.

If the status of the output does not correspond to the status that is expected (e.g. short circuit or motor spin-out), a warning bit is set.

Information:

When channel monitoring is triggered, a warning is given. The output remains switched even if there is a short circuit and is cycled to the output by the internal protective circuit.

If the motor is still spinning out, the voltage drops slowly. That means the warning bit StatusDigitalOutput can show a warning while the motor is spinning out.

If the motor is moved externally, voltage is induced into the module, which results in StatusDigitalOutput being set and the red LED being lit (warning).

4.25.3.15 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The outputs are switched off (short-circuited)

As soon as the temperature sinks back down below 85°C, the error must be acknowledged with OvertemperatureAcknowledge so that the channels can be switched on again.

4.25.3.16 Register description

4.25.3.16.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.25.3.16.2 Function model 0 - Standard

In this function model, control of full bridges takes place using 3 bits per channel.

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
0	Motor configuration 1 - Default	USINT			•	
	StartChannel01	Bit 0				
	ShortCircuitChannel01	Bit 1				
	DirectionChannel01	Bit 2				
	StartChannel02	Bit 4				
	ShortCircuitChannel02	Bit 5				
	DirectionChannel02	Bit 6				
1	Motor configuration 2 - Default	USINT			•	
	StartChannel03	Bit 0				
	ShortCircuitChannel03	Bit 1				
	DirectionChannel03	Bit 2				
18	Error acknowledged	USINT			•	
	OvercurrentAcknowledge01	Bit 0				
	OvercurrentAcknowledge02	Bit 1				
	OvercurrentAcknowledge03	Bit 2				
	OvertemperatureAcknowledge	Bit 6				
	UndervoltageAcknowledge	Bit 7				
Communication						
4	CurrentInput01	USINT	•			
6	CurrentInput02	USINT	•			
8	CurrentInput03	USINT	•			
20	Module and channel status	USINT	•			
	OvercurrentError01	Bit 0				
	OvercurrentError02	Bit 1				
	OvercurrentError03	Bit 2				
	StatusDigitalOutput01	Bit 3				
	StatusDigitalOutput02	Bit 4				
	StatusDigitalOutput03	Bit 5				
	OvertemperatureError	Bit 6				
	UndervoltageError	Bit 7				

4.25.3.16.3 Function model 1 - Byte control and Function model 254 - bus controller

Control of the half bridges takes place using one byte (two bits per channel). All other registers are the same as in Function model 0 - Standard.

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
0	0	Motor configuration - Byte control	USINT			●	
18	4	Error acknowledged	USINT			●	
		OvercurrentAcknowledge01	Bit 0				
		OvercurrentAcknowledge02	Bit 1				
		OvercurrentAcknowledge03	Bit 2				
		OvertemperatureAcknowledge	Bit 6				
		UndervoltageAcknowledge	Bit 7				
Communication							
4	0	CurrentInput01	USINT	●			
6	2	CurrentInput02	USINT	●			
8	4	CurrentInput03	USINT	●			
20	6	Module and channel status	USINT	●			
		OvercurrentError01	Bit 0				
		OvercurrentError02	Bit 1				
		OvercurrentError03	Bit 2				
		StatusDigitalOutput01	Bit 3				
		StatusDigitalOutput02	Bit 4				
		StatusDigitalOutput03	Bit 5				
		OvertemperatureError	Bit 6				
		UndervoltageError	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.25.3.16.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.25.3.16.4 Configuration

4.25.3.16.4.1 Motor configuration 1 - Default

Name:
StartChannel01 to StartChannel02
ShortCircuitChannel01 to ShortCircuitChannel02
DirectionChannel01 to DirectionChannel02

This register contains the control bits for the first two channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	StartChannel01	0	Switch off channel 1
		1	Channel 1 is started (bridge control)
1	ShortCircuitChannel01	0	Do not short circuit channel 1.
		1	Short circuit channel 1.
2	DirectionChannel01	0	Rotational direction 1
		1	Rotational direction 2: The polarity of the connections for motor 1 are reversed internally.[1)]
3	Reserved	-	Reserved
4	StartChannel02	0	Switch off channel 2
		1	Channel 2 is started (bridge control)
5	ShortCircuitChannel02	0	Do not short circuit channel 2.
		1	Short circuit channel 2.
6	DirectionChannel02	0	Rotational direction 1
		1	Rotational direction 2: The polarity of the connections for motor 2 are reversed internally.[1)]
7	Reserved	-	

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

StartChannel 1 to 2 and ShortCircuitChannel 1 to 2:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

4.25.3.16.4.2 Motor configuration 2 - Default

Name:
StartChannel03
ShortCircuitChannel03
DirectionChannel03

This register contains the control bits for the third channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	StartChannel03	0	Switch off channel 3
		1	Switch on channel 3
1	ShortCircuitChannel03	0	Do not short circuit channel 3.
		1	Short circuit channel 3.
2	DirectionChannel03	0	Rotational direction 1
		1	Rotational direction 2: The polarity of the connections for motor 3 are reversed internally.[1)]
3 - 7	Reserved	-	

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

StartChannel 3 and ShortCircuitChannel 3:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

4.25.3.16.4.3 Motor configuration - Byte control

Name:
ControlByte01

This register is used to control all 3 channels. Two bits per channels are always grouped together. This register is only used in Function model 1 - Byte control and Function model 254 - bus controller.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0 - 1	Channel 1	00	No-load operation
		01	Rotational direction 1
		10	Rotational direction 2: The polarity of the connections for motor 1 are reversed internally.[1)]
		11	Short circuit
...		...	
4 - 5	Channel 3	00	No-load operation
		01	Rotational direction 1
		10	Rotational direction 2: The polarity of the connections for motor 3 are reversed internally.[1)]
		11	Short circuit
6 - 7	Reserved	-	

1) The direction of rotation on the motor is changed by internally reversing the polarity of the connections.

Information:

When the direction of the motor is changed, the polarity is reversed. If the direction of rotation on the motor is changed during operation, the motor immediately brakes and turns in the other direction. This can result in very high current values. Therefore, we recommend short-circuiting the motor first (braking) and then changing to the other direction.

4.25.3.16.4.4 Error acknowledged

Name:
OvercurrentAcknowledge01 to OvercurrentAcknowledge03
OvertemperatureAcknowledge
UndervoltageAcknowledge

This register contains bits used to acknowledge an overcurrent error, an undervoltage error and an overtemperature error.

The errors are acknowledged with a rising edge. An existing error can only be acknowledged if the cause of the error has been corrected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	OvercurrentAcknowledge01	1	With a rising edge, the overcurrent error shown on channel 1 is acknowledged.
1	OvercurrentAcknowledge02	1	With a rising edge, the overcurrent error shown on channel 2 is acknowledged.
2	OvercurrentAcknowledge03	1	With a rising edge, the overcurrent error shown on channel 3 is acknowledged.
3 - 5	Reserved	-	
6	OvertemperatureAcknowledge	1	With a rising edge, the overtemperature error shown is acknowledged.
7	UndervoltageAcknowledge	1	With a rising edge, the undervoltage error shown is acknowledged.

4.25.3.16.5 Communication

4.25.3.16.5.1 Voltage of the channels

Name:
CurrentInput01 to CurrentInput03

Every 700 µs, the current that flows through a channel is measured with a resolution of 8 bits. The value measured is stored in these registers.

Data type	Value	Information
USINT	0 to 255	0 to 5 A

4.25.3.16.5.2 Module and channel status

Name:
OvercurrentError01 to OvercurrentError03
StatusDigitalOutput01 to StatusDigitalOutput03
OvertemperatureError
UndervoltageError

Some operating states are monitored by the module. They are:

- Module supply
- Module current
- Status channels
- Module temperature

The states are stored in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	OvercurrentError01	0	No overcurrent on channel 1
		1	Overcurrent on channel 1
1	OvercurrentError02	0	No overcurrent on channel 2
		1	Overcurrent on channel 2
2	OvercurrentError03	0	No overcurrent on channel 3
		1	Overcurrent on channel 3
3	StatusDigitalOutput01	0	Channel 1 output status OK
		1	Channel 1 output warning: Short-circuit or invalid output status
4	StatusDigitalOutput02	0	Channel 2 output status OK
		1	Channel 2 output warning: Short-circuit or invalid output status
5	StatusDigitalOutput03	0	Channel 3 output status OK
		1	Channel 3 output warning: Short-circuit or invalid output status
6	OvertemperatureError	0	Module temperature within permitted range
		1	Module overtemperature error
7	UndervoltageError	0	Supply voltage within permitted range
		1	Supply voltage has dropped below 18V

4.25.3.16.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
400 µs

4.25.3.16.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
400 µs

4.25.4 X20MM4331

4.25.4.1 General information

The 4 outputs on the motor module are designed as half-bridge outputs. The continuous current per channel is 3 A at a peak current of up to 5 A. Integrated diagnostics offer the possibility to read back the output current for each channel using the application.

The module offers extensive possibilities for controlling motors, valves or resistive loads and is particularly well suited for controlling brush DC motors. The outputs can be switched on/off and short-circuited.

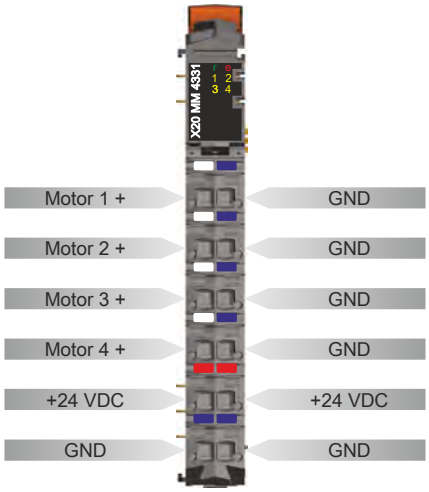
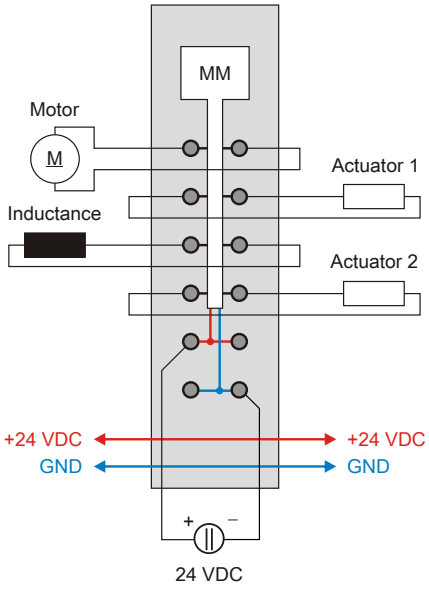
Warning!

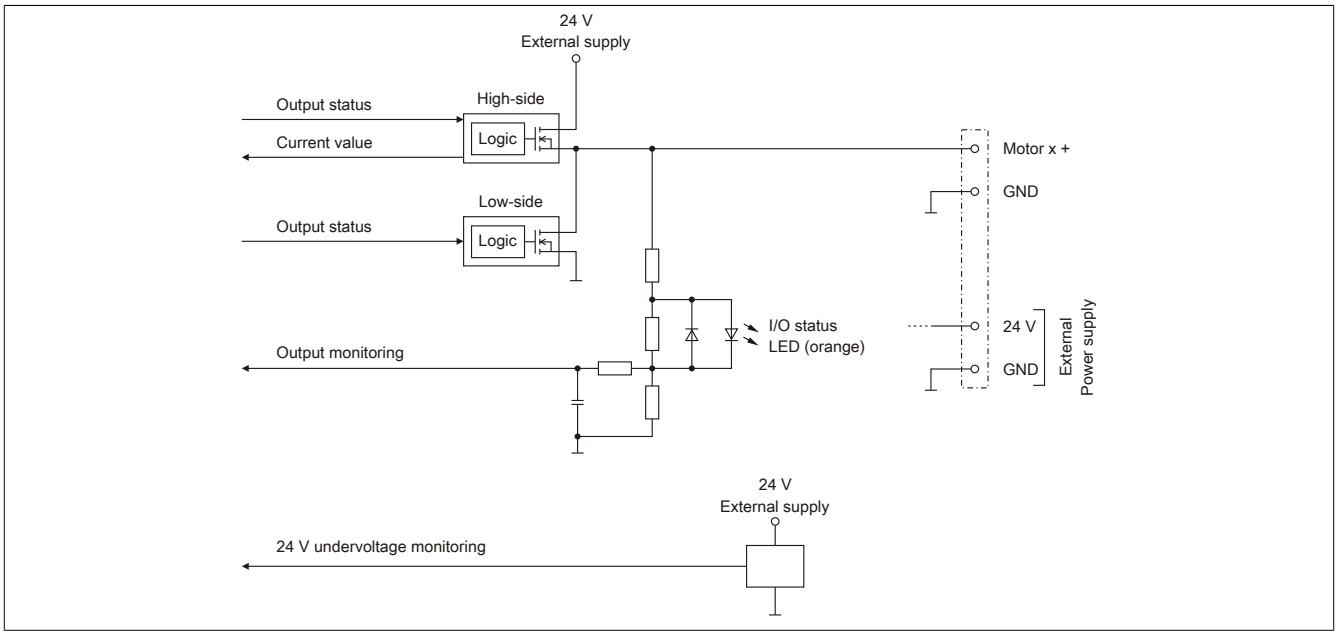
The terminal block is not permitted to be plugged in or unplugged during operation.



4.25.4.6 Connection example

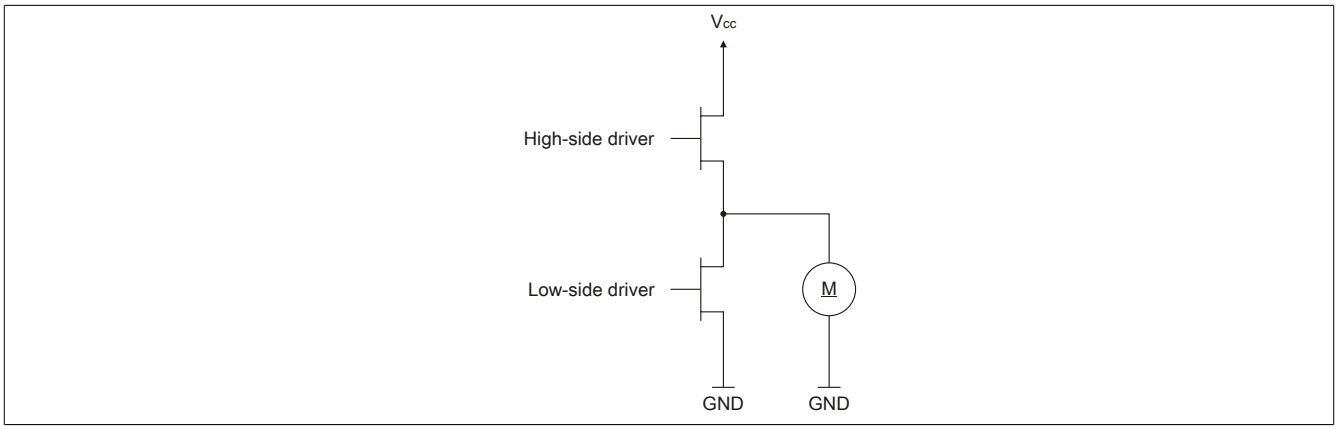


4.25.4.7 Output circuit diagram



4.25.4.8 Function description - Motor operation

Four DC motors can be operated with the module. Each output is designed as a half-bridge.



Description of the operating modes using the basic circuit diagram shown above:

Operating mode	Description
Motor is running	If the high-side driver is active, the motor is switched on.
Brakes	If motor braking should take place, the high-side driver is first switched off and then the low-side driver is activated. In this way, the motor windings are short-circuited and the motor braking takes place.

4.25.4.9 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

I_{Mains}	≤	I_b	≤	I_Z
Mains	≤	Fuse	≤	Line/cable

Wire cross section [mm²]	Current load of the cable cross section I_Z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to IEC 60204-1			
	B1	**B2**	**C**	**E**
1.5	13.5 / 13	13.1 / 10	15.2 / 13	16.1 / 16
2.5	18.3 / 16	16.5 / 16	21 / 20	22 / 20
4.0	24.0 / 24.0	23.0 / 20.0	28.0 / 25.0	30.0 / 25.0
6.0	32.0 / 32.0	29.0 / 25.0	36.0 / 32.0	37.0 / 32.0

Table 562: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b.

Type of layout	Description
B1	Wires in conduit or cable duct
B2	Cables in conduit or cable duct
C	Cables or wires on walls
E	Cables or wires on open cable tray

Table 563: Type of layout for the mains supply line

4.25.4.10 Derating

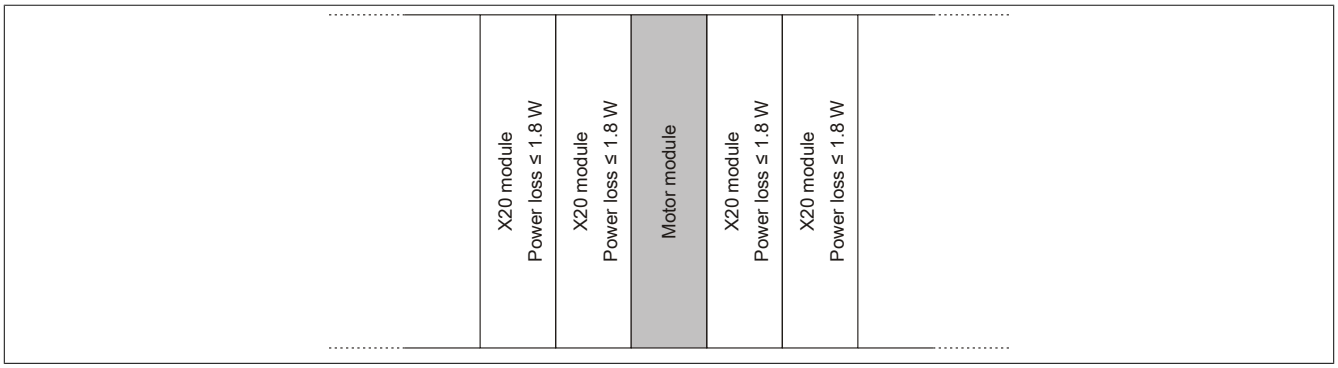
In order to be able to operate the motor module over the entire temperature range, only modules with a maximum power loss of of 0.5 W can be installed next to the motor module or respective turn-off times must be implemented.

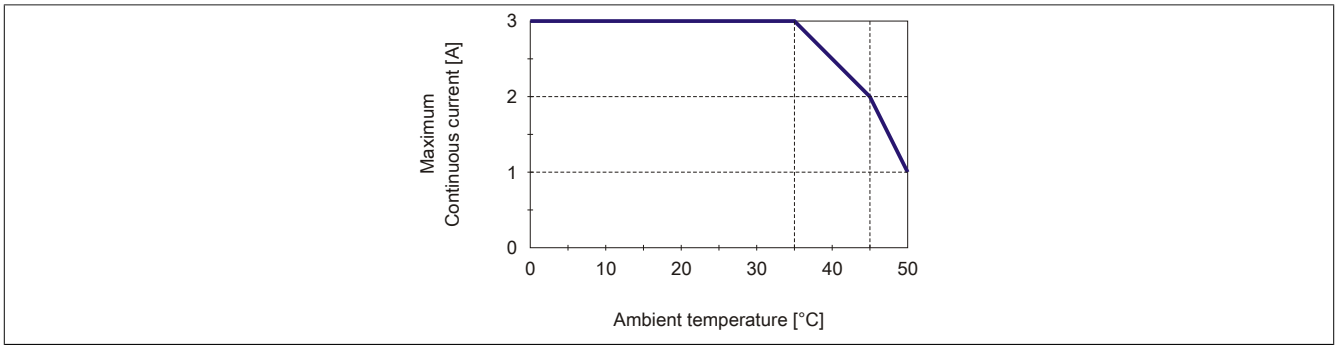
If the neighboring modules have a higher power loss and all channels are operated continuously, the motor current must be derated.

When a motor is switched on, the current is increased for a short time. This behavior has no influence on the derating.

Current derating 1 of the motor module

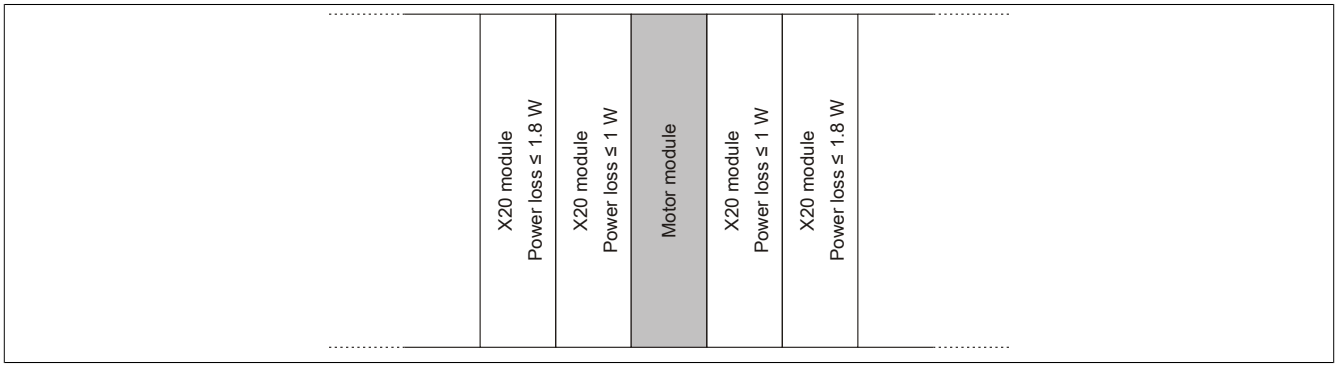
Current derating for the motor module for neighboring modules with ≤1.8 W thermal power loss.

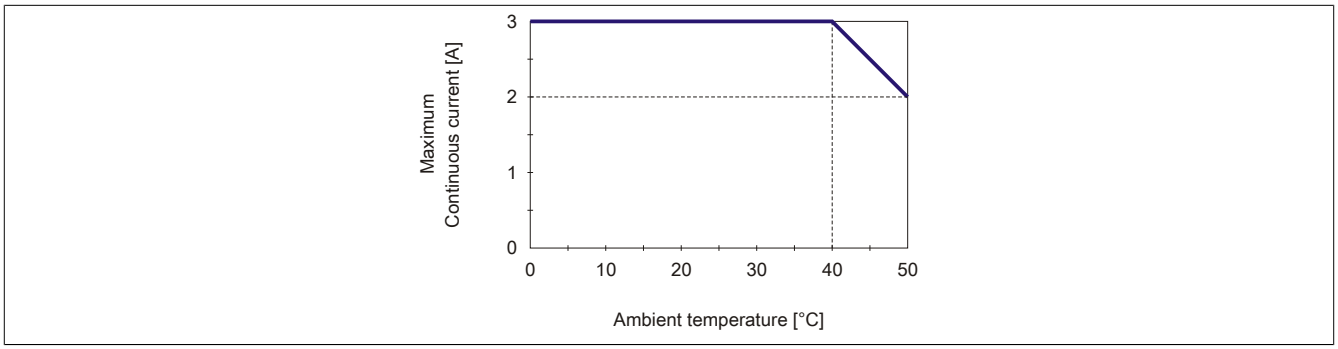




Current derating 2 of the motor module

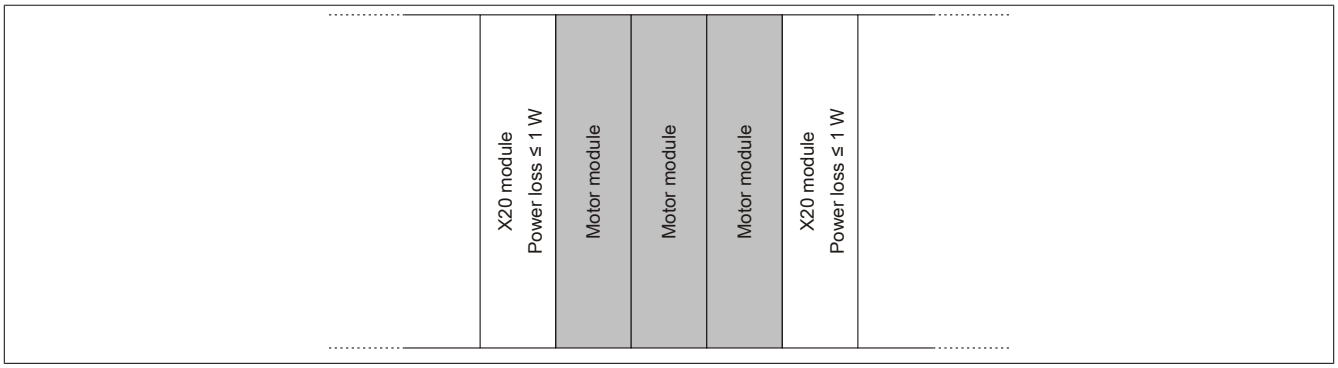
Current derating for the motor module for neighboring modules with ≤1 W thermal power loss.

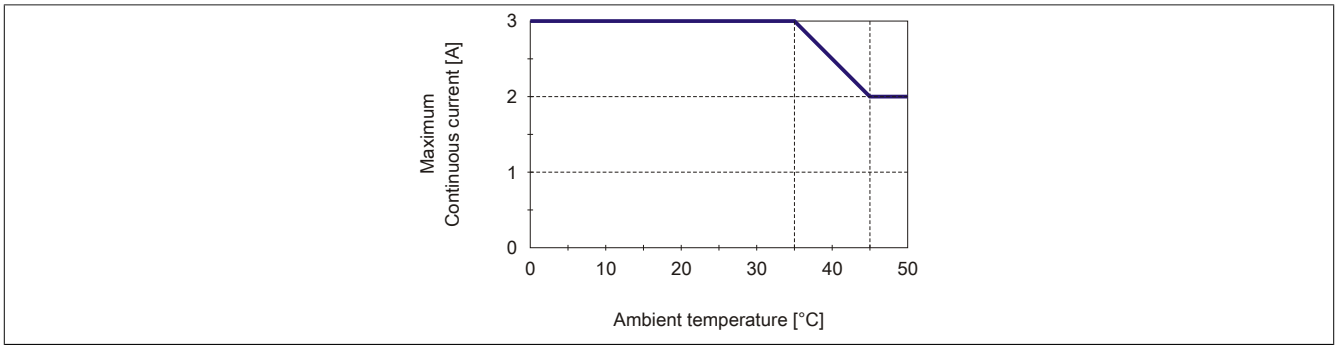




Current derating 3 of the motor module

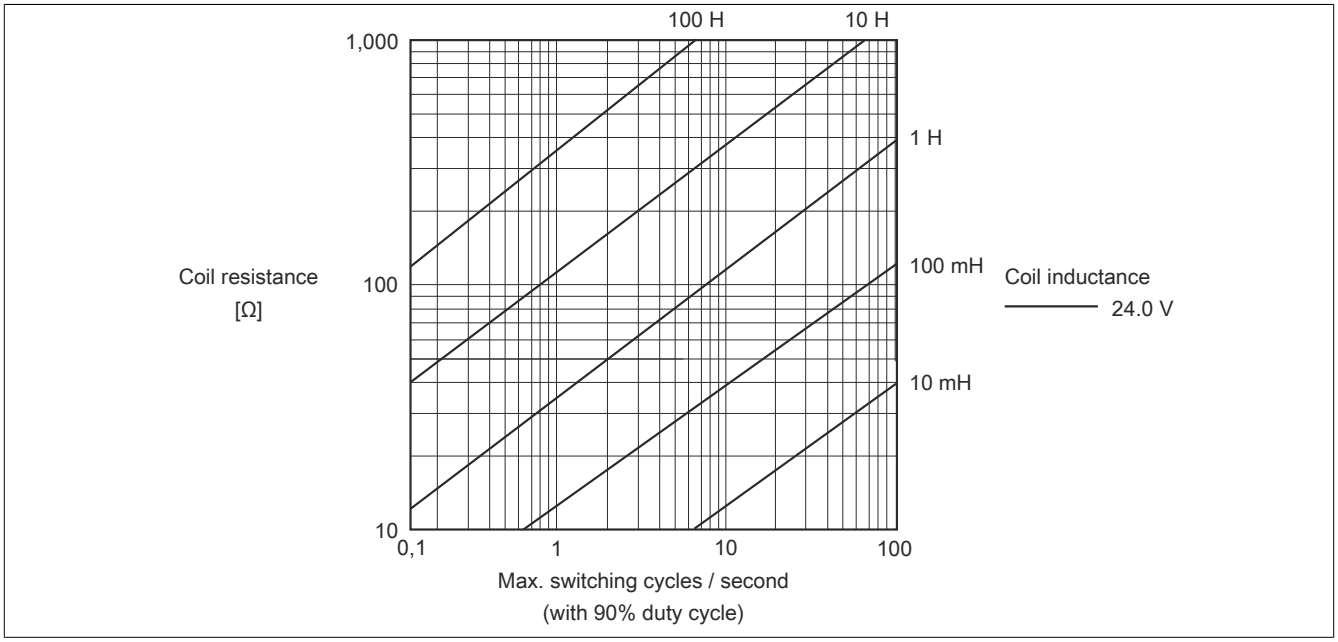
Current derating with multiple motor modules next to each other.





4.25.4.11 Switching inductive loads (e.g. valves)

All outputs with the same load.



4.25.4.12 Monitoring the module supply

The module supply is continually monitored. If the supply voltage drops below 18V, all channels are switched off and an error bit is set.

Information:

The undervoltage must be present for longer than 250 ms, before all channels are switched off. Power dips can occur when starting motors or capacitive loads!

4.25.4.13 Monitoring the module current

The module current is continually monitored. If an overcurrent occurs, the respective channel is switched off and an error bit is set.

Information:

The overcurrent must be present for longer than 250 ms, before the channel is switched off. High starting currents occur when starting motors or capacitive loads!

4.25.4.14 Channel monitoring

After each switching process, the status inputs are checked with a 2 ms delay to ensure they are correct. This is done so that faulty status signals are not generated when switching motors or capacitive loads.

If the status of the output does not correspond to the status that is expected (e.g. short circuit or motor spin-out), a warning bit is set.

Information:

When channel monitoring is triggered, a warning is given. The output remains switched even if there is a short circuit and is cycled to the output by the internal protective circuit.

If the motor is still spinning out, the voltage drops slowly. That means the warning bit StatusDigitalOutput can show a warning while the motor is spinning out.

If the motor is moved externally, voltage is induced into the module, which results in StatusDigitalOutput being set and the red LED being lit (warning).

4.25.4.15 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The outputs are switched off (short-circuited)

As soon as the temperature sinks back down below 85°C, the error must be acknowledged with OvertemperatureAcknowledge so that the channels can be switched on again.

4.25.4.16 Register description

4.25.4.16.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.25.4.16.2 Function model 0 - Standard

In this function model, control of full bridges takes place using 3 bits per channel.

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
0	Motor configuration - Default	USINT			•	
	StartChannel01	Bit 0				
	ShortCircuitChannel01	Bit 1				
	StartChannel02	Bit 2				
	ShortCircuitChannel02	Bit 3				
	StartChannel03	Bit 4				
	ShortCircuitChannel03	Bit 5				
	StartChannel04	Bit 6				
	ShortCircuitChannel04	Bit 7				
18	Error acknowledged	USINT			•	
	OvercurrentAcknowledge01	Bit 0				
	...	...				
	OvercurrentAcknowledge04	Bit 3				
	OvertemperatureAcknowledge	Bit 5				
	UndervoltageAcknowledge	Bit 6				
Communication						
2 + N * 2	CurrentInput0N (Index N = 1 to 4)	USINT	•			
20	Status of current and channels	USINT	•			
	OvercurrentError01	Bit 0				
	...	...				
	OvercurrentError04	Bit 3				
	StatusDigitalOutput01	Bit 4				
	...	...				
	StatusDigitalOutput04	Bit 7				
21	Module status	USINT	•			
	OvertemperatureError	Bit 0				
	UndervoltageError	Bit 1				

4.25.4.16.3 Function model 1 - Byte control and Function model 254 - bus controller

Control of the half bridges takes place using one byte (two bits per channel). All other registers are the same as in Function model 0 - Standard.

This function model supports all of the module's functions. Control of the half bridges takes place using one byte (2 bits per channel). All other registers are the same as the standard function model.

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
0	0	Motor configuration - Byte control	USINT			•	
18	12	Error acknowledged	USINT			•	
		OvercurrentAcknowledge01	Bit 0				
		...	...				
		OvercurrentAcknowledge04	Bit 3				
		OvertemperatureAcknowledge	Bit 5				
		UndervoltageAcknowledge	Bit 6				
Communication							
2 + N * 2	2 + N * 2	CurrentInput0N (Index N = 1 to 4)	USINT	•			
20	8	Status of current and channels	USINT	•			
		OvercurrentError01	Bit 0				
		...	...				
		OvercurrentError04	Bit 3				
		StatusDigitalOutput01	Bit 4				
		...	...				
		StatusDigitalOutput04	Bit 7				
21	10	Module status	USINT	•			
		OvertemperatureError	Bit 0				
		UndervoltageError	Bit 1				

1) The offset specifies the position of the register within the CAN object.

4.25.4.16.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.25.4.16.4 Configuration

4.25.4.16.4.1 Motor configuration - Default

Name:
StartChannel01 to StartChannel04
ShortCircuitChannel01 to ShortCircuitChannel04

This register contains the control bits for all channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	StartChannel01	0	Switch off channel 1
		1	Channel 1 is started (bridge control)
1	ShortCircuitChannel01	0	Do not short circuit channel 1.
		1	Short circuit channel 1.
2	StartChannel02	0	Switch off channel 2
		1	Channel 2 is started (bridge control)
3	ShortCircuitChannel02	0	Do not short circuit channel 2.
		1	Short circuit channel 2.
4	StartChannel03	0	Switch off channel 3
		1	Channel 3 is started (bridge control)
5	ShortCircuitChannel03	0	Do not short circuit channel 3.
		1	Short circuit channel 3.
6	StartChannel04	0	Switch off channel 4
		1	Channel 4 is started (bridge control)
7	ShortCircuitChannel04	0	Do not short circuit channel 4.
		1	Short circuit channel 4.

Information:

To avoid internal bridge shorts, the outputs are delayed by 200 µs when switching to another state or a short circuit.

4.25.4.16.4.2 Motor configuration - Byte control

Name:
ControlByte01

This register is used to control all four channels. Two bits per channels are always grouped together. This register is only used in Function model 1 - Byte control and Function model 254 - bus controller.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0 - 1	Channel 1	00	Off
		01	On
		10	Off
		11	Short circuit
...		...	
6 - 7	Channel 4	00	Off
		01	On
		10	Off
		11	Short circuit

4.25.4.16.4.3 Error acknowledged

Name:
OvercurrentAcknowledge01 to OvercurrentAcknowledge04
OvertemperatureAcknowledge
UndervoltageAcknowledge

This register contains bits used to acknowledge an overcurrent error, an undervoltage error and an overtemperature error.

The errors are acknowledged with a rising edge. An existing error can only be acknowledged if the cause of the error has been corrected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	OvercurrentAcknowledge01	1	With a rising edge, the overcurrent error shown on channel 1 is acknowledged.
...		...	
3	OvercurrentAcknowledge04	1	With a rising edge, the overcurrent error shown on channel 4 is acknowledged.
4 - 5	Reserved	-	
6	OvertemperatureAcknowledge	1	With a rising edge, the overtemperature error shown is acknowledged.
7	UndervoltageAcknowledge	1	With a rising edge, the undervoltage error shown is acknowledged.

4.25.4.16.5 Communication

4.25.4.16.5.1 Voltage of the channels

Name:
CurrentInput01 to CurrentInput04

Every 500 µs, the current that flows through a channel is measured with a resolution of 8 bits. The value measured is stored in these registers.

Data type	Value	Information
USINT	0 to 255	0 to 5 A

4.25.4.16.5.2 Status of current and channels

Name:
OvercurrentError01 to OvercurrentError04
StatusDigitalOutput01 to StatusDigitalOutput04

Some operating states are monitored by the module. They are:

- Module current
- Status channels

The states are stored in this register. For other operating modes, see 4.25.4.16.5.3 "Module status"

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	OvercurrentError0	0	No overcurrent on channel 1
		1	Overcurrent on channel 1
...		...	
3	OvercurrentError04	0	No overcurrent on channel 4
		1	Overcurrent on channel 4
4	StatusDigitalOutput01	0	Channel 1 output status OK
		1	Channel 1 output warning: Short-circuit or invalid output status
...		...	
7	StatusDigitalOutput04	0	Channel 4 output status OK
		1	Channel 4 output warning: Short-circuit or invalid output status

4.25.4.16.5.3 Module status

Name:
OvertemperatureError
UndervoltageError

Some operating states are monitored by the module. They are:

- Module supply
- Module temperature

The states are stored in this register. For other operating modes, see 4.25.4.16.5.2 "Status of current and channels"

Data type	Value
USINT	See bit structure.

Bit structure:

Bit			Description
0	OvertemperatureError	0	Module temperature within permitted range
		1	Module overtemperature error
1	UndervoltageError	0	Supply voltage within permitted range
		1	Supply voltage has dropped below 18V
2 - 7	Reserved	-	

4.25.4.16.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
400 µs

4.25.4.16.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
400 µs

4.25.5 X20MM4456

4.25.5.1 General information

The PWM motor bridge module is used to control 4 DC motors with a nominal voltage of 24 to 48 VDC ±25% at a nominal current up to 6 A. The module can be reconfigured and used in current controller mode for controlling inductive loads. The module is also equipped with 16 digital inputs, which can be used as incremental counters. The 4 motors are controlled with a full-bridge (H-bridge). This enables the motors to be moved in both directions.

- 4x outputs (H bridge) with PWM control and 24 to 48 VDC ±25% supply
- 6 A nominal current (10 A max current)
- 15 Hz to 50 kHz frequency, 16-bit
- PWM resolution, 15-bit, + sign, minimum 10 ns
- Configurable dither
- 4x 4 inputs 24V, can be configured as ABR
- Sink connection
- 1-wire connections

4.25.5.2 Order data

Model number	Short description	Figure
	Motor controllers	
X20MM4456	X20 PWM motor module, 24 to 48 VDC ±25%, 4 PWM motor bridges, 6 A continuous current, 10 A peak current, 4x 4 digital inputs 24 VDC, sink, configurable as incremental encoder

4.25.5.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Status LED, left

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Green		Input state of the corresponding digital input
	M1 + M2	Orange	On	The corresponding output is active

1) Depending on the configuration, a firmware update can take up to several minutes.

Status LED, right

Figure	LED	Color	Status	Description
	9 - 16	Green		Input state of the corresponding digital input
	M3 + M4	Orange	On	The corresponding output is active

4.25.5.5 Connection elements

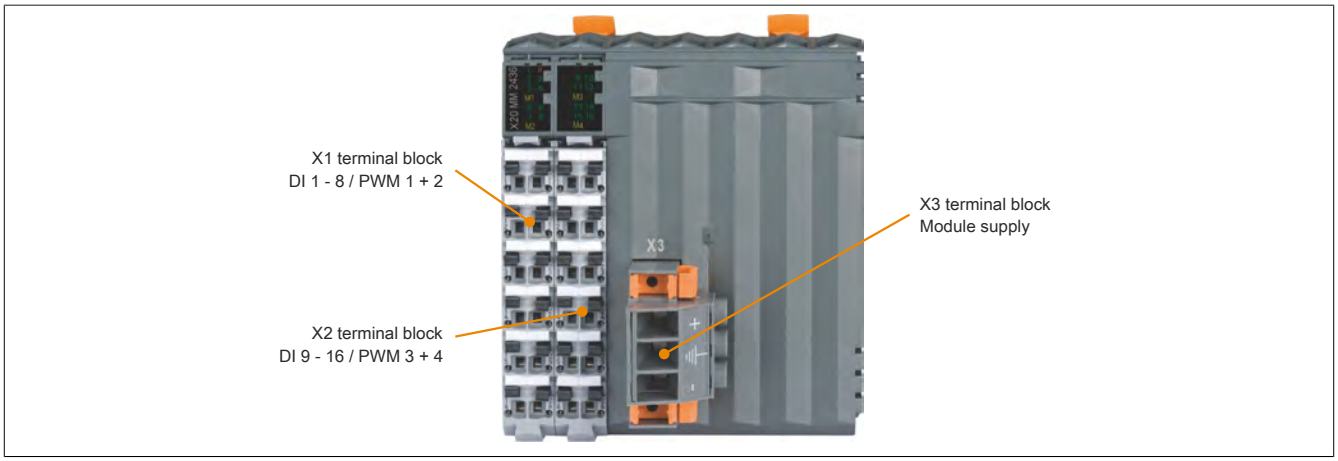
In accordance with the EN60204-1 standard, a cable cross section of 1.5 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 10 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

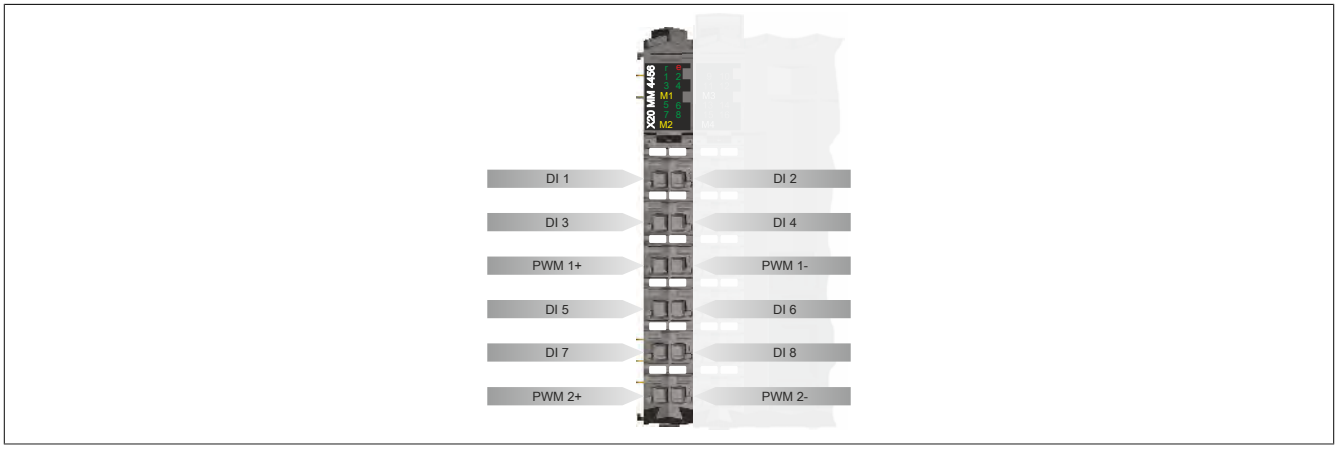
The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

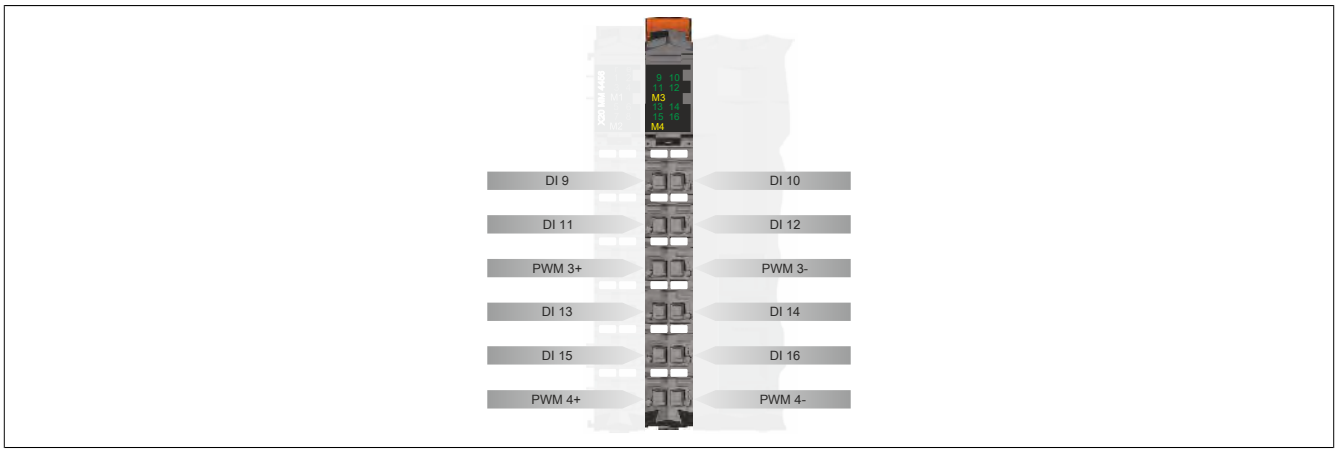
Shielded motor cables must be used in order to meet the limits according to the EN55011 standard (emissions).



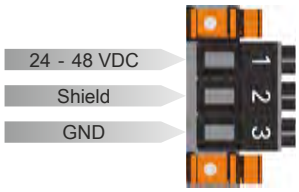
4.25.5.5.1 Terminal block X1 - DI 1 - 8 / PWM 1 + 2



4.25.5.5.2 Terminal block X2 - DI 9 - 16 / PWM 3 + 4



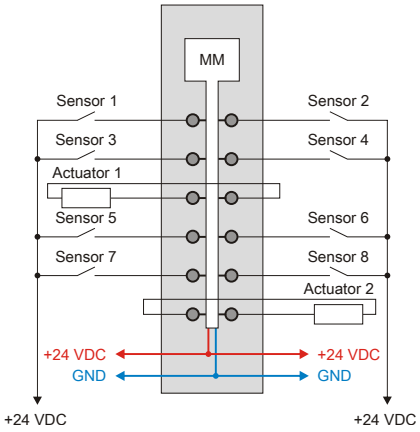
4.25.5.5.3 X3 terminal block - Module supply



4.25.5.6 Connection examples

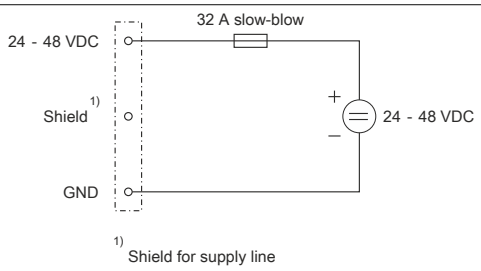
X1 and X2 terminal blocks

The following image shows a connection example for the X1 terminal block. The connection example also applies to the X2 terminal block.



X3 terminal block

For information on the fuse used, see 4.25.3.9 "Protection"



4.25.5.7 Possible uses for digital inputs

Digital input channels 1 to 16 can be used as follows:

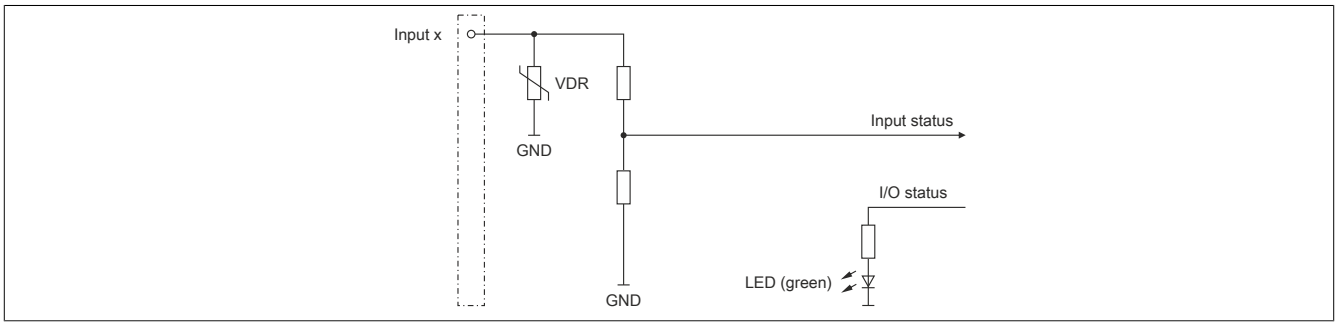
Channel	Function	Special functions
DI 1	Digital input	A
DI 2	Digital input	B
DI 3	Digital input	Limit switch, trigger, reference pulse
DI 4	Digital input	Limit switch, trigger, reference enable
DI 5	Digital input	A
DI 6	Digital input	B
DI 7	Digital input	Limit switch, trigger, reference pulse
DI 8	Digital input	Limit switch, trigger, reference enable
DI 9	Digital input	A
DI 10	Digital input	B
DI 11	Digital input	Limit switch, trigger, reference pulse
DI 12	Digital input	Limit switch, trigger, reference enable
DI 13	Digital input	A
DI 14	Digital input	B
DI 15	Digital input	Limit switch, trigger, reference pulse
DI 16	Digital input	Limit switch, trigger, reference enable

The functions can also be mixed:

Example 1	
Channel	**Function**
DI 1	Digital input
DI 2	Digital input
DI 3	Digital input
DI 4	Digital input
DI 5	Digital input
DI 6	Digital input
DI 7	Digital input
DI 8	Digital input
DI 9	A
DI 10	B
DI 11	R
DI 12	
DI 13	A
DI 14	B
DI 15	R
DI 16	

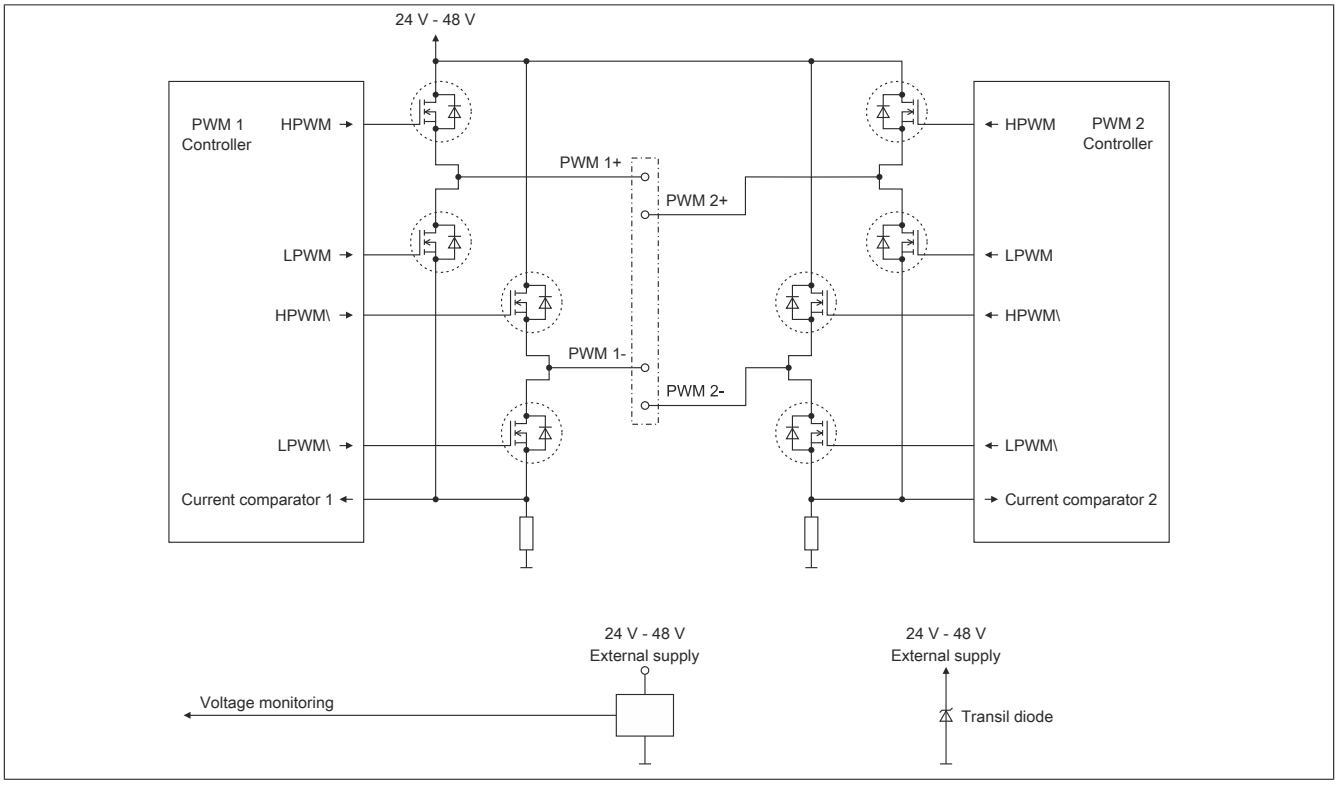
Example 2	
Channel	**Function**
DI 1	A
DI 2	B
DI 3	R
DI 4	
DI 5	Digital input
DI 6	Digital input
DI 7	Digital input
DI 8	Digital input
DI 8	Digital input
DI 10	Digital input
DI 11	Digital input
DI 12	Digital input
DI 13	A
DI 14	B
DI 15	R
DI 16	

4.25.5.8 Input circuit diagram



4.25.5.9 Output circuit diagram

The following image shows the output circuit diagram for the outputs 1 and 2. The diagram also applies to the outputs 3 and 4.



4.25.5.10 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load, but is always less than the sum of the output currents. Make sure that the maximum nominal current of 31 A per pin is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of layout, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of layout, see table):

I_{Mains}	≤	I_b	≤	I_Z
Mains	≤	Fuse	≤	Line/cable

Wire cross section [mm²]	Current load of the cable cross section I_Z / rated current of the over current protection I_b [A] according to type of installation in an ambient air temperature of 40°C in accordance to IEC 60204-1			
	B1	**B2**	**C**	**E**
1.5	13.5 / 13	13.1 / 10	15.2 / 13	16.1 / 16
2.5	18.3 / 16	16.5 / 16	21 / 20	22 / 20
4.0	24.0 / 24.0	23.0 / 20.0	28.0 / 25.0	30.0 / 25.0
6.0	32.0 / 32.0	29.0 / 25.0	36.0 / 32.0	37.0 / 32.0

Table 566: Cable cross section of the mains supply line depending on the type of layout

The tripping current of the fuse cannot exceed the rated current of fuse I_b.

Type of layout	Description
B1	Wires in conduit or cable duct
B2	Cables in conduit or cable duct
C	Cables or wires on walls
E	Cables or wires on open cable tray

Table 567: Type of layout for the mains supply line

4.25.5.11 Monitoring the module supply

The module supply is continually monitored. If the following limits are exceeded in either direction, an error bit is set.

Upper limit:	>80 V
Warning stage:	>60 V
Lower limit:	<18 V

4.25.5.12 Overvoltage cutoff

If the supply voltage on the module exceeds 80V (e.g. through feedback during generator operation), then all PWM outputs are disabled (PWM output pins are short-circuited). The outputs are reactivated as soon as the supply voltage is back in the valid range. Switching the outputs on again can cause an open load error in current mode (depending on the current setpoint and load inductance) as well as with any other abrupt change to the current setpoint value.

4.25.5.13 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The PWM outputs are disabled (short-circuited)

Once the module temperature sinks to 83°C, the error bit is automatically cleared by the module and the outputs become operational again.

4.25.5.14 Measurement of effective current

In current controller mode (see bit 12 in the configuration register), there is an apparent deviation between the current setpoint and the measured effective current.

This is due to how the module operates. The PWM output remains "On" or in "Fast Decay" as long as needed to reach the current setpoint. Therefore, the current setpoint is the maximum or minimum current in a specified PWM cycle. This is why the effective current of this cycle (average current of this cycle) is lower (PWM = "On") or higher (PWM = "Fast Decay") than the current setpoint.

The size of the deviation depends on the load impedance.

4.25.5.15 Register description

4.25.5.15.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.25.5.15.2 Function model 0 - Standard

Register	Name	Data type	Read		Write

1) The offset specifies the position of the register within the CAN object.

4.25.5.15.3.1 CAN I/O bus controller

The module occupies 4 analog logical slots on CAN-I/O.

4.25.5.15.4 Configuration

4.25.5.15.4.1 Configuration

Name:
Configuration01 to Configuration04

These registers can be used to configure the four DC motors.

The following placeholders are used in the configuration table:

Register	[x]	In1	In2
Configuration01	1	DI3	DI4
Configuration02	2	DI7	DI8
Configuration03	3	DI11	DI12
Configuration04	4	DI15	DI16

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Configuration of latch function for ABR counter **[x]**. Activation of the latch function is described in the control register (bit 2):	00	ABR counter **[x]** is latched unconditionally (default setting). The reference enable input is ignored.
		01	ABR counter **[x]** is latched if a rising edge occurs on digital input **In1** and the reference enable input **In2** is "1". The reference enable input must be activated to do this (see bit 2).
		10	ABR counter 1 is latched if a rising edge occurs on digital input **In1** and the reference enable input **In2** is "1". The reference enable input must be activated to do this (see bit 2).
		11	The latch function is disabled.
2	Reference enable input:	0	No reference enable input
		1	Digital input **In2** is used as a reference enable input
3	Active level of the reference enable for ABR counter **[x]**:	0	Active level = High
		1	Active level = Low
4 - 5	Reserved	0	
6 - 7	Definition of the limit switch **[x]** (see also Limit switch function):	00	Limit switch 1 is disabled
		01	Digital input **In1** is used as the limit switch
		10	Digital input **In2** is used as the limit switch
		11	Digital inputs **In1** and **In2** are used as left and right limit switches
8	Active level for limit switch **[x]**:	0	Active level = High
		1	Active level = Low
9 - 10	Trigger input for trigger counter "µs Since Trigger **[x]**":	00	Trigger counter disabled
		01	Digital input **In1** is used as trigger input
		10	Digital input **In2** is used as trigger input
		11	Reserved
11	Displays the current average for output **[x]**:	0	If the corresponding setting has been activated, then the average current value is shown in the 4.25.5.15.5.2 "ABR counter**[x]** register (see bit 5 in the control register)
		1	If the corresponding setting has been activated, then the average current value is shown in the 4.25.5.15.5.3 "us_since_Trigger**[x]** register (see bit 5 in the control register).
12	Type of control for output **[x]**:	0	PWM control
		1	Current control
13 - 14	Decay configuration PWM **[x]** (see also 4.25.5.15.6 "Decay configuration"):	00	Slow decay (default setting)
		01	Mixed decay
		10 - 11	Reserved
15	Reserved	0	

Limit switch function

The limit switch function serves to quickly shut off the PWM outputs when a limit position is reached.

The limit switch is activated and the disable edge (rising or falling) on the limit switch input is selected using bits 6 to 8.

A PWM output is deactivated as soon as the configured disable edge is reached on the corresponding input of the limit switch. It remains deactivated until either the limit switch function is deactivated or the limit switch is acknowledged with bit 4 in the respective control register.

4.25.5.15.4.2 Control

Name:
TriggerEdge01 to TriggerEdge04
StartTrigger01 to StartTrigger04
StartLatch01 to StartLatch04
DitherDisable01 to DitherDisable04
ClearError01 to ClearError04
ShowMeanCurrent01 to ShowMeanCurrent04
ResetCounter01 to ResetCounter04

These registers can be used to configure the behavior of the trigger, the ABR counter and the dither.

[x] represents the corresponding control number.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	TriggerEdge**[x]** Configuration of trigger edge for "µs Since Trigger":	0	Counting starts at rising edge
		1	Counting starts at falling edge
1	StartTrigger**[x]** Status change of bit 1 enables the "µs Since Trigger"	x	Counting starts at the next trigger edge (see bit 0). For more information about trigger functionality, see "Trigger function procedure".
2	StartLatch**[x]** Latching and referencing ABR counter:	0	Disabled
		1	Enabled
3	DitherDisable **[x]**	0	Dither for PWM output **[x]** is enabled (default setting). The dither frequency and dither amplitude must be >0 (see 4.25.5.15.4.5 "Dither").
		1	Dither for PWM output **[x]** is disabled.
4	ClearError**[x]** Acknowledge error or limit switch:	0	No effect
		1	Error acknowledgment on output **[x]** (overcurrent or open load) or acknowledgment from limit switch **[x]**
5	ShowMeanCurrent**[x]** Configuration of registers ABR counter latch and us_since_Trigger	0	The register ABR counter latch **[x]** contains the latched counter value. The register µs Since Trigger **[x]** contains the trigger counter.
		1	Both registers contain the current PWM output current
6	ResetCounter[x] Reset ABR counter	0	Enable ABR counter (default)
		1	Reset ABR counter
7	Reserved	0	

Trigger function procedure

The following points must be taken into consideration when configuring or activating the trigger function:

- Select the desired trigger edge using bit 0
- Enable the trigger function by changing the state of StartTrigger (bit 1). This edge clears the register us_since_Trigger (µs counter).
- When the trigger event occurs, the µs counter "µs Since Trigger" is started
- The "µs Since Trigger" counter cannot overrun, i.e. the counter is stopped at 2^{16}-1 and retains this value until the next time the trigger function is activated
- The trigger function can be re-activated at any time by changing the state of StartTrigger (bit 1) regardless of if a trigger event has occurred or if "µs Since Trigger" has reached its maximum value.

Reset ABR counter

Bit 6 sets the following counters and status bits to 0:

- ABR counter
- Latch value of the ABR counter
- Latching started on the ABR counter (bit 4 of the status register)
- ABR counter successfully latched (bit 5 of the status register)

Please note that a started latch procedure is no longer active after the ABR counter has been reset. This means that latching must be restarted by a rising edge on bit 2.

4.25.5.15.4.3 PWM period duration

Name:
PeriodDurationPWM

This register can be used to set the period duration between 20 µs (50 kHz) and 65535 µs (15 Hz).

Data type	Value	Information
UINT	20 to 65535	Time in µs

4.25.5.15.4.4 PWM pulse width

Name:
PulseWidthCurrentPWM01 to PulseWidthCurrentPWM04

The PWM pulse width (PWM mode) or current setting (in current mode) is entered in this register according to the setting in the module configuration register. A negative value changes the output polarity.

PWM mode

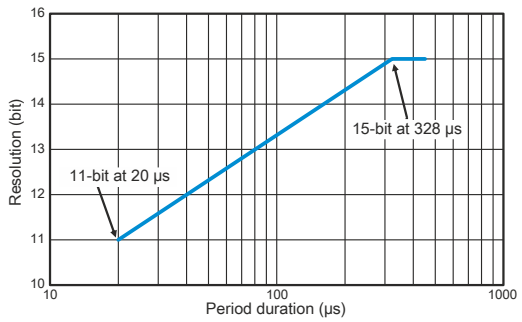
Data type	Value	Output +	Output -
INT	32767	High	Low
	16384	PWM 50/50	Low
	0	Low	Low
	-16384	Low	PWM 50/50
	-32767	Low	High

Current mode

Data type	Value	Current mode
INT	19661 to 32767	6 to 10 A (max. 2 s)
	19660	6 A
	0	0 A
	-19660	-6 A
	-19661 to -32767	-6 to -10 A (max. 2 s)

Resolution/Derating

As mentioned earlier in the technical data, the PWM resolution is 15-bit (+ sign). This value is derated for a period duration of less than 328 µs because of the minimal PWM timing resolution (10 ns) (see following diagram). With the minimum PWM period duration of 20 µs, the PWM has 11-bit resolution (+ sign):



4.25.5.15.4.5 Dither

A dither is used to prevent valves from sticking. This function is supported in both PWM mode and in current mode. The pulse width or current is adjusted according to the dither amplitude and dither frequency.

By default, the dither is active for both outputs as soon as the dither amplitude and dither frequency are set to a value >0. If necessary, the dither can be deactivated for each output individually or simultaneously (see bit 3 in the respective control register).

Dither amplitude

Name:
ConfigOutput01

This register can be used to configure the amplitude value or pulse width.
0 to 255 corresponds with an amplitude value from 0.0 to 25.5% of the nominal current or the maximum pulse width of 32767.

Data type	Value	Information
USINT	0 to 255	Amplitude value or pulse width

Dither frequency

Name:
ConfigOutput02

This register can be used to set the frequency in 2 Hz steps.

Data type	Value	Information
USINT	0 to 255	Corresponds to 0 to 510 Hz

Dither example

Valve specification	Valve specification is 20 to 35% peak to peak of the valve current at 5 A.
	This corresponds to a dither amplitude of ±5 to ±9% at 10 A. A midrange dither amplitude of 7% at 10 A is selected. This corresponds to a setting of 70.
Dither frequency specification	**40 to 70 Hz**
	A setting of 28 is selected. This corresponds to a frequency of 56 Hz.

4.25.5.15.5 Communication

4.25.5.15.5.1 ABR counter

Name:
Counter01 to Counter04

These registers are 16-bit AB(R) counters.

Data type	Value
INT	-32768 to 32767

4.25.5.15.5.2 ABR counter latch

Name:
CounterLatch01 to CounterLatch04

When a latch event occurs, the current counter values are saved in these registers. For additional features, see bit 5 in the respective control register.

Data type	Value
INT	-32768 to 32767

4.25.5.15.5.3 us_since_Trigger

Name:
usSinceTrigger01 to usSinceTrigger04

This register shows either the time in µs since the last trigger event or the average current value.

- The "µs Since Trigger" counter cannot overrun, i.e. the counter is stopped at 2^{16}-1 and retains this value until the next time the trigger function is activated
- If the average current is displayed in this register (bit 11 in the respective configuration register), then the data type of µs Since Trigger in Automation Studio must be unsigned integer (UINT). The average current value, on the other hand, is an Integer (INT). This means that negative currents are displayed between 32,769 and 65,535.

Counting mode

Data type	Value
UINT	0 to 65535

Measurement of average current value

Data type	Value	Information
INT	19,661 to 32,767	6 to 10 A
	19,660	6 A
	1	305 µA (= 10 A / 32,767)
	0	0 A
	65,535	-305 µA (= -10 A / 32,767)
	45,876	-6 A
	45,875 to 32,769	-6 to -10 A

4.25.5.15.5.4 Status of inputs

Name:
StatusInput01 to StatusInput16
nLatchPending01 to nLatchPending04
LatchDone01 to LatchDone04
EndswitchReached01 to EndswitchReached04
PWMError01 to PWMError0

These registers indicate the status of the inputs and outputs for each DC motor.

The following placeholders are used in the status table.

Register	[x]	In1	In2	In3	In4
Status of input 1	1	DI1	DI2	DI3	DI4
Status of input 2	2	DI5	DI6	DI7	DI8
Status of input 3	3	DI9	DI10	DI11	DI12
Status of input 4	4	DI13	DI14	DI15	DI16

Data type	Value
USINT[1)]	See bit structure.
UINT[2)]	See bit structure.

1) Function model 0 and function model 254 → Register "Status of input 3" and "Status of input 4"
2) Only function model 254 → Register "Status of input 1" and "Status of input 2"

Bit structure:

Bit	Description	Value	Information
0	StatusInput **[In1]**	x	**In1** is used for the encoder signal A of ABR counter **[x]**.
1	StatusInput **[In2]**	x	**In2** is used for the encoder signal B of ABR counter **[x]**.
2	StatusInput **[In3]**	0	Possible uses for the digital input • Trigger input **[x]** • Reference pulse for ABR counter **[x]** • Limit switch **[x]** (left)
3	StatusInput **[In4]**	0	Possible uses for the digital input • Reference enable **[x]** • Trigger input **[x]** • Limit switch **[x]** (right)
4	nLatchPending **[x]**	00	Latching started
		01	ABR counter latch **[x]** ready. Latch not yet started.
5	LatchDone **[x]**	0	The status of this bit is changed each time ABR counter **[x]** is successfully latched
6	EndswitchReached **[x]**	00	No effect on PWM output **[x]**
		01	Endswitch **[x]** reached. PWM output **[x]** disabled.
7	PWMError **[x]**	0	Error free operation
		1	An error has occurred. The error can be determined by evaluating the two error registers 4.25.5.15.5.6 "Global errors" and 4.25.5.15.5.5 "Channel errors".
8 - 15	**Only Function model 254**		
	Status of input 1	x	With "Status of inputs 1", bits 12 to 15 contain error bits 4 to 7 from the 4.25.5.15.5.6 "Global error" register.
	Status of input 2	x	With "Status of inputs 2", bits 8 to 15 contain error bits 0 to 7 from the 4.25.5.15.5.5 "Channel errors" register

4.25.5.15.5.5 Channel errors

Name:
CurrentError01 to CurrentError04
OverCurrentError01 to OverCurrentError04

If an error is detected, the corresponding error bit in this register remains set until the error is acknowledged using bit 4 in the respective "control register".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	CurrentError01	0	No error
		1	Open load error
1	OverCurrentError01	0	No error
		1	Overcurrent errorOutput deactivated.
2	CurrentError02	0	No error
		1	Open load error
3	OverCurrentError02	0	No error
		1	Overcurrent errorOutput deactivated.
4	CurrentError03	0	No error
		1	Open load error
5	OverCurrentError03	0	No error
		1	Overcurrent errorOutput deactivated.
6	CurrentError04	0	No error
		1	Open load error
7	OverCurrentError04	0	No error
		1	Overcurrent errorOutput deactivated.

Overcurrent error

An overcurrent error is registered if one of the following conditions is met:

- ≥10 A flow from a PWM output for at least 2 seconds
- ≥16 A flow for 3 consecutive PWM cycles
- All PWM outputs together consume more than 32 A on the X3 connector

In all three cases, the affected PWM output is deactivated by the firmware (i.e. the pins on the PWM output are short-circuited). The user must acknowledge the error using bit 4 in the respective control register before a PWM output deactivated in this manner can be made operational again.

Open load error

An open load error is only registered in current control mode (see bit 12 in the respective configuration register) if the current setpoint is not reached. In some cases this can be caused by an open line, although usually the impedance of the load is too high.

4.25.5.15.5.6 Global error

Name:
OverVoltageError
UnderVoltageError
VoltageWarning
OvertemperatureError

This register indicates overtemperature and errors in the module supply. The error bits are automatically acknowledged by the module as soon as the values are back within the permissible limits.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	0	
4	OverVoltageError	0	No error
		1	Voltage >80 V. All outputs are deactivated.
5	UnderVoltageError	0	No error
		1	Voltage <18 V
6	VoltageWarning	0	No error
		1	Voltage >60 V
7	OvertemperatureError	0	No error
		1	Module overtemperature; all outputs are deactivated.

4.25.5.15.5.7 Temperature

Name:
ModuleTemperature

The module temperature is displayed in this register.

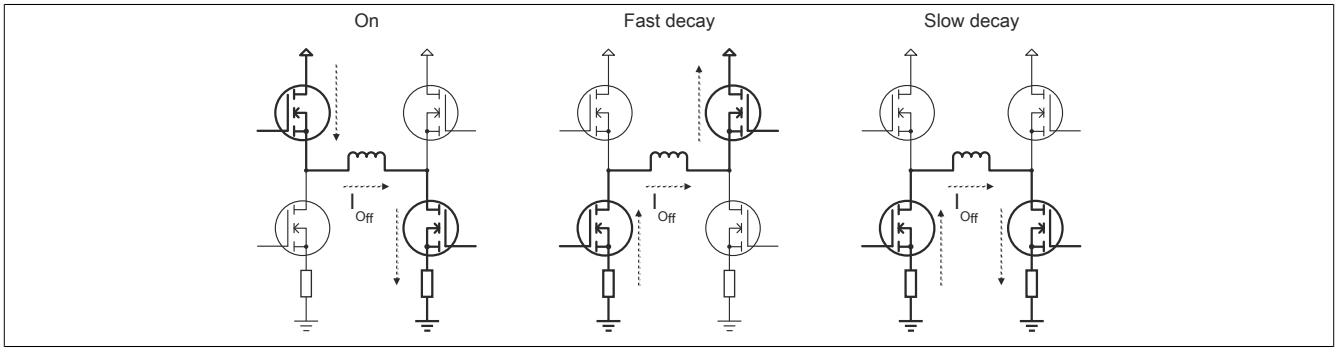
Data type	Value	Information
SINT	-40 to 125	Module temperature in °C

4.25.5.15.6 Decay configuration

The decay configuration determines the method and dynamics of current reduction for inductive loads or motors.

"Slow decay" is configured by default. In this mode, the current is automatically reduced relatively slowly with resistance in the load. No energy is regenerated into the module.

"Mixed decay" mode is recommended for applications that require a dynamic and linear reduction of current. In this mode, energy is regenerated into the module during part of the PWM cycle (fast decay).



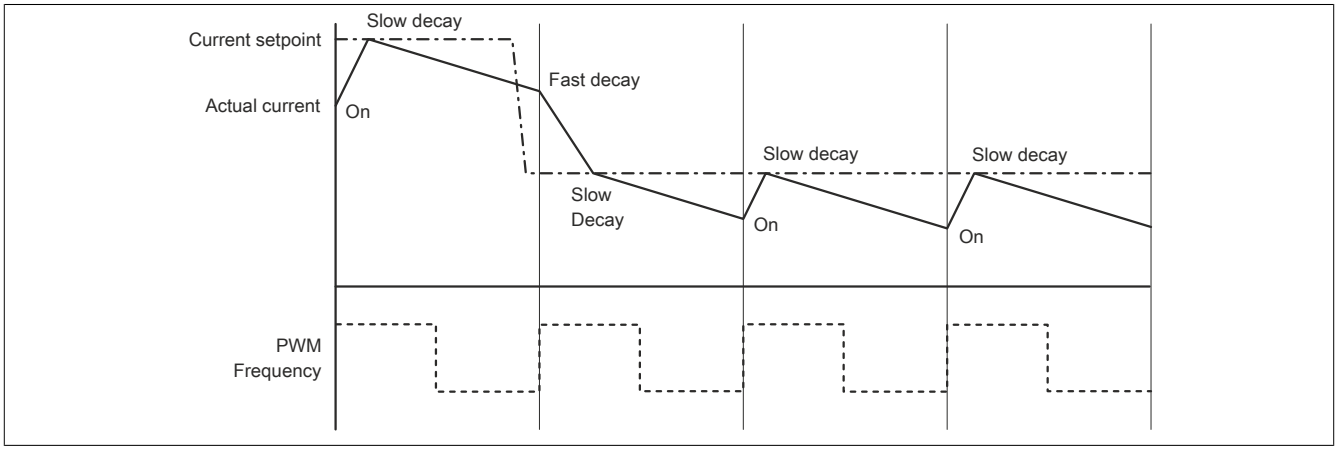
4.25.5.15.6.1 Current control

As its name suggests, mixed decay mode is a mix of "slow decay" and "fast decay". This occurs as follows:

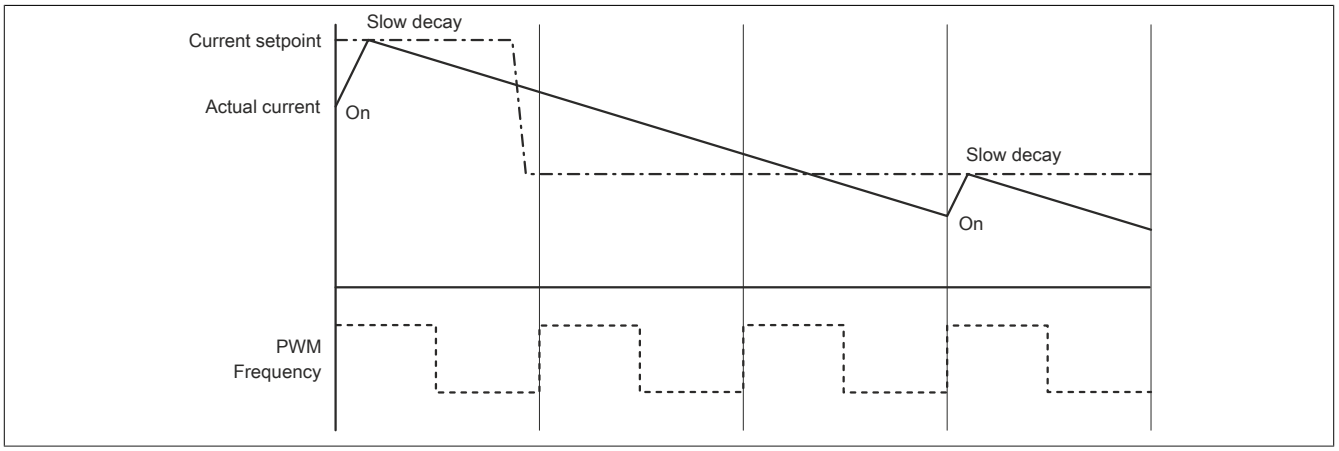
A check is made at the beginning of each PWM cycle to determine if the actual current for the phases is below the set current. If this is the case, PWM is enabled (On) until the current setpoint is reached. If the current setpoint has already been exceeded at the beginning of the PWM cycle (generator operation), the system immediately switches to fast decay mode until the current setpoint is exceeded. The rest of the PWM cycle always takes place in slow decay mode.

This also permits generator operation as long as the valid range for the supply voltage has not been exceeded due to the regeneration into the DC circuit.

Current control in Mixed Decay mode



Current control in Slow Decay mode

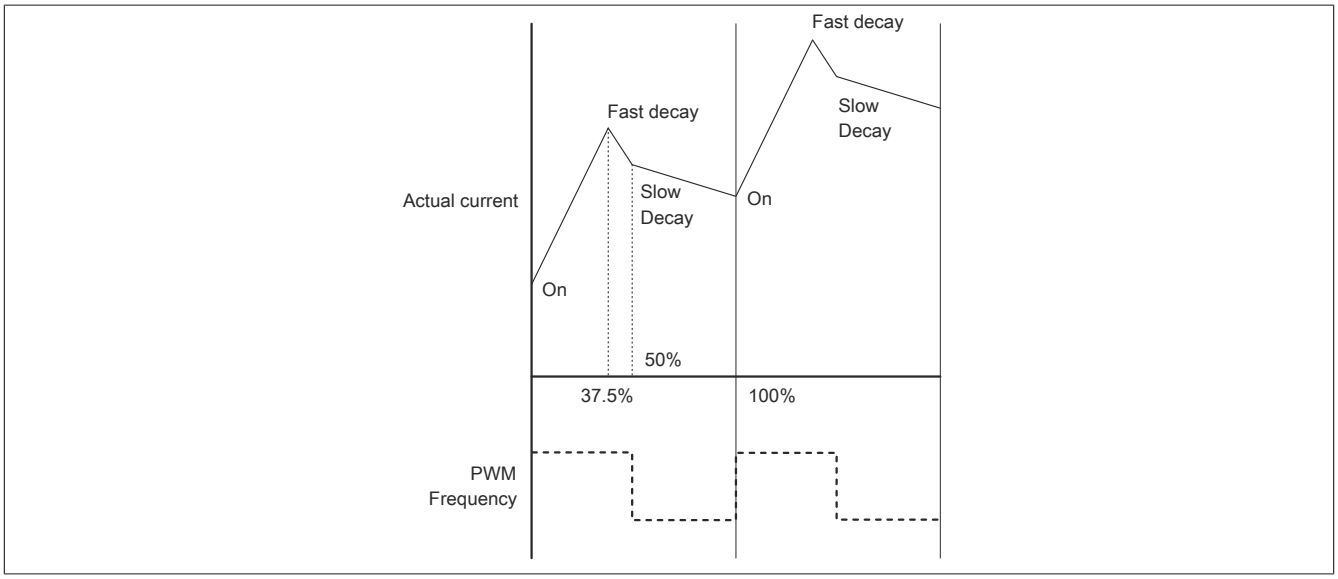


4.25.5.15.6.2 PWM control

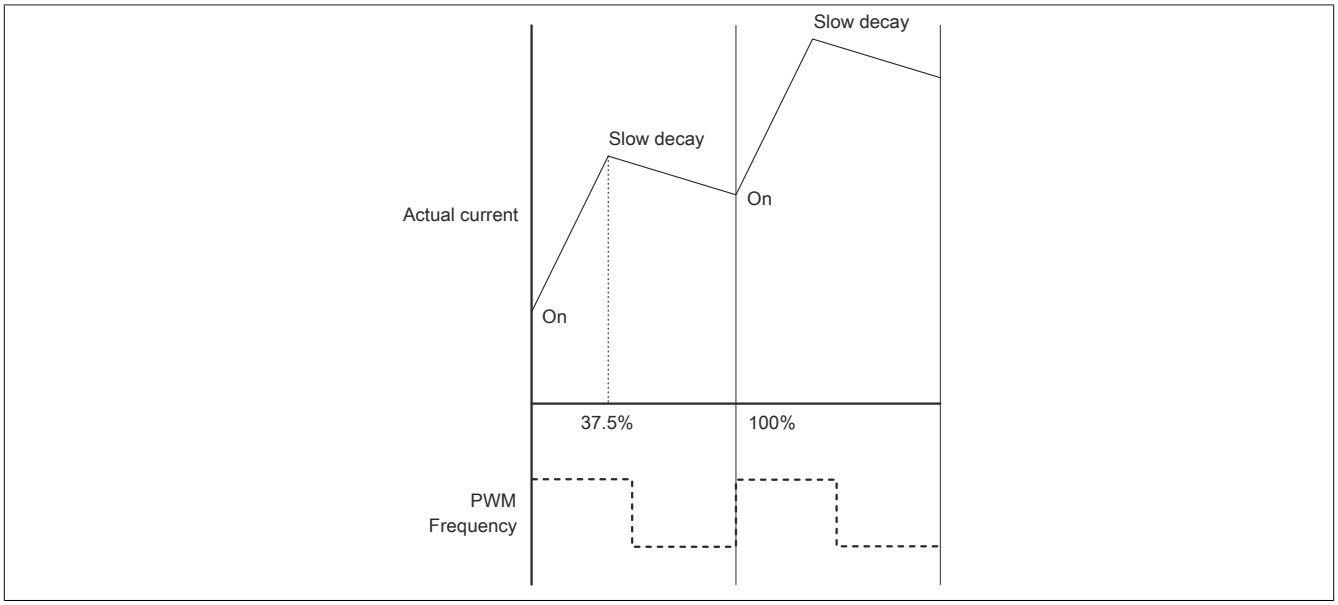
When Mixed Decay mode is enabled, the outputs are driven in Fast Decay mode up until 50% of the period and in Slow Decay mode for the remainder of the switch-off phase.

When Slow Decay mode is used, it is immediately enabled during the switch-off phase.

PWM control in Mixed Decay mode (pulse duty factor = 37.5%)



PWM control in Slow Decay mode (pulse duty factor = 37.5%)



Operating DC motors

In PWM mode, the motor current is limited to the maximum current (10 A), independent of the supply voltage.

However, the motor switches to generator operation when braking. Because of the counter EMF, which is dependent on the rotary speed, a current is generated in the module that is only limited by the internal resistance of the motor. This is not permitted to exceed 15 A (maximum 2 seconds).

The counter EMF closely corresponds to the voltage needed to achieve this speed. Therefore, the maximum brake current is very easy to calculate with the following formula.

$$I_{Brake} = U_e.Pulse\ width(in\ \%)/100.\frac{1}{R_{Motor}}$$

Example:

Module supply	42 V
Pulse width	16364 (equal to 50%)
Internal resistance of motor	3.5 Ω

$$I_{Brake} = 42V.50/100.\frac{1}{3.5\Omega} = 6A$$

4.25.5.15.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
400 µs

4.25.5.15.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
400 µs

4.25.6 X20SM1426

4.25.6.1 General information

The stepper motor module is used to control stepper motors with a rated voltage of 24 VDC at a motor current up to 1 A (1.2 A peak). Additionally, this module has four digital inputs that can be used as limit switches or as encoder inputs.

By individually adjusting the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because the latter reduces energy consumption and thermal load, the effects are positive on the lifespan of the complete system. Complete flexibility is achieved by using the values for holding current, maximum current and rated current, which are completely independent of each other. The current for the microsteps is automatically adjusted to the configured current values.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. The stall is recognized using a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 VDC, 1 A (1.2 A peak)
- Resolution of current values at 1%
- Maximum, rated and holding current configured independent of each other
- 38.5 kHz PWM frequency
- Integrated motor detection
- 256 micro-steps
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, can be configured as ABR
- Ramp function model based on the CANopen communication profile DS402

4.25.6.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset state
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input state of the corresponding digital input
	M	Orange	On	Motor is active

1) Depending on the configuration, a firmware update can take up to several minutes.

4.25.6.5 Pinout

In accordance with the EN60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 1.2 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

Shielded motor cables must be used in order to meet the limits according to the EN55011 standard (emissions).

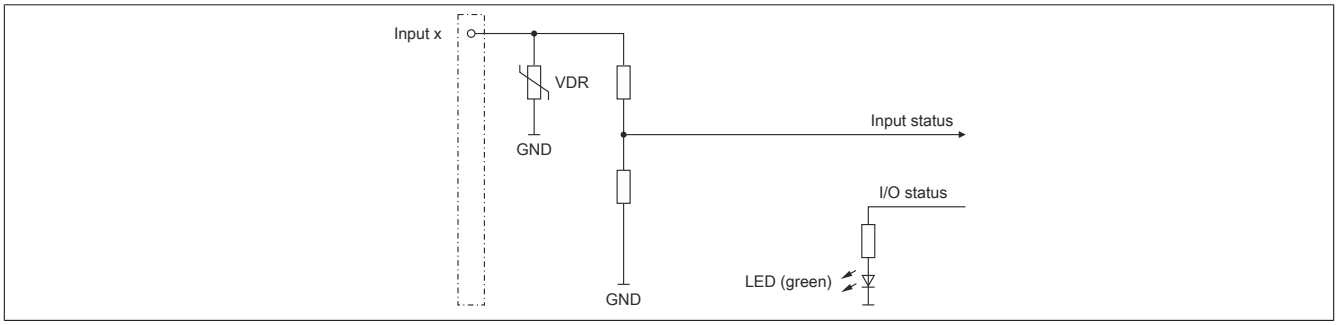
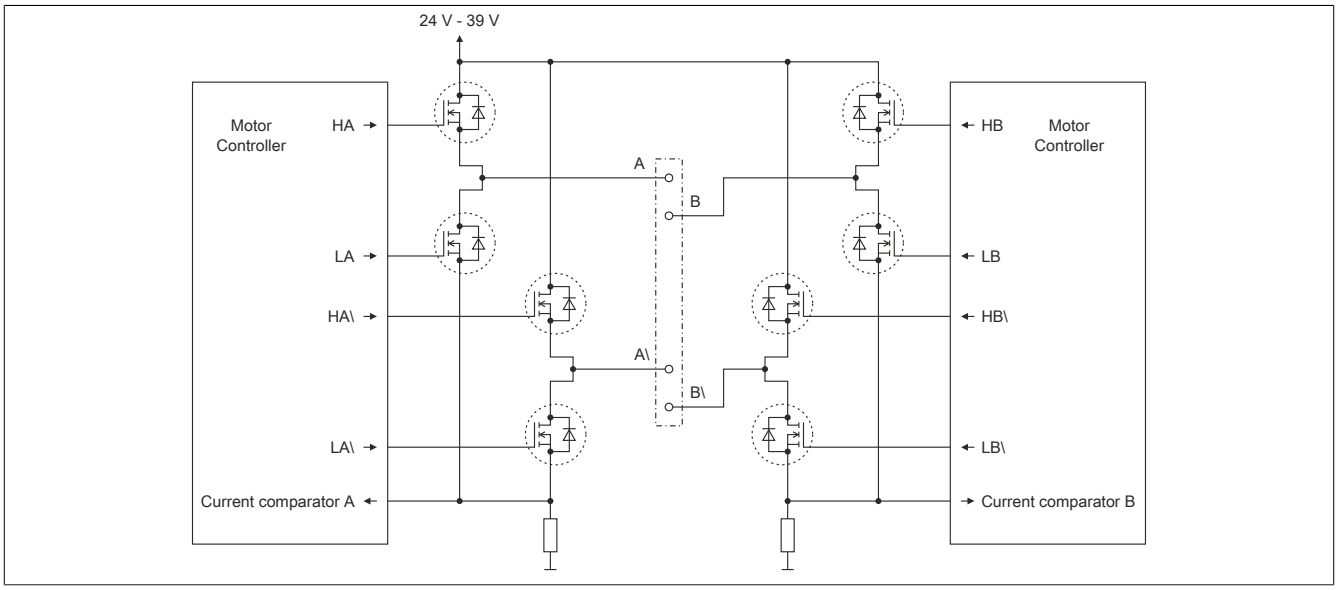
DI 4	Digital input	Digital input	Positive limit switch

4.25.6.8 Input circuit diagram



4.25.6.9 Output circuit diagram



4.25.6.10 Overvoltage cutoff

The module supply voltage is continually monitored. Its status can be read. The error "Module power supply error" occurs when the voltage is above or below the limits.

If the supply voltage on the module rises or falls outside the limit values (e.g. due to regeneration), then the motor output is switched off. The outputs are reactivated as soon as the supply voltage is back in the valid range and the error bit is reset.

Supply voltage limit values

	Drive is switched off	Drive is switched back on
Lower limit	<17.5 V	>19.5 V
Upper limit	>30 V	<29.0 V

4.25.6.11 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The outputs are switched off (short-circuited)

As soon as the temperature sinks back down below 85°C, the error must be acknowledged with OvertemperatureAcknowledge so that the channels can be switched on again.

4.25.6.12 Derating

Modules next to the SM module can have a maximum power consumption of 1 W. To ensure proper operation, the derating values listed below must be adhered to:

Power loss derating for neighboring modules

Modules directly next to the SM module can have a power loss of 1 W. If the SM module is operated at the rated load over the entire temperature range (1 A rated current), the power loss of neighboring modules must be derated starting at 45°C.

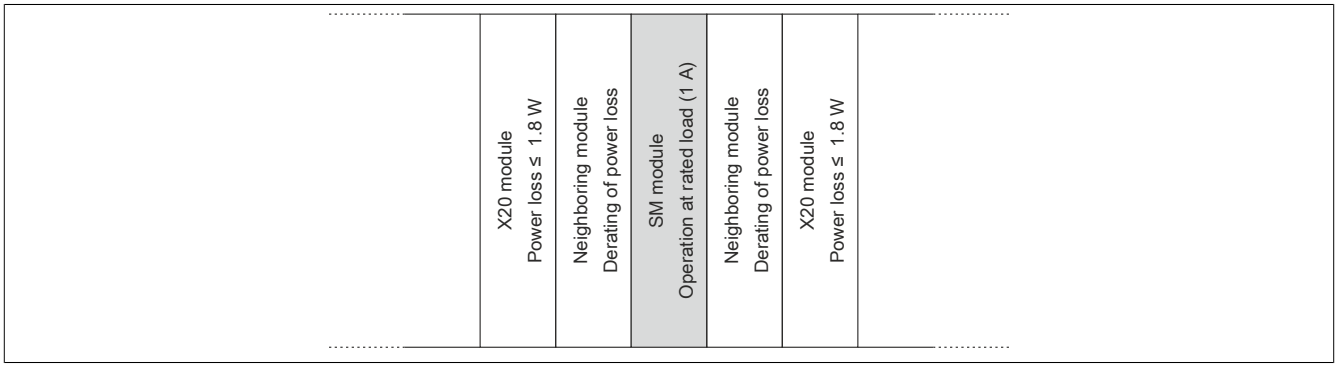


Figure 380: Operating the SM module over the entire temperature range at 1 A rated current

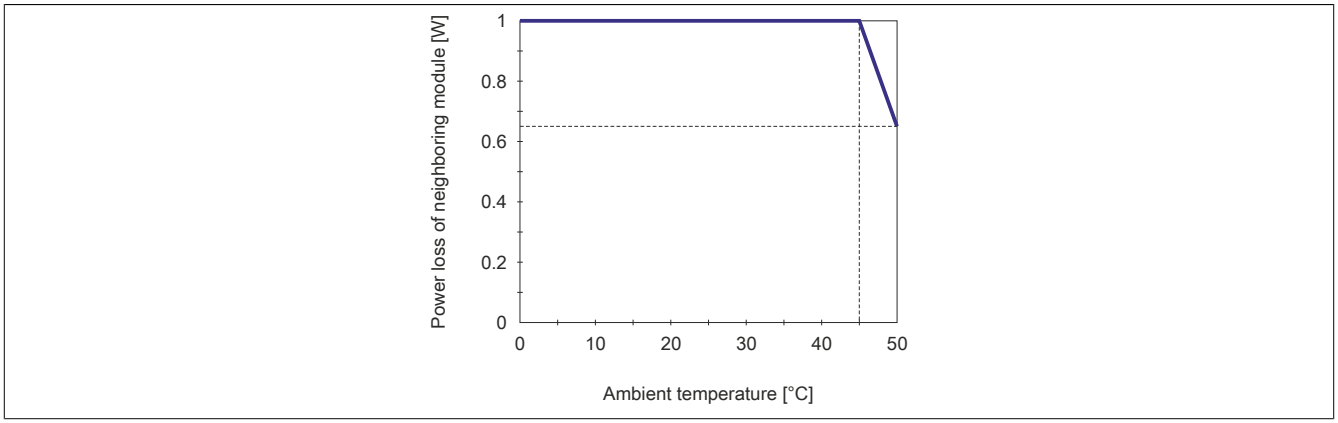

Figure 381: Power loss derating for directly neighboring modules

Current derating of the SM module

If the power loss of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

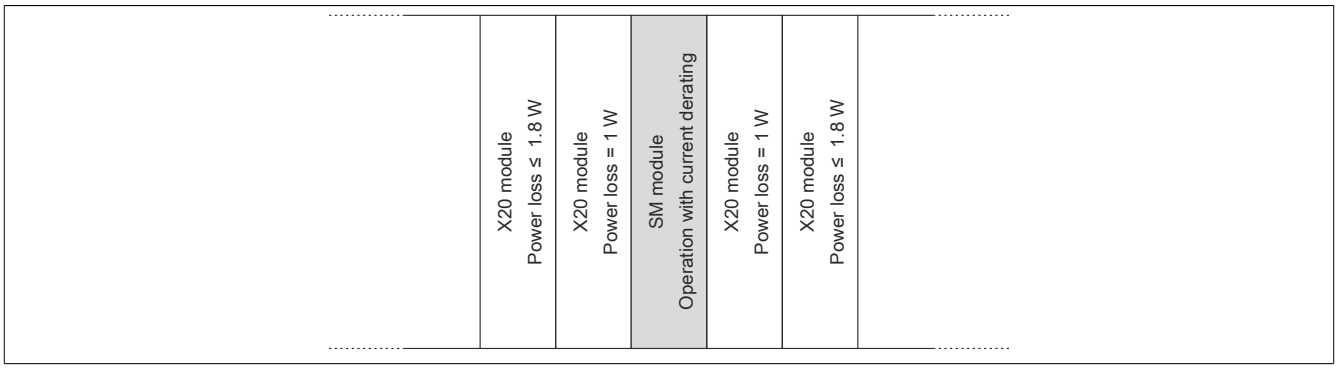

Figure 382: Neighboring modules to the SM module have a power loss of 1 W

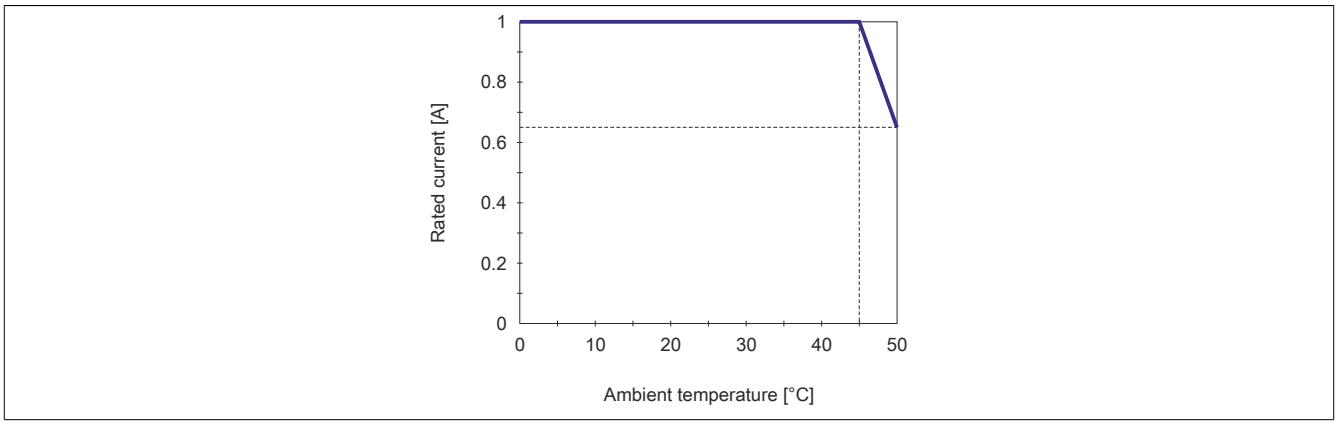

Figure 383: Current derating

Current derating for multiple SM modules

If three or more SM modules are operated in a cluster, the current of the SM modules must be derated as follows starting at 40°C.

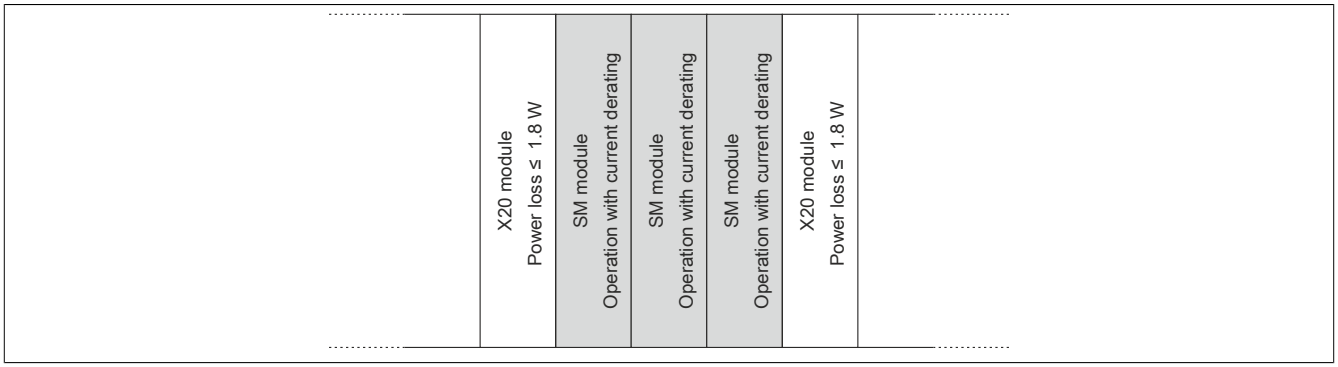

Figure 384: Operating three or more SM modules in a cluster

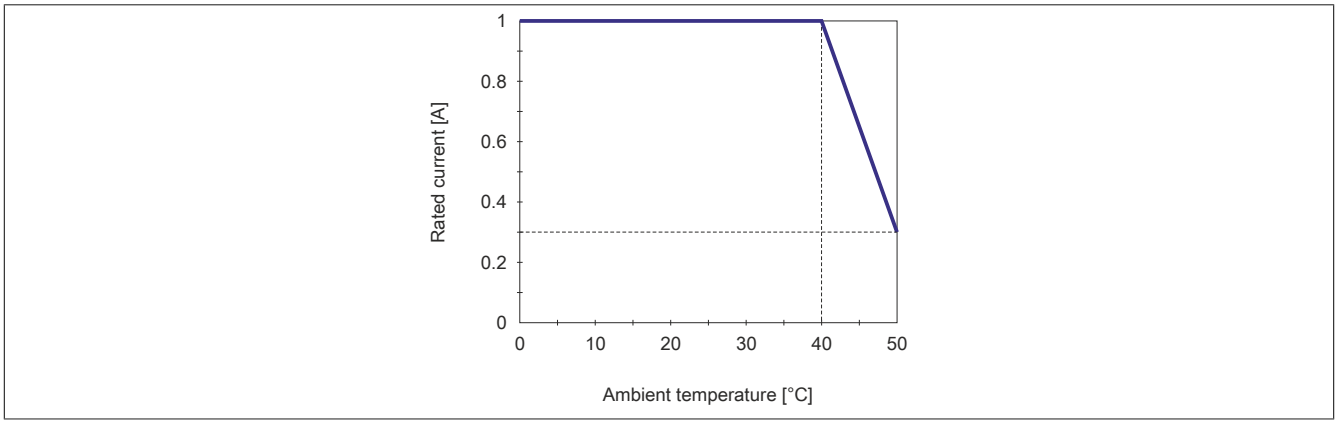

Figure 385: Current derating

4.25.6.13 Register description

4.25.6.13.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

1) The offset specifies the position of the register within the CAN object.

4.25.6.13.4.1 Operation with bus controller

The following function model can be used when the SM module is used together with a bus controller.

Bus controller	Function model
X20BC0083, X20BC1083, X20BC8083, X20BC8084	All function models
All others	Function model 254 - Bus controller (identical to Ramp function model)

4.25.6.13.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.25.6.13.5 Register description: Standard functional model, shared registers

4.25.6.13.5.1 Configuration registers

Stall threshold

Name:
ConfigOutput01

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

With the "stall threshold" register, a threshold can be defined according to the motor load, and the module detects a stall condition started at this threshold (see "Error status").

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection (see "Mixed decay threshold")

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Trigger threshold for stall detection	0	Stall detection is disabled
		1	Minimum sensitivity for stall detection
		2 to 6	Setting the sensitivity of stall detection
		7	Maximum sensitivity for stall detection
3 - 15	Reserved	0	

Mixed decay threshold

Name:
ConfigOutput16

The mixed decay threshold is configured in this register. This value must be adjusted according to the motor being used, current and voltage when using stall detection. Otherwise, the default value 15 will be used.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Mixed Decay Threshold	0	Mixed decay disabled
		1 to 14	Setting for mixed decay threshold
		15	Mixed decay always enabled
4 - 15	Reserved	-	

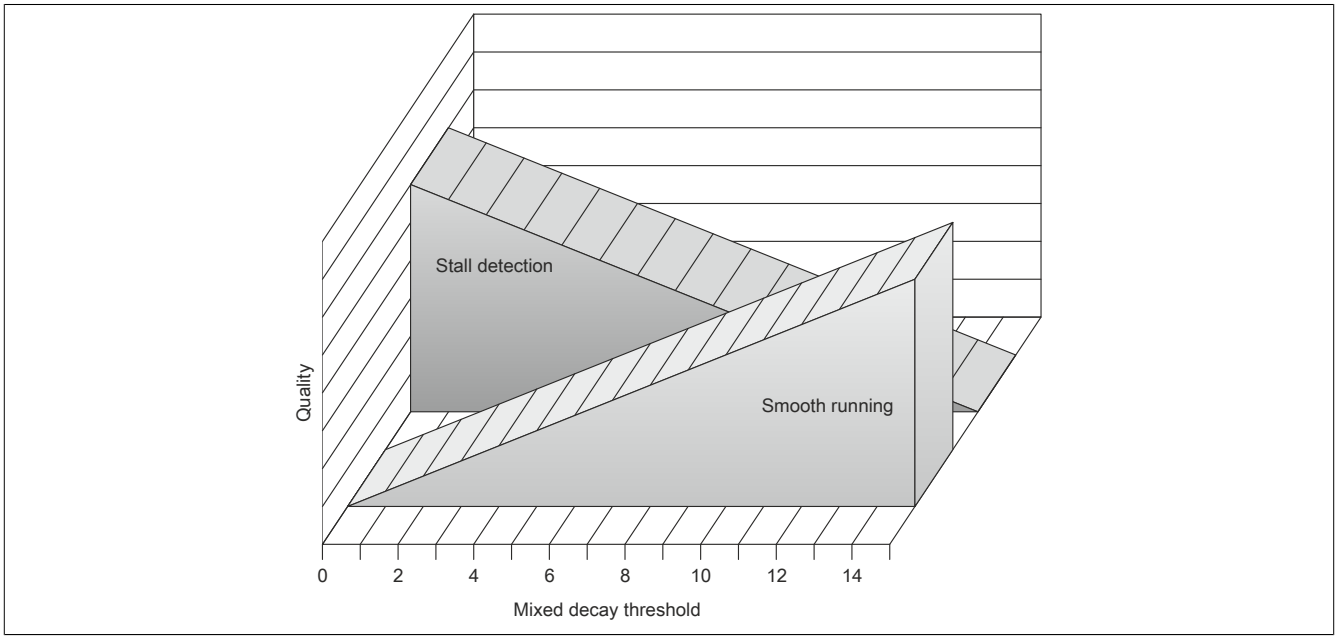
Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.



Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured mixed decay threshold is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

Data type	Value	Information
UINT	0 to 65535	Minimum speed in steps per second.

Full step threshold

Name:
FullStepThreshold01

This register is used to configure a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimum concentricity at lower speeds.

It does not make sense to change to full step mode when at a standstill because fine positioning would then no longer be possible. This is why the value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

Data type	Value	Information
UINT	0	Full step mode disabled
	1 to 65,535	steps/second

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500\ steps/second}{200\ steps/round} = 2.5\ \frac{rounds}{second} = 150\ \mathrm{min}^{-1}$$

Holding current, rated current and maximum current

Name:
ConfigOutput03 (holding current)
ConfigOutput04 (rated current)
ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

Register	Description
Nominal current	Current during normal operation
Maximum current	Should be selected if a higher motor torque is required briefly during acceleration phases.
Holding current	The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor.

Switching between preset current values (holding current, rated current, maximum current):

Function model	Switching between preset current values at runtime
Default	Using bits 14 and 15 in the registers Motor StepX
Standard with enabled SDC information	Using the register Motor current

Data type	Value	Unit
USINT	0 to 117	Percent of the module's rated current • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data

Counter configuration

Name:
ConfigOutput09

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ABR latch function	0	Negative edge: Disable ABR latch function.
		1	Positive edge: Enable latch ABR latch function. After a latch event has occurred, the latch function can be started again with a new rising edge.
1 - 2	Definition of the latch mode	00	Latch ABR counter state unconditionally
		01	Latch ABR counter state at a positive edge on the R input
		10	Latch ABR counter state at a negative edge on the R input
		11	Reserved
3		0	• Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state
		1	• Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter
4 - 7	Reserved		

1) These registers are not available in the standard function model with SDC information enabled.

Motor ID trigger

Name:
MotorIdentTrigger

This register can be used to trigger acyclic motor identification (see "Motor ID"). The application must ensure that the conditions for reading the motor ID are fulfilled (see "Notes" under).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0		0	No effect
		1	Rising edge triggers motor identifier measurement
1 - 7	Reserved	0	

4.25.6.13.5.2 Register for reading back the configuration

Read ing the holding current, rated current and maximum current

ConfigOutput03Read (holding current)
ConfigOutput04Read (rated current)
ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases
Holding current	Current when motor is at standstill

Data type	Value	Unit
USINT	0 to 255	Percent of the module's rated current (100% corresponds to the rated current of the motor bridge power unit listed in the technical data)

4.25.6.13.5.3 Communication registers

Measuring motor load

Name:
MotorLoad

This register contains the current measured load value for stall detection. This can be used to tune stall detection.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Motor	0 to 7	Motor load value
3 - 8	Reserved	-	

Module configuration 1

Name:
ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	The setting for these two bits determines the meaning of bits 2 and 3 in the "Input counter state" register.	x	
1 - 2	Reserved	0	
3 - 4	Number of transfer values per X2X cycle (See "Motor StepX".)	00	1 x Δs / Δt (transfer values: MotorStep0)
		01	2 x Δs / Δt (transfer values: MotorStep0 - MotorStep1
		10	4 x Δs / Δt (transfer values: MotorStep0 - MotorStep3
		11	Reserved
5 - 6	Resolution of microsteps for the following registers: • "Motor StepX" • "Position sync/async"	00	Resolution: 5 bits (bit 0 - 4) microsteps; 8 bits (bit 5 - 13) full steps
		01	Resolution: 6 bits (bit 0 - 5) microsteps; 7 bits (bit 6 - 13) full steps
		10	Resolution: 7 bits (bit 0 - 6) microsteps; 6 bits (bit 7 - 13) full steps
		11	Resolution: 8 bits (bit 0 - 7) microsteps; 5 bits (bit 8 - 13) full steps
7 - 15	Reserved	0	

Position sync/async

Name:
PositionSync
Positionasync

Depending on the Counter configuration, these registers can be used to read either the internal position counter or the counter state of the ABR input.

Data type	Value
INT	-32768 to 32767

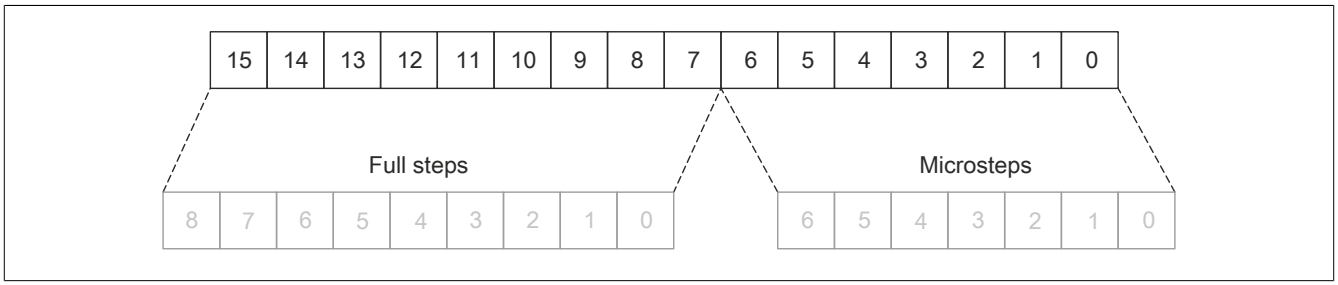
Register	Counter configuration	
	Bit 3 … 0	Bit 3 … 1
Position sync	Internal position counter	ABR counter
Position async	ABR counter	Internal position counter

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register Module configuration 1). In the standard function model with SDC, this value is set to "8-bit microsteps" and can not be changed.

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):



ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor ID

Name:
Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. Following measurement, this register contains the time [µs] needed to apply a current increase of ΔI = 1 A to a motor winding.

This depends on:

- Operating voltage
- The inductance and resistance of the motor winding

Notes		
1)	To achieve reproducible results, the measurement must be made under the following defined conditions:	
	a)	Motor is at standstill
	b)	The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: • Full steps are divisible by 4 • Microsteps = 0
2)	Condition 1b) is fulfilled after a the SM module is reset or powered on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application.	
3)	The current range from approximately 1/3 of the rated current up to the rated current is used as operating range for determining the motor identifier.	

Data type	Motor ID values	Function
UINT	0	No motor identifier available (after turning on for as long as the measurement conditions are not met)
	1 to 32767	Valid range of values for the motor ID register (in µs)
	65504 to 65519	Ground fault: Motor identification not possible
	65528	Motor ID trigger not possible • Motor has no power applied • Motor in movement • Rated current is set to 0A • Ground fault present
	65529	Invalid value: Underflow
	65530	Overtemperature: Measurement not possible
	65532	Open line: Measurement not possible
	65533	Motor position incorrect: Measurement not possible
	65534	Invalid value: Overrun
	65535	Measurement in progress

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Error status

Name: The names of the bits are different depending on whether SDC information is enabled or disabled.

Without SDC	With SDC
StallError	StallError01
Overtemperature	Overtemperature01
ErrorCurrentError	ErrorCurrentError01
OvercurrentError	OvercurrentError01
-	DrvOK01

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see "Module configuration 2" and "Error acknowledgment").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StallError(01)	0	No stall
		1	Stall
1	Overtemperature error OvertemperatureError(01)	0	No overtemperature
		1	Overtemperature
2	Current error CurrentError(01)	0	No current error
		1	Current error
3	Overcurrent error OvercurrentError(01)	0	No overcurrent
		1	Overcurrent
4	Status of the drive DrvOk0[1)]	0	An error was triggered for the motor axis
		1	The drive is running error-free
5 - 15	Reserved	0	

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- Module temperature exceeds 85°C

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open line. At higher speeds (depending on the motor), this error can also occur without an open line. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if the motor current measured in the motor windings is twice as high as it should be (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see "Motor current")
- Ground fault detection is completed and OK
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see "SDC life sign monitoring")

4.25.6.13.6 Register description: Standard functional model without SDC information

4.25.6.13.6.1 Communication registers

Input counter state

Name:
ModulePowerSupplyError
StatusInput01 to StatusInput04

This register is used to indicate the status of the digital inputs and counters.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ModulePowerSupplyError	0	OK
		1	Module supply error
1	Reserved	0	
2	StatusInput01	**When bit 0 in Module configuration 1 = 0**	
		0 or 1	Input state - Digital input 1
		When bit 0 in Module configuration 1 = 1	
		x	Ref toggle bit for counter 1: The state of this bit is changed after the homing procedure is complete.
3	StatusInput02	**When bit 0 in Module configuration 1 = 0**	
		0 or 1	Input state - Digital input 2
		When bit 0 in Module configuration 1 = 1	
		0	Homing of ABR counter active
		1	Homing of ABR counter complete
4	StatusInput03	0 or 1	Input state - Digital input 3
5	StatusInput04	0 or 1	Input state - Digital input 4
6 - 7	Reserved	0	

Motor StepX

Name:
MotorStep0 to MotorStep3

These registers are used to specify the number and direction of steps that must be carried out by the module during the next X2X cycle, and to select the motor current (see also "Holding current, rated current and maximum current").

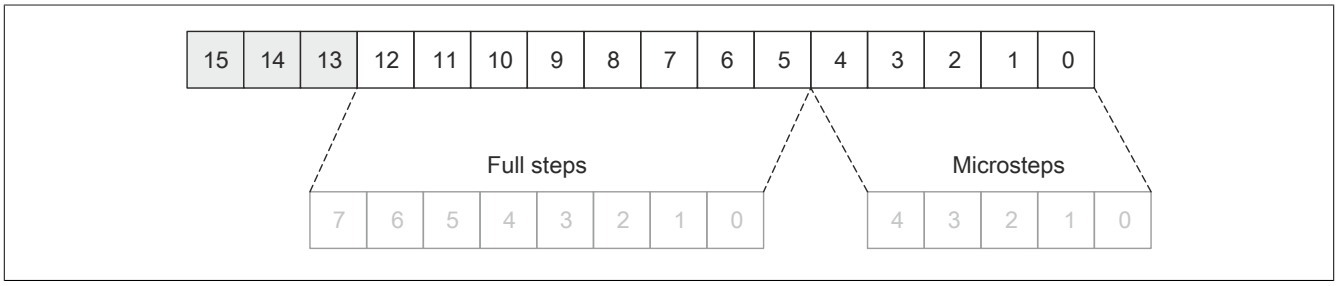
Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 12	Number of steps for the module to move during the next X2X cycle	x	
13	Direction of movement	0	Positive
		1	Negative
14 - 15	Selection of motor current	00	Motor not powered
		01	Holding current
		10	Rated current
		11	Maximum current

Depending on the required resolution and maximum configurable speed, "Module configuration 1" can be used to specify which bit position is used as the 1's position for full steps (see bits 5 and 6 of Module configuration 1).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):



The number of transfer values per X2X cycle is specified by bits 3 and 4 in "Module configuration 1" (see "Module configuration 1"). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, then the X2X cycle is divided accordingly.

Example: X2X cycle = 1 ms (1000 µs)

Time	Number of transfer values (see Module configuration 1)		
	1 (bits 3 - 4 = 00)	2 (bits 3 - 4 = 01)	4 (bits 3 - 4 = 10)
0 - 250 µs)	MotorStep0	MotorStep0	MotorStep0
250 - 500 µs)			MotorStep1
500 - 750 µs)		MotorStep1	MotorStep2
750 - 1000 µs)			MotorStep3

Position latched sync/async

Name:
PositionLatchedSync
PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2"). Bits 3 and 7 of the Counter configuration register are used to determine which counter state (internal position counter or ABR encoder) should be saved in the registers "Position latched sync" and "Position latched async".

Data type	Value
INT	-32768 to 32767

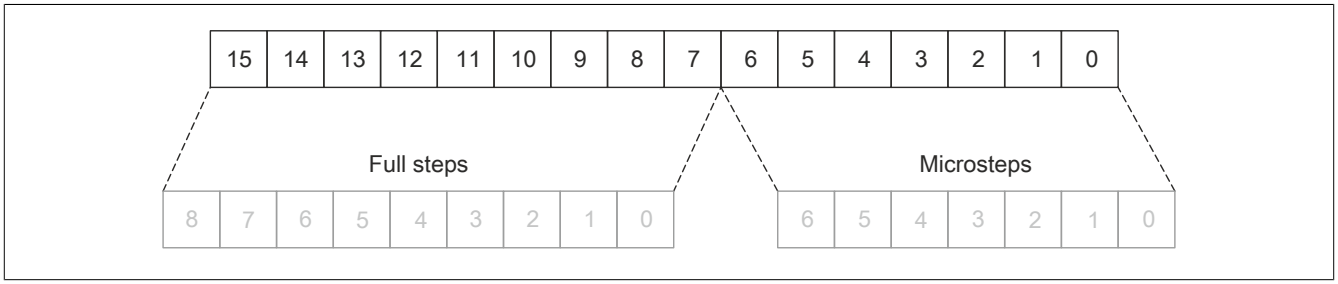
Register	Counter configuration	
	Bit 3 … 0	Bit 3 … 1
Position sync	Internal position counter	ABR counter
Position async	ABR counter	Internal position counter

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register Module configuration 1).

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):



ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:
usSinceTrigger

This register indicates the time (in µs) that has passed since the trigger event occurred (see "Module configuration 2").

Data type	Value
UINT	0 to 65535

Stepper latch trigger status

Name:
LatchInput
LatchDone
TriggerInput

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Latch input:	x	Digital input for the latch event (level)
1	LatchDone	x	State changes each time the counter state is successfully latched (reset value = 0)
2 - 3	Reserved	-	
4	TriggerInput	x	Trigger input (level)
5 - 7	Reserved	0	

4.25.6.13.6.2 Configuration registers

Module configuration 2

Name:
StartLatch
TriggerEdgePos
TriggerEdgeNeg
StartTrigger
TriggerEdge
ClearError

The trigger functions for the stepper motor can be configured with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Latch function for stepper motor Latch byte	0	The latch function for stepper motor position is deactivated at the negative edge of this bit
		1	The latch function for stepper motor position is deactivated at the positive edge of this bit
1 - 2	Latch mode for stepper motor TriggerEdgePos (Bit 1) TriggerEdgeNeg (Bit 2)	00	Latch position of stepper motor, unconditional
		01	Latch position of stepper motor at positive edge on input DI 3
		10	Latch position of stepper motor at negative edge on input DI 3
		11	Reserved
3	TriggerEdge	0	Trigger edge (input DI 4) = positive
		1	Trigger edge (input DI 4) = negative
4	Enable trigger (when changes occur) StartTrigger	x	
5	ClearError	0	No effect
		1	Error acknowledgment for the motor (for more info, see "Error status")
6 - 7	Reserved	-	

Trigger function procedure:

- Select the desired trigger edge using bit 3
- Enable the trigger function by changing the state of bit 4. When this bit changes, usSinceTrigger (µs counter) is cleared.
- When the trigger event occurs, usSinceTrigger (µs counter) is started.
- The usSinceTrigger counter cannot overrun, i.e. it is stopped at 2^{16} and retains this value until the next time the trigger function is activated.

The trigger function can be re-activated at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if usSinceTrigger has reached the maximum value.

Position sync 2

Name:
PositionSync02

Depending on Counter configuration (bit 3), this register contains the state of either the position counter or the ABR counter. It's an exact complement to the Position sync register.

If the position sync register contains the position counter, then the PositionSync02 register contains the ABR counter state and vice versa.

By default, the register cannot be seen in the I/O map; instead, it has to first be activated in the I/O configuration.

Data type	Value
INT	-32768 to 32767

4.25.6.13.7 Register description: Standard functional model with SDC information

4.25.6.13.7.1 Configuration registers

SDC configuration

Name:
SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. It is comparable to the two variants of the standard function model with and without SDC information.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Trigger edge	0	Rising trigger edge
		1	Falling trigger edge
1 - 5	Reserved	0	
6	SDC life sign monitoring	0	Disabled
		1	Enabled
7	SDC information[1)]	0	Disabled
		1	Enabled

1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Note:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

The Module configuration 1 register is ignored in the standard function model with SDC information enabled. The module behaves as if the module configuration were described as follows:

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Meaning of bits 2 and 3 in the register "Input counter value"		
1 - 2	Reserved	0	
3 - 4	Number of transfer values per X2X cycle	00	1x Δs / Δt (transfer values: Motor settings Motor1Step0)
5 - 6	Resolution of microsteps	11	8-bit microsteps
7 - 15	Reserved	0	

Motor settling time

Name:
MotorSettlingTime01

This register determines the motor setting time. The motor settling time determines the minimum time between when the motor is powered on to when the DrvOk bit is set (see "Error status"). The setting is made in steps of 10 ms.

Data type	Value	Information
USINT	1 to 255	10 ms to 2.55 s, default: 10 ms

Turn-off delay

Name:
DelayedCurrentSwitchOff01

When the SDC life sign monitoring is triggered (i.e. the net time timestamp is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

Data type	Value	Information
USINT	0 to 255	0 to 25.5 ms in steps of 100 ms (default: 100 ms)

4.25.6.13.7.2 Communication registers

SDC life sign monitoring

Name:
SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint. SDC life sign monitoring is activated in the SDC configuration register by setting bit 6 (SDCSetTime = on).

If the specified NetTime timestamp is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

1) The CPU is informed of the error using the Drive bit (DrvOk) = 0

2) Braking at configured rated current with speed setpoint = 0

3) Wait for configured turn-off delay to expire

4) Power off motor

When the timestamp is back in the valid range, the motor can be powered on again by a rising edge on the DriveEnable bit (see "Motor current").

Data type	Value
INT	-32768 to 32767

Motor current

Name:
DriveEnable01
BoostCurrent01
StandstillCurrent01

Bits 0 to 2 of this register can be used to control the motor's current supply.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DriveEnable01	x	Motor powered
1	BoostCurrent01	x	Maximum current
2	StandstillCurrent01	x	Holding current
3 - 7	Reserved	0	

The possible status of bits 0 to 2

StandstillCurrent01	BoostCurrent01	DriveEnable01	Description
x	x	0	Motor not supplied with current
0	0	1	Rated current supplied to motor
0	1	1	Maximum current supplied to motor
1	0	1	Holding current supplied to motor
1	1	1	Holding current supplied to motor

Life cycle counter

Name:
LifeCnt

This register is incremented by one with each X2X Link cycle.

Data type	Value
SINT	-128 to 127

Input counter value

Name:
ModulePowerSupplyError
StatusInput01 to StatusInput04

This register is used to indicate the status of the digital inputs and the counter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ModulePowerSupplyError	0	OK
		1	Module supply error
1	Reserved	0	
2	StatusInput01	0 or 1	Input state - Digital input 1
...		...	
5	StatusInput04	0 or 1	Input state - Digital input 4
6 - 7	Reserved	0	

Error acknowledgment

Name:
ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see "Error status".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Reserved	0	
5	ClearError01	0	No effect
		1	Error acknowledgment for motor
6 - 7	Reserved	0	

Motor1Step0

Name:
Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

Data type	Value	Information
INT	>0	Movement in positive direction in 1/256 full steps
	<0	Movement in negative direction in 1/256 full steps

Unlike the standard function model without enabled SDC information, the motor current is selected using a separate register (see Motor current).

Home position

Name:
RefPulsePos01

These 2 registers contain the following:

Register	Description
Home position of the internal position counter	This register indicates the home position of the internal position counter.
Home position for the ABR counter	This register indicates the home position of the ABR counter.

Data type	Value
INT	-32768 to 32767

The "Position Sync" setting in the Automation Studio I/O configuration can be used to select which of the two registers is be addressed by the variable RefPulsePos01.

Variables in Automation Studio	I/O configuration, Counter 01, "Position Sync" option	
	Stepper counter 01 shown at ActPos01	ABR counter 01 shown at ActPos01
RefPulsePos01	Home position of internal position counter	Home position of ABR counter
The "Position Sync" option also sets bit 3 in the Counter configuration register for Counter 1:		
Bit 3 (counter 1)	0	1

Reference pulse counter

Name:
RefPulseCnt01

These 2 registers contain the following:

Register	Description
Reference pulse counter for the internal position counter	The reference pulses of the internal position counter are counted in this register.
Reference pulse counter for the ABR counter	The reference pulses of the ABR counter are counted in this register.

Data type	Value
SINT	-128 to 127

The "Position Sync" setting in the Automation Studio I/O configuration can be used to select which of the two registers is addressed by the variable RefPulseCnt01.

Variables in Automation Studio	I/O configuration, Counter 01, "Position Sync" option	
	Stepper counter 01 shown at ActPos01	ABR counter 01 shown at ActPos01
RefPulseCnt01	Reference pulse counter for internal position counter	Reference pulse counter of ABR counter
The "Position Sync" option also sets bit 3 in the Counter configuration register for Counter 1:		
Bit 3 (counter 1)	0	1

Net time of the position value

Name:
ActTime01

This register contains the net time of the most recent valid position value.

Data type	Value
INT	-32768 to 32767

Trigger counter

Name:
TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

Data type	Value
SINT	-128 to 127

Trigger timestamp

Name:
TriggerTime01

This register indicates the point in time (net time) of the most recent trigger event. The trigger edge must be configured in the "SDC configuration" register.

Data type	Value
INT	-32768 to 32767

4.25.6.13.8 Register description: Function model 254 - Bus controller and function model 3 - Ramp

4.25.6.13.8.1 Configuration registers

Holding current, rated current and maximum current

Name:
ConfigOutput03a (holding current)
ConfigOutput04a (rated current)
ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases. In the mode "Homing during stall", the rated current is always used instead of the maximum current, even in acceleration phases.
Holding current	Current when motor is at standstill

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. This is done according to the following priority regardless of the actual defined values: maximum current before nominal current before holding current.

Data type	Value	Unit
USINT	0 to 117	Percent of the module's rated current • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data

Full step threshold

Name:
FullStepThreshold01

This register defines the threshold speed, above which the motor is operated in full step mode, and below which it is operated in microstep mode.

Data type	Value	Information
UINT	1 to 65534	Speed in microsteps / cycle
	65535	Motor is always operated in microstep mode

Maximum speed

Name:
MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

Data type	Value	Information
UNIT	0 to 65,535	Speed in microsteps / cycle

Maximum acceleration

Name:
MaxAcc01

This register defines the maximum acceleration (also applies for homing modes).

Data type	Value	Information
UINT	0 to 65,535	Acceleration in microsteps / cycle²

Maximum deceleration

Name:
MaxDec01

This register defines the maximum deceleration (also applies for homing modes).

Data type	Value	Information
UINT	0 to 65,535	Deceleration in microsteps / cycle²

Reversing loop

Name:
RevLoop01

This parameter is only used in mode 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the position setpoint is approached directly when coming from one direction; when coming from the other direction, the position setpoint is initially exceeded by the configured number of steps before finally moving to the position setpoint. This ensures that the position setpoint is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

Sign	Effective direction
Positive	Reversing loop in positive direction of movement
Negative	Reversing loop in negative direction of movement

Data type	Value
INT	-32768 to 32767

Fixed position A

Name:
FixedPos01a

This register defines the position to move to in modes -124 (when 1 is set at the digital input) and -125.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes -124 (when 0 is set at the digital input) and -126.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes -127 and -128.

Data type	Value	Information
UINT	0 to 65,535	Speed in microsteps / cycle

Stall recognition delay

Name:
StallRecognitionDelay01

The value in this register is only relevant for "Homing during stall".

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

Data type	Value	Information
USINT	0 to 255	in cycles, see "General configuration"

Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured mixed decay threshold is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

Data type	Value	Information
UINT	0 to 65535	Minimum speed in microsteps per cycle.

Jolt time

Name:
JoltTime01

If a value other than 0 is assigned to this register, then jolt limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using FIFO memory. The jolt time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- the motor has reached the position setpoint (positioning modes only)
- the motor has stopped (all modes)

Data type	Value	Information
USINT	0	No jolt time limitation
	1 to 80[1)]	Number of FIFO elements

1) Starting with upgrade 1.4.1.0 (firmware version 14); For older versions: 16

Homing configuration

Name:
RefConfig01

The homing mode can be set with this register.

Data type	Value	Information
SINT	-120	Set home position
	-121	Homing at positive edge on input DI 4
	-122	Homing at negative edge on input DI 4
	-125	Homing at positive edge on input DI 3 (R pulse)
	-126	Homing at negative edge on input DI 3 (R pulse)
	-127	Homing during stall detection
	-128	Immediate homing
	Everything else	No effect

Stall detection configuration / Mixed decay

Name:
StallDetectConfig01

The mixed decay threshold and stall detection sensitivity can be configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Mixed decay threshold	0	Mixed decay disabled
		1 to 14	Setting for mixed decay threshold
		15	Mixed decay always enabled
4 - 6	Stall threshold	0	Stall detection is disabled
		1 to 6	Steps involved in setting stall detection sensitivity
		7	Maximum sensitivity for stall detection
7	Motor load	0	Motor load value not shown
		1	Show value in register Status word[1)]

1) If this bit is 1, then the motor load value is shown in bits 13 to 15 of the status word register (otherwise these bits are 0). This value can help when testing the stall detection and the Home during stall mode.

Stall threshold

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

The "stall threshold" (bits 4 to 6 of this register) can be used to define a threshold value for each axis individually according to the motor load, beyond which the motor will detect a stall condition.

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection.

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Mixed decay threshold

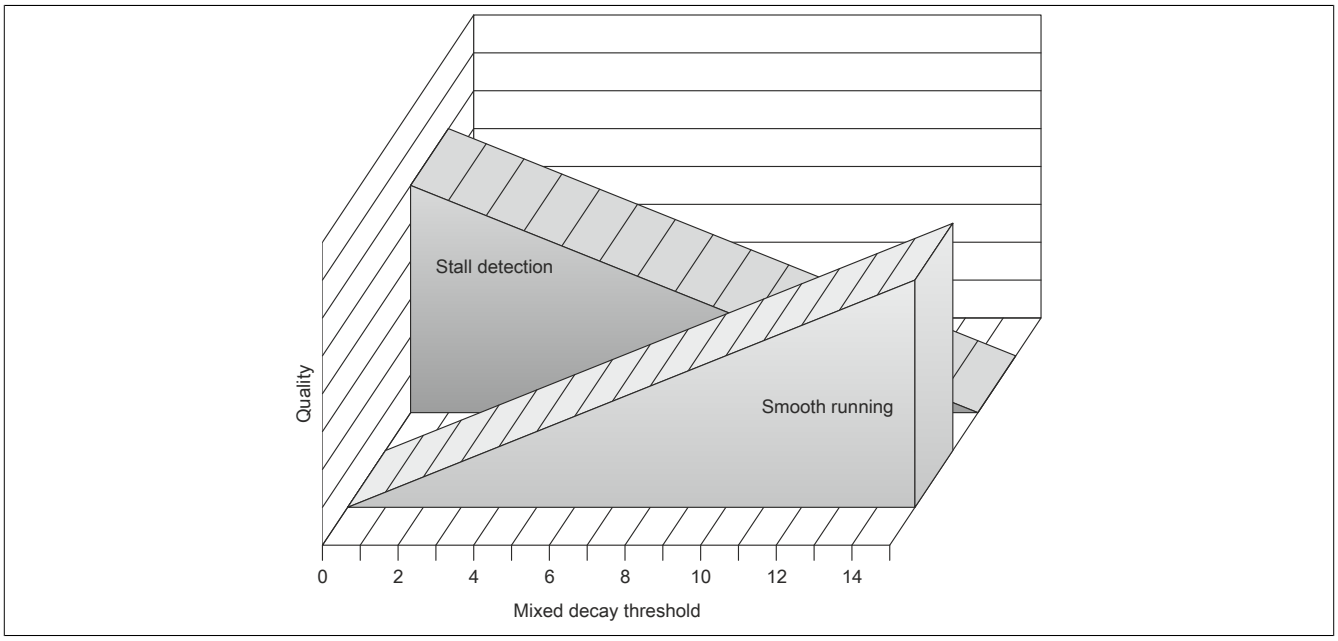
Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.



General configuration

Name:
GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Position mode	0	Without extended control word
		1	With extended control word
1 - 2	Cycle time of the motion profile generator[1)]	00	25 ms
		01	10 ms
		10	5 ms
		11	Reserved
3 - 7	Reserved	0	

1) This parameter is supported starting with upgrade 1.4.1.0 (firmware version 14).

Limit switch configuration

Name:
LimitSwitchConfig01

This register can be used to configure the behavior of the limit switch.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Negative limit switch	00	Off
		01	Active if low
		10	Reserved
		11	Active if high
2 - 3	Positive limit switch	00	Off
		01	Active if low
		10	Reserved
		11	Active if high
4 - 6	Reserved	0	
7	Direction monitoring	0	Off (default)
		1	On

Negative/positive limit switch

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. The "Device Control State Machine" state is not changed. This keeps current flowing to the motor.

The error that occurred can be read from the Error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Exceeding the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative direction and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:
PositionLimitMin01
PositionLimitMax01

This register configures software limits. The function is active if at least one of the two registers is unequal to zero.

These limits are effective in all positioning modes. Position overrun is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the Status word register. The motor movement will be stopped until a position is specified within the limits.

The "Internal limit active" bit will also be set in the "Status word" register if there is a configuration error (minimum > maximum).

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

The software limits will only be monitored in connection with the following CANopen bus controllers:

- **X20BC0043-10**
- **X20BC0143-10**
- **X67BC4321-10**
- **X67BC4321.L08-10**
- **X67BC4321.L12-10**

4.25.6.13.8.2 Reading back the configuration

Read ing the holding current, rated current and maximum current

ConfigOutput03aRead (holding current)
ConfigOutput04aRead (rated current)
ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases
Holding current	Current when motor is at standstill

Data type	Value	Unit
USINT	0 to 255	Percent of the module's rated current (100% corresponds to the rated current of the motor bridge power unit listed in the technical data)

4.25.6.13.8.3 Communication registers

Set position/speed

Name:
AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see "Mode"): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see "Mode"): In this mode, this register is used as a signed speed setpoint.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Control word

Name:
MpGenControl01

This register can be used to issue commands based on the module's state (see 4.25.6.13.8.4 "Ramp function model operation").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Switch on	x	
1	Enable voltage	x	
2	Quick stop	x	
3	Enable operation	x	
4 - 6	Mode-specific	x	
7	Fault reset	x	
8	Halt (stop)[1)]	x	
9 - 10	Reserved	0	
11	Motor ID trigger	0	No effect
		1	Rising edge: Motor ID trigger[2)]
12	Warning reset	0	No effect
		1	Rising edge: Reset warnings
13	Undercurrent detection	0	Disable current error detection (default)
		1	Enable current error detection
14	ABR counter sync/async	0	Default: • Internal position counter, cyclic • ABR counter, non-cyclic
		1	• Internal position counter, non-cyclic • ABR counter, cyclic
15	Stall detection	0	Disable stall detection (default)
		1	Enable stall detection

1) The "Halt" bit is only evaluated when the extended control word is enabled (see "General configuration").
2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the "Motor ID" register).

Mode

Name:
MpGenMode01

Data type	Value	Information
SINT	0	No mode selected
	1	Depending on bit 0 in the General configuration register, the position mode will behave as follows: • Position mode without extended control word: Move to position setpoint as soon as position setpoint is changed • Position mode with extended control word: Move to position setpoint as described in "Mode 1 - Position mode with extended control word"
	2	Speed mode: Constant speed
	-120	Set home position
	-121	Remaining distance mode
	-122	Set the actual position
	-123	Move to position setpoint when external input is set
	-124	Two-position module
	-125	Move to fixed position A (position set asynchronously)
	-126	Move to fixed position B (position set asynchronously)
	-127	Positive homing (see also "Homing configuration")
	-128	Negative homing (see also "Homing configuration")

Information:

For all modes: The "Target reached" bit is set in the Status word register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the Set position/speed register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the General configuration register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. The new position is then moved to.

However, if bit 0 in the General configuration register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word".

Mode 1 - Position mode with extended control word

The position mode with extended control word behaves like the previously described Position mode 1 (without extended control word) except that the new position setpoint (Position/speed register) is applied according to the extended control word.

Extended control word

This register can be used to issue commands based on the module's state (see 4.25.6.13.8.4 "Ramp function model operation").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Corresponds to the default Control word	x	
4	New setpoint	0	Do not apply position setpoint
		1	Apply position setpoint
5	Change set immediately	0	Complete current positioning movement and then start next positioning movement
		1	Interrupt current positioning movement and then start next positioning movement
6	abs / rel	0	Position setpoint is an absolute value
		1	Position setpoint is a relative value
7	Corresponds to the defaultControl word	x	
8	stop[1)]	0	Execute positioning
		1	Stop axis with deceleration
9 - 15	Corresponds to the defaultControl word	x	

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" and "State machine").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 9	Corresponds to the defaultStatus word	x	
10	Target reached, depending on bit 8 (Halt) in the register Control word		**If Halt = 0**
		0	Position setpoint not reached
		1	Position setpoint reached
			If Halt = 1
		0	Axis decelerating
		1	Axis speed = 0
11	Corresponds to the defaultStatus word	x	
12	Setpoint acknowledge	0	Ramp generator did not apply the position value
		1	Ramp generator applied the position value
13 - 15	Corresponds to the defaultStatus word	x	

Position setting

The position setpoint can be defined in two different ways:

Type of setpoint definition	Description
Single setpoint	Once the position setpoint is reached, the *Target reached* bit in the Status word register is set. Then a new position setpoint is defined. The drive stops at each position setpoint before starting the movement to the next position setpoint.
Set of setpoints	Once a setpoint has been reached, the movement to the next setpoint is started immediately without stopping the drive. It is therefore not possible to initiate a new positioning movement by transferring a new position setpoint during an active positioning movement.

Table 570: Types of position setpoint definition

The two modes "Single setpoint" and "Set of setpoints" are controlled by the timing of the bits *New setpoint* and *Change set immediately* in the *extended control word* and *Setpoint acknowledge* in the *Extended control word* register.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a position setpoint while previous setpoint is still being processed.

Transferring the position setpoint

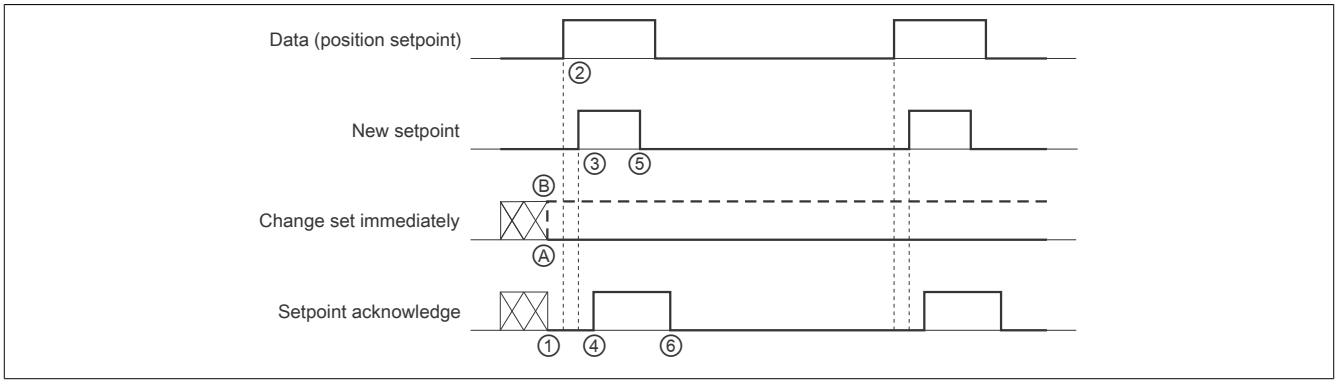


Figure 386: Principle for applying the setpoint

Transferring a new setpoint:

1. When the *Setpoint acknowledge* bit in the Extended status word register is 0, the module will accept a new position setpoint.
2. The new position setpoint is specified in the *Set position/speed*.
3. A rising edge of the *New setpoint* bit in the Extended control word register signalizes that the new position setpoint in the *Set position/speed* register is valid and can be used for the next positioning movement.
4. Once the module has received and saved the new position setpoint, the *Setpoint acknowledge* bit in the *Status word* register is set to 1.
5. Now the controller can reset the *New setpoint* bit to 0.
6. Then the module resets the *Setpoint acknowledge* bit to 0 to signal when a new position setpoint is accepted.

"Single setpoint" mode

When the *Change set immediately* bit is set to 0 (Ⓐ in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This mechanism results in a speed of 0 when the motor reaches position setpoint x_1 at time t_1. After the controller has been notified that the setpoint has been reached, the next setpoint x_2 will be processed at time t_2 and reached at t_3.

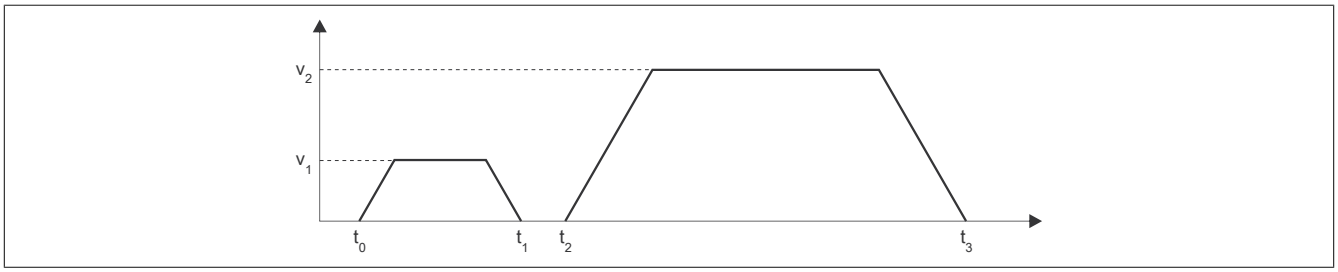

Figure 387: Ramp in *Single setpoint mode*

"Set of setpoints" mode

When the *Change set immediately* bit is set to 1 (Ⓑ in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This means that the module receives the first position setpoint at t_0. A second position setpoint is received at the time t_1. The drive immediately adapts the current movement to the new setpoint.

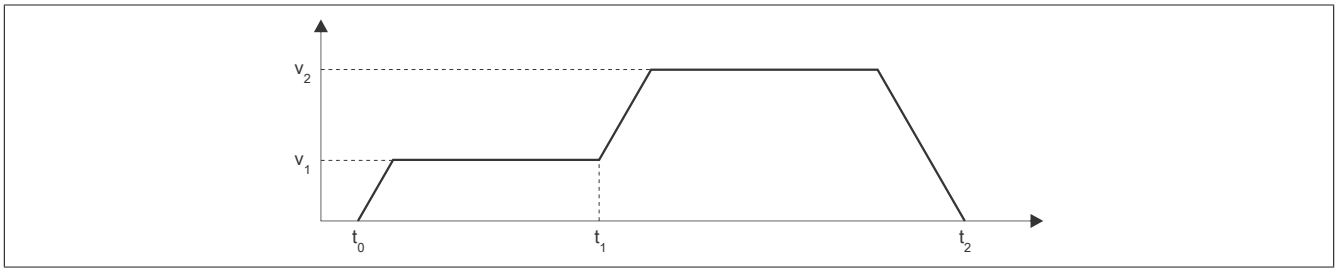

Figure 388: Ramp in *Set of setpoints mode*

Relative position setting

When the *abs / rel* bit in the Extended control word register is set, then the position setpoint is interpreted as a relative value. At each *New setpoint* trigger, the position setpoint will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in the Position/speed register is now interpreted as the speed setpoint (microsteps/ cycle).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

This mode is supported starting with upgrade 1.4.1.0 (firmware version 14).

The current actual position is modified so that the position specified by the Position/speed register is at the home position. If you subsequently move to this position, the motor is at the home position.

The home position in the "Home position" register is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using the "Positive / negative homing" mode. In order to set the position, the State machine must be in the state "Operation Enable".

Mode -121: Remaining distance mode (like Modus 1)

The number of steps defined in the "Fixed position A" register are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Note:

Steps are not added to the position setpoint, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in "Fixed position A".

New position setpoints are no longer accepted in the Position/speed register after the trigger event. There must first be a switch made to mode 0 and then back to mode -121.

The "Target reached" bit in the Status word register is not set to 1 until the end position (after the trigger event) has been reached.

The Homing configuration determines whether a rising or falling edge of the digital input is used as a trigger.

The Reversing loop is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set the actual position

The position setpoint set in the "Position/speed" register is accepted as the current actual position in the internal position counter when the state machine is in the "Operation Enable" state.

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the position setpoint when the external input is set

The set position defined in the "Position/speed" is moved to when a rising edge occurs on the corresponding digital input.

A new position setpoint is not accepted until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two position mode

The positions "Fixed position A" and "Fixed position B" are defined in the non-cyclic registers.

The value 1 on digital input 3 moves to fixed position A. The value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise isn't possible because of the double use of the register for position and speed setpoints.

- Mode -125: Fixed position A
- Mode -126: Fixed position B

Mode -127/-128: Homing (positive/negative)

Mode -127 and -128 are used to select which direction to move in.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the homing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the homing condition occurs are written to the Homed zero position register.

You must specify in the Homing configuration whether homing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active homing level not yet reached → Motor not yet at end position:

Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input.

Case 2: Active homing level already reached → Motor at end position:

Movement continues at the homing speed, counter to the homing direction, until the active level for "homing-stop" is no longer on the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Homing during stall

Movement continues in the homing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the Homed zero position register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the rated current is always used instead of the maximum current, even in acceleration phases.

To test the response behavior of this homing mode, the motor load value used for identifying a stall can be made visible in the status word (see "Stall detection configuration / Mixed decay").

Homing unconditional (immediate)

Immediate homing: The current values of the position counter and ABR counter are immediately entered in the Homed zero position register (no motor movement).

Current position (cyclic)

Name:
AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Status word

Name:
MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see "Status word" and "State machine".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Ready to switch on	x	
1	Switched on	x	
2	Operation enabled	x	
3	Fault (error bit)	x	
4	Voltage enabled	x	
5	Quick stop	x	
6	Switch on disabled	x	
7	Warning	x	
8	Reserved	0	
9	Remote	1	Always 1 because there is no local mode for the SM module
10	Target reached	x	
11	Internal limit active	0	No limit violation
		1	Internal limit is active (upper/lower software limit violated)
12	Mode-specific	x	
13 - 15	Reserved / Motor load value	0	Always 0 when bit 7 in the Stall detection configuration / Mixed decay register is set to 0.
		x	Returned motor load value

Input status

Name:
InputStatus

This register indicates the logical states of digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Digital input 1	0 or 1	Input state - Digital input 1
...		...	
3	Digital input 4	0 or 1	Input state - Digital input 4
4 - 15	Reserved	0	

Motor ID

Name:
Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. Following measurement, this register contains the time [µs] needed to apply a current increase of ΔI = 1 A to a motor winding.

This depends on:

- Operating voltage
- The inductance and resistance of the motor winding

Notes		
1)	To achieve reproducible results, the measurement must be made under the following defined conditions:	
	a)	Motor is at standstill
	b)	The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: • Full steps are divisible by 4 • Microsteps = 0
2)	Condition 1b) is fulfilled after a the SM module is reset or powered on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application.	
3)	The current range from approximately 1/3 of the rated current up to the rated current is used as operating range for determining the motor identifier.	

Data type	Motor ID values	Function
UINT	0	No motor identifier available (after turning on for as long as the measurement conditions are not met)
	1 to 32767	Valid range of values for the motor ID register (in µs)
	65504 to 65519	Ground fault: Motor identification not possible
	65528	Motor ID trigger not possible • Motor has no power applied • Motor in movement • Rated current is set to 0A • Ground fault present
	65529	Invalid value: Underflow
	65530	Overtemperature: Measurement not possible
	65532	Open line: Measurement not possible
	65533	Motor position incorrect: Measurement not possible
	65534	Invalid value: Overrun
	65535	Measurement in progress

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Homed zero position

Name:
RefPos01CyclicCounter
RefPos01AcyclicCounter

After a homing procedure, the homing position for the cyclic and non-cyclic position counter can be read using these registers (either the internal position counter or ABR counter depending on bit 14 of the "Control word" register).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for non-cyclic counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Current position (acyclic)

Name:
AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Reads the extended control word

Name:
ControlReadback01

This register can be used to read the content of the Control word register.

Data type	Value
UINT	0 to 65535

Read back mode

Name:
ModeReadback01

This register can be used to read the content of the Mode register.

Data type	Value
SINT	-128 to 127

Error code

Name:
ErrorCode01

The cause of an error or warning can be read in this register.

Data type	Error code	Error type	Priority	Description
UINT	0x0000	-	-	No error
	0x3000	Error	High	Voltage
	0x4200	Error	:	Overtemperature
	0xFF20	Warning	:	Negative limit switch
	0xFF21	Warning	:	Positive limit switch
	0x2300	Warning	:	Overcurrent
	0xFF00	Warning	:	Current error[1)]
	0xFF01	Warning	Low	Stall [2)]

1) A current error is only detected if bit 13 = 1 in the control word (current error detection enabled).
2) Stall is only detected if bit 15 = 1 in the control word (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (Fault) and bit 7 (Warning) in the status word can be used to query whether an error or a warning was reported in the error code register.
- Bit 7 (Fault Reset) and bit 12 (Warning Reset) in the control word are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the error code register.

4.25.6.13.8.4 Ramp function model operation

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word". The current module state is returned to the "Status word" register. The function mode (absolute position, constant speed, homing, etc.) is set in the "Mode" register.

Control word

Control word bits and their state for the commands of the state machine:

Command	Reserved	ABR counter sync/async	Current error detection	Warning reset	Motor ID trigger	Reserved	Reserved	Halt 2)	Fault reset	Mode specific	Mode specific	Mode specific	Enable operation	Quick stop	Enable voltage	Switch on
Bit[1]	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Shutdown	x	x	x	x	x	0	0	x	0	x	x	x	x	1	1	0
Switch on	x	x	x	x	x	0	0	x	0	x	x	x	0	1	1	1
Disable voltage	x	x	x	x	x	0	0	x	0	x	x	x	x	x	0	x
Quick stop	x	x	x	x	x	0	0	x	0	x	x	x	x	0	1	x
Disable operation	x	x	x	x	x	0	0	x	0	x	x	x	0	1	1	1
Enable operation	x	x	x	x	x	0	0	x	0	x	x	x	1	1	1	1
Fault reset	x	x	x	x	x	0	0	x	↑	x	x	x	x	x	x	x

1) x ... Any; ↑ ... Rising edge
2) Bit 8 (Halt) is only evaluated if the extended control word is enabled in the "General configuration" register.

Bits 0, 1, 2, 3 and 7 (light gray in the previous table)	These bits control the state of the "State machine" according to the commands in the table above.
stop	0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is activated in the "General configuration" register.
Motor ID trigger	A rising edge enables the motor ID measurement.
Warning reset	A rising edge resets warnings (no effect on errors, which are reset using "Fault Reset"; the state machine is not affected by this bit)
Fault reset	A rising edge resets errors and warnings (see "State machine" on page 2429)
Current error detection	0 ... Current error detection disabled 1 ... Current error detection enabled
ABR counter sync/async	0 ... Value of the ABR counter on the "Current position (non-cyclic)" register. Internal position counter of the ramp generator on the "Current position (cyclic)" register. 1 ... Value of the ABR counter on the "Current position (cyclic)" register. Internal position counter of the ramp generator on the "Current position (non-cyclic)" register.
Stall detection	0 ... Stall detection disabled 1 ... Stall detection enabled

Status word

The individual bits of this register and its states depend on the current state of the state machine:

Status	Reserviert / MotorLoadBit 2 [1]	Reserviert / MotorLoadBit 1 [1]	Reserviert / MotorLoadBit 0 [1]	Mode-specific	Int. limit active	Target reached	Remote	Reserved	Warning	Switch on disabled	Quick stop	Voltage enabled	Fault	Operation enabled	Switched on	Ready to switch on
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not ready to switch on	x	x	x	x	x	x	1	0	x	0	x	0	0	0	0	0
Switch on disabled	x	x	x	x	x	x	1	0	x	1	x	0	0	0	0	0
Ready to switch on	x	x	x	x	x	x	1	0	x	0	1	0	0	0	0	1
Switched on	x	x	x	x	x	x	1	0	x	0	1	1	0	0	1	1
Operation enable	x	x	x	x	x	x	1	0	x	0	1	1	0	1	1	1
Quick stop active	x	x	x	x	x	x	1	0	x	0	0	1	0	1	1	1
Fault reaction active	x	x	x	x	x	x	1	0	x	0	x	0	1	1	1	1
Fault	x	x	x	x	x	x	1	0	x	0	x	0	1	0	0	0

1) If bit 7 is set to 1 in the Mixed decay / Stall detection register, then the motor load value is returned in bits 13-15 of the status word. Otherwise these bits are always 0.

Information about the status word:

Bits 0,1,2,3,5 and 6 (light gray in the previous table)	These bits are set according to the current state of the "State machine".	
Voltage enabled	Becomes 1 as soon as the motor is powered	
Warning	Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in the "Error code" register. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word.	
Remote	Always 1 since there is no local mode on the SM module	
Target reached[1], depending on bit 8 (Halt) in the register Control word	**If Halt = 0**	**If Halt = 1**
	In modes 1, -123, -124, -125 and -126 (absolute positioning): 0 ... Positioning begins 1 ... Target has been reached **In mode 2 (constant speed):** 0 ... Motor accelerates/brakes 1 ... Speed setpoint reached **In modes -127 and -128 (homing):** 0 ... Homing started 1 ... Homing ended **In mode -122 (set actual position):** The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.	**In all modes:** 0 ... Axis decelerating 1 ... Axis speed = 0
Internal limit active	0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated)	

Table 571: Information about the status word

1) If Halt has not been activated in the "General configuration" register, then "Target Reached" behaves the same as when Halt = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to the state "*Not ready to switch on*". The application then operates the state machine by writing commands to the "Control word".

The state machine successively reaches the states "*Ready to switch on*", "*Switched on*" and "*Operation enable*" by writing the consecutive commands "*Shutdown*", "*Switch on*" and "*Enable operation*".

Information:

Motor movements are not performed until the "*Operation enable*" state, according to the setting in the Mode register.

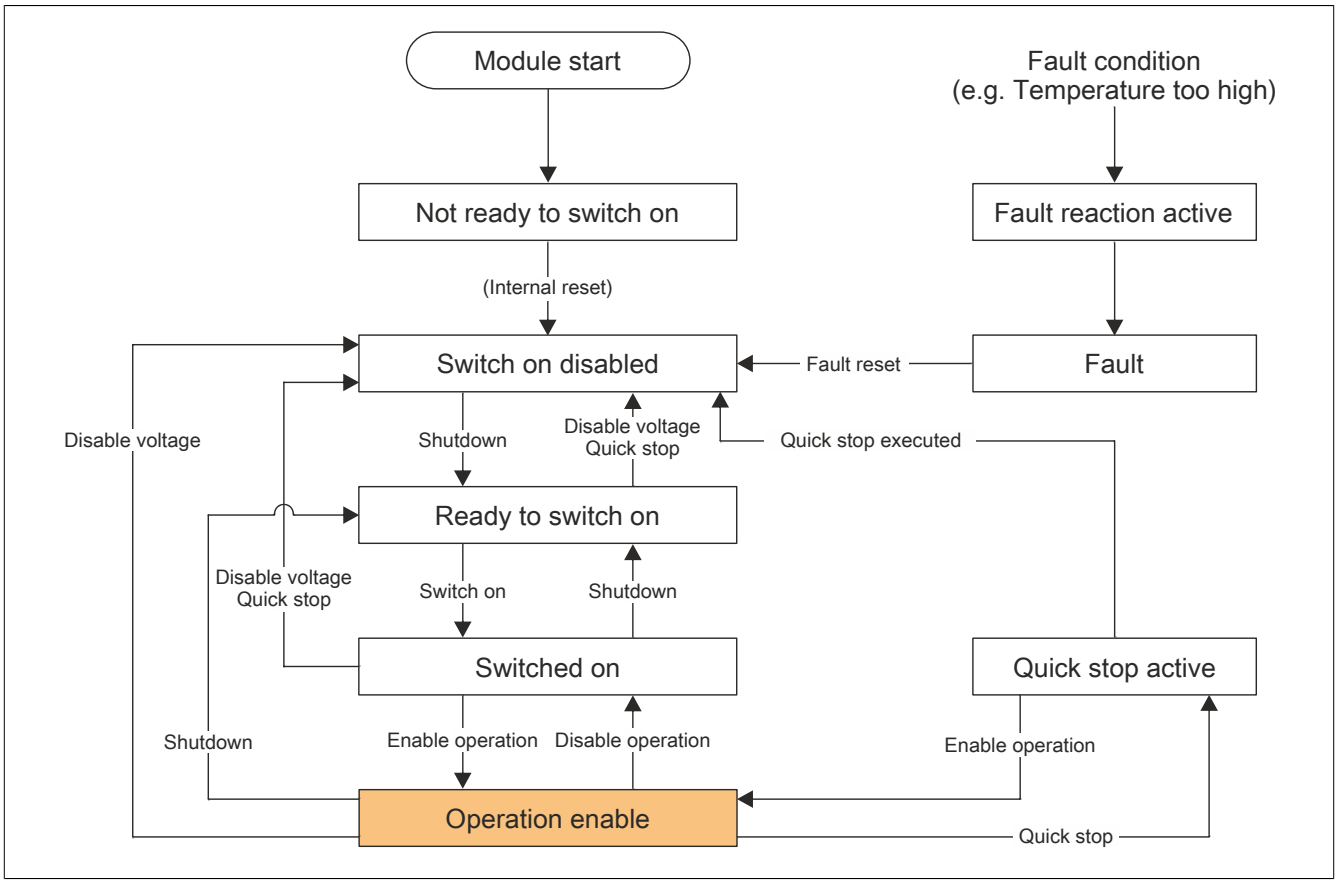

Figure 389: State machine - Flow chart

State change	Description
Not ready to switch on → Switch On Disabled	This state change occurs automatically after starting the module and internal initialization has taken place.
Switch on disabled → Ready to Switch On	This state change is brought on by the *Shutdown* command. No others actions are performed.
Ready to switch on → Switch On Disabled	This state change is brought on by the command *Disable voltage* or *Quick stop*. No others actions are performed.
Switched on → Switch On Disabled	This state change is brought on by the command *Disable voltage* or *Quick stop*. The motor voltage is switched off immediately.
Ready to switch on → Switched On	This state change is brought on by the *Switch on* command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before the *Switched on* state is achieved. This can take approximately 1 second.
Switched on → Ready to Switch On	This state change is brought on by the *Shutdown* command. The motor voltage is switched off immediately.
Switched on → Operation Enable	This state change is brought on by the *Enable operation* command. Motor movements are now performed depending on the defined mode.
Operation enable → Switched On	This state change is brought on by the *Disable operation* command. If in motion, the motor is decelerated with the configured deceleration. Motor voltage remains on in the *Switched on* state.
Operation enable → Ready to Switch On	This state change is brought on by the *Shutdown* command. The motor voltage is switched off immediately.
Operation enable → Switch On Disabled	This state change is brought on by the *Disable voltage* command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210).
Operation enable → Quick Stop Active	This state change is brought on by the *Quick stop* command. If in motion, the motor is decelerated with the configured deceleration. During the deceleration, the state machine remains in the *Quick stop active* state. Once the motor is at standstill, the state automatically changes to the *Switch on disabled* state. While the state machine is in the *Quick stop active* state, the *Enable operation* command can be used to switch it back to the *Operation enable* state.
→ Fault reaction active	This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code"). (Other error types listed as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change in the state machine.) Motor voltage is switched off and the state machine then changes immediately to the *Fault* state. The type of error is listed in the error code register (see the table under "Error code"). The highest priority error is shown. The priority corresponds to the order in the error code table.
Fault → Switch On Disabled	This state change is brought on by the *Fault reset* command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present.

Table 572: State machine - State change

4.25.6.13.9 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Standard function model	250 µs
Ramp function model	250 µs

4.25.6.13.10 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Standard function model	250 µs
Ramp function model	
Inputs	250 µs
Outputs[1)]	25 ms

1) Depending on the configuration of the motion profile generator

4.25.7 X20SM1436

4.25.7.1 General information

The stepper motor module is used to control stepper motors with a rated voltage of 24 to 39 VDC (±25%) at a motor current up to 3 A (3.5 A peak). Additionally, this module has four digital inputs that can be used as limit switches or as encoder inputs.

By individually adjusting the coil currents, the motor is only operated with the current it actually needs. This simplifies the selection of the available motors and prevents unnecessary heating. Because the latter reduces energy consumption and thermal load, the effects are positive on the lifespan of the complete system. Complete flexibility is achieved by using the values for holding current, maximum current and rated current, which are completely independent of each other. The current for the microsteps is automatically adjusted to the configured current values.

The automatic motor identification system is an enormous help during standstills. The stepper motor modules can identify the connected motors using their coil characteristics and generate feedback in the form of an analog value. This makes it possible to detect not only wiring errors, but also incorrect motor types being used mistakenly. A stall detection mechanism is integrated to analyze the motor load. The stall is recognized using a configurable threshold. This allows an overload or motor standstill to be detected precisely in many different types of applications.

- 1 stepper motor, 24 to 39 VDC ±25%, 3 A (3.5 A peak)
- Resolution of current values at 1%
- Boost, rated and holding current configured independent of each other
- 38.5 kHz PWM frequency
- Integrated motor detection
- 256 micro-steps
- Stall detection
- Complete integration in Automation Studio and CNC applications
- 4 inputs, 24 VDC, can be configured as ABR
- Ramp function model based on the CANopen communication profile DS402

4.25.7.2 Order data

Model number	Short description	Figure
	Motor controllers	
X20SM1436	X20 stepper motor module, module supply 24-39 VDC ±25%, 1 motor connection, 3 A continuous current, 3.5 A peak current, 4 digital inputs 24 VDC, sink, can be configured as incremental encoder

GOST-R	Yes
Motor bridge - Power unit	
Quantity	1
Type	2-phase bipolar stepper motor (full bridge)
Nominal voltage	24 to 39 VDC ±25%
Nominal current	3 A
Maximum current	3,5 A for 2 s (after a recovery time of at least 10 s at maximal 3 A)
Controller frequency	38.4 kHz
DC bus capacitance	100 µF
Step resolution	Max. 256 microsteps per step
Module supply	
Supply	External
Fuse	Required line fuse: Max. 16 A, slow-blow
Output protection	No reverse polarity protection for supply voltage
Digital inputs	
Quantity	4
Nominal voltage	24 VDC
Input filter	
Hardware	<5 µs
Software	-
Connection type	1-wire connections
Input circuit	Sink
Additional functions	1x ABR incremental encoder
Input resistance	Typ. 18.2 kΩ
ABR incremental encoder	
Quantity	1
Encoder inputs	24 V, asymmetrical
Counter size	16-bit
Input frequency	Max. 50 kHz
Evaluation	4x
Operating conditions	
Mounting orientation	
Horizontal	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions

4.25.7.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset state
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input state of the corresponding digital input
	M	Orange	On	Motor is active

1) Depending on the configuration, a firmware update can take up to several minutes.

4.25.7.5 Pinout

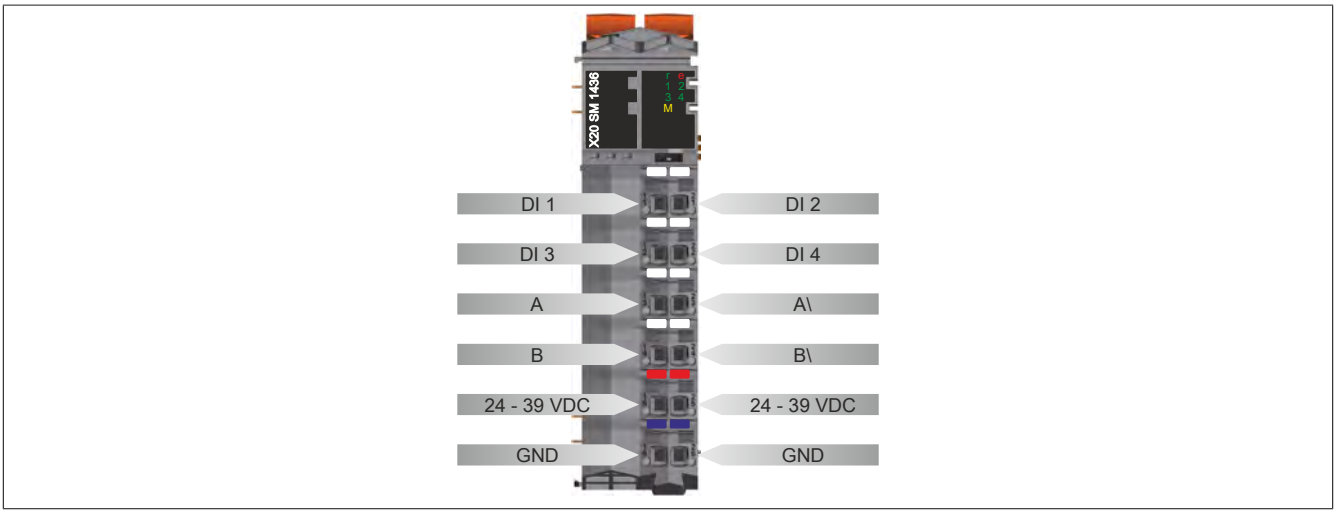
In accordance with the EN60204-1 standard, a cable cross section of 0.75 mm² or larger must be used for the motor outputs in order to handle the maximum motor current of 3.5 A. To ensure full motor power, voltage drops that could result from the cable length and the electrical connections must also be taken into consideration when selecting the attachment cable.

Warning!

The terminal block is not permitted to be plugged in or unplugged during operation.

Information:

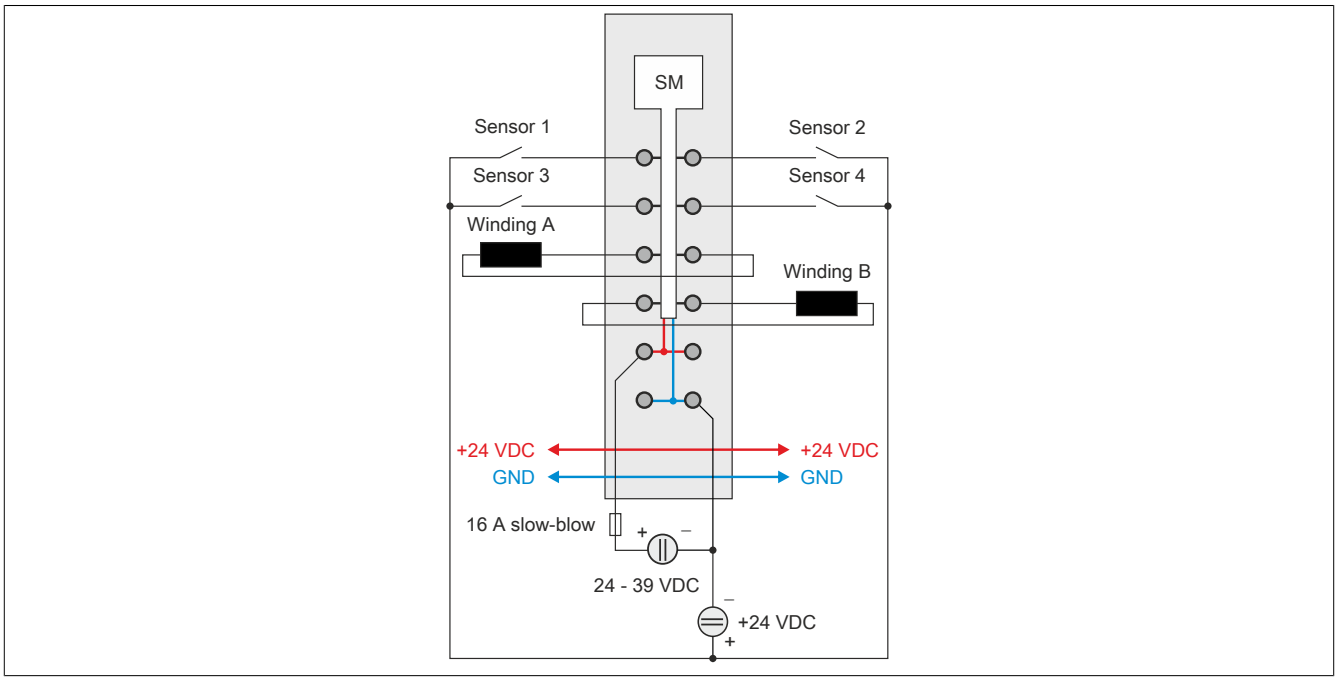
Shielded motor cables must be used in order to meet the limits according to the EN55011 standard (emissions).



4.25.7.6 Connection example

Information:

This module can only be operated if supplied with power via the terminal block.



4.25.7.7 Connection options for digital inputs

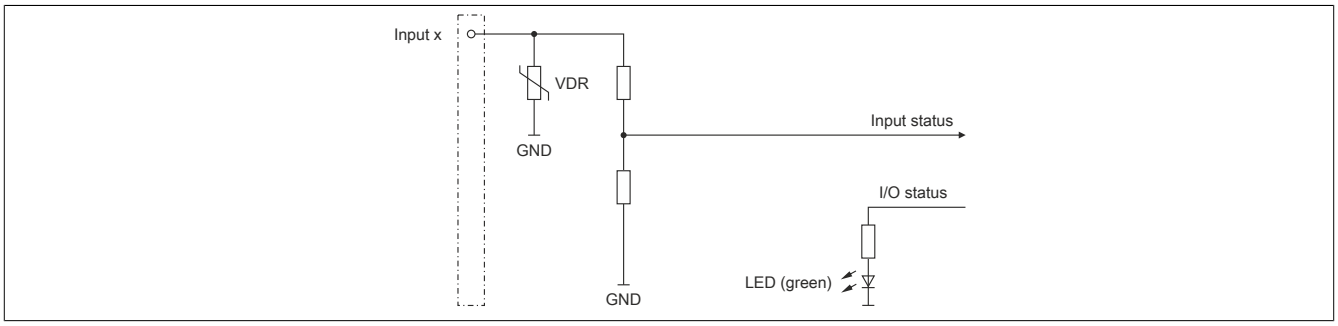
Standard function model

Channel	Function	
DI 1	Digital input	A
DI 2	Digital input	B
DI 3	Digital input	R
DI 4	Digital input	Trigger input

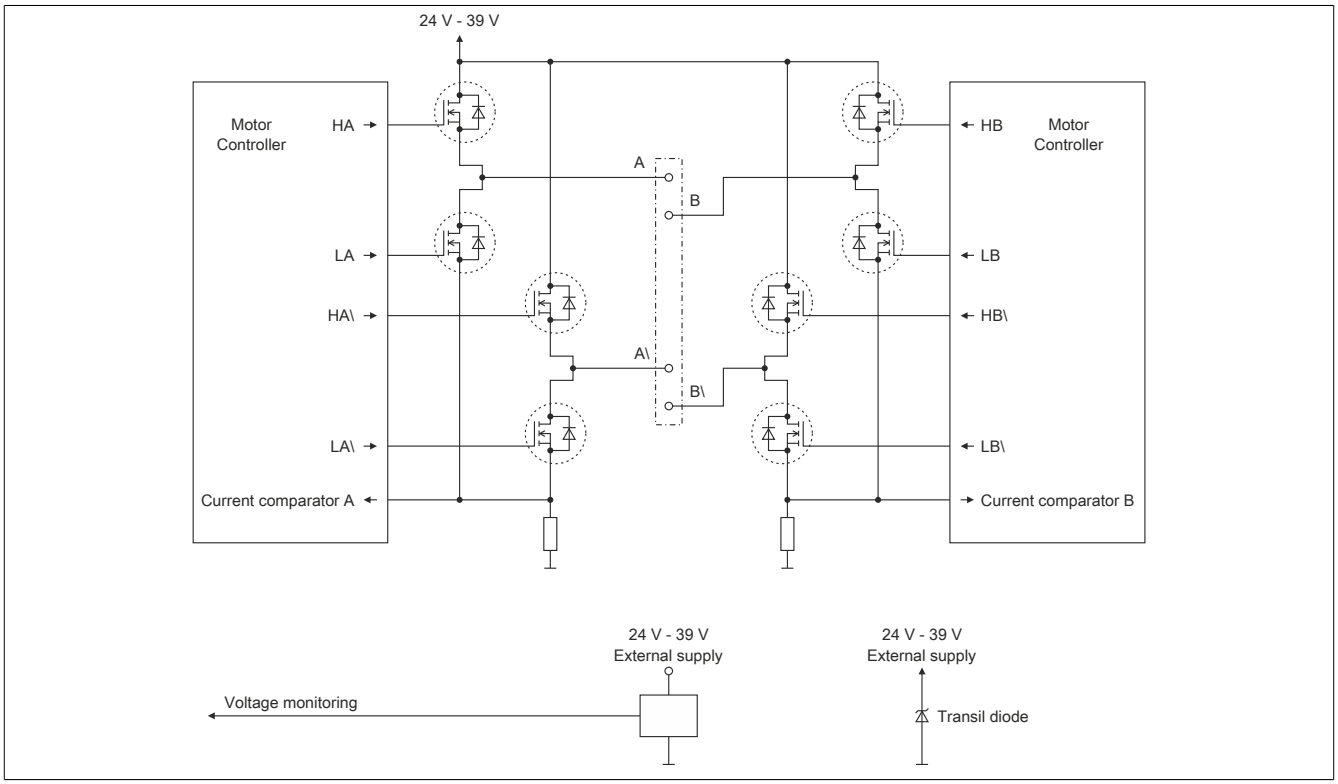
Ramp function model

Channel	Function		
DI 1	Digital input	A	A
DI 2	Digital input	B	B
DI 3	Digital input	R	Negative limit switch
DI 4	Digital input	Digital input	Positive limit switch

4.25.7.8 Input circuit diagram



4.25.7.9 Output circuit diagram



4.25.7.10 Overvoltage motor cutoff

The module supply voltage is continually monitored. Its status can be read. The error "Module power supply error" occurs when the voltage is above or below the limits.

If the supply voltage on the module rises or falls outside the limit values (e.g. due to regeneration), then the motor output is switched off.

The outputs are reactivated as soon as the supply voltage is back in the valid range and the error bit is reset.

Supply voltage limit values

	Drive is switched off	Drive is switched back on
Lower limit	<18 V	>19.5 V
Upper limit	>50 V	<49 V

4.25.7.11 Overtemperature cutoff (at 85°C)

If the module temperature reaches or exceeds the limit value of 85°C, then the module executes the following actions:

- Setting the "overtemperature" error bit
- The outputs are switched off (short-circuited)

As soon as the temperature sinks back down below 85°C, the error must be acknowledged with OvertemperatureAcknowledge so that the channels can be switched on again.

4.25.7.12 Power supply dimensioning

The motor's current consumption depends on the defined motor currents, the available power and the actual motor being used.

Example	
Motor model number	80MPD5.300S000-01
Defined current in the motor module	3 A
Motor module supply voltage	48 VDC
Motor load	1 Nm

Table 575: Power supply dimensioning example - Basic data

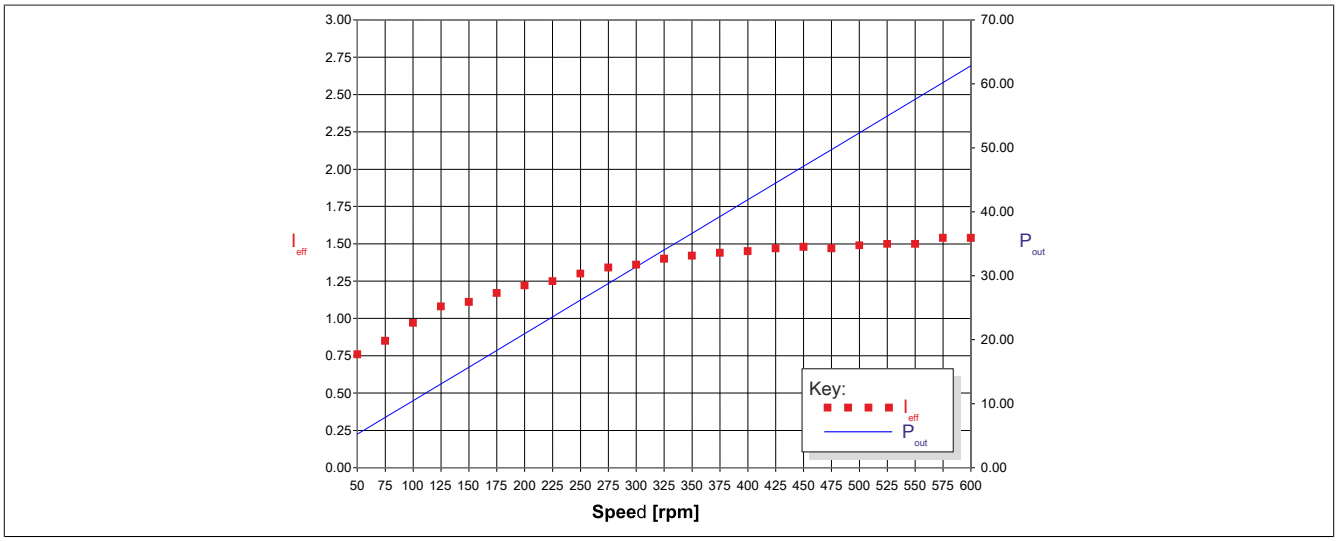


Figure 390: Power supply dimensioning example - Power/speed dependency

The example is based on a constant load throughout the entire speed range.

An increase in the motor load causes an increase in the effective current of the module supply.

4.25.7.13 Protection

The power supply line should be protected by a circuit breaker or a fuse. In general, dimensioning the supply line and overcurrent protection depends on the structure of the power supply (modules can be connected individually or in groups).

Information:

The effective current for the power supply depends on the load but is always less than the motor current. Make sure the maximum nominal current of 10 A is not exceeded on the power supply terminals of the power unit.

When choosing a suitable fuse, the user must also account for characteristics such as aging effects, temperature derating, overcurrent capacity and the definition of the rated current, which can vary by manufacturer and type. In addition, the fuse that is selected must also be able to handle application-specific characteristics (e.g. overcurrent that occurs in acceleration cycles).

The cross section of the power mains and the rated current of the overcurrent protection used are chosen according to the current load so that the maximum current load for the cable cross section selected (based on the type of wiring, see table) is greater than or equal to the current load in the power mains. The rated current of the overcurrent protection must be less than or equal to the maximum current load for the cable cross section selected (based on the type of wiring, see table):

I_{Mains}	≤	I_b	≤	I_Z
Mains	≤	Fuse	≤	Line/cable

	Maximum current load for cable cross section I_Z / rated current for overcurrent protection I_b [A] depending on the type of wiring at an ambient air temperature of 40°C in accordance with IEC 60204-1			
Wire cross section [mm²]	**B1**	**B2**	**C**	**E**
1.5	13.5 / 13	13.1 / 10	15.2 / 13	16.1 / 16
2.5	18.3 / 16	16.5 / 16	21 / 20	22 / 20

Table 576: Cable cross section of the mains supply line depending on the type of wiring

The tripping current of the fuse must not exceed the rated current for overcurrent protection I_b.

Type of wiring	Description
B1	Wires in conduit or cable duct
B2	Cables in conduit or cable duct
C	Cables or wires on walls
E	Cables or wires on open-ended cable tray

Table 577: Type of wiring used for the mains supply line

4.25.7.14 Derating

Modules next to the SM module can have a maximum power consumption of 1 W. To ensure proper operation, the derating values listed below must be adhered to:

Power loss derating for neighboring modules

Modules directly next to the SM module can have a power loss of 1 W. If the SM module is operated at the rated load over the entire temperature range (3 A rated current), the power loss of neighboring modules must be derated starting at 45°C.

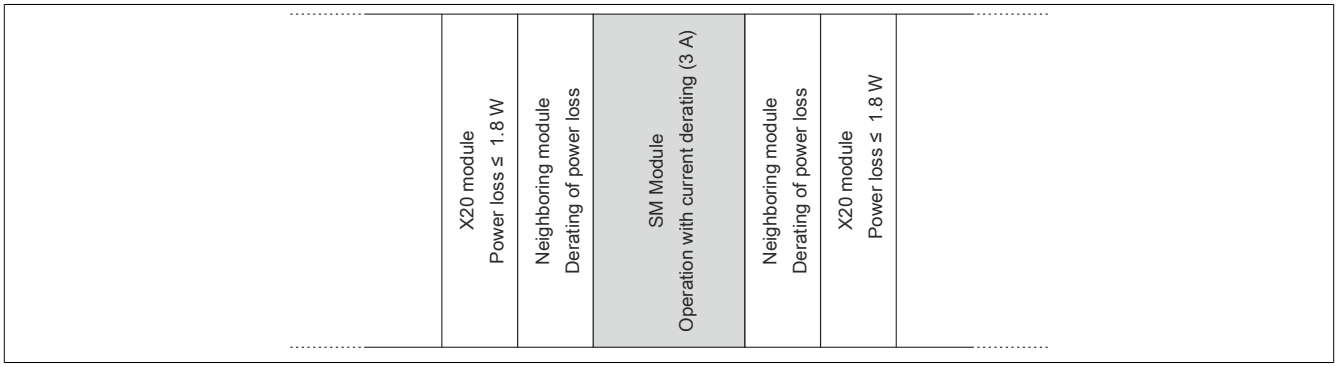

Figure 391: Operating the SM module over the entire temperature range at 3 A rated current

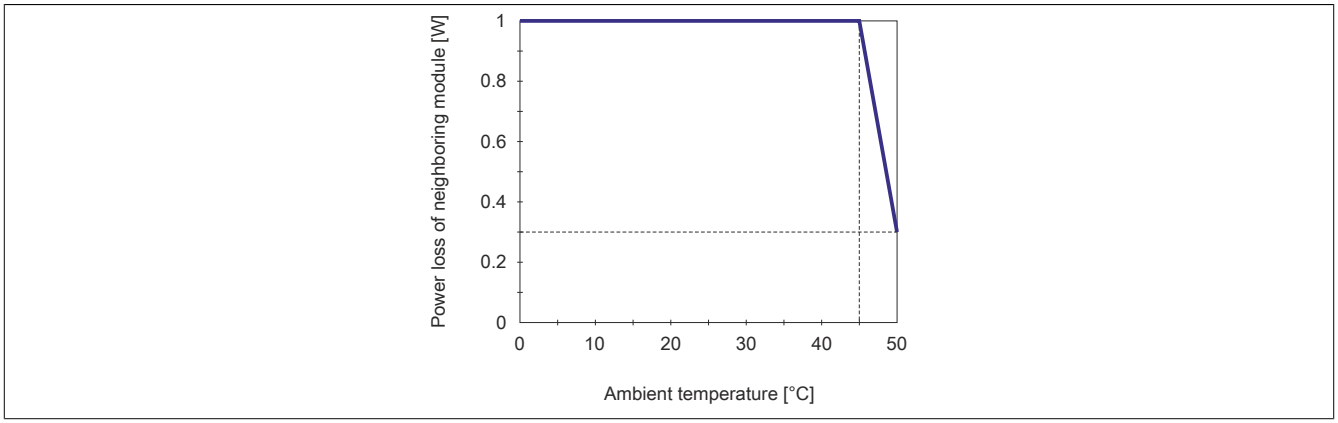

Figure 392: Power loss derating for directly neighboring modules

Current derating of the SM module

If the power loss of the neighboring modules to the SM module is 1 W, then the current of the SM module must be derated starting at 45°C.

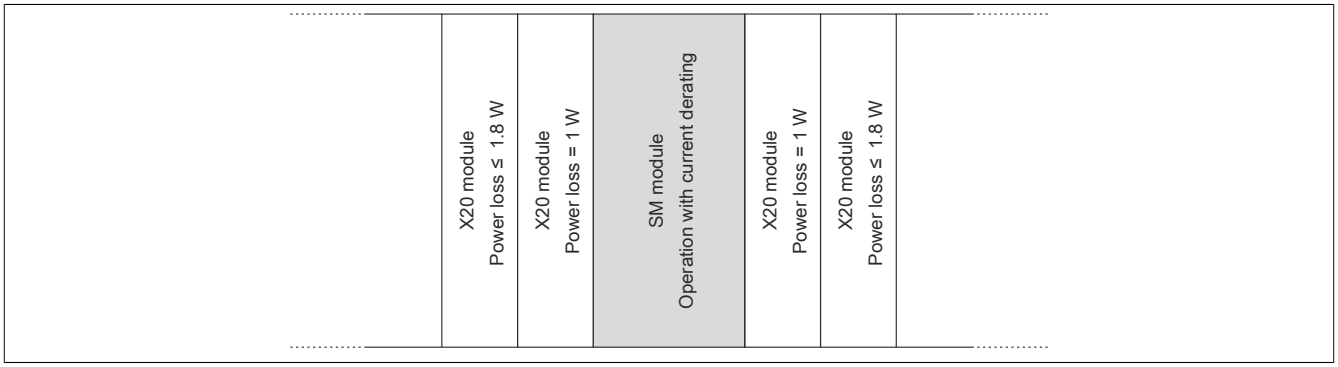

Figure 393: Neighboring modules to the SM module have a power loss of 1 W

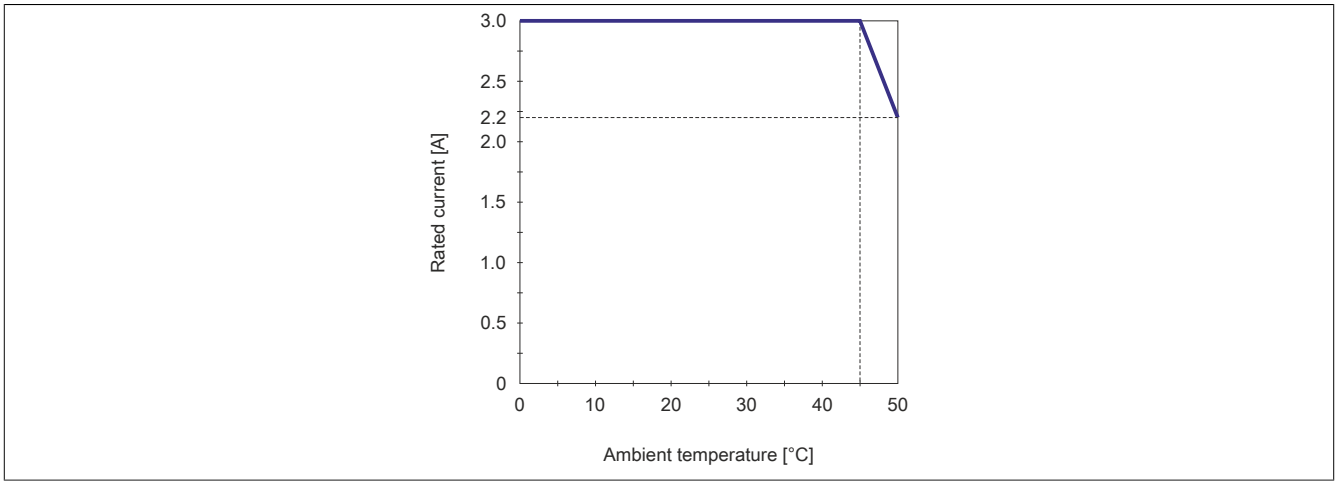

Figure 394: Current derating of the SM module

Hardware configuration for multiple SM modules

If three or more SM modules are operated in a cluster, a dummy module must be inserted between the SM modules. There is no derating in this configuration.

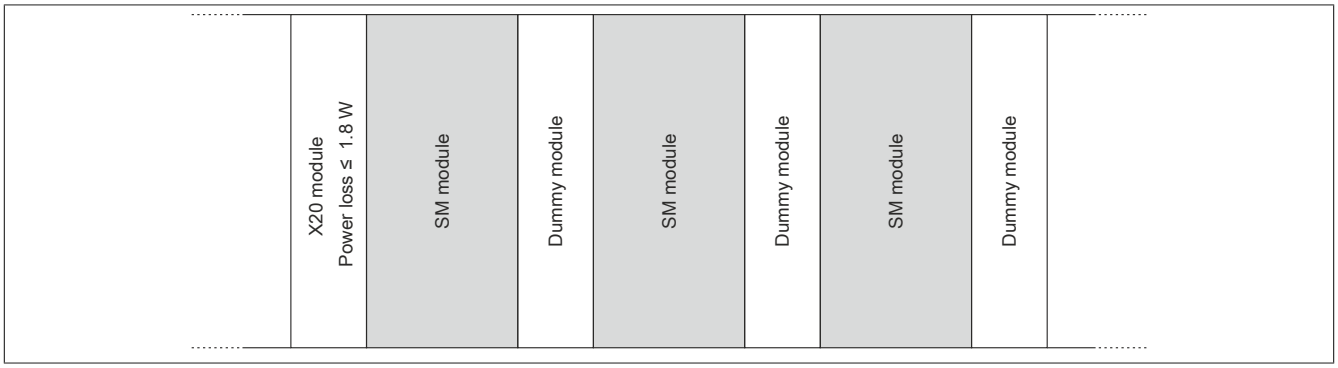

Figure 395: Operating three or more SM modules in a cluster

4.25.7.15 Register description

4.25.7.15.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.25.7.15.4.1 Operation with bus controller

The following function model can be used when the SM module is used together with a bus controller.

Bus controller	Function model
X20BC0083, X20BC1083, X20BC8083, X20BC8084	All function models
All others	Function model 254 - Bus controller (identical to Ramp function model)

4.25.7.15.4.2 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.25.7.15.5 Register description: Standard functional model, shared registers

4.25.7.15.5.1 Configuration registers

Stall threshold

Name:
ConfigOutput01

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

With the "stall threshold" register, a threshold can be defined according to the motor load, and the module detects a stall condition started at this threshold (see "Error status").

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection (see "Mixed decay threshold")

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Trigger threshold for stall detection	0	Stall detection is disabled
		1	Minimum sensitivity for stall detection
		2 to 6	Setting the sensitivity of stall detection
		7	Maximum sensitivity for stall detection
3 - 15	Reserved	0	

Mixed decay threshold

Name:
ConfigOutput16

The mixed decay threshold is configured in this register. This value must be adjusted according to the motor being used, current and voltage when using stall detection. Otherwise, the default value 15 will be used.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Mixed Decay Threshold	0	Mixed decay disabled
		1 to 14	Setting for mixed decay threshold
		15	Mixed decay always enabled
4 - 15	Reserved	-	

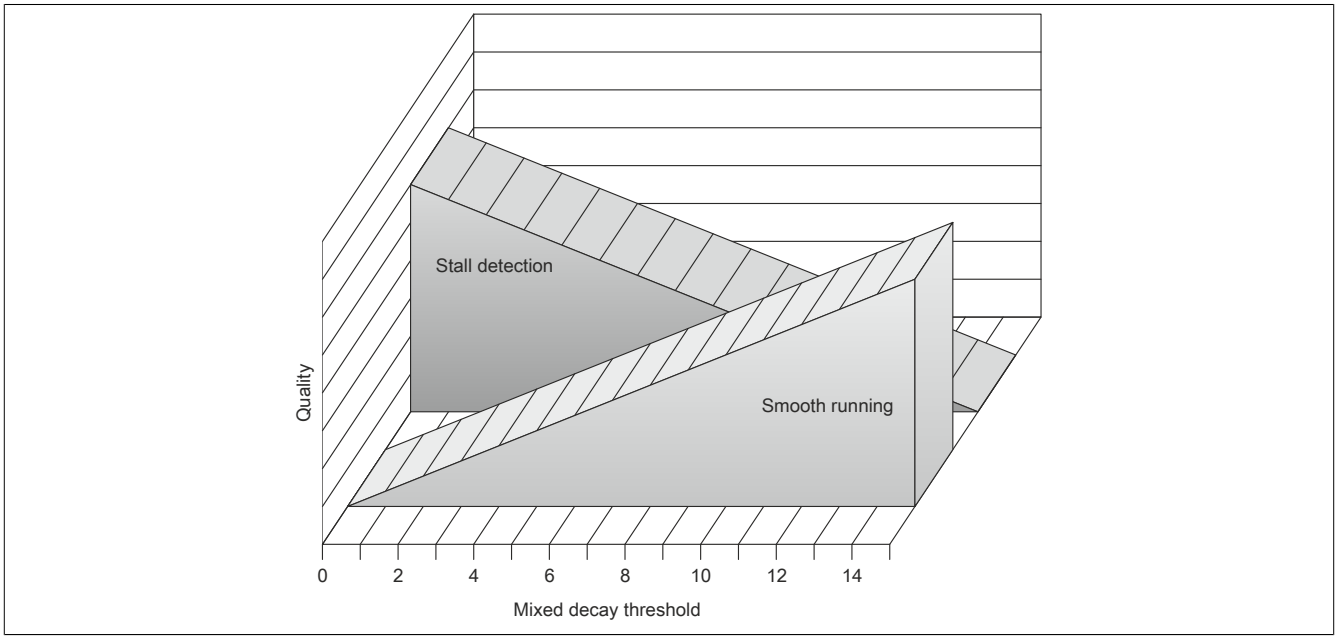
Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.



Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured mixed decay threshold is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

Data type	Value	Information
UINT	0 to 65535	Minimum speed in steps per second.

Full step threshold

Name:
FullStepThreshold01

This register is used to configure a rotational speed. When this defined speed has been reached, the drive will automatically change from microsteps to full step mode. This makes it possible to optimize the torque at higher speeds, while microstep mode ensures optimum concentricity at lower speeds.

It does not make sense to change to full step mode when at a standstill because fine positioning would then no longer be possible. This is why the value "0" does not make sense in the full step threshold register and is interpreted as disabling full step mode (i.e. the motor will always be operated in microstep mode).

Data type	Value	Information
UINT	0	Full step mode disabled
	1 to 65,535	steps/second

Example

Microstep mode should change to full step mode at 500 steps/second. On a motor with 200 steps per revolution, this would be equal to a speed of:

$$T^{-1} = \frac{500\ steps/second}{200\ steps/round} = 2.5\ \frac{rounds}{second} = 150\ \mathrm{min}^{-1}$$

Holding current, rated current and maximum current

Name:
ConfigOutput03 (holding current)
ConfigOutput04 (rated current)
ConfigOutput05 (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

Register	Description
Nominal current	Current during normal operation
Maximum current	Should be selected if a higher motor torque is required briefly during acceleration phases.
Holding current	The holding current should be used in situations when less torque is required (e.g. at a standstill). This reduces the amount of heat generated by the motor.

Switching between preset current values (holding current, rated current, maximum current):

Function model	Switching between preset current values at runtime
Default	Using bits 14 and 15 in the registers Motor StepX
Standard with enabled SDC information	Using the register Motor current

Data type	Value	Unit
USINT	0 to 117	Percent of the module's rated current • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data

Counter configuration

Name:
ConfigOutput09

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ABR latch function	0	Negative edge: Disable ABR latch function.
		1	Positive edge: Enable latch ABR latch function. After a latch event has occurred, the latch function can be started again with a new rising edge.
1 - 2	Definition of the latch mode	00	Latch ABR counter state unconditionally
		01	Latch ABR counter state at a positive edge on the R input
		10	Latch ABR counter state at a negative edge on the R input
		11	Reserved
3		0	• Position sync: Internal position counter • Position async: ABR counter state • Position latched sync: Internal position counter • Position latched async: ABR counter state
		1	• Position sync: ABR counter state • Position async: Internal position counter • Position latched sync: ABR counter state • Position latched async: Internal position counter
4 - 7	Reserved		

1) These registers are not available in the standard function model with SDC information enabled.

Motor ID trigger

Name:
MotorIdentTrigger

This register can be used to trigger acyclic motor identification (see "Motor ID"). The application must ensure that the conditions for reading the motor ID are fulfilled (see "Notes" under).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0		0	No effect
		1	Rising edge triggers motor identifier measurement
1 - 7	Reserved	0	

4.25.7.15.5.2 Register for reading back the configuration

Read ing the holding current, rated current and maximum current

ConfigOutput03Read (holding current)
ConfigOutput04Read (rated current)
ConfigOutput05Read (maximum current)

These registers are used to read the respective current values in percent.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases
Holding current	Current when motor is at standstill

Data type	Value	Unit
USINT	0 to 255	Percent of the module's rated current (100% corresponds to the rated current of the motor bridge power unit listed in the technical data)

4.25.7.15.5.3 Communication registers

Measuring motor load

Name:
MotorLoad

This register contains the current measured load value for stall detection. This can be used to tune stall detection.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Motor	0 to 7	Motor load value
3 - 8	Reserved	-	

Module configuration 1

Name:
ConfigOutput02

The number of transfer values and the resolution of microsteps for the drive can be configured in this register.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	The setting for these two bits determines the meaning of bits 2 and 3 in the "Input counter state" register.	x	
1 - 2	Reserved	0	
3 - 4	Number of transfer values per X2X cycle (See "Motor StepX".)	00	1 x Δs / Δt (transfer values: MotorStep0)
		01	2 x Δs / Δt (transfer values: MotorStep0 - MotorStep1
		10	4 x Δs / Δt (transfer values: MotorStep0 - MotorStep3
		11	Reserved
5 - 6	Resolution of microsteps for the following registers: • "Motor StepX" • "Position sync/async"	00	Resolution: 5 bits (bit 0 - 4) microsteps; 8 bits (bit 5 - 13) full steps
		01	Resolution: 6 bits (bit 0 - 5) microsteps; 7 bits (bit 6 - 13) full steps
		10	Resolution: 7 bits (bit 0 - 6) microsteps; 6 bits (bit 7 - 13) full steps
		11	Resolution: 8 bits (bit 0 - 7) microsteps; 5 bits (bit 8 - 13) full steps
7 - 15	Reserved	0	

Position sync/async

Name:
PositionSync
Positionasync

Depending on the Counter configuration, these registers can be used to read either the internal position counter or the counter state of the ABR input.

Data type	Value
INT	-32768 to 32767

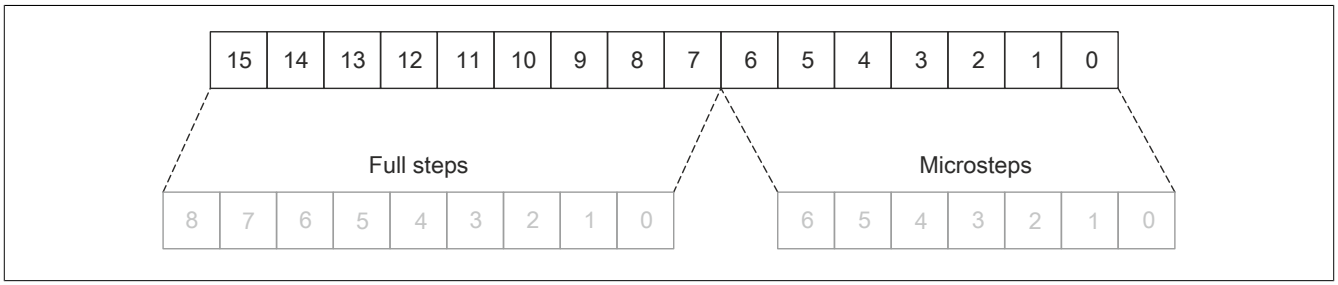
Register	Counter configuration	
	Bit 3 … 0	Bit 3 … 1
Position sync	Internal position counter	ABR counter
Position async	ABR counter	Internal position counter

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register Module configuration 1). In the standard function model with SDC, this value is set to "8-bit microsteps" and can not be changed.

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):



ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

Motor ID

Name:
Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. Following measurement, this register contains the time [µs] needed to apply a current increase of ΔI = 1 A to a motor winding.

This depends on:

- Operating voltage
- The inductance and resistance of the motor winding

Notes		
1)	To achieve reproducible results, the measurement must be made under the following defined conditions:	
	a)	Motor is at standstill
	b)	The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: • Full steps are divisible by 4 • Microsteps = 0
2)	Condition 1b) is fulfilled after a the SM module is reset or powered on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application.	
3)	The current range from approximately 1/3 of the rated current up to the rated current is used as operating range for determining the motor identifier.	

Data type	Motor ID values	Function
UINT	0	No motor identifier available (after turning on for as long as the measurement conditions are not met)
	1 to 32767	Valid range of values for the motor ID register (in µs)
	65504 to 65519	Ground fault: Motor identification not possible
	65528	Motor ID trigger not possible • Motor has no power applied • Motor in movement • Rated current is set to 0A • Ground fault present
	65529	Invalid value: Underflow
	65530	Overtemperature: Measurement not possible
	65532	Open line: Measurement not possible
	65533	Motor position incorrect: Measurement not possible
	65534	Invalid value: Overrun
	65535	Measurement in progress

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Error status

Name: The names of the bits are different depending on whether SDC information is enabled or disabled.

Without SDC	With SDC
StallError	StallError01
Overtemperature	Overtemperature01
ErrorCurrentError	ErrorCurrentError01
OvercurrentError	OvercurrentError01
-	DrvOK01

The current error status of the drive is indicated in this register. Each bit indicates a certain error or status. If an error is registered in bits 0 to 3, then the corresponding bit remains set until the error has been acknowledged (see "Module configuration 2" and "Error acknowledgment").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StallError(01)	0	No stall
		1	Stall
1	Overtemperature error OvertemperatureError(01)	0	No overtemperature
		1	Overtemperature
2	Current error CurrentError(01)	0	No current error
		1	Current error
3	Overcurrent error OvercurrentError(01)	0	No overcurrent
		1	Overcurrent
4	Status of the drive DrvOk0[1)]	0	An error was triggered for the motor axis
		1	The drive is running error-free
5 - 15	Reserved	0	

1) Only when SDC information is enabled

Overtemperature error

The "Overtemperature" error bit can be set for the following reasons:

- A specific temperature was exceeded near the channel due to overload
- Module temperature exceeds 85°C

Current error

This error bit occurs whenever the required current cannot be supplied to the motor windings. This can be (but is not necessarily) caused by an open line. At higher speeds (depending on the motor), this error can also occur without an open line. In this case it is simply no longer possible to supply the desired current to the motor windings. Because of the Back-EMF on the motor, this bit is set at slightly lower speeds if the motor is operated with no load compared with full or partial loads.

Overcurrent error

Overcurrent occurs if the motor current measured in the motor windings is twice as high as it should be (e.g. short circuit).

Status of the drive

The status of the drive is only shown when SDC information is enabled. The drive bit is 1 when the following conditions are met:

- Motor turned on (see "Motor current")
- Ground fault detection is completed and OK
- MotorID measurement is completed
- Motor is supplied with current
- Motor settling time has passed
- Supply voltage is in the valid range
- No overtemperature fault
- Preset position value is valid (see "SDC life sign monitoring")

4.25.7.15.6 Register description: Standard functional model without SDC information

4.25.7.15.6.1 Communication registers

Input counter state

Name:
ModulePowerSupplyError
StatusInput01 to StatusInput04

This register is used to indicate the status of the digital inputs and counters.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ModulePowerSupplyError	0	OK
		1	Module supply error
1	Reserved	0	
2	StatusInput01	**When bit 0 in Module configuration 1 = 0**	
		0 or 1	Input state - Digital input 1
		When bit 0 in Module configuration 1 = 1	
		x	Ref toggle bit for counter 1: The state of this bit is changed after the homing procedure is complete.
3	StatusInput02	**When bit 0 in Module configuration 1 = 0**	
		0 or 1	Input state - Digital input 2
		When bit 0 in Module configuration 1 = 1	
		0	Homing of ABR counter active
		1	Homing of ABR counter complete
4	StatusInput03	0 or 1	Input state - Digital input 3
5	StatusInput04	0 or 1	Input state - Digital input 4
6 - 7	Reserved	0	

Motor StepX

Name:
MotorStep0 to MotorStep3

These registers are used to specify the number and direction of steps that must be carried out by the module during the next X2X cycle, and to select the motor current (see also "Holding current, rated current and maximum current").

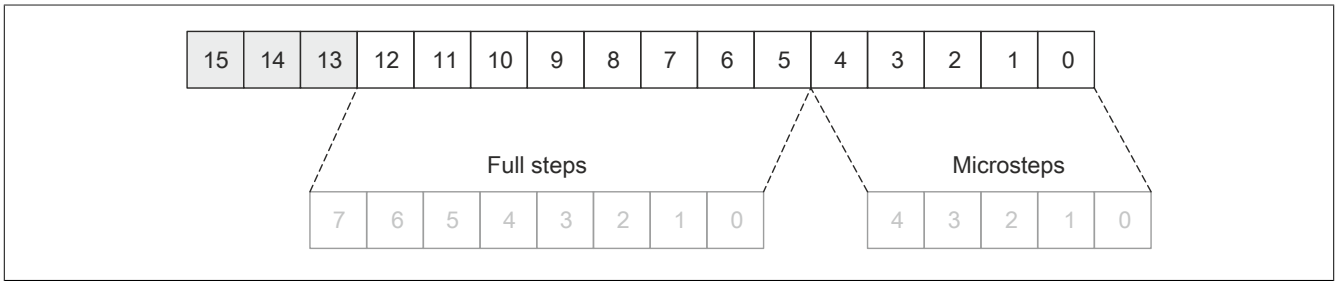
Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 12	Number of steps for the module to move during the next X2X cycle	x	
13	Direction of movement	0	Positive
		1	Negative
14 - 15	Selection of motor current	00	Motor not powered
		01	Holding current
		10	Rated current
		11	Maximum current

Depending on the required resolution and maximum configurable speed, "Module configuration 1" can be used to specify which bit position is used as the 1's position for full steps (see bits 5 and 6 of Module configuration 1).

Example for 5-bit microsteps (set bits 5 and 6 of the module configuration to binary 00):



The number of transfer values per X2X cycle is specified by bits 3 and 4 in "Module configuration 1" (see "Module configuration 1"). If only one transfer value (bits 3 and 4 = 00) is specified, then the motor is advanced by MotorStep0 until the next X2X cycle. If 2 or 4 transfer values are specified, then the X2X cycle is divided accordingly.

Example: X2X cycle = 1 ms (1000 µs)

Time	Number of transfer values (see Module configuration 1)		
	1 (bits 3 - 4 = 00)	2 (bits 3 - 4 = 01)	4 (bits 3 - 4 = 10)
0 - 250 µs)	MotorStep0	MotorStep0	MotorStep0
250 - 500 µs)			MotorStep1
500 - 750 µs)		MotorStep1	MotorStep2
750 - 1000 µs)			MotorStep3

Position latched sync/async

Name:
PositionLatchedSync
PositionLatchedASync

The position counter (internal position counter or ABR counter) is applied at the latch event (see "Module configuration 2"). Bits 3 and 7 of the Counter configuration register are used to determine which counter state (internal position counter or ABR encoder) should be saved in the registers "Position latched sync" and "Position latched async".

Data type	Value
INT	-32768 to 32767

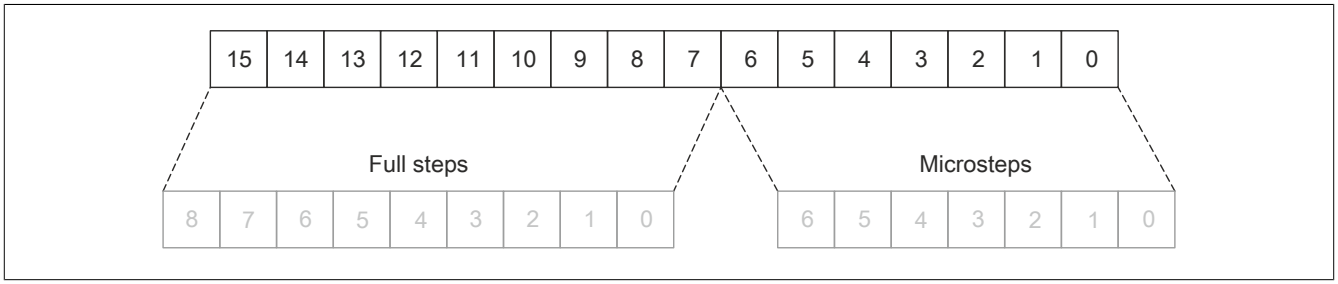
Register	Counter configuration	
	Bit 3 … 0	Bit 3 … 1
Position sync	Internal position counter	ABR counter
Position async	ABR counter	Internal position counter

Internal position counter

The internal position counter is the position calculated by the SM module (set position). This is a cyclic 16-bit counter.

The lowest 5 to 8 bits represent microsteps, while the highest 8 to 11 bits represent full steps (depending on bits 5 and 6 of the register Module configuration 1).

Example of the internal position counter format (7-bit micro steps, i.e. set bit 5 and 6 of the module configuration to binary 10):



ABR counter

This counter is a cyclic 16-bit counter. The relationship between this counter and the internal position counter depends on the resolution of the ABR encoder and the microsteps defined for the internal position counter.

usSinceTrigger

Name:
usSinceTrigger

This register indicates the time (in µs) that has passed since the trigger event occurred (see "Module configuration 2").

Data type	Value
UINT	0 to 65535

Stepper latch trigger status

Name:
LatchInput
LatchDone
TriggerInput

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Latch input:	x	Digital input for the latch event (level)
1	LatchDone	x	State changes each time the counter state is successfully latched (reset value = 0)
2 - 3	Reserved	-	
4	TriggerInput	x	Trigger input (level)
5 - 7	Reserved	0	

4.25.7.15.6.2 Configuration registers

Module configuration 2

Name:
StartLatch
TriggerEdgePos
TriggerEdgeNeg
StartTrigger
TriggerEdge
ClearError

The trigger functions for the stepper motor can be configured with this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Latch function for stepper motor Latch byte	0	The latch function for stepper motor position is deactivated at the negative edge of this bit
		1	The latch function for stepper motor position is deactivated at the positive edge of this bit
1 - 2	Latch mode for stepper motor TriggerEdgePos (Bit 1) TriggerEdgeNeg (Bit 2)	00	Latch position of stepper motor, unconditional
		01	Latch position of stepper motor at positive edge on input DI 3
		10	Latch position of stepper motor at negative edge on input DI 3
		11	Reserved
3	TriggerEdge	0	Trigger edge (input DI 4) = positive
		1	Trigger edge (input DI 4) = negative
4	Enable trigger (when changes occur) StartTrigger	x	
5	ClearError	0	No effect
		1	Error acknowledgment for the motor (for more info, see "Error status")
6 - 7	Reserved	-	

Trigger function procedure:

- Select the desired trigger edge using bit 3
- Enable the trigger function by changing the state of bit 4. When this bit changes, usSinceTrigger (µs counter) is cleared.
- When the trigger event occurs, usSinceTrigger (µs counter) is started.
- The usSinceTrigger counter cannot overrun, i.e. it is stopped at 2^{16} and retains this value until the next time the trigger function is activated.

The trigger function can be re-activated at any time by changing the state of bit 4, regardless of whether a trigger event has occurred or if usSinceTrigger has reached the maximum value.

Position sync 2

Name:
PositionSync02

Depending on Counter configuration (bit 3), this register contains the state of either the position counter or the ABR counter. It's an exact complement to the Position sync register.

If the position sync register contains the position counter, then the PositionSync02 register contains the ABR counter state and vice versa.

By default, the register cannot be seen in the I/O map; instead, it has to first be activated in the I/O configuration.

Data type	Value
INT	-32768 to 32767

4.25.7.15.7 Register description: Standard functional model with SDC information

4.25.7.15.7.1 Configuration registers

SDC configuration

Name:
SDCConfig01

This register can be used to enable/disable additional SDC information.

The additional cyclic registers are hidden or shown depending on whether SDC information is disabled or enabled. It is comparable to the two variants of the standard function model with and without SDC information.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Trigger edge	0	Rising trigger edge
		1	Falling trigger edge
1 - 5	Reserved	0	
6	SDC life sign monitoring	0	Disabled
		1	Enabled
7	SDC information[1)]	0	Disabled
		1	Enabled

1) When the "SDC information" bit is enabled, the "EncOK01" bit is shown in the Automation Studio I/O mapping. This bit is linked to the ModulOK bit and always indicates its value.

Note:

Neither SDC information nor SDC life sign monitoring is permitted to be changed at runtime.

Module configuration 1 with SDC

The Module configuration 1 register is ignored in the standard function model with SDC information enabled. The module behaves as if the module configuration were described as follows:

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Meaning of bits 2 and 3 in the register "Input counter value"		
1 - 2	Reserved	0	
3 - 4	Number of transfer values per X2X cycle	00	1x Δs / Δt (transfer values: Motor settings Motor1Step0)
5 - 6	Resolution of microsteps	11	8-bit microsteps
7 - 15	Reserved	0	

Motor settling time

Name:
MotorSettlingTime01

This register determines the motor setting time. The motor settling time determines the minimum time between when the motor is powered on to when the DrvOk bit is set (see "Error status"). The setting is made in steps of 10 ms.

Data type	Value	Information
USINT	1 to 255	10 ms to 2.55 s, default: 10 ms

Turn-off delay

Name:
DelayedCurrentSwitchOff01

When the SDC life sign monitoring is triggered (i.e. the net time timestamp is in the past) the motor is decelerated at nominal current with speed setpoint = 0.

Then the motor is switched off after the delay configured with this register.

Data type	Value	Information
USINT	0 to 255	0 to 25.5 ms in steps of 100 ms (default: 100 ms)

4.25.7.15.7.2 Communication registers

SDC life sign monitoring

Name:
SetTime01

The module uses SDC life sign monitoring to check whether valid values have been received for the speed setpoint. SDC life sign monitoring is activated in the SDC configuration register by setting bit 6 (SDCSetTime = on).

If the specified NetTime timestamp is in the past, then an error is triggered for the motor axis (only when the motor is switched on). The module performs the following steps:

1) The CPU is informed of the error using the Drive bit (DrvOk) = 0

2) Braking at configured rated current with speed setpoint = 0

3) Wait for configured turn-off delay to expire

4) Power off motor

When the timestamp is back in the valid range, the motor can be powered on again by a rising edge on the DriveEnable bit (see "Motor current").

Data type	Value
INT	-32768 to 32767

Motor current

Name:
DriveEnable01
BoostCurrent01
StandstillCurrent01

Bits 0 to 2 of this register can be used to control the motor's current supply.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DriveEnable01	x	Motor powered
1	BoostCurrent01	x	Maximum current
2	StandstillCurrent01	x	Holding current
3 - 7	Reserved	0	

The possible status of bits 0 to 2

StandstillCurrent01	BoostCurrent01	DriveEnable01	Description
x	x	0	Motor not supplied with current
0	0	1	Rated current supplied to motor
0	1	1	Maximum current supplied to motor
1	0	1	Holding current supplied to motor
1	1	1	Holding current supplied to motor

Life cycle counter

Name:
LifeCnt

This register is incremented by one with each X2X Link cycle.

Data type	Value
SINT	-128 to 127

Input counter value

Name:
ModulePowerSupplyError
StatusInput01 to StatusInput04

This register is used to indicate the status of the digital inputs and the counter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ModulePowerSupplyError	0	OK
		1	Module supply error
1	Reserved	0	
2	StatusInput01	0 or 1	Input state - Digital input 1
...		...	
5	StatusInput04	0 or 1	Input state - Digital input 4
6 - 7	Reserved	0	

Error acknowledgment

Name:
ClearError01

This register can be used to acknowledge errors that have occurred on the motor.

For more info, see "Error status".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 4	Reserved	0	
5	ClearError01	0	No effect
		1	Error acknowledgment for motor
6 - 7	Reserved	0	

Motor1Step0

Name:
Motor1Step0

This registers is used to specify the number and direction of steps that should be carried out by the module during the next X2X cycle.

The value is specified with a resolution of 1/256 of a full step (corresponds to 8-bit microsteps).

The direction of movement is derived from the value's sign:

Data type	Value	Information
INT	>0	Movement in positive direction in 1/256 full steps
	<0	Movement in negative direction in 1/256 full steps

Unlike the standard function model without enabled SDC information, the motor current is selected using a separate register (see Motor current).

Home position

Name:
RefPulsePos01

These 2 registers contain the following:

Register	Description
Home position of the internal position counter	This register indicates the home position of the internal position counter.
Home position for the ABR counter	This register indicates the home position of the ABR counter.

Data type	Value
INT	-32768 to 32767

The "Position Sync" setting in the Automation Studio I/O configuration can be used to select which of the two registers is be addressed by the variable RefPulsePos01.

Variables in Automation Studio	I/O configuration, Counter 01, "Position Sync" option	
	Stepper counter 01 shown at ActPos01	ABR counter 01 shown at ActPos01
RefPulsePos01	Home position of internal position counter	Home position of ABR counter
The "Position Sync" option also sets bit 3 in the Counter configuration register for Counter 1:		
Bit 3 (counter 1)	0	1

Reference pulse counter

Name:
RefPulseCnt01

These 2 registers contain the following:

Register	Description
Reference pulse counter for the internal position counter	The reference pulses of the internal position counter are counted in this register.
Reference pulse counter for the ABR counter	The reference pulses of the ABR counter are counted in this register.

Data type	Value
SINT	-128 to 127

The "Position Sync" setting in the Automation Studio I/O configuration can be used to select which of the two registers is addressed by the variable RefPulseCnt01.

Variables in Automation Studio	I/O configuration, Counter 01, "Position Sync" option	
	Stepper counter 01 shown at ActPos01	ABR counter 01 shown at ActPos01
RefPulseCnt01	Reference pulse counter for internal position counter	Reference pulse counter of ABR counter
The "Position Sync" option also sets bit 3 in the Counter configuration register for Counter 1:		
Bit 3 (counter 1)	0	1

Net time of the position value

Name:
ActTime01

This register contains the net time of the most recent valid position value.

Data type	Value
INT	-32768 to 32767

Trigger counter

Name:
TriggerCnt01

This register contains a cyclic counter that is incremented with each trigger event.

Data type	Value
SINT	-128 to 127

Trigger timestamp

Name:
TriggerTime01

This register indicates the point in time (net time) of the most recent trigger event. The trigger edge must be configured in the "SDC configuration" register.

Data type	Value
INT	-32768 to 32767

4.25.7.15.8 Register description: Function model 254 - Bus controller and function model 3 - Ramp

4.25.7.15.8.1 Configuration registers

Holding current, rated current and maximum current

Name:
ConfigOutput03a (holding current)
ConfigOutput04a (rated current)
ConfigOutput05a (maximum current)

The holding current, nominal current and maximum current registers are used to configure the desired motor current.

Reasonable values are:

- Holding current < Nominal current < Maximum current

The motor's nominal current is entered in the nominal current register according to the motor's data sheet.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases. In the mode "Homing during stall", the rated current is always used instead of the maximum current, even in acceleration phases.
Holding current	Current when motor is at standstill

When the current changes to a weaker value (e.g. when transitioning from the acceleration phase to the constant speed mode), the stronger current is maintained for an additional 100 ms. This is done according to the following priority regardless of the actual defined values: maximum current before nominal current before holding current.

Data type	Value	Unit
USINT	0 to 117	Percent of the module's rated current • 100% corresponds to the rated current of the motor bridge power unit listed in the technical data • 117% corresponds to the maximum current of the motor bridge power unit listed in the technical data

Full step threshold

Name:
FullStepThreshold01

This register defines the threshold speed, above which the motor is operated in full step mode, and below which it is operated in microstep mode.

Data type	Value	Information
UINT	1 to 65534	Speed in microsteps / cycle
	65535	Motor is always operated in microstep mode

Maximum speed

Name:
MaxSpeed01pos

This register defines the maximum speed for the absolute positioning modes (1, -123, -124, -125, -126).

Information:

The setting does not apply to the speed and homing modes (2, -127, -128).

Data type	Value	Information
UNIT	0 to 65,535	Speed in microsteps / cycle

Maximum acceleration

Name:
MaxAcc01

This register defines the maximum acceleration (also applies for homing modes).

Data type	Value	Information
UINT	0 to 65,535	Acceleration in microsteps / cycle²

Maximum deceleration

Name:
MaxDec01

This register defines the maximum deceleration (also applies for homing modes).

Data type	Value	Information
UINT	0 to 65,535	Deceleration in microsteps / cycle²

Reversing loop

Name:
RevLoop01

This parameter is only used in mode 1, -123, -124, -125, -126 (absolute positioning modes).

If the value for the reversing loop is not equal to 0, the position setpoint is approached directly when coming from one direction; when coming from the other direction, the position setpoint is initially exceeded by the configured number of steps before finally moving to the position setpoint. This ensures that the position setpoint is always approached from the same direction (to avoid mechanical backlash).

The sign of the defined value determines the direction in which the reversing loop runs.

Sign	Effective direction
Positive	Reversing loop in positive direction of movement
Negative	Reversing loop in negative direction of movement

Data type	Value
INT	-32768 to 32767

Fixed position A

Name:
FixedPos01a

This register defines the position to move to in modes -124 (when 1 is set at the digital input) and -125.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Fixed position B

Name:
FixedPos01b

This register defines the position to move to in modes -124 (when 0 is set at the digital input) and -126.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Homing speed

Name:
RefSpeed01

This register sets the speed for homing modes -127 and -128.

Data type	Value	Information
UINT	0 to 65,535	Speed in microsteps / cycle

Stall recognition delay

Name:
StallRecognitionDelay01

The value in this register is only relevant for "Homing during stall".

A stall is only detected after the time specified here has expired and after the homing procedure has started.

For example, a setting of 4 (and a cycle time of 25 ms) means that a stall will not be detected until 100 ms after the motor starts moving (start of the homing procedure).

Set to 0 to eliminate delay.

Data type	Value	Information
USINT	0 to 255	in cycles, see "General configuration"

Minimum speed for stall detection

Name:
StallDetectMinSpeed01

If the motor speed exceeds the value set in this register, then stall detection is enabled and the configured mixed decay threshold is used. The value 15 is always used for the mixed decay threshold below this threshold value, and no stall error is reported. This means that mixed decay mode is always enabled at low speeds where stall detection principally does not work.

Data type	Value	Information
UINT	0 to 65535	Minimum speed in microsteps per cycle.

Jolt time

Name:
JoltTime01

If a value other than 0 is assigned to this register, then jolt limitation is performed. This is done by averaging the values for the steps to be carried out (speed setpoint) in each cycle using FIFO memory. The jolt time corresponds to the number of FIFO elements (0 to 80). If a value greater than 80 is entered, then it will be limited internally to 80.

Changes made while a motor is running will be applied as soon as ...

- the motor has reached the position setpoint (positioning modes only)
- the motor has stopped (all modes)

Data type	Value	Information
USINT	0	No jolt time limitation
	1 to 80[1)]	Number of FIFO elements

1) Starting with upgrade 1.3.1.0 (firmware version 16); For older versions: 16

Homing configuration

Name:
RefConfig01

The homing mode can be set with this register.

Data type	Value	Information
SINT	-120	Set home position
	-121	Homing at positive edge on input DI 4
	-122	Homing at negative edge on input DI 4
	-125	Homing at positive edge on input DI 3 (R pulse)
	-126	Homing at negative edge on input DI 3 (R pulse)
	-127	Homing during stall detection
	-128	Immediate homing
	Everything else	No effect

Stall detection configuration / Mixed decay

Name:
StallDetectConfig01

The mixed decay threshold and stall detection sensitivity can be configured in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Mixed decay threshold	0	Mixed decay disabled
		1 to 14	Setting for mixed decay threshold
		15	Mixed decay always enabled
4 - 6	Stall threshold	0	Stall detection is disabled
		1 to 6	Steps involved in setting stall detection sensitivity
		7	Maximum sensitivity for stall detection
7	Motor load	0	Motor load value not shown
		1	Show value in register Status word[1)]

1) If this bit is 1, then the motor load value is shown in bits 13 to 15 of the status word register (otherwise these bits are 0). This value can help when testing the stall detection and the Home during stall mode.

Stall threshold

The SM module features integrated sensorless load measurement for the motor axis. This is especially useful for detecting a "stall condition" (e.g. if the motor moves to the end point during a homing procedure). It cannot be used for torque monitoring during dynamic movements.

The "stall threshold" (bits 4 to 6 of this register) can be used to define a threshold value for each axis individually according to the motor load, beyond which the motor will detect a stall condition.

This threshold value must be determined on a case-by-case basis, since the results of load measurement are influenced by a variety of factors.

- Motor speed: A higher speed results in higher measurement values
- Speeds that cause motor resonances (which interfere with load measurement) are to be avoided
- Motor accelerations that create a dynamic load (and also affect the measurement) should also be avoided
- It is especially important to be aware that mixed decay mode must be optimized for reliable stall detection.

The higher the load measurement value, the lower the load. This means that a stall condition is detected if the load measurement value drops below the trigger threshold for stall detection.

Mixed decay threshold

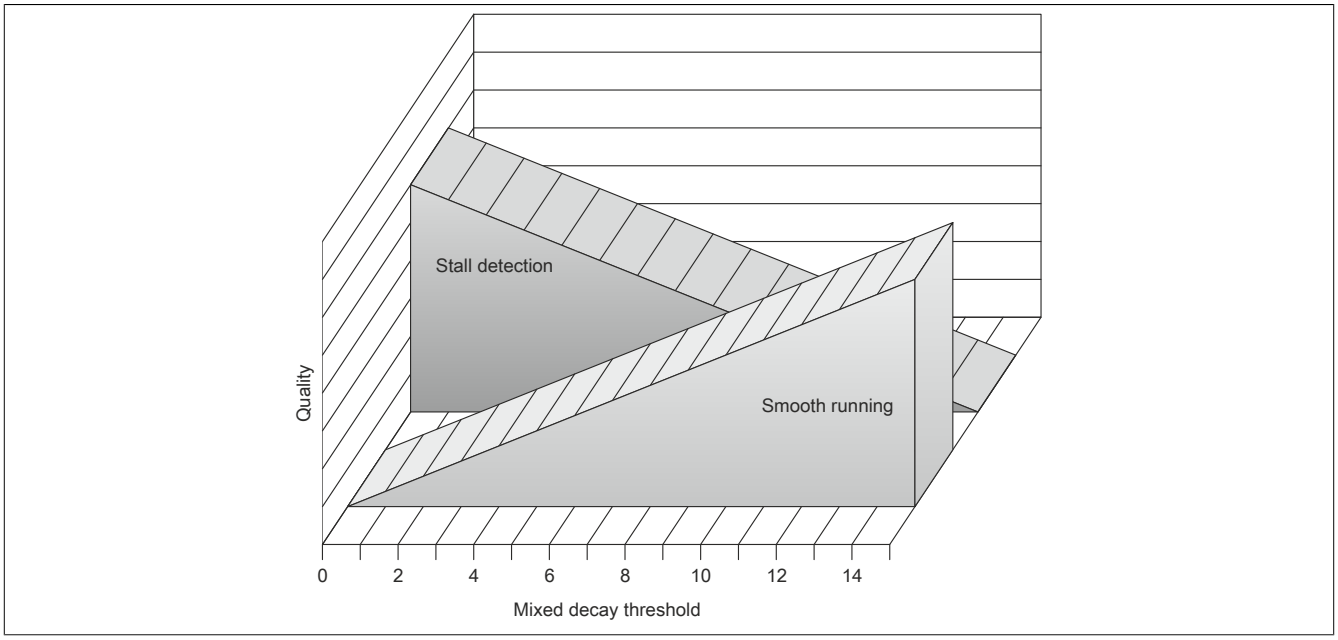
Mixed decay modules provide a greatly optimized sinusoidal current profile in the individual phases of the stepper motor, especially for fast current changes and low current values.

Mixed decay interferes with reliable stall detection, however. For this reason, mixed decay mode can be disabled during stall detection (motor load measurement) using the mixed decay threshold. The smaller the configured mixed decay threshold, the larger the range in which mixed decay is disabled while motor load measurement takes place.

Mixed decay mode is always enabled if the mixed decay threshold is set to 15.

Relationship between stall detection and mixed decay

Depending on the application and the motor used, satisfactorily smooth operation can be achieved while using stall detection by setting the mixed decay threshold to a value between 1 and 14. This is a compromise between smooth operation and stall detection quality and must be fine tuned during commissioning.



General configuration

Name:
GeneralConfig01

Bit 0 of this register can be used to switch the positioning mode. This register can also be used to configure the cycle time of the motion profile generator.

- 0: "Mode 1: Position mode" without extended control word
- 1: "Mode 1: Position mode with extended control word"

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Position mode	0	Without extended control word
		1	With extended control word
1 - 2	Cycle time of the motion profile generator[1)]	00	25 ms
		01	10 ms
		10	5 ms
		11	Reserved
3 - 7	Reserved	0	

1) This parameter is supported starting with upgrade 1.3.1.0 (firmware version 16).

Limit switch configuration

Name:
LimitSwitchConfig01

This register can be used to configure the behavior of the limit switch.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Negative limit switch	00	Off
		01	Active if low
		10	Reserved
		11	Active if high
2 - 3	Positive limit switch	00	Off
		01	Active if low
		10	Reserved
		11	Active if high
4 - 6	Reserved	0	
7	Direction monitoring	0	Off (default)
		1	On

Negative/positive limit switch

When one of the limit switches is reached, a warning is triggered and the speed is decelerated to 0. The "Device Control State Machine" state is not changed. This keeps current flowing to the motor.

The error that occurred can be read from the Error code register. Normal operation can be resumed by acknowledging the warning. This will not restrict motor movement to a specific direction and the limit switch will not be triggered until the next active edge.

Exceeding the limit switch while braking

The limit switches are not linked with the corresponding direction of movement. If the limit switch is exceeded, another error will be triggered when reversing after acknowledging the initial error.

Direction monitoring

If this function is enabled, then the two limit switches will be linked with the respective direction of movement. This means that the negative limit switch is only triggered in the negative direction and the positive limit switch only in the positive direction of movement (specified direction).

This prevents specifying a movement in the wrong direction when direction monitoring is enabled and limit switches are active.

Warning!

If the motor is wired incorrectly with this configuration (wrong direction of movement), then the limit switch will not be triggered and the actual correct direction of movement will be denied. This will also be the case when the limit switch connections are reversed.

Software limit

Name:
PositionLimitMin01
PositionLimitMax01

This register configures software limits. The function is active if at least one of the two registers is unequal to zero.

These limits are effective in all positioning modes. Position overrun is not possible when this function is enabled. Movement is always contained within the two limits.

If a position is specified that violates the minimum/maximum software limit, the "Internal limit active" bit will be set in the Status word register. The motor movement will be stopped until a position is specified within the limits.

The "Internal limit active" bit will also be set in the "Status word" register if there is a configuration error (minimum > maximum).

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

The software limits will only be monitored in connection with the following CANopen bus controllers:

- **X20BC0043-10**
- **X20BC0143-10**
- **X67BC4321-10**
- **X67BC4321.L08-10**
- **X67BC4321.L12-10**

4.25.7.15.8.2 Reading back the configuration

Read ing the holding current, rated current and maximum current

ConfigOutput03aRead (holding current)
ConfigOutput04aRead (rated current)
ConfigOutput05aRead (maximum current)

These registers are used to read the respective current values in percent.

Register	Description
Nominal current	Current during operation at constant speed
Maximum current	Current during acceleration phases
Holding current	Current when motor is at standstill

Data type	Value	Unit
USINT	0 to 255	Percent of the module's rated current (100% corresponds to the rated current of the motor bridge power unit listed in the technical data)

4.25.7.15.8.3 Communication registers

Set position/speed

Name:
AbsPos01

This register is used to set position or speed, depending on the operating mode.

- Position mode (see "Mode"): Cyclic setting of the position setpoint in microsteps. In this mode, one micro-step is always 1/256 full-step.
- Speed mode (see "Mode"): In this mode, this register is used as a signed speed setpoint.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Control word

Name:
MpGenControl01

This register can be used to issue commands based on the module's state (see 4.25.7.15.8.4 "Ramp function model operation").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Switch on	x	
1	Enable voltage	x	
2	Quick stop	x	
3	Enable operation	x	
4 - 6	Mode-specific	x	
7	Fault reset	x	
8	stop[1)]	x	
9 - 10	Reserved	0	
11	Motor ID trigger	0	No effect
		1	Rising edge: Motor ID trigger[2)]
12	Warning reset	0	No effect
		1	Rising edge: Reset warnings
13	Undercurrent detection	0	Disable current error detection (default)
		1	Enable current error detection
14	ABR counter sync/async	0	Default: • Internal position counter, cyclic • ABR counter, non-cyclic
		1	• Internal position counter, non-cyclic • ABR counter, cyclic
15	Stall detection	0	Disable stall detection (default)
		1	Enable stall detection

1) The "Halt" bit is only evaluated when the extended control word is enabled (see "General configuration").
2) This bit can be used to trigger a measurement of the motor ID. Keep in mind that the application must ensure that the conditions for measurement are fulfilled (see table in the "Motor ID" register).

Mode

Name:
MpGenMode01

Data type	Value	Information
SINT	0	No mode selected
	1	Depending on bit 0 in the General configuration register, the position mode will behave as follows: • Position mode without extended control word: Move to position setpoint as soon as position setpoint is changed • Position mode with extended control word: Move to position setpoint as described in "Mode 1 - Position mode with extended control word"
	2	Speed mode: Constant speed
	-120	Set home position
	-121	Remaining distance mode
	-122	Set the actual position
	-123	Move to position setpoint when external input is set
	-124	Two-position module
	-125	Move to fixed position A (position set asynchronously)
	-126	Move to fixed position B (position set asynchronously)
	-127	Positive homing (see also "Homing configuration")
	-128	Negative homing (see also "Homing configuration")

Information:

For all modes: The "Target reached" bit is set in the Status word register when the current action is finished (i.e. when the position or speed is reached, depending on the mode).

A new position or speed can be specified even before the current action is finished.

Mode 1 - Position mode

The position setpoint is specified in the Set position/speed register. The motor is then moved to this new position. This is done with a ramp function that accounts for the defined maximum speed and acceleration values.

The position setpoint can also be changed during an active positioning procedure.

The position setpoint is specified in microsteps (1/256 of a full step).

If bit 0 in the General configuration register is 0 (no extended control word), then the position setpoint will be applied as soon as it is different from the current position. The new position is then moved to.

However, if bit 0 in the General configuration register is set to 1 (extended control word), then the position setpoint will be applied as described under "Mode 1 - Position mode with extended control word".

Mode 1 - Position mode with extended control word

The position mode with extended control word behaves like the previously described Position mode 1 (without extended control word) except that the new position setpoint (Position/speed register) is applied according to the extended control word.

Extended control word

This register can be used to issue commands based on the module's state (see 4.25.7.15.8.4 "Ramp function model operation").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Corresponds to the defaultControl word	x	
4	New setpoint	0	Do not apply position setpoint
		1	Apply position setpoint
5	Change set immediately	0	Complete current positioning movement and then start next positioning movement
		1	Interrupt current positioning movement and then start next positioning movement
6	abs / rel	0	Position setpoint is an absolute value
		1	Position setpoint is a relative value
7	Corresponds to the defaultControl word	x	
8	Halt[1)]	0	Execute positioning
		1	Stop axis with deceleration
9 - 15	Corresponds to the defaultControl word	x	

1) This bit applies to all modes.

Extended status word

The bits in the status word reflect the status of the state machine (for a detailed description, see "Status word" and "State machine").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 9	Corresponds to the defaultStatus word	x	
10	Target reached, depending on bit 8 (Halt) in the register Control word		**If Halt = 0**
		0	Position setpoint not reached
		1	Position setpoint reached
			If Halt = 1
		0	Axis decelerating
		1	Axis speed = 0
11	Corresponds to the defaultStatus word	x	
12	Setpoint acknowledge	0	Ramp generator did not apply the position value
		1	Ramp generator applied the position value
13 - 15	Corresponds to the defaultStatus word	x	

Position setting

The position setpoint can be defined in two different ways:

Type of setpoint definition	Description
Single setpoint	Once the position setpoint is reached, the *Target reached* bit in the Status word register is set. Then a new position setpoint is defined. The drive stops at each position setpoint before starting the movement to the next position setpoint.
Set of setpoints	Once a setpoint has been reached, the movement to the next setpoint is started immediately without stopping the drive. It is therefore not possible to initiate a new positioning movement by transferring a new position setpoint during an active positioning movement.

Table 578: Types of position setpoint definition

The two modes "Single setpoint" and "Set of setpoints" are controlled by the timing of the bits *New setpoint* and *Change set immediately* in the *extended control word* and *Setpoint acknowledge* in the *Extended control word* register.

These bits can be used to create a Request-Response mechanism. This makes it possible to specify a position setpoint while previous setpoint is still being processed.

Transferring the position setpoint

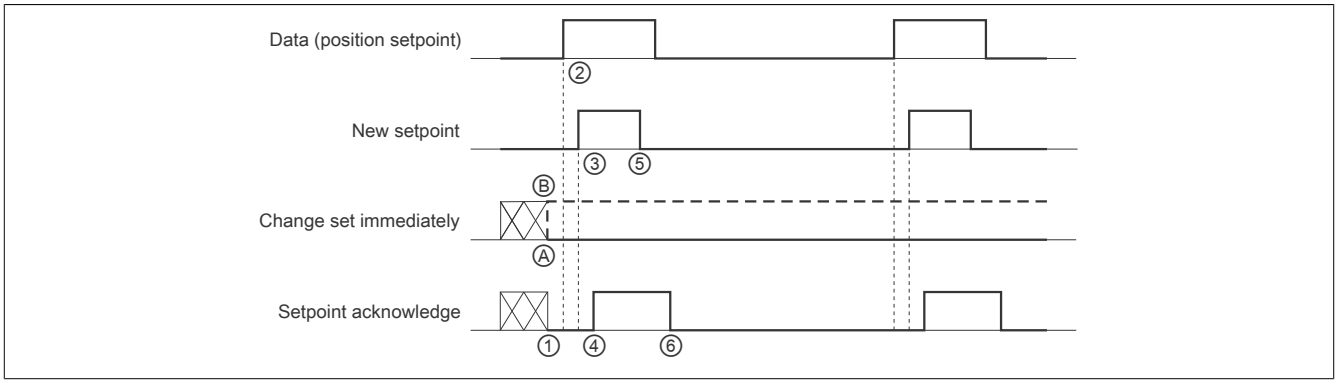


Figure 396: Principle for applying the setpoint

Transferring a new setpoint:

1. When the *Setpoint acknowledge* bit in the Extended status word register is 0, the module will accept a new position setpoint.
2. The new position setpoint is specified in the *Set position/speed*.
3. A rising edge of the *New setpoint* bit in the Extended control word register signalizes that the new position setpoint in the *Set position/speed* register is valid and can be used for the next positioning movement.
4. Once the module has received and saved the new position setpoint, the *Setpoint acknowledge* bit in the *Status word* register is set to 1.
5. Now the controller can reset the *New setpoint* bit to 0.
6. Then the module resets the *Setpoint acknowledge* bit to 0 to signal when a new position setpoint is accepted.

"Single setpoint" mode

When the *Change set immediately* bit is set to 0 (Ⓐ in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This mechanism results in a speed of 0 when the motor reaches position setpoint x_1 at time t_1. After the controller has been notified that the setpoint has been reached, the next setpoint x_2 will be processed at time t_2 and reached at t_3.

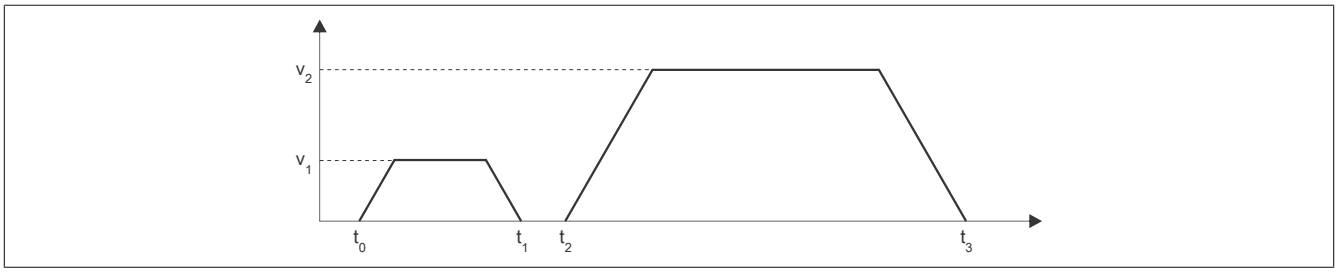

Figure 397: Ramp in *Single setpoint mode*

"Set of setpoints" mode

When the *Change set immediately* bit is set to 1 (Ⓑ in figure "Principle for applying the setpoint"), then the module is operating in *Single setpoint* mode. This means that the module receives the first position setpoint at t_0. A second position setpoint is received at the time t_1. The drive immediately adapts the current movement to the new setpoint.

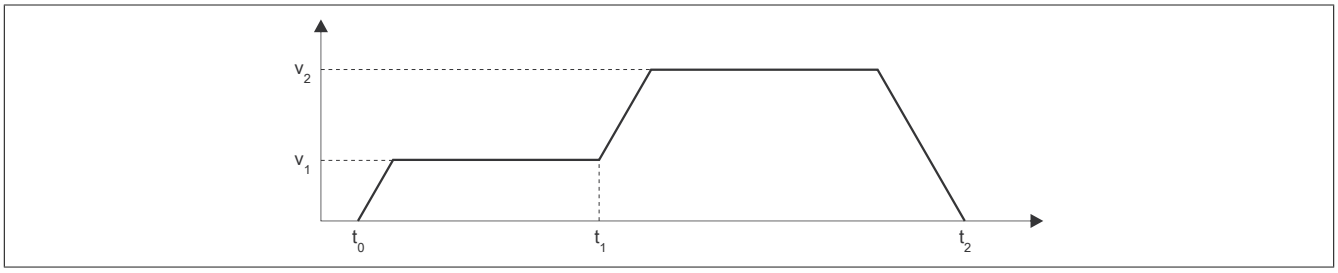

Figure 398: Ramp in *Set of setpoints mode*

Relative position setting

When the *abs / rel* bit in the Extended control word register is set, then the position setpoint is interpreted as a relative value. At each *New setpoint* trigger, the position setpoint will be increased by this value (or decreased if the value is negative).

If the mode changes between the position settings, relative movement will then proceed starting at the last specified position. The position setpoint mode is initialized with 0 when the module is started.

Mode 2: Speed mode - Constant speed (pos./neg.)

The value in the Position/speed register is now interpreted as the speed setpoint (microsteps/ cycle).

Observing the maximum permissible acceleration, the motor moves with a ramp to the desired speed setpoint and maintains this speed until a new speed setpoint is specified.

Values are allowed within the range -65535 to 65535. When a value is entered outside of this range, it is readjusted to these limits.

Mode -120: Set home position

This mode is supported starting with upgrade 1.3.1.0 (firmware version 16).

The current actual position is modified so that the position specified by the Position/speed register is at the home position. If you subsequently move to this position, the motor is at the home position.

The home position in the "Home position" register is also set to this value.

Before this mode is called, the motor must be at a standstill and the home position must have been determined using the "Positive / negative homing" mode. In order to set the position, the State machine must be in the state "Operation Enable".

Mode -121: Remaining distance mode (like Modus 1)

The number of steps defined in the "Fixed position A" register are added to the current position and the resulting position is approached at a rising/falling edge on digital input 3.

Note:

Steps are not added to the position setpoint, but rather to the current position at the moment the trigger occurs.

Negative values are also allowed for the offset defined in "Fixed position A".

New position setpoints are no longer accepted in the Position/speed register after the trigger event. There must first be a switch made to mode 0 and then back to mode -121.

The "Target reached" bit in the Status word register is not set to 1 until the end position (after the trigger event) has been reached.

The Homing configuration determines whether a rising or falling edge of the digital input is used as a trigger.

The Reversing loop is not enabled in this mode (i.e. any configured values not equal to 0 are ignored).

Mode -122: Set the actual position

The position setpoint set in the "Position/speed" register is accepted as the current actual position in the internal position counter when the state machine is in the "Operation Enable" state.

Before this mode is started, the motor must be at a standstill and physically located at the point for which the position being set should be applied.

Mode -123: Move to the position setpoint when the external input is set

The set position defined in the "Position/speed" is moved to when a rising edge occurs on the corresponding digital input.

A new position setpoint is not accepted until another rising edge occurs on the corresponding digital input. This can also occur during the active positioning procedure and will be applied immediately.

Mode -124: Two position mode

The positions "Fixed position A" and "Fixed position B" are defined in the non-cyclic registers.

The value 1 on digital input 3 moves to fixed position A. The value 0 moves to fixed position B. It is also possible to switch between the two during an active positioning movement.

Mode -125/-126: Move to fixed position X

The purpose of these modes is to enable a virtual switch from speed mode to position mode, which otherwise isn't possible because of the double use of the register for position and speed setpoints.

- Mode -125: Fixed position A
- Mode -126: Fixed position B

Mode -127/-128: Homing (positive/negative)

Mode -127 and -128 are used to select which direction to move in.

The motor must be at a standstill before switching from another mode to one of the homing modes.

If the homing condition occurs, then the motor stops and the values of the position counter and ABR counter valid at the moment when the homing condition occurs are written to the Homed zero position register.

You must specify in the Homing configuration whether homing should occur at low/high level on the digital input, during stall or unconditionally.

Homing via digital input

Case 1: Active homing level not yet reached → Motor not yet at end position:

Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input.

Case 2: Active homing level already reached → Motor at end position:

Movement continues at the homing speed, counter to the homing direction, until the active level for "homing-stop" is no longer on the digital input. Movement continues at homing speed in the homing direction until the active level for "homing-stop" is on the digital input again.

Homing during stall

Movement continues in the homing direction until a stall is detected. When a stall is detected, the value of the position counter is entered in the Homed zero position register within one millisecond. The motor is then stopped abruptly (not using the deceleration ramp). However, it can take up to 25 ms to stop the motor because the ramp generator runs with a configurable internal cycle of up to 25 ms.

In this mode, the rated current is always used instead of the maximum current, even in acceleration phases.

To test the response behavior of this homing mode, the motor load value used for identifying a stall can be made visible in the status word (see "Stall detection configuration / Mixed decay").

Homing unconditional (immediate)

Immediate homing: The current values of the position counter and ABR counter are immediately entered in the Homed zero position register (no motor movement).

Current position (cyclic)

Name:
AbsPos01ActVal

This cyclic register contains the current position.

Default: Value of the internal position counter, can be changed to ABR counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Status word

Name:
MpGenStatus01

The bits in this register reflect the state of the state machine. For a more detailed description, see "Status word" and "State machine".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Ready to switch on	x	
1	Switched on	x	
2	Operation enabled	x	
3	Fault (error bit)	x	
4	Voltage enabled	x	
5	Quick stop	x	
6	Switch on disabled	x	
7	Warning	x	
8	Reserved	0	
9	Remote	1	Always 1 because there is no local mode for the SM module
10	Target reached	x	
11	Internal limit active	0	No limit violation
		1	Internal limit is active (upper/lower software limit violated)
12	Mode-specific	x	
13 - 15	Reserved / Motor load value	0	Always 0 when bit 7 in the Stall detection configuration / Mixed decay register is set to 0.
		x	Returned motor load value

Input status

Name:
InputStatus

This register indicates the logical states of digital inputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Digital input 1	0 or 1	Input state - Digital input 1
...		...	
3	Digital input 4	0 or 1	Input state - Digital input 4
4 - 15	Reserved	0	

Motor ID

Name:
Motoridentification01

This register is used to identify the connected motor type for service purposes and to differentiate between motors in the application. Following measurement, this register contains the time [µs] needed to apply a current increase of ΔI = 1 A to a motor winding.

This depends on:

- Operating voltage
- The inductance and resistance of the motor winding

Notes		
1)	To achieve reproducible results, the measurement must be made under the following defined conditions:	
	a)	Motor is at standstill
	b)	The motor must be in a half-step position (phase A fully powered, phase B not powered). This means the internal position counter on the SM module must have a value that fulfills the following conditions: • Full steps are divisible by 4 • Microsteps = 0
2)	Condition 1b) is fulfilled after a the SM module is reset or powered on. Immediately afterwards, when the holding current is applied to the motor for the first time (at standstill), the duration for applying the current is measured. This is therefore a suitable time to read the motor identification register in the application.	
3)	The current range from approximately 1/3 of the rated current up to the rated current is used as operating range for determining the motor identifier.	

Data type	Motor ID values	Function
UINT	0	No motor identifier available (after turning on for as long as the measurement conditions are not met)
	1 to 32767	Valid range of values for the motor ID register (in µs)
	65504 to 65519	Ground fault: Motor identification not possible
	65528	Motor ID trigger not possible • Motor has no power applied • Motor in movement • Rated current is set to 0A • Ground fault present
	65529	Invalid value: Underflow
	65530	Overtemperature: Measurement not possible
	65532	Open line: Measurement not possible
	65533	Motor position incorrect: Measurement not possible
	65534	Invalid value: Overrun
	65535	Measurement in progress

Ground fault detection

When the motor is powered on, a ground fault check is performed before motor identification. Error numbers have been added in the motor identification register for the event of a ground fault error (values 65504 to 65519 in the table above).

Homed zero position

Name:
RefPos01CyclicCounter
RefPos01AcyclicCounter

After a homing procedure, the homing position for the cyclic and non-cyclic position counter can be read using these registers (either the internal position counter or ABR counter depending on bit 14 of the "Control word" register).

The following two registers are provided for the motor:

- Homed zero position for cyclic counter
- Homed zero position for non-cyclic counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Current position (acyclic)

Name:
AbsPos1ActValAcyclic

This acyclic register contains the current position.

Default: Value of the ABR counter, can be changed to internal position counter

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Reads the extended control word

Name:
ControlReadback01

This register can be used to read the content of the Control word register.

Data type	Value
UINT	0 to 65535

Read back mode

Name:
ModeReadback01

This register can be used to read the content of the Mode register.

Data type	Value
SINT	-128 to 127

Error code

Name:
ErrorCode01

The cause of an error or warning can be read in this register.

Data type	Error code	Error type	Priority	Description
UINT	0x0000	-	-	No error
	0x3000	Error	High	Voltage
	0x4200	Error	:	Overtemperature
	0xFF20	Warning	:	Negative limit switch
	0xFF21	Warning	:	Positive limit switch
	0x2300	Warning	:	Overcurrent
	0xFF00	Warning	:	Current error[1)]
	0xFF01	Warning	Low	Stall [2)]

1) A current error is only detected if bit 13 = 1 in the control word (current error detection enabled).
2) Stall is only detected if bit 15 = 1 in the control word (stall detection enabled).

Information regarding the handling of errors and warnings:

- Bit 3 (Fault) and bit 8 (Warning) in the status word can be used to query whether an error or a warning was reported in the error code register.
- Bit 7 (Fault Reset) and bit 8 (Warning Reset) in the control word are used to acknowledge pending errors and warnings.
- If two or more errors/warnings are pending, the one with the highest priority (the order in the table above) will be displayed in the error code register.

4.25.7.15.8.4 Ramp function model operation

Control for this model has been based on the CANopen communication profile DS402.

Commands for controlling the modules are written to the "Control word". The current module state is returned to the "Status word" register. The function mode (absolute position, constant speed, homing, etc.) is set in the "Mode" register.

Control word

Control word bits and their state for the commands of the state machine:

Command	Reserved	ABR counter sync/async	Current error detection	Warning reset	Motor ID trigger	Reserved	Reserved	Halt 2)	Fault reset	Mode specific	Mode specific	Mode specific	Enable operation	Quick stop	Enable voltage	Switch on
Bit[1]	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Shutdown	x	x	x	x	x	0	0	x	0	x	x	x	x	1	1	0
Switch on	x	x	x	x	x	0	0	x	0	x	x	x	0	1	1	1
Disable voltage	x	x	x	x	x	0	0	x	0	x	x	x	x	x	0	x
Quick stop	x	x	x	x	x	0	0	x	0	x	x	x	x	0	1	x
Disable operation	x	x	x	x	x	0	0	x	0	x	x	x	0	1	1	1
Enable operation	x	x	x	x	x	0	0	x	0	x	x	x	1	1	1	1
Fault reset	x	x	x	x	x	0	0	x	↑	x	x	x	x	x	x	x

1) x ... Any; ↑ ... Rising edge
2) Bit 8 (Halt) is only evaluated if the extended control word is enabled in the "General configuration" register.

Bits 0, 1, 2, 3 and 7 (light gray in the previous table)	These bits control the state of the "State machine" according to the commands in the table above.
stop	0 ... Perform motor movement 1 ... Stop axis with deceleration This bit is only evaluated when the extended control word is activated in the "General configuration" register.
Motor ID trigger	A rising edge enables the motor ID measurement.
Warning reset	A rising edge resets warnings (no effect on errors, which are reset using "Fault Reset"; the state machine is not affected by this bit)
Fault reset	A rising edge resets errors and warnings (see "State machine" on page 2476)
Current error detection	0 ... Current error detection disabled 1 ... Current error detection enabled
ABR counter sync/async	0 ... Value of the ABR counter on the "Current position (non-cyclic)" register. Internal position counter of the ramp generator on the "Current position (cyclic)" register. 1 ... Value of the ABR counter on the "Current position (cyclic)" register. Internal position counter of the ramp generator on the "Current position (non-cyclic)" register.
Stall detection	0 ... Stall detection disabled 1 ... Stall detection enabled

Status word

The individual bits of this register and its states depend on the current state of the state machine:

Status	Reserviert / MotorLoadBit 2 [1]	Reserviert / MotorLoadBit 1 [1]	Reserviert / MotorLoadBit 0 [1]	Mode-specific	Int. limit active	Target reached	Remote	Reserved	Warning	Switch on disabled	Quick stop	Voltage enabled	Fault	Operation enabled	Switched on	Ready to switch on
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not ready to switch on	x	x	x	x	x	x	1	0	x	0	x	0	0	0	0	0
Switch on disabled	x	x	x	x	x	x	1	0	x	1	x	0	0	0	0	0
Ready to switch on	x	x	x	x	x	x	1	0	x	0	1	0	0	0	0	1
Switched on	x	x	x	x	x	x	1	0	x	0	1	1	0	0	1	1
Operation enable	x	x	x	x	x	x	1	0	x	0	1	1	0	1	1	1
Quick stop active	x	x	x	x	x	x	1	0	x	0	0	1	0	1	1	1
Fault reaction active	x	x	x	x	x	x	1	0	x	0	x	0	1	1	1	1
Fault	x	x	x	x	x	x	1	0	x	0	x	0	1	0	0	0

1) If bit 7 is set to 1 in the Mixed decay / Stall detection register, then the motor load value is returned in bits 13-15 of the status word. Otherwise these bits are always 0.

Information about the status word:

Bits 0,1,2,3,5 and 6 (light gray in the previous table)	These bits are set according to the current state of the "State machine".	
Voltage enabled	Becomes 1 as soon as the motor is powered	
Warning	Becomes 1 if a warning is detected ("Overcurrent", "Undercurrent"). The type of warning is indicated in the "Error code" register. The highest priority error / warning is shown in each case, with the priority corresponding to the order in the respective table. Warnings can be reset with a rising edge on the "Warning reset" bit in the control word.	
Remote	Always 1 since there is no local mode on the SM module	
Target reached[1], depending on bit 8 (Halt) in the register Control word	**If Halt = 0**	**If Halt = 1**
	In modes 1, -123, -124, -125 and -126 (absolute positioning): 0 ... Positioning begins 1 ... Target has been reached **In mode 2 (constant speed):** 0 ... Motor accelerates/brakes 1 ... Speed setpoint reached **In modes -127 and -128 (homing):** 0 ... Homing started 1 ... Homing ended **In mode -122 (set actual position):** The bit briefly becomes 0 and immediately becomes 1 again as soon as the position is set.	**In all modes:** 0 ... Axis decelerating 1 ... Axis speed = 0
Internal limit active	0 ... No limit violation 1 ... Internal limit is active (upper/lower software limit violated)	

Table 579: Information about the status word

1) If Halt has not been activated in the "General configuration" register, then "Target Reached" behaves the same as when Halt = 0.

State machine

The motor is controlled according to the state machine illustrated below. After the module is started, the state machine automatically changes to the state "*Not ready to switch on*". The application then operates the state machine by writing commands to the "Control word".

The state machine successively reaches the states "*Ready to switch on*", "*Switched on*" and "*Operation enable*" by writing the consecutive commands "*Shutdown*", "*Switch on*" and "*Enable operation*".

Information:

Motor movements are not performed until the "*Operation enable*" state, according to the setting in the Mode register.

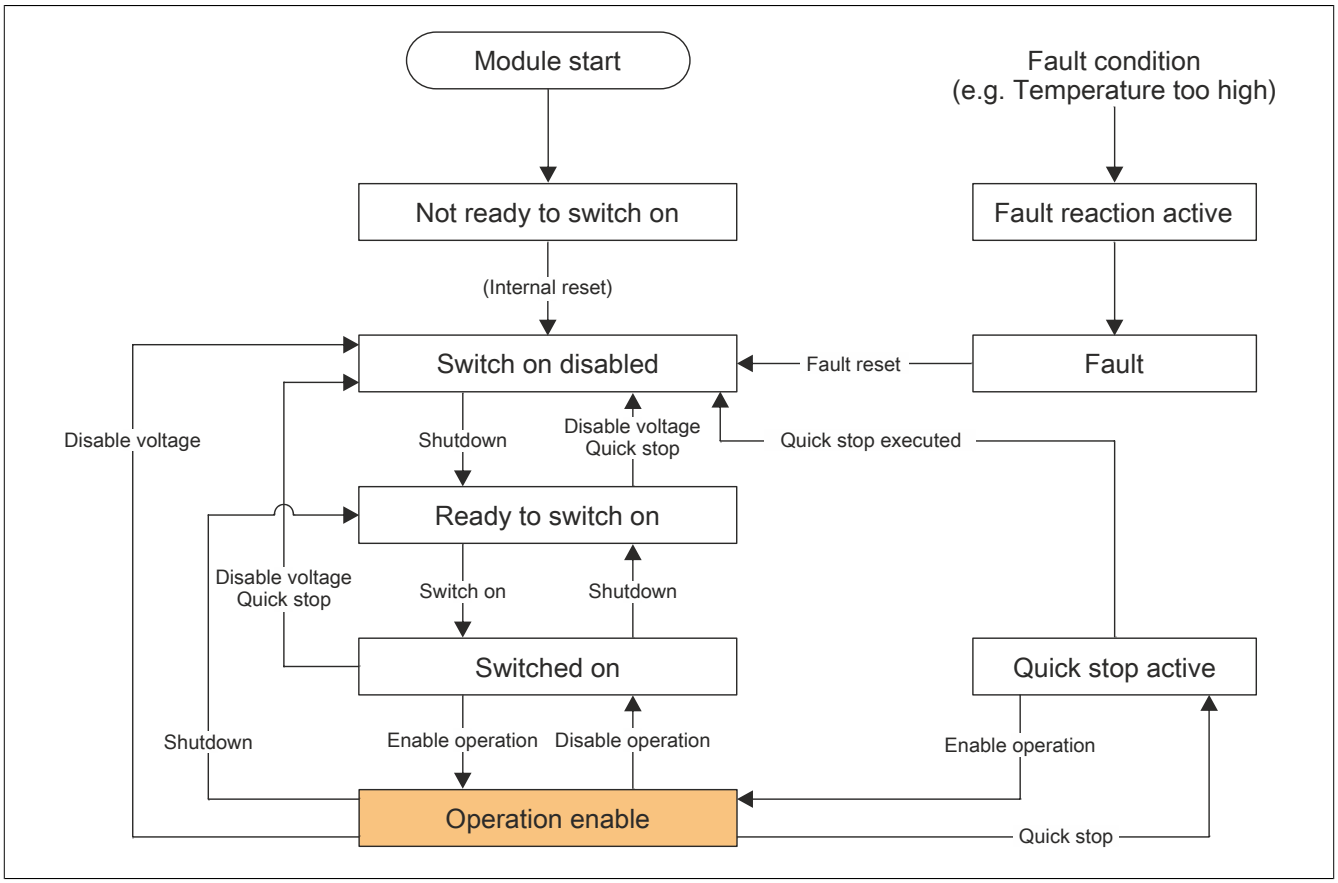

Figure 399: State machine - Flow chart

State change	Description
Not ready to switch on → Switch On Disabled	This state change occurs automatically after starting the module and internal initialization has taken place.
Switch on disabled → Ready to Switch On	This state change is brought on by the *Shutdown* command. No others actions are performed.
Ready to switch on → Switch On Disabled	This state change is brought on by the command *Disable voltage* or *Quick stop*. No others actions are performed.
Switched on → Switch On Disabled	This state change is brought on by the command *Disable voltage* or *Quick stop*. The motor voltage is switched off immediately.
Ready to switch on → Switched On	This state change is brought on by the *Switch on* command. The motor voltage is switched on. When this state change occurs for the first time since the module is started, the motor ID measurement is performed before the *Switched on* state is achieved. This can take approximately 1 second.
Switched on → Ready to Switch On	This state change is brought on by the *Shutdown* command. The motor voltage is switched off immediately.
Switched on → Operation Enable	This state change is brought on by the *Enable operation* command. Motor movements are now performed depending on the defined mode.
Operation enable → Switched On	This state change is brought on by the *Disable operation* command. If in motion, the motor is decelerated with the configured deceleration. Motor voltage remains on in the *Switched on* state.
Operation enable → Ready to Switch On	This state change is brought on by the *Shutdown* command. The motor voltage is switched off immediately.
Operation enable → Switch On Disabled	This state change is brought on by the *Disable voltage* command. Motor voltage switched off. It is strongly recommended to only make this state change on a stopped motor since regeneration on a motor running at no load can cause an overvoltage error on the DC bus (0x3210).
Operation enable → Quick Stop Active	This state change is brought on by the *Quick stop* command. If in motion, the motor is decelerated with the configured deceleration. During the deceleration, the state machine remains in the *Quick stop active* state. Once the motor is at standstill, the state automatically changes to the *Switch on disabled* state. While the state machine is in the *Quick stop active* state, the *Enable operation* command can be used to switch it back to the *Operation enable* state.
→ Fault reaction active	This state change is brought on when an error occurs and cannot be triggered by a command from the user. It can be triggered by error types classified as an "Error" (see "Error code"). (Other error types listed as "Warning" only cause the "Warning" bit to be set in the status word and do not cause a state change in the state machine.) Motor voltage is switched off and the state machine then changes immediately to the *Fault* state. The type of error is listed in the error code register (see the table under "Error code"). The highest priority error is shown. The priority corresponds to the order in the error code table.
Fault → Switch On Disabled	This state change is brought on by the *Fault reset* command. However, the state only changes if no more errors are present when the command is written. All errors and warnings are reset. The error code register contains 0 or the warning code if a warning is still present.

Table 580: State machine - State change

4.25.7.15.9 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

	Minimum cycle time
Standard function model	250 µs
Ramp function model	250 µs

4.25.7.15.10 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

	Minimum I/O update time
Standard function model	250 µs
Ramp function model	
Inputs	250 µs
Outputs[1)]	25 ms

1) Depending on the configuration of the motion profile generator

4.26 Other functions

The following modules are included in this module group:

- Multi-measurement transformers / synchronization modules
- Universal mixed modules and combination modules
- Diode array modules
- PWM modules
- IO-Link master modules
- Potential distribution modules
- Supply modules for potentiometers
- Condition monitoring modules
- Specialty modules

4.26.1 Brief information

Product ID	Short description	on page
0ACS100A.00-1	Acceleration sensor, nominal sensitivity 100 mV/g, top exit	2731
0ACS100A.90-1	Acceleration sensor, nominal sensitivity 100 mV/g, side exit	2733
X20CM0985	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately.	2552
X20CM0985-1	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A, source, 1 relay 1 A, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, additional software functions, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x X20TB12 separately	2481
X20CM4810	X20 analog input module for vibration measurement and analyse of condition monitoring exercises. 4 IEPE analog input 51,5625 kHz sampling frequency 24 bit converter resolution	2594
X20CM6209	X20 diode array module, 1 A, 40 V reverse voltage, no module status data	2737
X20CM8281	X20 universal mixed module, 4 digital inputs, 24 VDC, sink, 1-wire connections, 2 digital outputs, 0.5 A, source, 1-wire connections, 1 analog input, ±10 V or 0 to 20 mA / 4 to 20 mA, 12-bit converter resolution, 1 analog output, ±10 V / 0 to 20 mA, 12-bit converter resolution, 2 counters as event counters or gate measurement	2740
X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection	2759
X20DS4387	X20 digital signal module, 4x IO-Link master, 4 digital channels configurable as inputs or outputs, 3-wire connections	2777
X20DS438A	X20 digital signal module, 4x I/O-Link master V1.1, can also be configured as 4x digital input or output channels, 3-wire connections	2794
X20PD0011	X20 potential distributor module, 12x GND, integrated microfuse	2858
X20PD0012	X20 potential distributor module, 12x 24 VDC, integrated microfuse	2862
X20PD0016	X20 potential distributor module, 5x GND, 5x 24 VDC, each with 1x floating feed, integrated microfuse	2866
X20PD2113	X20 potential distributor module, 6x GND, 6x 24 VDC, with feed option, integrated microfuse	2871
X20PS4951	X20 power supply module, for potentiometers, 4x ±10 V for potentiometer supply	2877
X20cPD2113	X20 potential distributor, coated, 6x GND, 6x 24 VDC, with supply option, integrated microfuse	2871

4.26.2 X20CM0985-1

4.26.2.1 General information

The module has a compact size and combines a power measurement module that has special features with a synchronization unit that is able to meet all demands.

The measurement unit's 3 current inputs are suitable for both X: 1 A and X: 5 A current transformers. Overcurrent resistance and the high resolution of the measurement unit round off its features. For the voltage inputs, the value range can be configured between 480 VAC and 120 VAC.

The area of use includes 4-wire AC networks with a phase voltage up to 480 VAC and 3-wire systems, whereas L2 can be grounded (V-connection). The module can also handle Aron measuring circuits.

The resulting measured values include the pure phase current; line-to-line voltage or phase voltage; the effective, reactive and apparent power parts; the mains frequency; the power factor and much more. In addition, peak values and energy meters are stored on the module in nonvolatile memory. Depending on the configuration, it is also possible to use a digital output as a pulse encoder for an external energy meter.

The synchronization unit doesn't just take the phasing and phase voltage into consideration; integrated intelligence also monitors the rate of change and other parameters, allowing them to influence when the synchronization output is switched. It is also possible to monitor a generator using a large number of additional conditions. A total of 4 voltage inputs provide substantial overall flexibility.

Monitoring functions expand the features of the module. Rating-dependent overcurrent monitoring is included, which utilizes the thermal capacity of the motor/generator to allow short overloads while still providing full protection. The dependent, delayed imbalanced load monitoring used to protect three-phase generator and three-phase networks from imbalanced load can be adapted to the characteristics of different generator types using parameters while taking their special thermal time constants into account.

- Energy measurement for 120 to 480 VAC
- Simultaneous measurement of 2 AC mains networks plus 2 additional voltages
- For multifunctional measurement tasks
- Intelligent mains synchronization unit

Information:

Please refer to section 4.26.2.4 "Safety guidelines" before operating the module.

4.26.2.3 Technical data

Product ID	X20CM0985-1
Short description	
I/O module	X20 energy measurement and synchronization module
General information	
B&R ID code	0xB768
Status indicators	Channel status, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Analog inputs	Yes, using status LED (measurement range of analog inputs)
Digital outputs	Yes, using status LED and software
Overvoltage category	II [1]
Measurable frequency	15.2 Hz to 2x rated frequency [2]
Power consumption	
Bus	1.05 W
Internal I/O	4 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Bus - I/O supply	Yes
Input/Output - Bus	Yes
Digital outputs - Analog inputs	Yes
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [3]	Yes
KC	Yes
GOST-R	Yes
Digital outputs	
Design	FET positive switching
Quantity	5
Nominal voltage	24 VDC
Switching voltage	24 VDC -15 % / +20 %
Nominal output current	0.1 A
Total nominal current	0.5 A
Connection type	1-wire connections
Output circuit	Source
Output protection	Thermal cutoff for overcurrent and short circuit
Diagnostic status	Output monitoring with 10 ms delay
Leakage current when switched off	5 µA
Residual voltage	<0.3 V at 0.1 A rated current
Peak short circuit current	<2 A
Switching on after overload or short circuit cutoff	Approx. 10 ms, depends on the module temperature
Switching delay	
0 -> 1	<300 µs
1 -> 0	<300 µs
Switching frequency	
Resistive load	Max. 100 Hz
Isolation voltage between channel and bus	500 V_{eff}
Relay outputs	
Quantity	1

Table 582: X20CM0985-1 - Technical data

Product ID	X20CM0985-1
Design	Relay / Changeover contact
Nominal voltage	30 VDC / 240 VAC
Rated frequency	DC / 45 to 63 Hz
Switching capacity	
Min.	10 mA / 5 VDC
Max.	30 W / 240 VAC
Nominal output current	1 A at 30 VDC / 1 A at 240 VAC
Actuator supply	External
Switching voltage	Max. 60 VDC / 250 VAC
Switching delay	
0 -> 1	≤10 ms
1 -> 0	≤10 ms
Service life [4]	
Mechanics	Min. 10 x 10^6 ops.
Electrical	Min. 60 x 10^3 ops. (NC) at 1 A Min. 30 x 10^3 ops. (NO) at 1 A
Contact resistance	Max. 100 mΩ
Protective circuit	
Internal	None
External	None
DC	Inverse diode, RC combination or VDR
AC	RC combination or VDR
Isolation voltage	
Contact - Contact	1000 VAC / 1 min
Contact - Coil	4000 VAC / 1 min
Analog input voltage	
Channels	8
Input	120 VAC / 480 VAC
Input type	Single-ended
Digital converter resolution	±15-bit
Conversion time	
50 Hz	10 ms
60 Hz	8.33 ms
Permitted input signal	Max. 132 VAC / 528 VAC
Output format [5]	
±120 VAC	1 LSB = 0x0001 = 5.707 mV
±480 VAC	1 LSB = 0x0001 = 22.787 mV
Output of the digital value during overload	
Above upper limit	0x7FFF
Below lower limit	0x8001
Conversion method	SAR
Input filter	
Cutoff frequency	10 kHz
Slope	60 dB
Maximum gain drift [6]	0.02% per °C
Maximum offset drift [7]	0.003% per °C
Crosstalk between channels	-70 dB
Nonlinearity [7]	≤0.5% at 45 to 65 Hz
Protection against electrical shock	Protective impedance in accordance with IEC 61131-2
Test voltage between channel and bus (type test)	3700 V_{eff}
Output format	INT
Input impedance in signal range	Approx. 3 MΩ
Max. error at 25°C	
Gain	0.09% [6]
Offset	0.03% [7]
Input protection	Overvoltage protection
Analog input current	
Channels	3
Input	1 A / 5 A AC
Input type	Isolated current transformer according to the compensation principle with a magnetic sensor, for connecting an external transformer
Digital converter resolution	±15-bit
Conversion time	
50 Hz	10 ms
60 Hz	8.33 ms
Permitted input signal	Max. 1.5 A / 7.7 A
Output format [5]	
±1 A	1 LSB = 0x0001 = 189.903 µA
±5 A	1 LSB = 0x0001 = 949.513 µA
Output of the digital value during overload	
Above upper limit	0x7FFF
Below lower limit	0x8001
Conversion method	SAR

Table 582: X20CM0985-1 - Technical data

4.26.2.4 Safety guidelines

General information

Programmable logic controllers, operating and monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels etc.) as well as the uninterruptible power supplies have all been designed, developed, and produced by B&R for conventional use in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 or comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

Intended use

Danger!

Electronic devices are never completely failsafe. If the multi-measurement and synchronization unit fails, the user is responsible for making sure that the motor or generator is brought to a secure state.

Some errors are detected and prevented in the synchronization unit by the system's internal software monitoring. However, when the device is in operation it is always possible for errors, defective components, software errors or configuration mistakes to occur at any time. B&R emphasizes that the multi-measurement and synchronization unit possesses neither a failsafe function nor a redundancy system. For this reason, independent higher-level safety precautions need to be put in place to ensure that personnel and machines are protected.

Grounding the Mounting Rail

For grounding purposes, a good conductive connection between the mounting rail and the metal back wall is required. The mounting rail is to be connected conductively to the back wall. This is achieved by inserting a contact washer with the fastening screw.

Information:

The control cabinet back wall must be connected with GND

4.26.2.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

LED status indicators - Right

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Orange		Output status of the corresponding digital output

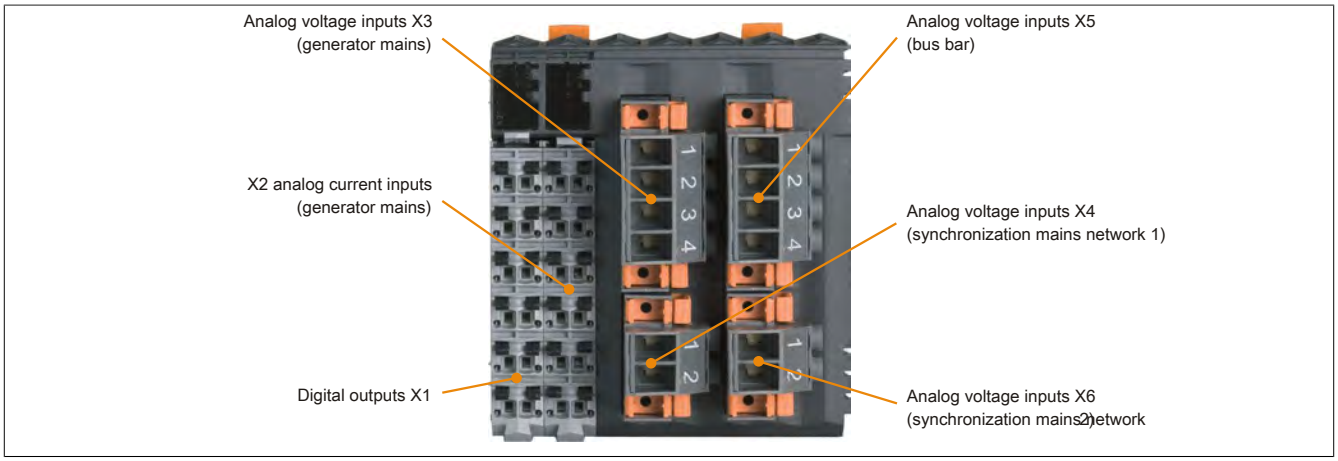
1) Depending on the configuration, a firmware update can take up to several minutes.

Status-LEDs right

Figure	LED[1]	Terminal	Color	Status	Description
	1	X3	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	2	X4	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	3	X5	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	4	X6	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	5	X2	Green	On	Measurement range: 1 A
			Red	On	Measurement range: 5 A

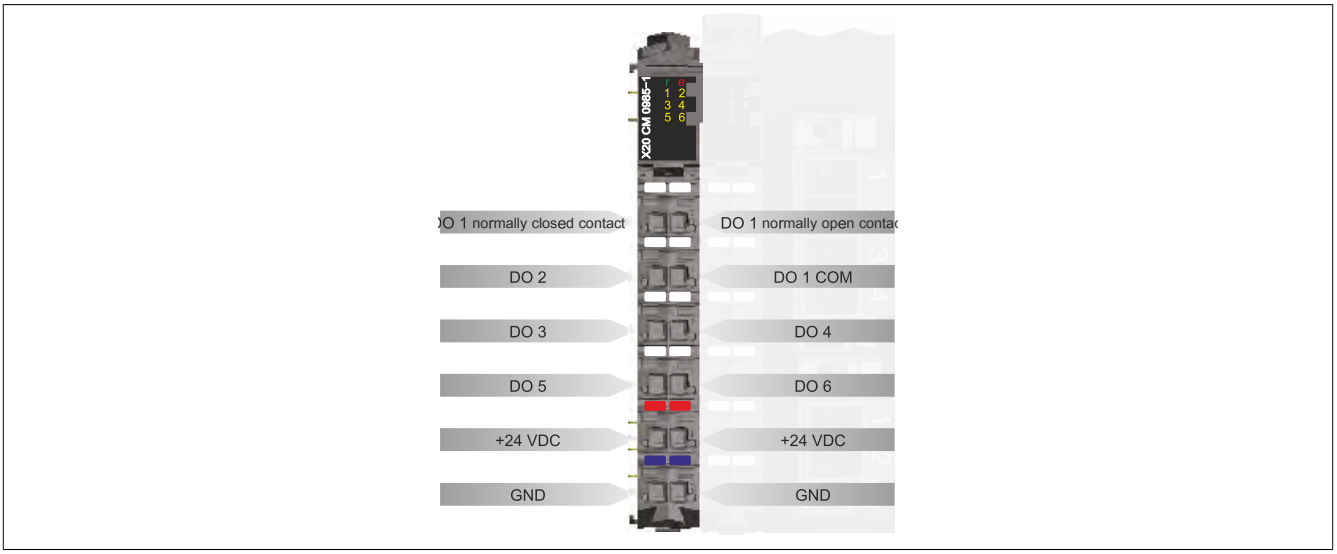
1) LEDs 1 - 5 are green/red dual LEDs.

4.26.2.6 Connection elements



4.26.2.7 Digital outputs X1

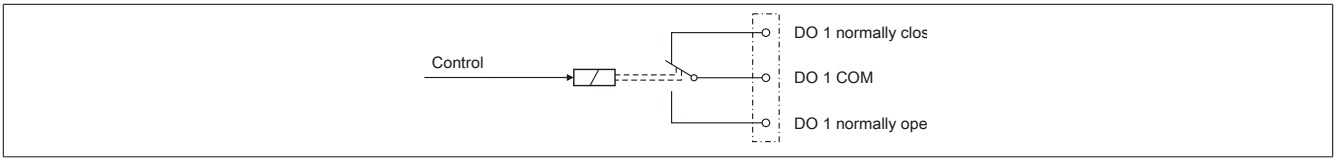
The X1 and X2 terminals can each be keyed differently to prevent them from being inadvertently plugged into the module incorrectly.



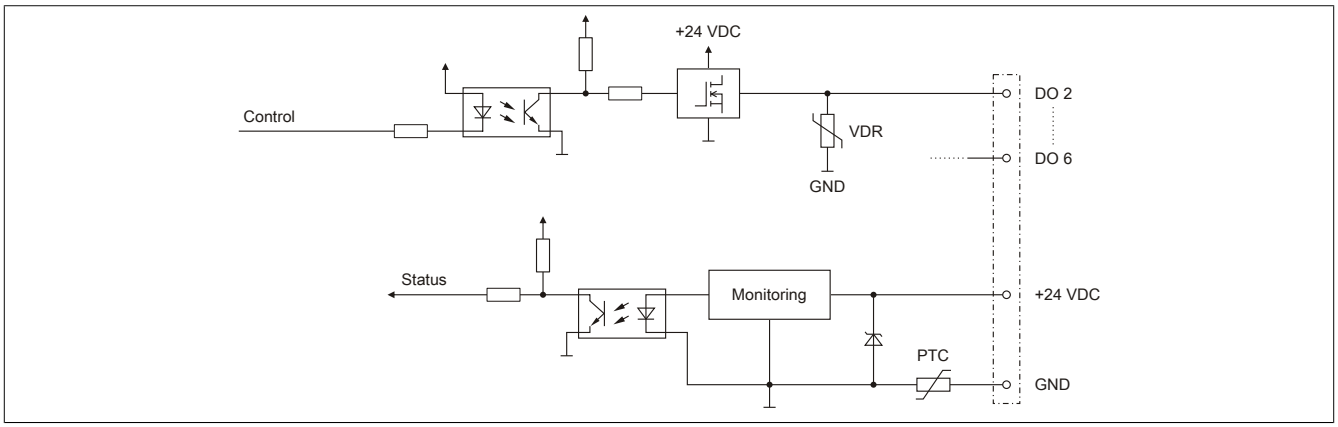
Function description of the digital outputs

Digital output	Description
DO1	This digital output is designed as a changeover contact switch. The monitoring relay allows selected monitoring of the following generator mains network measurement values: • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Current asymmetry • Calculated neutral conductor current (maximum) • Short circuit current • Rating-dependent overcurrent • Limit value of the capacitive reactive power (exciter failure) • Generator overload • Generator feedback
DO2	DO2 serves as a meter output. The generated pulses can be recorded by an external energy meter (kWh).
DO3	This output is set when there is no voltage on the bus bar (below the lower limit of the defined parameter). 3-phase monitoring takes place for the bus bar voltage.
DO4	DO4 serves as a synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (**exception:**Synchro check operating mode).
DO5	This output can be configured either as a digital output or monitoring output (see register "ConfigOutput24"). The monitoring function is only available with the "3-phase mains" configuration. When configured as monitoring output, the user can choose between monitoring the following mains measurement values: • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Phase shift • Frequency change The monitoring status can be output either normally or inverted. This can be defined using the "DigitalOutput" register. This setting is then disabled when shutting off, resetting, restarting, etc.
DO6	Can be configured as a digital output or synchronization output (see register "ConfigOutput24"). When configured as a synchronization output: DO6 serves as the synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (**exception:**Synchro check operating mode).

DO1 - Output circuit diagram



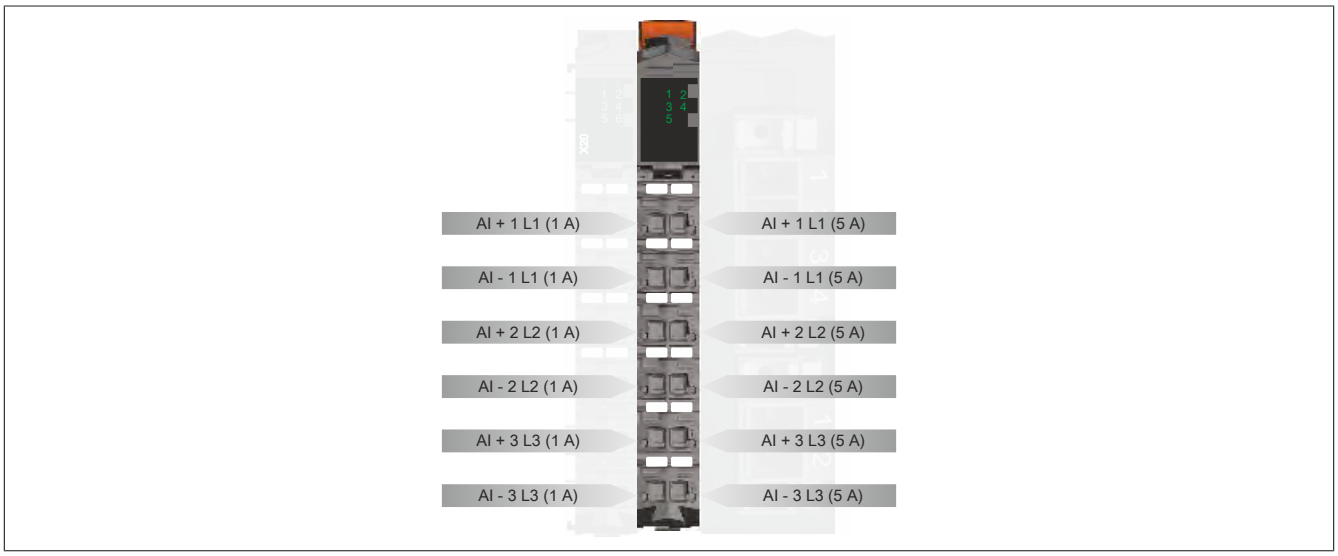
DO2 - DO 6 - Output circuit diagram



4.26.2.8 X2 analog current inputs

The X2 terminal measures the three phase currents of the generator mains using an externally connected current transformer. The measurement range of the current inputs can be configured as 1 A or 5 A.

The X1 and X2 terminals can each be keyed differently to prevent them from being inadvertently plugged into the module incorrectly.

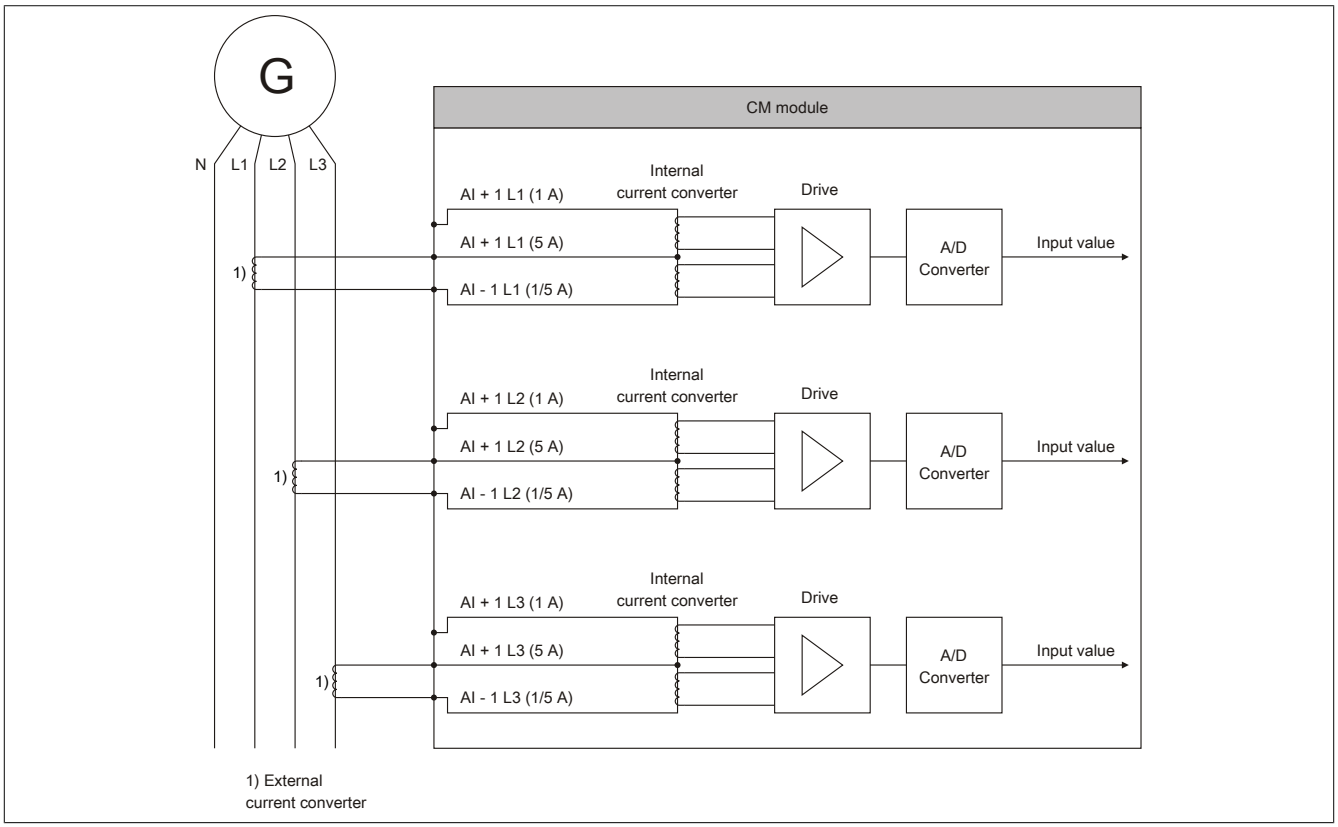


Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

Input circuit diagram - Analog current inputs

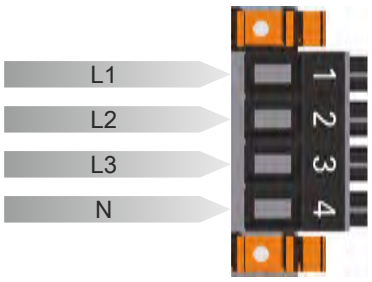


4.26.2.9 X3 and X5 analog voltage inputs

The X3 and X5 terminals are used to measure and monitor the line-to-line and phase voltages of the generator mains and bus bar.

- Terminal X3: Generator mains
- Terminal X5: Bus bar

The X3 and X5 terminals are each keyed differently to prevent them from being inadvertently plugged into the module incorrectly. Section 4.26.2.14 "Releasing the locking clip for terminals X3 - X6" describes how to release the terminal locking clip.



4.26.2.10 X4 and X6 analog voltage inputs

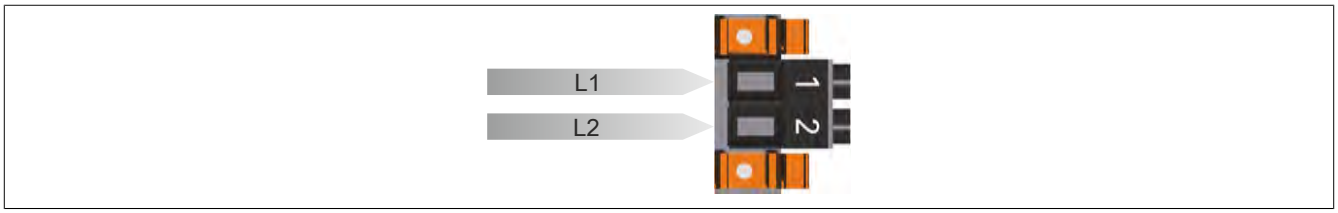
The X4 and X6 terminals are each keyed differently to prevent them from being inadvertently plugged into the module incorrectly. Section 4.26.2.14 "Releasing the locking clip for terminals X3 - X6" describes how to release the terminal locking clip.

The two terminals are connected differently depending on the selected configuration (see register "ConfigOutput68").

Configuration as Sync-mains 1 / Sync-mains 2

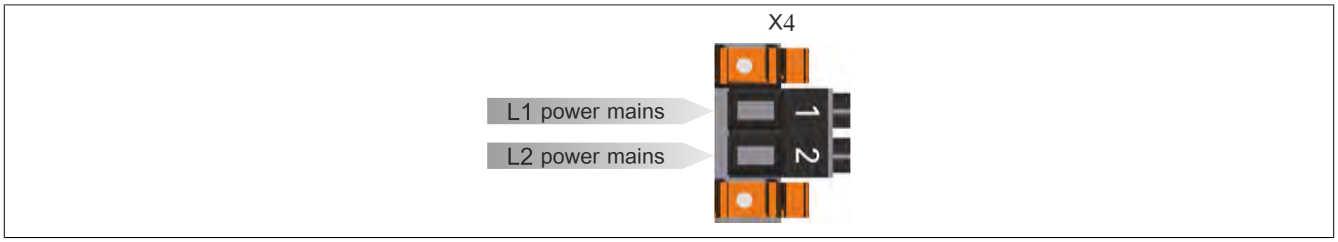
The voltage inputs on the X4 and X6 terminals are used to determine the line-to-line voltages for synchronization between two different mains networks.

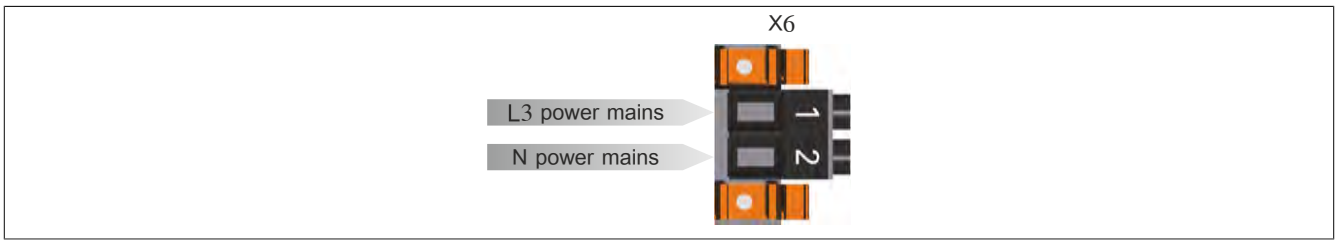
- Terminal X4: Synchronization mains network 1
- Terminal X6: Synchronization mains network 2



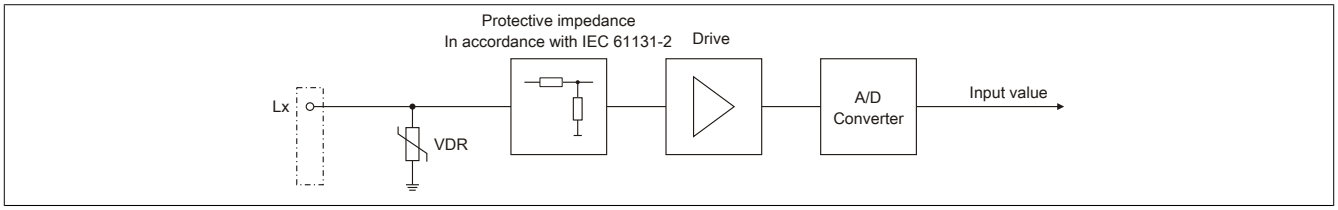
Configuration as 3-phase mains

The terminals X4 and X6 can be combined to form a 3-phase mains. The X4 and X6 terminals are used to measure and monitor the line-to-line voltages and phase voltages of the power mains.



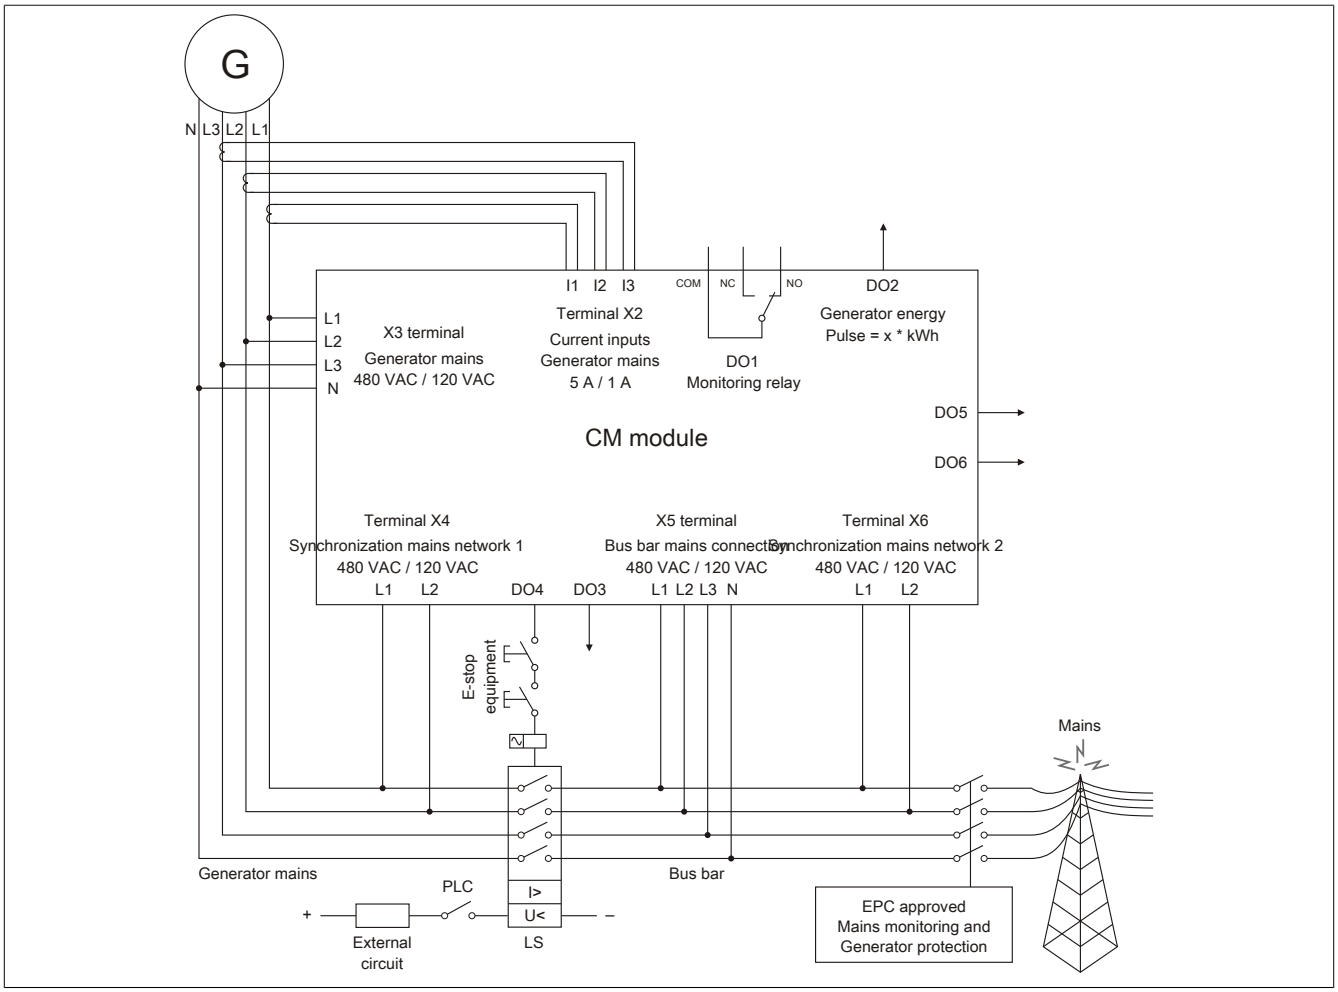


Input circuit diagram, analog voltage inputs

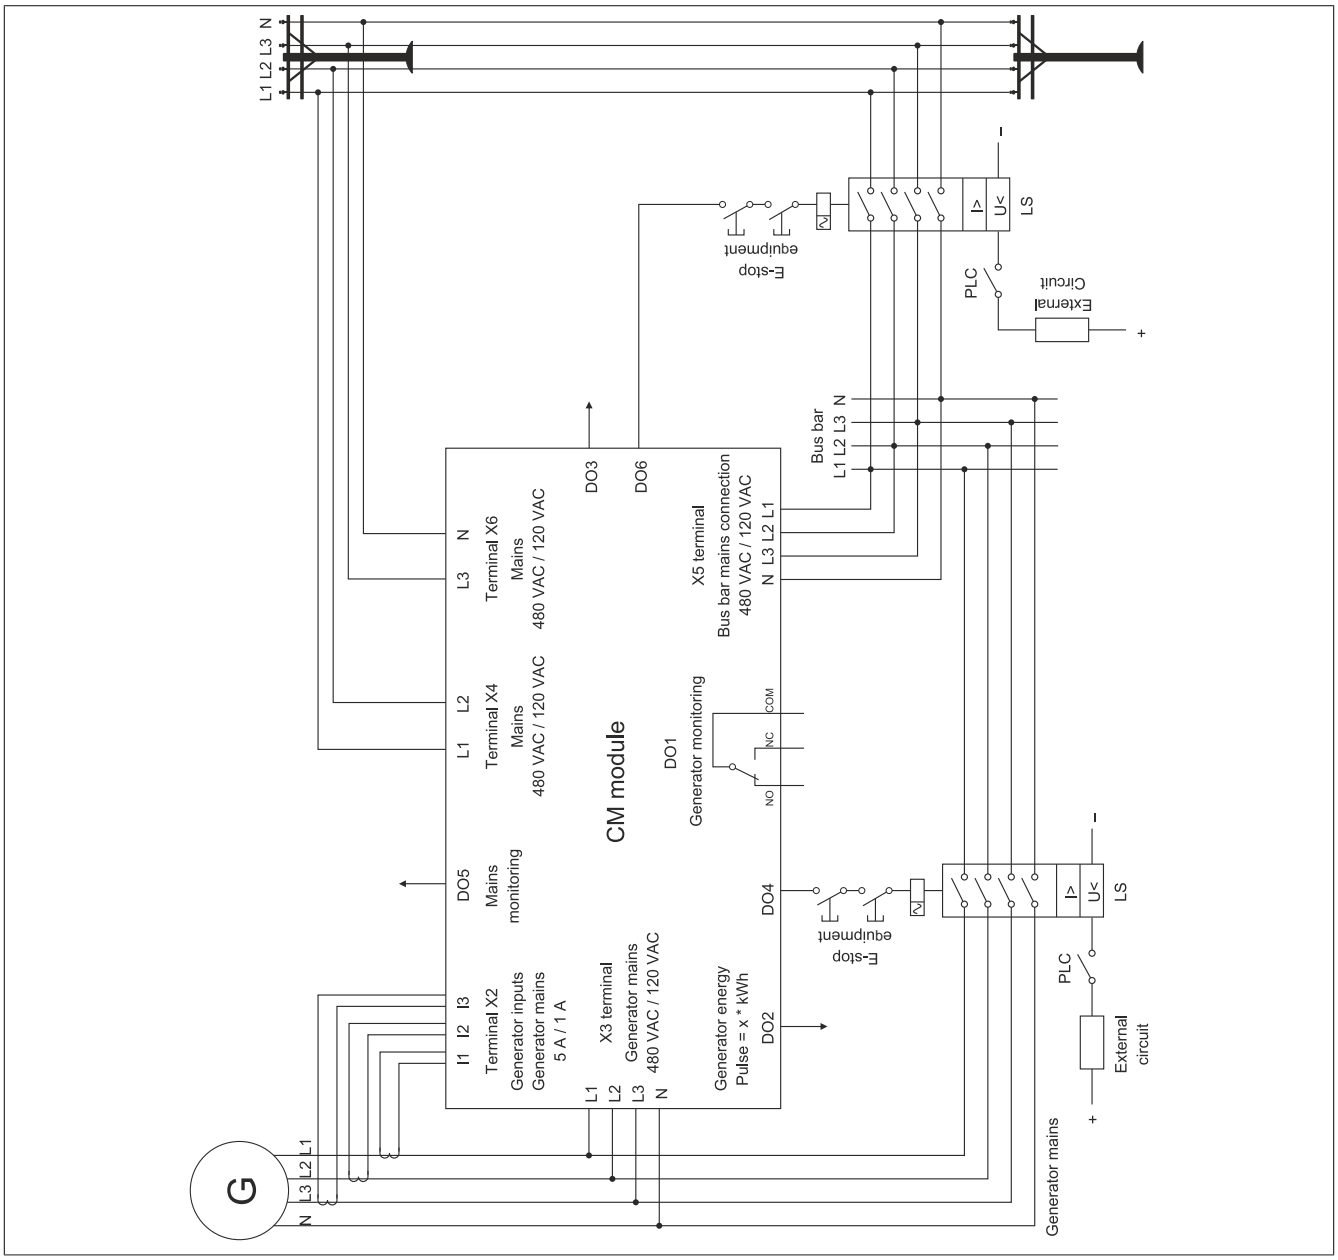


4.26.2.11 Circuit diagram

Example of mains configuration "Sync-mains 1 / Sync-mains 2"



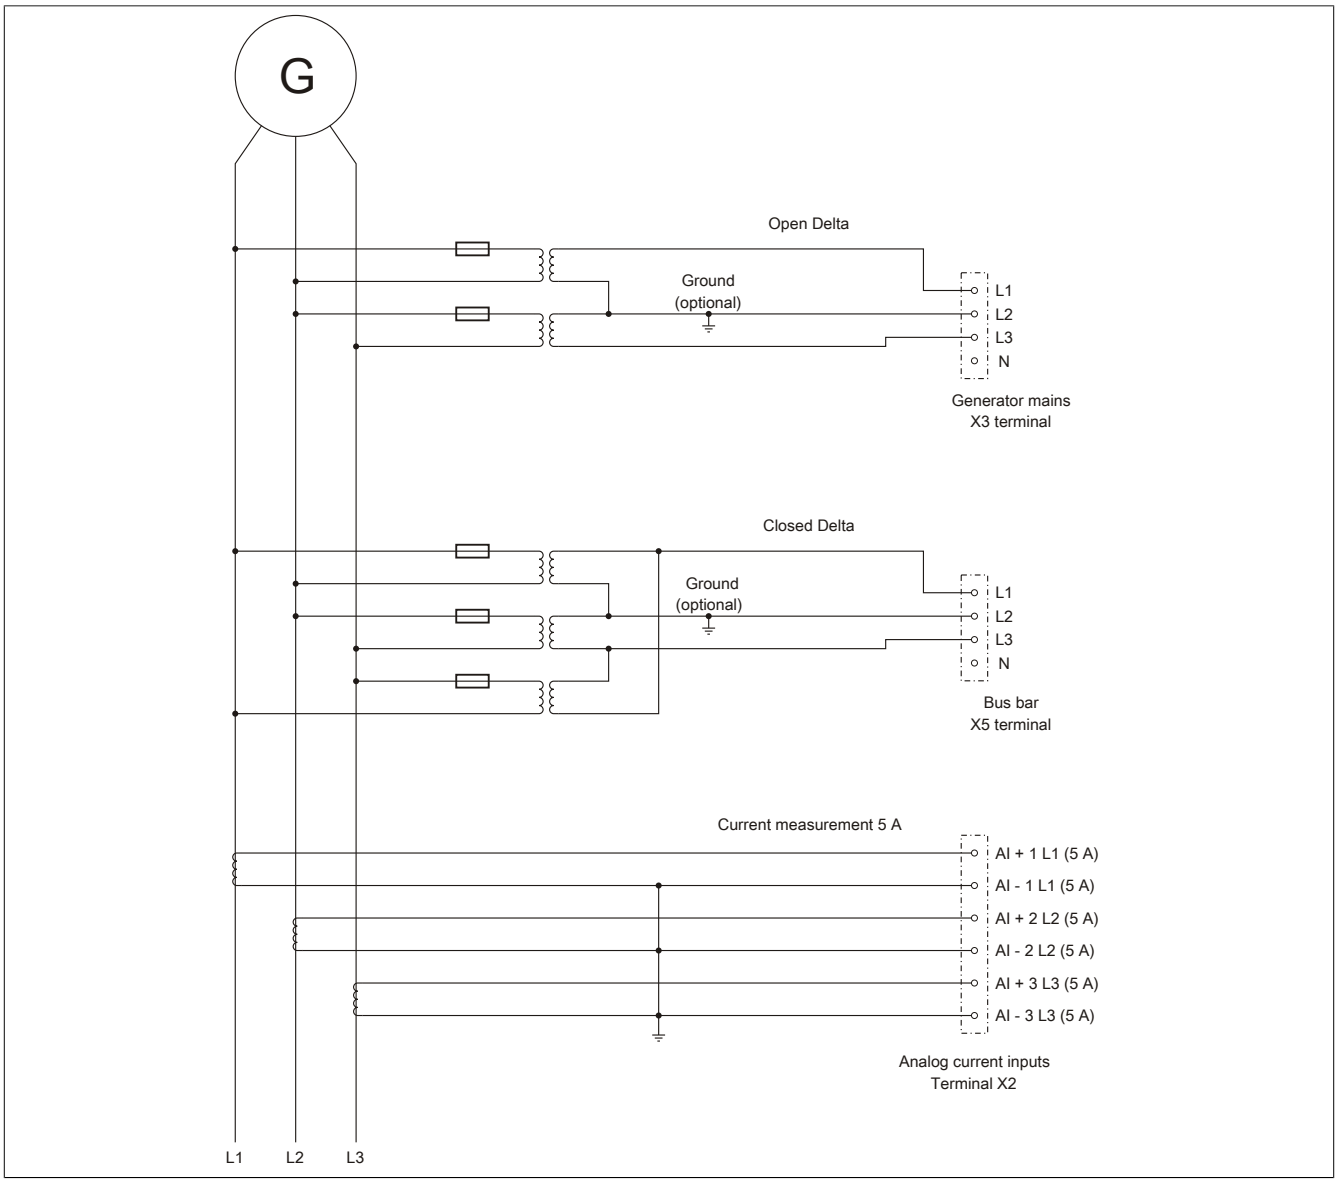
Example of mains configuration "3-phase mains"



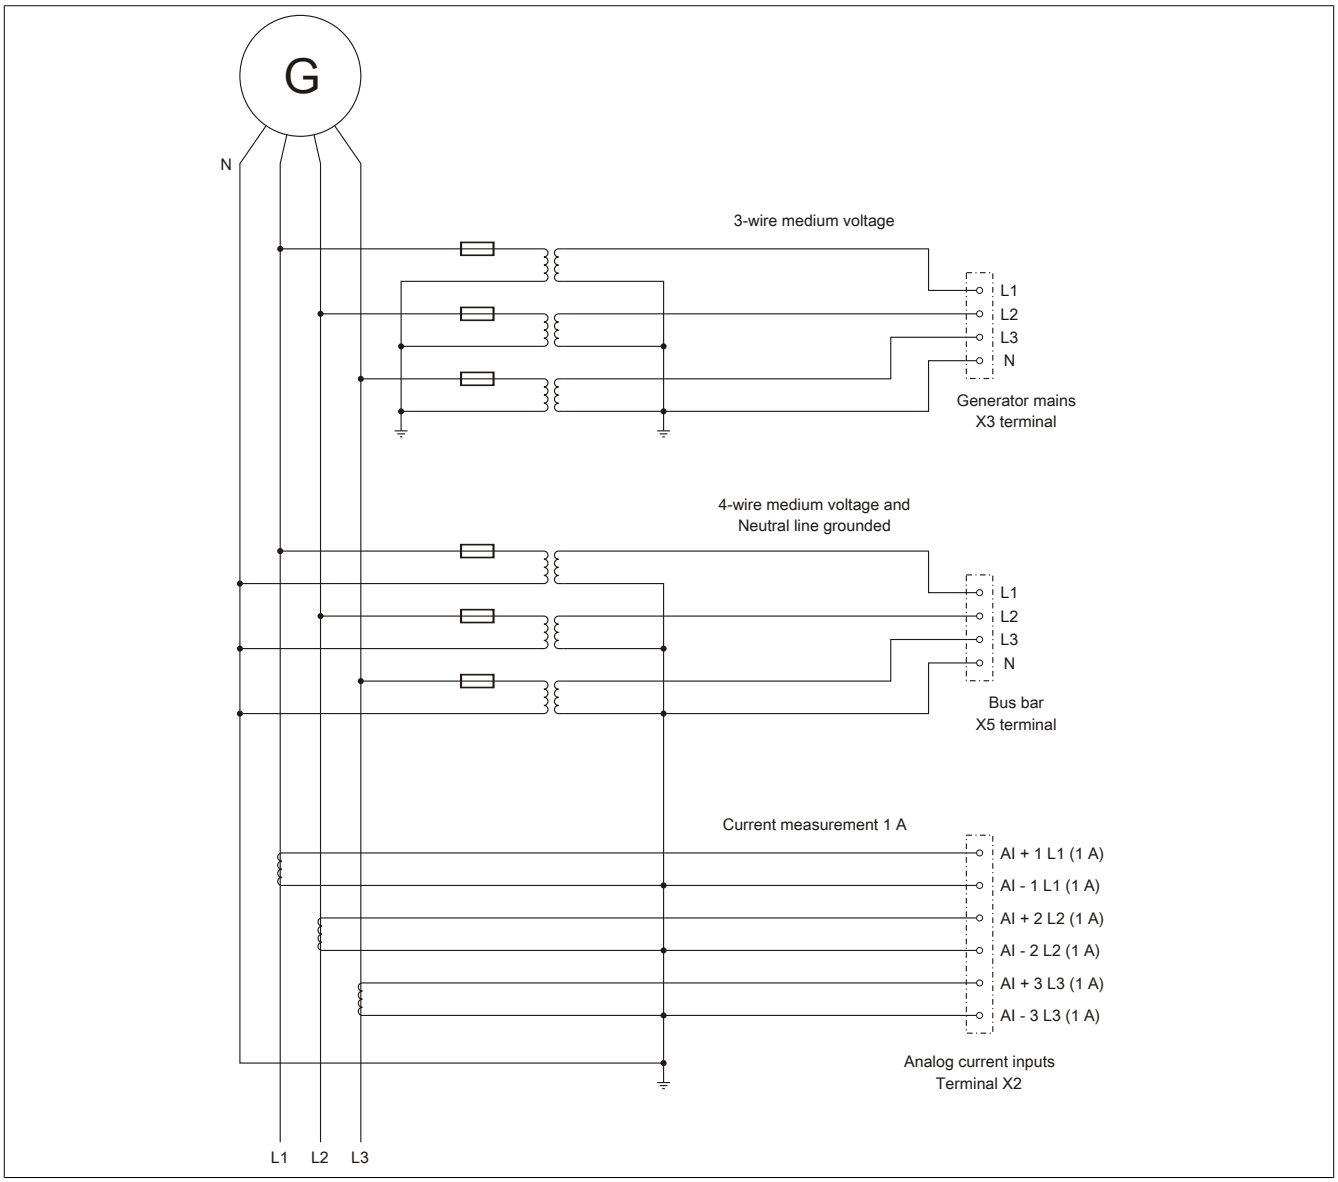
4.26.2.12 Typical connection examples for voltage/current measurement

For power measurement, the X3 terminal must always be used in connection with the X2 terminal! For single-phase measurement, always ensure that current input 1 is used for power measurement if voltage input 1 is being used. Otherwise, accurate power measurement is not possible for this phase!

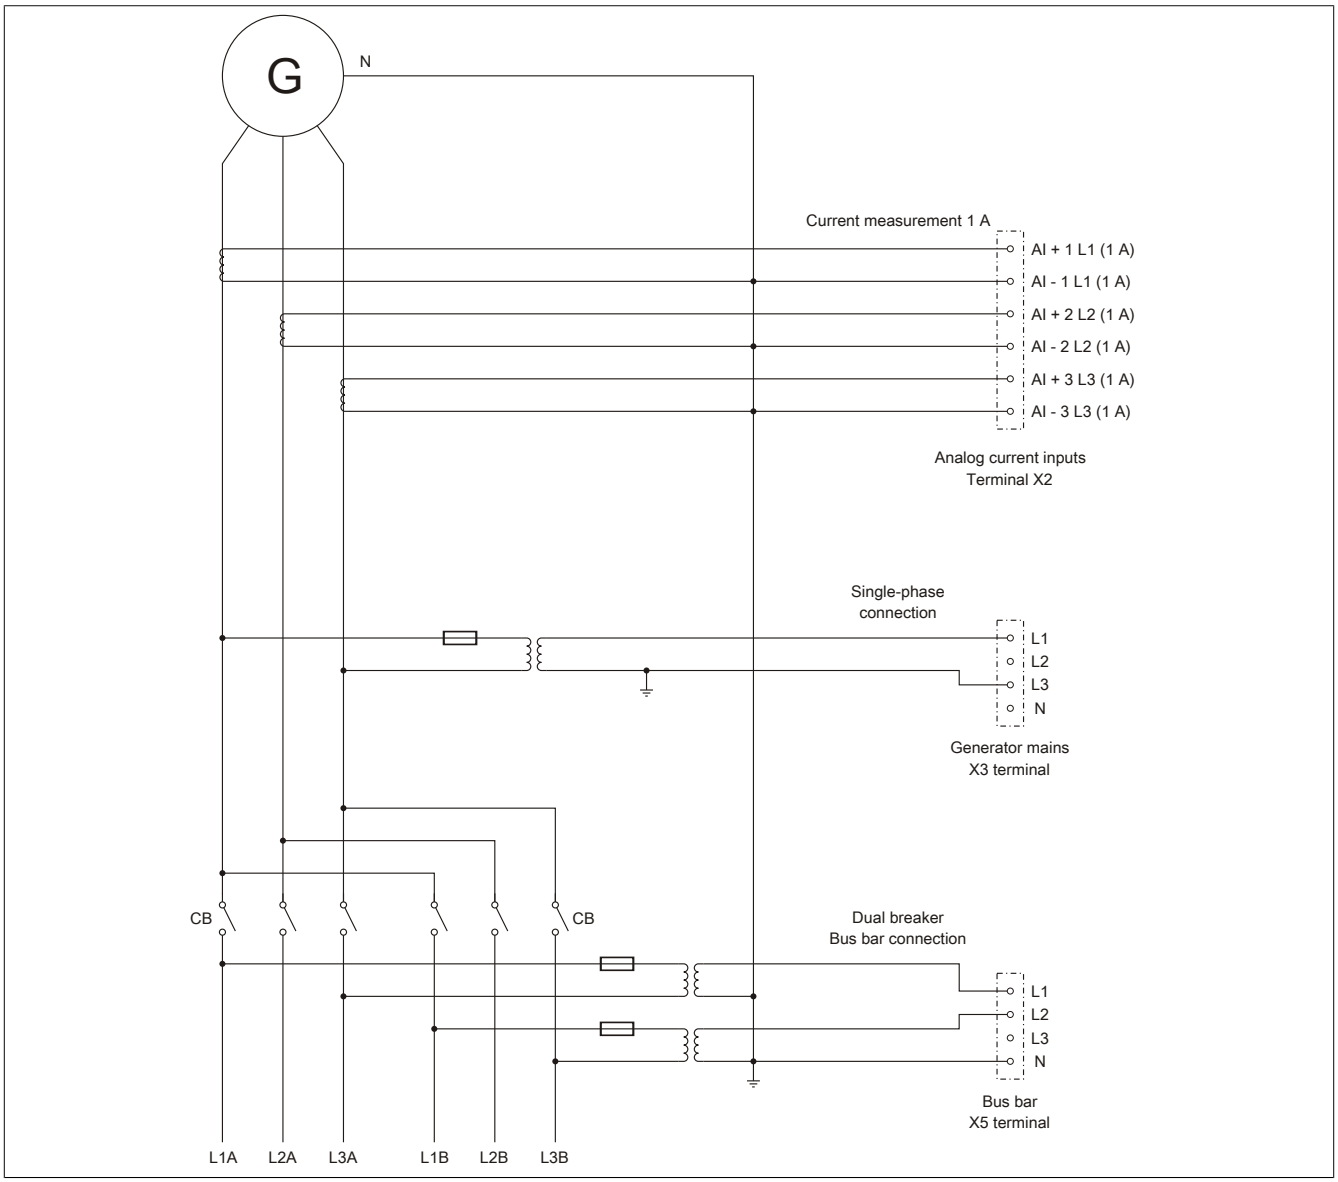
Connection example 1



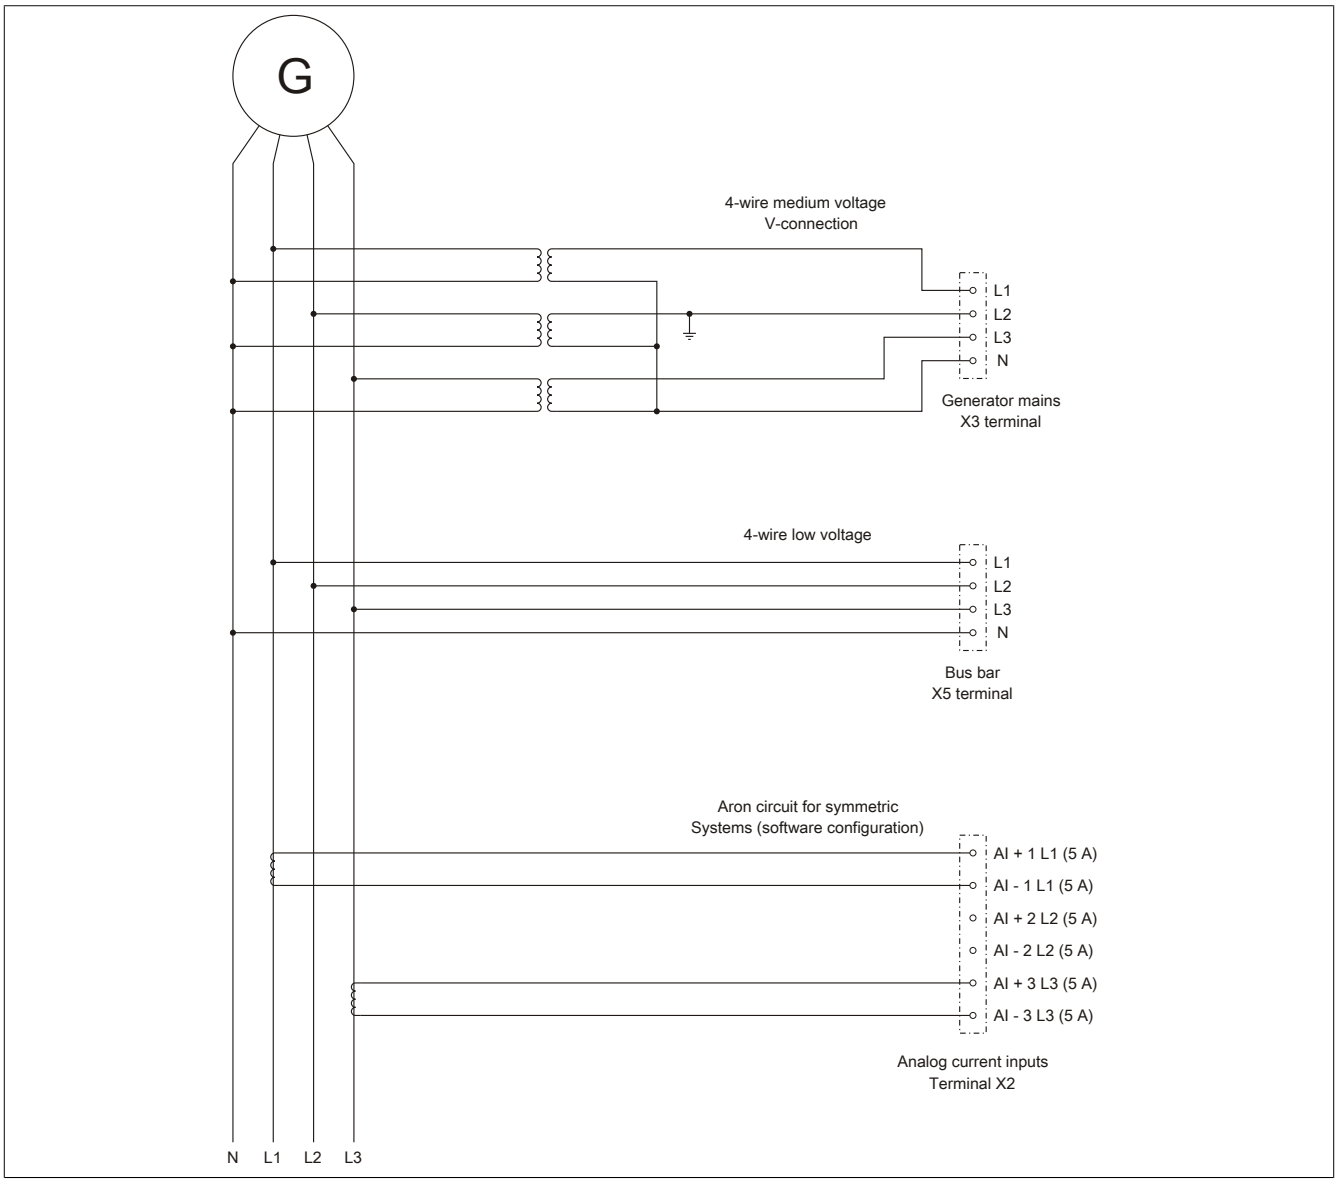
Connection example 2



Connection example 3

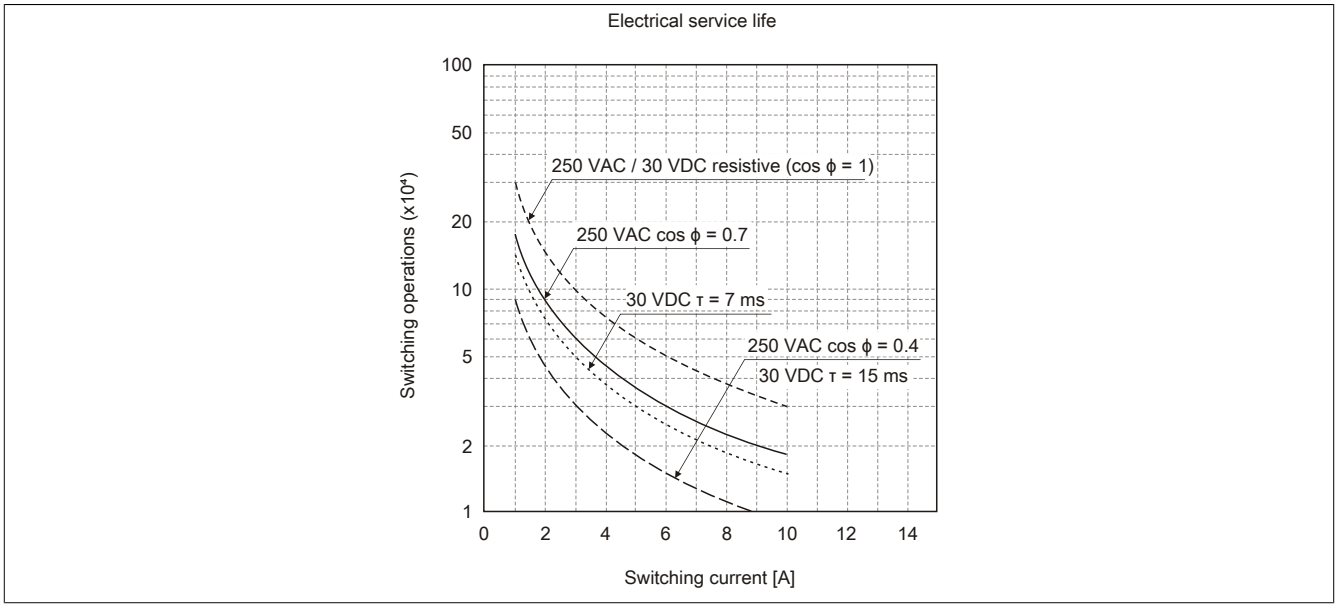


Connection example 4



4.26.2.13 Electrical service life

The electrical service life for the DO1 relay output can be seen in the following diagram.



4.26.2.14 Releasing the locking clip for terminals X3 - X6

Terminals X3 - X6 are equipped with a terminal locking clip. This clip attaches the terminal block securely to the electronic module. This prevents the terminal from accidentally being disconnected.

To release the locking clip, press inwards on the corrugated part of the lever with your fingertip (1) and then slide outwards (2). No additional tools are required for removing the terminal.

Terminals X5 and X6 must be removed first before terminals X3 and X4 can be removed.

4.26.2.15 Synchronization functions

The following three synchronization functions are available on the module:

- Synchronization with slip
- Synchro check
- Switching to voltage-free "dead bus"

Synchronization with slip

The following is valid for synchronization mains 1 and synchronization mains 2:

- 50% < U < 125% of the nominal voltage U_N
- 80% < f < 110% of the nominal frequency f_N

The generator voltage is adjusted to the synchronization voltage with regard to amplitude and frequency. Taking into account the configured phase angle (Δα), a defined transformer vector group and the switching response time, the switch-on command is calculated and transmitted in advance so that the main contacts of the power switch are closed at the point of synchronicity.

Synchronization occurs under the following conditions:

- Synchronization mode "Slip" is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{max}).
- The configured limits for frequency difference are not exceeded (Δf_{max} and Δf_{min}).
- The configured limit for the phase angle (including vector group transformer Δα) is not exceeded (j_{max}).

When the synchronization mode is set to "Slip", synchronization is not activated until the value of the differential angle between the two synchronized mains networks is >5° for at least 100 ms.

In other words, if the phase difference happens to be within ±5° at the time of the synchronization request, the synchronization won't be activated unless/until the phase difference is larger for 100 ms.

Resetting the mode "Synchronization with slip" cancels the synchronization.

In order to receive a synchronization pulse, the synchronization window must be entered from any phase direction after the synchronization command has been authorized and all of the synchronization conditions specified above are observed.
The switch is not engaged immediately after reaching the phase window. The switch is only engaged if synchronization is possible at the synchronization point while observing the switch lead time.

With very low frequency differences or equivalent frequencies and in adherence to the conditions described above, synchronization will also take place at a phase angle = 0°.

The synchronization output changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

Synchro check

In this operating mode, the device can be used to check the synchronization. The DO4 output remains set as long as the following conditions are met:

- The "-Check" command is set using software.
- The device is ready.
- The phase sequences of the mains networks being synchronized are OK (phase sequence detection).
- The configured limit for voltage difference is not exceeded (ΔU_{max}).
- The configured limits for frequency difference are not exceeded (Δf_{max} and Δf_{min}).
- The defined limit for the phase angle is not exceeded (ϕ_{max}).

DO4 stays at High as long as all conditions are met.

Switching to voltage-free "dead bus"

The switch-on command for the power switch is output without synchronization if the following conditions have been met:

- The "Dead Bus" command is set using software.
- The device is ready.
- The bus bar does not have voltage applied: $U_B < U_{BminSync}$ as a percentage of U_{NomBus}

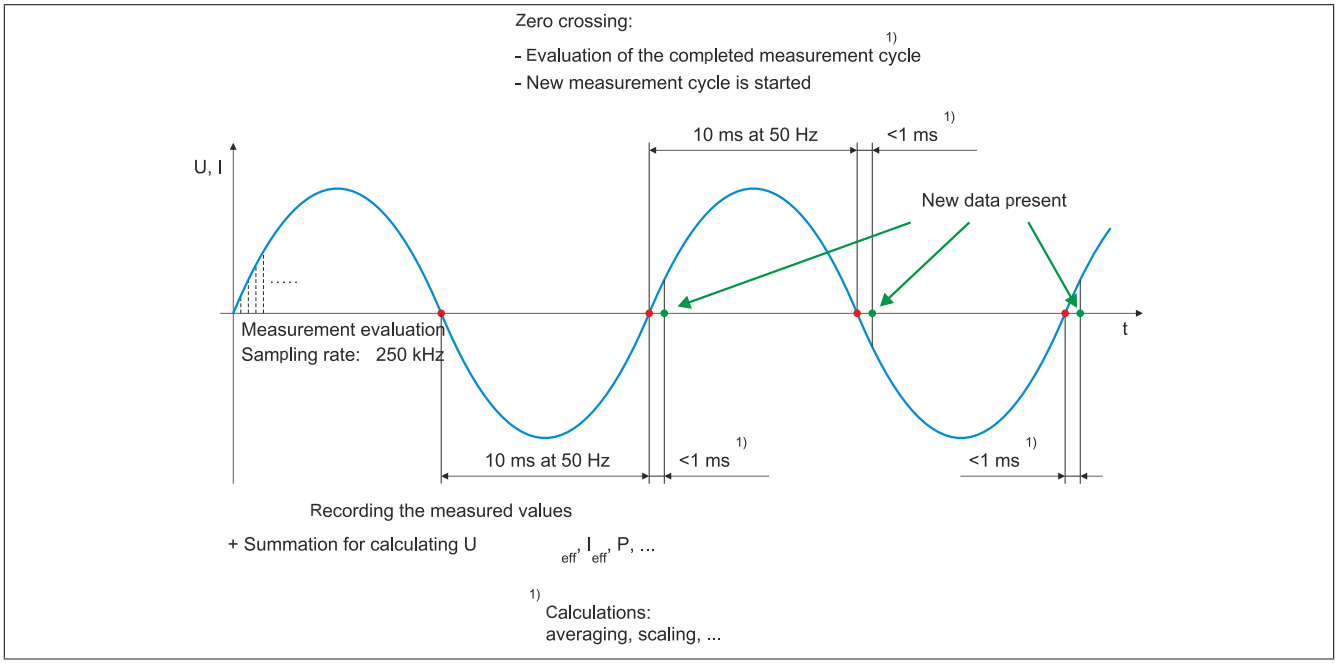
U_B ...	Bus bar phase voltage
$U_{BminSync}$ ...	Dead bus voltage
U_{NomBus} ...	Bus bar nominal voltage

- Frequency measurement of Sync Mains 1 must result in a valid value.

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

4.26.2.16 Measurement functions

Timing diagram



Measured parameters for generator mains (X3)

- Phase currents
- Current average
- Dynamic current average
- Neutral current
- Line-to-line voltages
- Phase voltages
- Voltage average
- Total apparent power
- Total reactive power
- Total active power
- Active power factor
- Frequency

Measured parameters between synchronization mains networks

- Differential angle
- Differential voltage

Rating-dependent overcurrent

Rating-dependent overcurrent monitoring is in accordance with the specifications of IEC 255-8 "Electrical relay; Relay for protecting against thermal overload (overload relay)" and IEC 255-17 "Electrical relay; Relay for protecting against the thermal overload of motors (overload relay for motors).

Dependent delayed imbalanced load monitoring

Dependent delayed imbalanced load monitoring protects against imbalanced loads in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An imbalanced load can be caused by uneven current distribution in the mains due to imbalanced load, asymmetrical short circuits, line interruptions or switching operations. Imbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An imbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an imbalanced load occurs, the characteristics that trigger imbalanced load protection should be adapted to the thermal characteristics of the generator. Imbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

Short circuit current monitoring

If overcurrent or a short circuit occurs and the limit value is exceeded, the error message "Short circuit current" is signaled after the configured time delay has passed.

Voltage asymmetry monitoring

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the set limit value, then the error message "Voltage asymmetry" is signaled after the response time has passed. For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

Bus bar voltage measurement and zero voltage monitoring

3-phase monitoring takes place for the bus bar voltage. The measured values are represented as phase-to-phase and phase-to-neutral values. The D03 output is set when there is no voltage (below the lower limit of the defined limit bus bar voltage minimum U_{Bmin}) on the bus bar (X5 terminal).

This monitoring can be used to determine which synchronization function should be used.

Synchronization function	Bus bar voltage measurement
Dead bus	No voltage is being supplied to the bus bar or the value is below the lower limit parameter. Output DO3 is set.
Synchronization with slip	The voltage measured on the bus bar is above the defined parameter value. Output DO3 is not set.

Exciter failure

The reactive power monitoring can be used to protect a generator against operating in the impermissible range. The capacitive reactive power monitor offers protection against under-excitation (exciter failure). If the lower limit is exceeded (in the negative direction), the error message "Capacitive reactive power" is signaled after the configured time delay has passed.

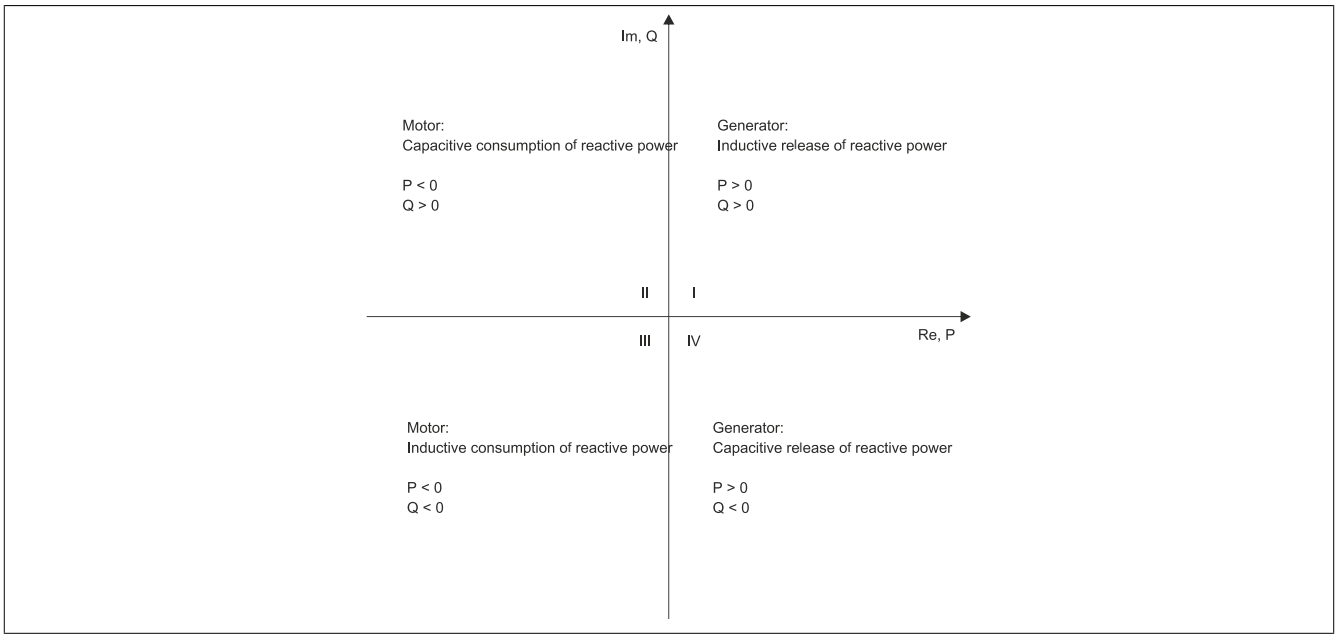
Phase sequence detection

Phase sequence detection is used to detect incorrectly wired voltage and current inputs or if the generator is rotating in the wrong direction (for information about configuration, see register "ConfigOutput24").

Phase sequence L1, L2 and L3 is monitored for this. If not correct, then an error message is output (see register "StatusDigitalOutput") and synchronization cannot take place.

4.26.2.17 Generator operating modes

The operating modes possible for the generator are illustrated in this 4 quadrant diagram.

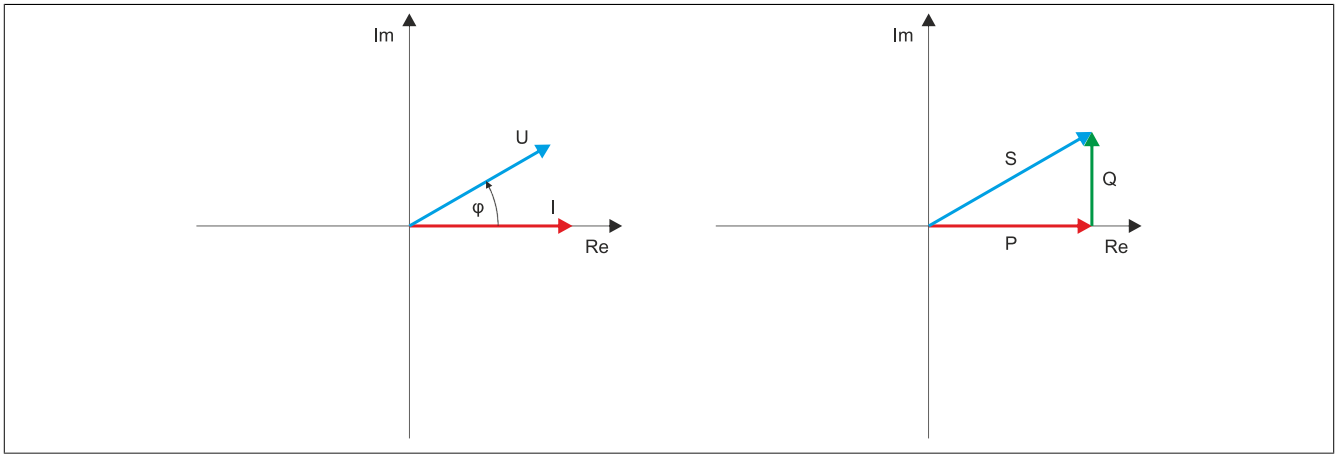


Quadrant I

Generator operation, inductive release of reactive power:

- The active power P and the reactive power Q are greater than 0.
- The phase angle ϕ is between 0 and 90°. This means that U keeps ahead of I.

Example: ϕ = 30°

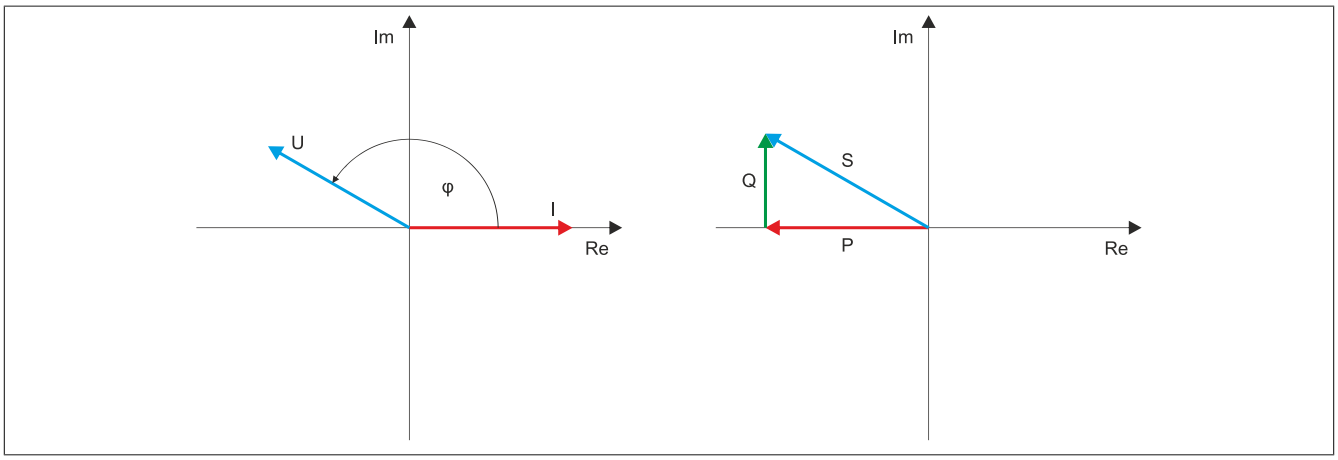


Quadrant II

Motor operation, capacitive reactive power consumption:

- The active power P is less than 0 while the reactive power Q is greater than 0.
- The phase angle ϕ is between 90 and 180°. This means that U keeps ahead of I.

Example: ϕ = 150°

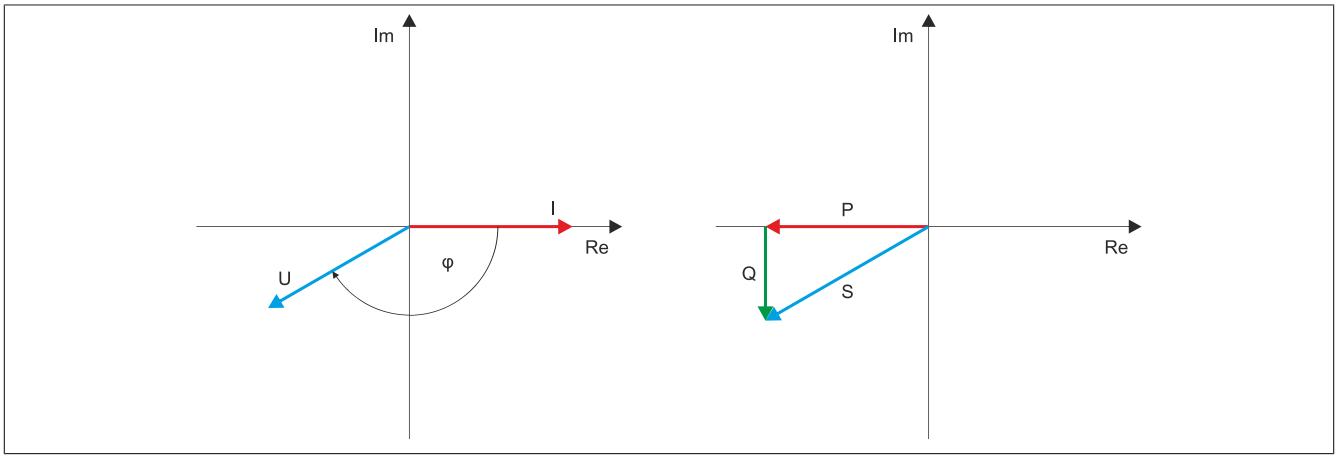


Quadrant III

Motor operation, inductive reactive power consumption:

- The active power P and the reactive power Q are less than 0.
- The phase angle ϕ is between -90 and -180°. This means that U lags behind I.

Example: ϕ = -150°

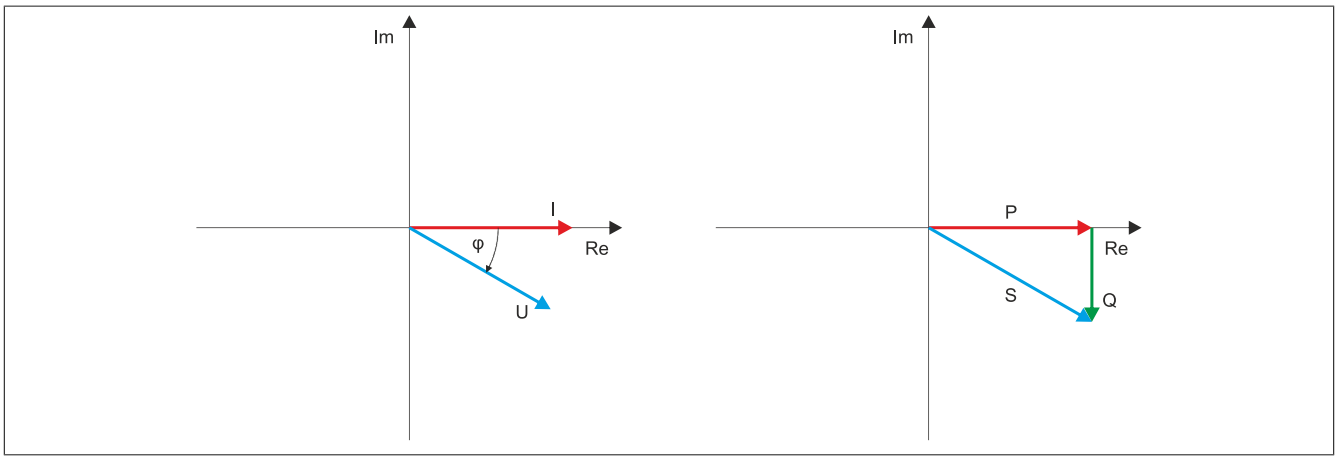


Quadrant IV

Generator operation, capacitive release of reactive power:

- The active power P is greater than 0 while the reactive power Q is less than 0.
- The phase angle ϕ is between 0 and -90°. This means that U lags behind I.

Example: ϕ = -30°



Power factor of the generator

The power factor is a product of the ratio between the active power P and apparent power S. With sinusoidal values, this corresponds to the cosine of the phase shift angle ϕ.

$$\left|Leistungsfaktor\right| = \left|\frac{P}{S}\right|$$

The module derives the sign used for the power factor from the signs used with the P and Q values. In this way, it depends on the generator's operating mode:

Sign	Description
Positive	• Quadrant I or III, P and Q positive or P and Q negative • Inductive release of reactive power or inductive reactive power consumption
Negative	• Quadrant II or IV, P negative and Q positive or P positive and Q negative • Capacitive release of reactive power or capacitive reactive power consumption

4.26.2.18 Register description

4.26.2.18.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.2.18.2 Function model 0 - default

1) This configuration register has a dual design. The register with "Read" in the name allows the configured value to be read back.

4.26.2.18.3 Configuration registers

4.26.2.18.3.1 General registers

Mains settings

Name:
ConfigOutput68
ConfigOutput68Read

This register is used to configure the module on the connected mains.

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Generator mains configuration	00	3-phase mains with neutral conductor (default)
		01	3-phase mains without neutral conductor
		10 to 11	Reserved
2 - 3	Busbar configuration	00	3-phase mains with neutral conductor (default)
		01	3-phase mains without neutral conductor
		10 to 11	Reserved
4 - 5	Mains configuration	00	3-phase mains with neutral conductor (default)

Mains without neutral conductor

If configured as "3-phase mains without neutral conductor", the potential of the neutral conductor is calculated from the 3 phases ("virtual neutral point").

The phase voltages are then measured in relation to this "virtual neutral point".

Mains with ground

If one of the phases of a mains system is grounded, then it must be configured as such. Otherwise, it is possible that the module will report a phase failure that blocks the mains synchronization function.

Monitoring functions disabled:

- Phase failure monitoring is not carried out for the phase configured as "grounded".
- Phase sequence monitoring is not performed on 2-phase mains that are grounded.

Mains configuration

The mains can be used as two 2-phase synchronization mains or combined into a 3-phase mains.

If the mains configuration is set to "3-phase mains" then the monitoring functions will be enabled for these combined mains.

Nominal voltage range, nominal current range and Aron circuit

Name:
ConfigOutput20
ConfigOutput20Read

The value of this register can be read back.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Nominal voltage range of generator mains	0	Voltage 100 V
		1	Voltage 400 V
1	Nominal voltage range of busbar	0	Voltage 100 V
		1	Voltage 400 V
2	Nominal voltage range of Sync Mains 1	0	Voltage 100 V
		1	Voltage 400 V
3	Nominal voltage range of Sync Mains 2	0	Voltage 100 V
		1	Voltage 400 V
4	Nominal current range of the generator mains	0	Current range 1 A
		1	Current range 5 A
5	Switch to power measurement principle of Aron circuit	0	Aron circuit disabled: Three-phase supply with neutral line
		1	Aron circuit enabled: Three-phase supply without neutral line
6 - 7	Reserved	0	

Nominal frequency (f_{Nom})

Name:
ConfigOutput10
ConfigOutput10Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	4800 to 6200	corresponds to 48 to 62 Hz.	0.01 Hz

General configuration register

Name:
ConfigOutput24
ConfigOutput24Read

The value of this register can be read back.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	DO5 function	00	DO5 is freely available to the user
		01	Monitoring output of the mains
		10	DO5 is freely available to the user or can be used as a mains monitoring output (the two signals are linked with an OR)
		11	Reserved

1 - 7	Reserved	0	

4.26.2.18.3.2 Generator mains

Nominal voltage of generator mains (U_{NomGen})

Name:
ConfigOutput02
ConfigOutput02Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	70 to 65000	Corresponds to 70 to 65000 V	1 V

Multiplier for generator mains

Name:
ConfigOutput06
ConfigOutput06Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value 100 corresponds to a multiplication factor of 1 (measured value not changed).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	Corresponds to 0.01 to 655.35	0.01

Nominal current of generator mains (I_{Nom})

Name:
ConfigOutput04
ConfigOutput04Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 65000	Corresponds to 0 to 65000 A	1 A

Multiplier for current transformer

Name:
ConfigOutput09
ConfigOutput09Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	Corresponds to 1 to 65535	1

Turns generator mains functions on/off

Name:
ConfigOutput21
ConfigOutput21Read

The value of this register can be read back.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Error acknowledgment mode	0	Error bits are reset by the module
		1	Error bits are reset by the user
2 - 3	Check all overvoltages and undervoltages[1)]	00	3 line-to-line voltages (default)
		01	3 phase voltages
		10	3 line-to-line and 3 phase voltages
		11	Reserved
4 - 5	Reserved	0	
6	Power measurement mode[2)]	0	Total output - Including the harmonic component (default)
		1	Fundamental power - 1st harmonic only
7	Reserved	0	

1) This parameter is supported starting with upgrade 1.6.0.0 (firmware version 102). For information about configuring limit values, see section 4.26.2.18.3.3 "Generator monitoring".
2) This parameter is supported starting with upgrade 1.5.0.0 (firmware version 101).

Power measurement mode

In real transmission networks, neither the voltages nor the currents are strictly sinusoidal. This means: The fundamental frequencies are generally subject to strong harmonics.

By default, the module always accounts for the contributions of the fundamental frequency as well as the harmonics. In addition to the voltage and current measured values, this also affects the power measurements.

When controlling with reactive power in applications, the part of the reactive power coming from the harmonic frequencies (distortion reactive power) can have negative effects. Only the displacement reactive power should be controlled (i.e. the reactive power component of the fundamental frequency). In particular, this can make a control to displacement reactive power = 0 (cos φ = 1) impossible.

This is why the module offers the possibility of accounting for only the fundamental frequency (1st harmonic) for power measurement, when necessary. This primarily serves to filter out the distortion reactive power. However, all other measured values associated with the power measurement as well as the corresponding generator protection functions are affected when re-configuring the power measurement to the fundamental frequency.

The voltage and current measured values from the generator mains are **not** affected. Just as before (as with the other voltage supply systems), they also always include the contribution of harmonics regardless of the mode being used for power measurement.

Measured value / Functionality	Corresponding data point	Corresponding output	Remarks/Details
Active power	AnalogInput19		P → P_H1
Reactive power	AnalogInput20		Q → Q_H1
Apparent power	AnalogInput21		S → S_H1
Power factor	AnalogInput23		Power factor -> cos φ |cos φ| = cos(arctan(Q_H1/P_H1)) The signs for cos φ are described in section 4.26.2.17 "Generator operating modes". "I" and "U" must be replaced by the respective 1st harmonics "I_H1" and "U_H1".
Maximum total active power	ConfigOutput52		Changing the parameter "Power measurement mode" during runtime has no immediate effect on any of these registers or the internal energy meters (e.g. meter reset). It only determines the summands or comparison value that is effective immediately (total output / fundamental frequency power).
Active energy meter for supply	ConfigOutput54		
Reactive energy meter for supply	ConfigOutput55		
Active energy meter for reference	ConfigOutput71		
Reactive energy meter for reference	ConfigOutput72		
Energy meter output		DO 2	
Generator monitoring function: Capacitive reactive power	StatusInput10	DO 1	
Generator monitoring function: Generator overload	StatusInput31	DO 1	
Generator monitoring function: Generator feedback	StatusInput32	DO 1	

Low-pass filter for total power ratings

Name:
ConfigOutput41
ConfigOutput41Read

Parameter for delay time of the low-pass filter of the total power values P, Q and S or P_H1, Q_H1 and S_H1 (see "Power measurement mode"). The maximum total power values are recorded independently of this without being filtered.

This parameter is used as a delay element so that current or voltage fluctuations have less effect on how the calculated power values are represented. The damping behavior of the low-pass filter acts in accordance with the configurable time constant of a decaying e-function.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 300	Corresponds to 0 to 300 ms	1 ms

4.26.2.18.3.3 Generator monitoring

Overvoltage limit of generator mains (Umax)

Name:
ConfigOutput16 (1st value)
ConfigOutput118 (2nd value)
ConfigOutput16Read (1st value)
ConfigOutput118Read (2nd value)

If the value of one of the generator voltages configured in the "ConfigOutput21" register exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked01") or "Overvoltage2" (register "StatusInput-Packed05") is indicated after the delay time has expired and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	Corresponds to 0 to 200% of U_{NomGen}	0.1%

Response time for generator overvoltage (U_{max})

Name:
ConfigOutput26 (1st time)
ConfigOutput119 (2nd time)
ConfigOutput26Read (1st time)
ConfigOutput119Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	Corresponds to 0.5 to 10 s	0.1 s

Undervoltage limit of generator mains (U_{min})

Name:
ConfigOutput27 (1st value)
ConfigOutput59 (2nd value)
ConfigOutput27Read (1st value)
ConfigOutput59Read (2nd value)

If the value of one of the generator voltages configured in the "ConfigOutput21" register falls below the value set here, then the "Undervoltage" or "Undervoltage2" error message (register "StatusInputPacked01") is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	Corresponds to 0 to 200% of U_{NomGen}	0.1%

Response time for generator undervoltage (U_{min})

Name:
ConfigOutput28 (1st time)
ConfigOutput65 (2nd time)
ConfigOutput28Read (1st time)
ConfigOutput65Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	Corresponds to 0.5 to 10 s	0.1 s

Generator over-frequency (f_{max})

Name:
ConfigOutput29 (1st frequency)
ConfigOutput122 (2nd frequency)
ConfigOutput29Read (1st frequency)
ConfigOutput122Read (2nd frequency)

If the value of the generator frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "StatusInputPacked01") or "Overfrequency 2" (register "StatusPacked05") is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for generator over-frequency (f_{max})

Name:
ConfigOutput30 (1st time)
ConfigOutput123 (2nd time)
ConfigOutput30Read (1st time)
ConfigOutput123Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 for 10 s	0.1 s

Generator under-frequency (f_{min})

Name:
ConfigOutput31 (1st frequency)
ConfigOutput120 (2nd frequency)
ConfigOutput31Read (1st frequency)
ConfigOutput120Read (2nd frequency)

If the value of the generator frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "StatusInputPacked01") or "Underfrequency 2" (register "StatusInputPacked05") is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for generator under-frequency (f_{min})

Name:
ConfigOutput32 (1st time)
ConfigOutput121 (2nd time)
ConfigOutput32Read (1st time)
ConfigOutput121Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Generator voltage asymmetry (U_{as})

Name:
ConfigOutput33
ConfigOutput33Read

This trigger value, specified as a percentage, is based on the nominal voltage of the generator. If the difference between the three line-to-line voltages of the generator mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "StatusInputPacked01") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 300	For 0 to 30% of U_{NomGen}	0.1%

Response time for generator voltage asymmetry (U_{as})

Name:
ConfigOutput34
ConfigOutput34Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Load time constant for current asymmetry (K1)

Name:
ConfigOutput35
ConfigOutput35Read

The dependent delayed unbalanced load monitoring function (see "Dependent delayed unbalanced load monitoring") continually monitors the AC currents coming from the main current converters and continually calculates the present unbalanced load current. This is compared with the threshold value, which is calculated using the load time constants. If this threshold value is exceeded, the error message "Current asymmetry" is indicated (register "StatusInputPacked01") and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.1 to 6553.5 s	0.1 s

Unbalanced load constant (K2)

Name:
ConfigOutput109
ConfigOutput109Read

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2 (see "Dependent delayed unbalanced load monitoring").

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	8 to 15	For 0.08 to 0.15 (default: 0.08)	0.01

Dependent delayed unbalanced load monitoring

Unbalanced load monitoring protects against unbalanced load in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An unbalanced load can be caused by uneven current distribution in the mains due to unbalanced load, asymmetrical short circuits, line interruptions or switching operations. Unbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An unbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an unbalanced load occurs, the characteristics that trigger unbalanced load protection should be adapted to the thermal characteristics of the generator. Unbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

When unbalanced load protection is tripped can be calculated using the following formula:

Operating mode	Formula
Short-term operation	$t = \frac{K1}{(\frac{I_2}{I_{Nom}})^2 - K2^2}$
Continuous operation	$\frac{I_2}{I_{Nom}} \leq K2 \rightarrow t = \infty$

Key	
t	Calculated tripping time
K1	Valid load time constant for the generator [s]
K2	Unbalanced load constant
I_2	Calculated inverse current / unbalanced load current [A]
I_{Nom}	Nominal current for the generator [A]

To calculate the tripping time instant, the scan duration of the measurement system (i.e. 20 ms for 50 Hz voltage) is divided by the calculated trigger time, and the results are continually added up. With short-term operation, the value of the summands increases; with continuous operation, it decreases. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The boundary between continuous operation and short-term operation is defined by the unbalanced load constant K2.

Information:

When the generator is at a standstill, the summand is neither reset nor is its value reduced.

Nominal current on generator mains for unbalanced load protection

Name:
ConfigOutput124
ConfigOutput124Read

The nominal current for unbalanced load protection can be set separately. If the value is set to 0 (default), the normal nominal current is used for calculations.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 65000	For 0 to 65000 A	1 A

Maximum limit of neutral conductor current

Name:
ConfigOutput36
ConfigOutput36Read

Configurable limit for the neutral conductor current. If the value is exceeded, then the error message "Maximum neutral conductor current" is indicated (register "StatusInputPacked01") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of I_{Nom}	0.1%

Response time for neutral conductor current monitor

Name:
ConfigOutput37
ConfigOutput37Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Short circuit current

Name:
ConfigOutput38
ConfigOutput38Read

If the value of the generator current exceeds the percentage based on the converter's nominal current set here, then the error message "Short circuit current" is indicated (register "StatusInputPacked01") and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1000 to 5000	For 100 to 500% of I_{Nom}	0.1%

Response time for short circuit current

Name:
ConfigOutput39
ConfigOutput39Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	4 to 500	For 0.04 to 5 s	0.01 s

Rating-dependent overcurrent

Name:
ConfigOutput42
ConfigOutput42Read

The response value percentage is based on the nominal current of the generator. If the response value is exceeded, then the error message "Rating-dependent overcurrent" is indicated (register "StatusInputPacked01") and, if configured, the DO1 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1000 to 2000	For 100 to 200% of I_{Nom}	0.1%

Rating-dependent overcurrent monitoring

A generator that is operated at its nominal current I_{Nom} normally reaches about half of its maximum thermal load. Operating it above the rated current I_{Nom} result in additional warming, which is permitted until the maximum temperature is reached. The highest permissible continuous temperature is determined by the class of the insulation material used in the generator.

Based on the settings and the current measurement, the device forms an internal model based on an I^2t characteristic curve of the generator temperature. This allows the heat capacity of the generator to be completely utilized for short overloads while at the same time providing full protection. The configurable parameters for determining the machine model include the nominal current I_{Nom} of the generator and the time multiplier.

Integration coefficient for rating-dependent overcurrent (iths)

Name:
ConfigOutput43
ConfigOutput43Read

To calculate the tripping time instant, the sampling duration of the measurement system is divided by the calculated trigger time (t). The results are continually added up. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 20	For 0.1 to 2	0.1

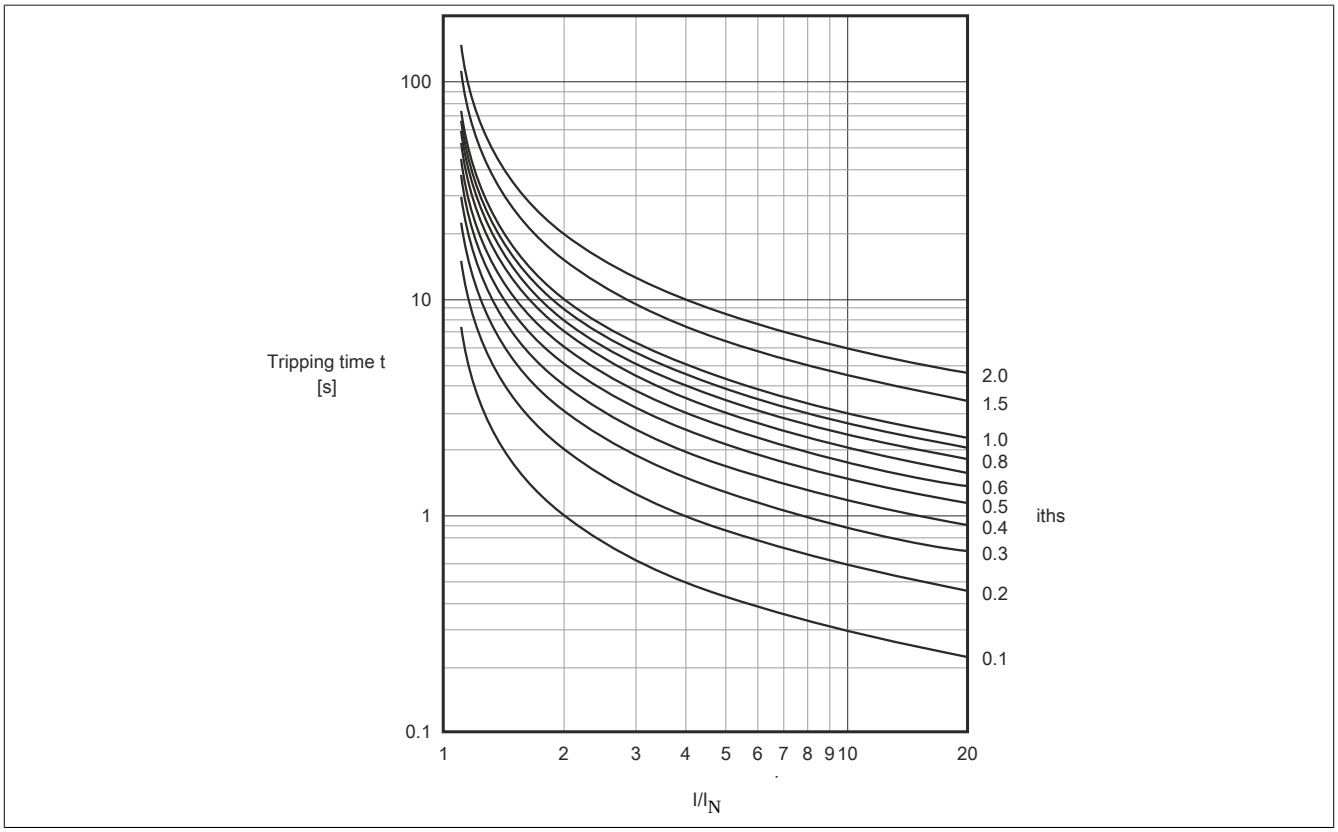
For a constant overcurrent, the trigger characteristic curve can be calculated based on the following formula:

$$t = \frac{0.14}{\left(\frac{I}{I_N}\right)^{0.02} - 1} * iths$$

Key:

t	Tripping time [s]
I	The highest value of the 3 phase currents [A]
I_N	Rating-dependent overcurrent [A]
iths	Integration coefficient

Trigger characteristic curve in accordance with IEC 255-4 (normal, inverse)



The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Capacitive reactive power

Name:
ConfigOutput44
ConfigOutput44Read

The capacitive reactive power for the generator is monitored to determine if it falls below the defined response value. In this way, monitoring the capacitive reactive power can be used to detect exciter failure. If the response value is fallen below, then the error message "Capacitive reactive power" is indicated (register "StatusInputPacked01") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" register, either the total reactive power or the fundamental frequency reactive power (displacement reactive power) is compared with the response value.

The value of this register can be read back.

Data type	Value	Information	Resolution
INT	-32768 to 32767	For -32768 to 32767 kvar	1 kvar

Response time for reactive power monitoring

Name:
ConfigOutput45
ConfigOutput45Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Generator overload

Name:
ConfigOutput89
ConfigOutput89Read

If the value of the active power of the generator exceeds the percentage of the generator's nominal power set here, then the error message "Generator overload" is indicated (register "StatusInputPacked01") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$P_{NomGen} = U_{NomGen} * I_{NomGen} * \sqrt{3}$

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of P_{NomGen}	0.1%

Response time for generator overload

Name:
ConfigOutput90
ConfigOutput90Read

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Generator feedback

Name:
ConfigOutput91
ConfigOutput91Read

If the value of the negative active power of the generator falls below the percentage of the generator's nominal power set here, then the error message "Generator feedback" is indicated (register "StatusInputPacked01") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" register, either the total active power or the fundamental frequency active power is compared with the response value.

The nominal power is calculated as follows:

$P_{NomGen} = U_{NomGen} * I_{NomGen} * \sqrt{3}$

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	0 to 200% of P_{NomGen}	0.1%

Response time for generator feedback

Name:
ConfigOutput92
ConfigOutput92Read

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

DO1 function

This digital output can be set after the defined response time has elapsed depending on the assignment of the generator mains' monitoring variables (X3). Assignments are made using the "ConfigOutput57" and "ConfigOutput97" registers.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the relay when there are multiple monitoring variables.

Assigning monitoring functions - 1

Name:
ConfigOutput57
ConfigOutput57Read

The following monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Overvoltage (of a phase)	0	Do not assign function
		1	Assign function
1	Undervoltage (or a phase)	0	Do not assign function
		1	Assign function
2	Overfrequency	0	Do not assign function
		1	Assign function
3	Underfrequency	0	Do not assign function
		1	Assign function
4	Voltage asymmetry	0	Do not assign function

		1	Assign function
13 - 14	Reserved	0	
15	Undervoltage 2 (one phase)	0	Do not assign function
		1	Assign function

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

Assigning monitoring functions - 2

Name:
ConfigOutput97

The following additional monitoring functions can be assigned to the monitoring relay using this register:

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Overvoltage 2 (one phase)	0	Do not assign function
		1	Assign function
1	Underfrequency 2	0	Do not assign function
		1	Assign function
2	Overfrequency	0	Do not assign function
		1	Assign function
3 - 15	Reserved	0	

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

4.26.2.18.3.4 Synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Nominal voltage of synchronization mains (U_{NomSyn})

Name:
ConfigOutput01
ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	70 to 65000	For 70 to 65000 V	1 V

Multiplier for synchronization mains

Name:
ConfigOutput07 (mains 1)
ConfigOutput08 (mains 2)
ConfigOutput07Read (mains 1)
ConfigOutput08Read (mains 2)

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.01 to 655.35	0.01

4.26.2.18.3.5 Mains

Mains (for mains configuration "3-phase mains")

Nominal voltage of mains ($U_{NomMains}$)

Name:
ConfigOutput01
ConfigOutput01Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	70 to 65000	For 70 to 65000 V	1 V

Multiplier for mains

Name:
ConfigOutput07
ConfigOutput07Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.01 to 655.35	0.01

Enable/disable mains functions

Name:
ConfigOutput22
ConfigOutput22Read

The value of this register can be read back.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Error acknowledgment mode	0	Mains error bits are reset by the module
		1	Mains error bits are reset by the user
1	Phase shift measurement	0	Three-phase only
		1	Single- or three-phase
2 - 3	Check all overvoltages and undervoltages	00	3 line-to-line voltages (default)
		01	3 phase voltages
		10	3 line-to-line and 3 phase voltages
		11	Reserved
4	Configuration of undervoltage monitoring	0	2-point mode
		1	6-point mode
5 - 7	Reserved	0	

1) This parameter is supported starting with upgrade 1.6.0.0 (firmware version 102). For information about configuring limit values, see section "Mains voltage monitoring".

4.26.2.18.3.6 Mains monitoring functions

(for "3-phase mains" configuration)

The following mains monitoring functions are available if the network configuration is set to a 3-phase mains (see register "Mains settings").

Mains voltage monitoring

Overvoltage limit of the mains ($U_{maxMains}$)

Name:
ConfigOutput73 (1st value)
ConfigOutput98 (2nd value)
ConfigOutput73Read (1st value)
ConfigOutput98Read (2nd value)

If the value of one of the mains voltages configured in the "ConfigOutput22" register exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked02") or "Overvoltage 2" (register "StatusInput-Packed04") is indicated after the delay time has expired and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of $U_{NomMains}$	0.1%

Response time for mains overvoltage ($U_{MaxMains}$)

Name:
ConfigOutput82 (1st time)
ConfigOutput99 (2nd time)
ConfigOutput82Read (1st time)
ConfigOutput99Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 60000	For 0.005 to 60 s	0.001 s

Mains over-frequency ($f_{maxMains}$)

Name:
ConfigOutput75 (1st frequency)
ConfigOutput102 (2nd frequency)
ConfigOutput75Read (1st frequency)
ConfigOutput102Read (2nd frequency)

If the value of the mains frequency exceeds the percent value set here in relation to the nominal frequency, then the error message "Overfrequency" (register "StatusInputPacked02") or "Overfrequency 2" (register "StatusInput-Packed04") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for mains over-frequency ($f_{maxMains}$)

Name:
ConfigOutput84 (1st time)
ConfigOutput103 (2nd time)
ConfigOutput84Read (1st time)
ConfigOutput103Read (2nd time)

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 60000	For 0.005 to 60 s	0.001 s

Mains under-frequency ($f_{minMains}$)

Name:
ConfigOutput76 (1st frequency)
ConfigOutput104 (2nd frequency)
ConfigOutput76Read (1st frequency)
ConfigOutput104Read (2nd frequency)

If the value of the mains frequency falls below the percent value set here in relation to the nominal frequency, then the error message "Underfrequency" (register "StatusInputPacked02") or "Underfrequency 2" (register "StatusInputPacked04") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for mains under-frequency ($f_{minMains}$)

Name:
ConfigOutput85 (1st time)
ConfigOutput105 (2nd time)
ConfigOutput85Read (1st time)
ConfigOutput105Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 60000	For 0.005 to 60 s	0.001 s

Mains voltage asymmetry ($U_{asMains}$)

Name:
ConfigOutput77
ConfigOutput77Read

This trigger value, specified as a percentage, is based on the nominal voltage of the mains. If the difference between the 3 line-to-line voltages of the mains exceeds the configured limit value, then the error message "Voltage asymmetry" is indicated (register "StatusInputPacked02") after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

For this to happen, only one of these voltages has to exceed the respective limit value (in either the positive or negative direction).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 300	For 0 to 30% of $U_{NomMains}$	0.1%

Response time for the mains voltage asymmetry ($U_{asMains}$)

Name:
ConfigOutput86
ConfigOutput86Read

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.005 to 0.1 s	0.001 s

Undervoltage monitoring in 2-point mode

2 independent limit values and response times can be defined for undervoltage monitoring.

Undervoltage limit of the mains ($U_{minMains}$)

Name:
ConfigOutput74
ConfigOutput74Read

If the value of one of the mains voltages configured in the "ConfigOutput22" register falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of $U_{NomMains}$	0.1%

Undervoltage limit 2 of the mains ($U_{minMains}$)

Name:
ConfigOutput100
ConfigOutput100Read

If the value of one of the linked mains voltages falls below the value set here, then the "Undervoltage" error message (register "StatusInputPacked02") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	0 to 200% of $U_{NomMains}$	0.1%

Response time for mains undervoltage ($U_{minMains}$)

Name:
ConfigOutput83 (1st time)
ConfigOutput101 (2nd time)
ConfigOutput83Read (1st time)
ConfigOutput101Read (2nd time)

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 60000	For 0.005 to 60 s	0.001 s

Undervoltage monitoring in 6-point mode

Up to 6 limit values and response times can be set for undervoltage monitoring. If not all 6 points are required, then unused limit values and response times should be set to 0.
Note that for each point, the specified limit value and response time must be greater than or equal to the preceding point (P1 ≤ P2 ≤ P3, etc.).

The defined points are used to create a limit value curve. If the voltage drops below the curve and a response time has expired, the error message "Undervoltage" is signaled ("StatusInputPacked02" register). If configured, the D05 monitoring relay is also switched.

A faulty undervoltage monitoring configuration also triggers the "Undervoltage" error message, and monitor relay DO5 is switched if configured to do so (e.g. P1 > P2 and P2 not equal to (0% / 0 ms)).

The types of voltages to be monitored are specified in the mains configuration ("ConfigOutput22" register):

- Line-to-line voltages
- Phase voltages
- Line-to-line and phase voltages

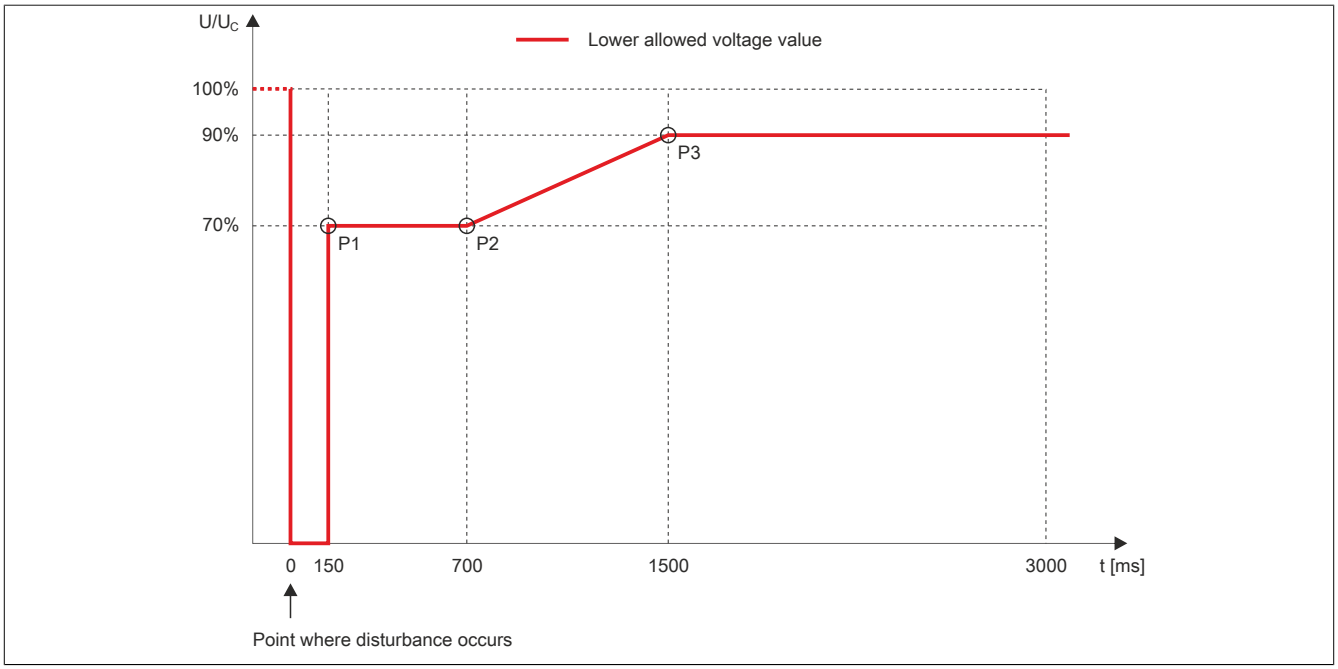
As soon as one of the monitored voltages drops below the limit curve, the corresponding time counter begins counting. The time counter is reset when all voltages are once again equal to or higher than the defined value.

The "Undervoltage" error message is generated when one of the time counters crosses over the limit curve.

Example 1 with 3 points:

In this example, 3 limit values are defined, along with the corresponding response times:

- P1 (70% / 150 ms)
- P2 (70% / 700 ms)
- P3 (90% / 1500 ms)
- P4 (0% / 0 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)



Notes regarding limit curve

- The red line marks the lowest permitted value for monitored voltages.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example above, this situation is shown with points 1 and 2.
- Between points 2 and 3 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.

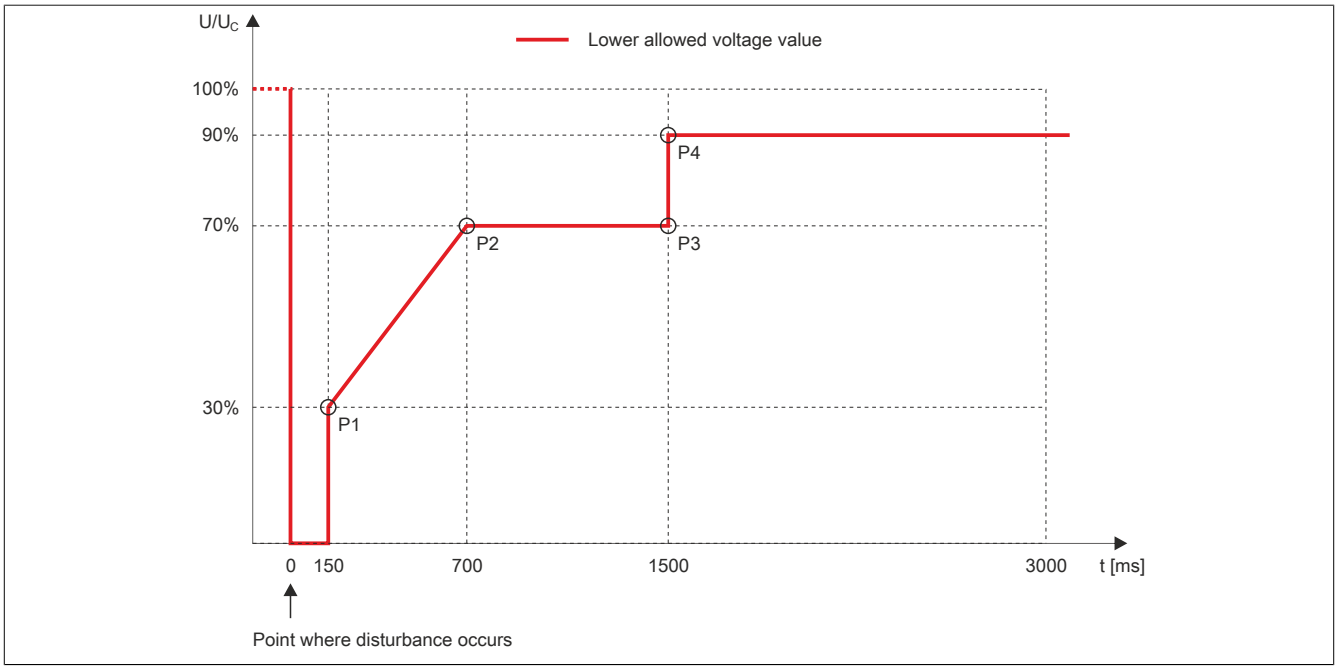
Determining the response time

1 Find voltage value on Y axis
2 Locate intersection on curve
3 Read the response time on the X axis

Example 2 with 4 points:

In this example, 4 limit values are defined, along with the corresponding response times:

- P1 (30% / 150 ms)
- P2 (70% / 700 ms)
- P3 (70% / 1500 ms)
- P4 (90% / 1500 ms)
- P5 (0% / 0 ms)
- P6 (0% / 0 ms)



Notes regarding limit curve

- The red line marks the lowest permitted value for monitored voltages.
- Between points 1 and 2 the curve has a positive linear slope. If one of the monitored voltages drops in this area, the module calculates the appropriate response time.
- If 2 consecutive points have the same limit value, then the response time of the first point is applied. In the example, this situation is shown with points 2 and 3.
- Points 1 and 2 are connected directly by a line with a positive slope. To avoid a direct connection between points 2 and 4, one would have to define another point between them with the same limit as point 2 and the same response time as point 4. In this case, that is point 3.

Determining the response time

1 Find voltage value on Y axis
2 Locate intersection on curve
3 Read the response time on the X axis

Undervoltage limit of the microgrid ($U_{MinMains}$)

Name:
ConfigOutput74 (1st mains)
ConfigOutput100 (2nd mains)
ConfigOutput110 (3rd mains)
ConfigOutput112 (4th mains)
ConfigOutput114 (5th mains)
ConfigOutput116 (6th mains)
ConfigOutput74Read (1st mains)
ConfigOutput100Read (2nd mains)
ConfigOutput110Read (3rd mains)
ConfigOutput112Read (4th mains)
ConfigOutput114Read (5th mains)
ConfigOutput115Read (6th mains)

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	0 to 200% of $U_{NomMains}$	0.1%

Response time for mains undervoltage ($U_{minMains}$)

Name:
ConfigOutput83 (1st mains)
ConfigOutput101 (2nd mains)
ConfigOutput111 (3rd mains)
ConfigOutput113 (4th mains)
ConfigOutput115 (5th mains)
ConfigOutput117 (6th mains)
ConfigOutput83Read (1st mains)
ConfigOutput101Read (2nd mains)
ConfigOutput111Read (3rd mains)
ConfigOutput113Read (4th mains)
ConfigOutput115Read (5th mains)
ConfigOutput117Read (6th mains)

The values of these registers can be read back.

Data type	Value	Information	Resolution
UINT	5 to 60000	For 0.005 to 60 s	0.001 s

Microgrid monitoring

A microgrid is a small mains power grid that only supplies a limited area and generally is not connected to other mains grids, which means it can function autonomously. This is in contrast to a synchronous grid, in which multiple smaller mains grids are connected together and synchronized.

With microgrid monitoring, the mains is monitored for over/undervoltage. After a defined response time elapses, a corresponding error message is generated. Microgrid monitoring always checks the line-to-line voltages independently of the configuration in the "ConfigOutput22" register.

Overvoltage limit of the mains ($U_{maxMains}$)

Name:
ConfigOutput106
ConfigOutput106Read

If the value of one of the linked mains voltages exceeds the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	0 to 200% of $U_{NomMains}$	0.1%

Undervoltage limit of the mains ($U_{minMains}$)

Name:
ConfigOutput107
ConfigOutput107Read

If the value of one of the linked mains voltages falls below the value set here, then the "Microgrid monitoring" error message (register "StatusInputPacked04") is indicated after the delay time has passed and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of $U_{NomMains}$	0.1%

Response time for microgrid limit

Name:
ConfigOutput108
ConfigOutput108Read

An error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	5 to 200	For 0.005 to 0.2 s	0.001 s

Phase shift monitoring

A phase shift is an abrupt change to the voltage curve that can be caused by a significant change to the load.

In this case, the device recognizes a single change to the period duration. This changed period duration is compared with the calculated average value from past measurements. Monitoring takes place for three phases and if desired also for a single phase. The phase shift monitoring function is only active if the mains voltage is higher than the set percentage value based on the nominal voltage for the converter.

If the response value is exceeded, the error message "Phase shift" is indicated (register "StatusInputPacked02") and, if configured, the DO5 monitoring relay is switched.

Phase shift monitoring response time

A phase shift is indicated on output DO5 within 2 ms after detection of the phase shift (i.e. after zero crossing of the extended/shortened period), as long as this is configured accordingly.

Phase shift detection

Phase shift detection is configured in the "ConfigOutput22" register.

Type of monitoring	Description
Only three-phase monitoring	Triggering takes place if the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods.
Single-phase or three-phase monitoring	Triggering takes place: • If the limit value for single-phase monitoring is exceeded on at least one of the 3 phases • If the limit value for three-phase monitoring was exceeded on all 3 phases within 2 periods.

Phase shift monitoring detects an abrupt change to the period duration of the mains voltage.

The period duration of the current period is compared with the average value for the period duration over the past 4 periods. If the difference exceeds the set limit value, then triggering takes place immediately.

Limit value

Setting of the limit value takes place in 0.1° steps. The internal limit value in µs is calculated as follows:

t_{hres}[µs] = t_{hres}[0.1°] * Period duration / 3600

When do this, the period duration for the set nominal frequency is used.

Example

Calculation of t_{hres}[µs] at 50 Hz (period duration = 20000 µs) and limit value of 7°:

t_{hres}[µs] = 70 * 20000 µs / 3600 = 388.88 µs (rounded to 389 µs)

If the period duration thus changes abruptly by more than +389 µs, triggering takes place.

Maximum phase difference for a single phase

Name:
ConfigOutput78
ConfigOutput78Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on at least one phase.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 990	For 0 to 99°	0.1°

Maximum phase difference for three phases

Name:
ConfigOutput79
ConfigOutput79Read

Triggering occurs if the electrical angle of the voltage curve shifts by more than the set angle on all 3 phases.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 990	For 0 to 99°	0.1°

Minimum voltage for phase shift monitoring

Name:
ConfigOutput88
ConfigOutput88Read

A minimum voltage can be set. Phase shift monitoring is only active if the voltage on all 3 phases exceeds this value.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of $U_{NomMains}$	0.1%

Mains frequency chance

Response value for mains frequency change (df/dt)

Name:
ConfigOutput80
ConfigOutput80Read

For df/dt monitoring, the frequency change in each period is compared to the previous period.

If this value exceeds the configured limit value in each of the periods for the specified number of periods and the sign for the frequency change is always the same, the error message "Df/dt (mains frequency change)" is indicated (register "StatusInputPacked02")and, if configured, the DO5 monitoring relay is switched.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100 Hz/s	0.1 Hz/s

Number of periods for mains frequency change (df/dt)

Name:
ConfigOutput87
ConfigOutput87Read

This register is used to define the number of periods for monitoring the mains frequency change. For activation, the response value must be continually exceeded at least for as many periods as specified in this register. The display of the error message on output DO5 takes place max. 2 ms after internal detection.

The value of this register can be read back.

Example

The maximum tripping time at 4 periods and 50 Hz mains frequency is calculated as follows:

Max. tripping time = 4 x 20 ms + 2 ms = 82 ms

The change in period duration caused by the frequency gradients must also be accounted for.

Data type	Value	Information	Resolution
UINT	1 to 250	-	-

DO5 function

DO5 function

Name:
ConfigOutput81
ConfigOutput81Read

This digital output can be set after the defined response time has elapsed depending on the assignment of the mains' monitoring variables.

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the output when there are multiple monitoring variables.

The following table is an overview of the monitoring functions that can be assigned to the monitoring output:

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Error notification
0	Overvoltage (of a phase)	0	Do not assign function
		1	Assign function
1	Undervoltage (or a phase)	0	Do not assign function
		1	Assign function
2	Overfrequency	0	Do not assign function
		1	Assign function
3	Underfrequency	0	Do not assign function
		1	Assign function
4	Voltage asymmetry	0	Do not assign function
		1	Assign function
5	Phase shift- 1/3 of a phase	0	Do not assign function
		1	Assign function
6	Df/dt exceeded	0	Do not assign function
		1	Assign function
7	Undervoltage 2 (one phase)	0	Do not assign function
		1	Assign function
8	Overvoltage 2 (one phase)	0	Do not assign function
		1	Assign function
9	Underfrequency 2	0	Do not assign function
		1	Assign function
10	Overfrequency 2	0	Do not assign function
		1	Assign function
11	Microgrid monitoring	0	Do not assign function
		1	Assign function
12 - 15	Reserved	-	

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the output is 500 ms.

4.26.2.18.3.7 Busbar

Busbar nominal voltage (U_{NomBus})

Name:
ConfigOutput03
ConfigOutput03Read

This is needed for converting the percentages based on this nominal value into physical units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	70 to 65000	For 70 to 65000 V	1 V

Multiplier for busbar

Name:
ConfigOutput05
ConfigOutput05Read

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 thus means a multiplier factor of 1 (measured value not changed).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.01 to 655.35	0.01

Minimum busbar voltage (U_{Bmin})

Name:
ConfigOutput40
ConfigOutput40Read

Configurable threshold for zero voltage monitoring of the busbar based on its nominal voltage. DO3 is set if the value falls below the configured threshold.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of U_{NomBus}	0.1%

4.26.2.18.3.8 Synchronization

Synchronization mode

Name:
ConfigOutputPacked01
ConfigOutput17 to ConfigOutput19

If multiple mode bits are set at the same time, then no mode will be selected (type BOOL).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ConfigOutput17	0	Sync mode ≠ Slip
		1	Sync mode = Slip
1	ConfigOutput18	0	Sync mode ≠ Check
		1	Sync mode = Check
2	ConfigOutput19	0	Sync mode ≠ Dead bus
		1	Sync Mode = Dead bus
3 - 7	Reserved	-	

Synchronization configuration

Name:
ConfigOutput56
ConfigOutput56Read

This register contains parameters for configuring which mains or voltages should be synchronized with each other.

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Synchronization configuration (synchronization mains - mains being synchronized)	00	X4 - X6: Synchronization mains 1 - Synchronization mains 2 **The configuration X4 - X6 is only possible if "Sync mains 1 / Sync mains 2" is configured in the "ConfigOutput68" register.**
		01	X4 - X5: Synchronization mains 1 - Busbar
		10	X4 - X3: Synchronization mains 1 - Generator
		11	X5 - X3: Busbar - Generator
2 - 7	Reserved	0	
8	Synchronization output	0	Digital output 4
		1	Digital output 6 - Output must be configured as a synchronization output (see register "ConfigOutput24")
9 - 15	Reserved	0	

Max. differential frequency (df_{max})

Name:
ConfigOutput11
ConfigOutput11Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded. This value specifies the upper frequency (positive value corresponds to positive slip → generator frequency is greater than the busbar frequency when synchronizing).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	2 to 49	For 0.02 to 0.49 Hz	0.01 Hz

Min. differential frequency (df_{min})

Name:
ConfigOutput12
ConfigOutput12Read

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded in the negative direction. This value specifies the lower frequency (negative value corresponds to negative slip → generator frequency is less than the busbar frequency when synchronizing).

The value of this register can be read back.

Data type	Value	Information	Resolution
INT	-49 to 0	For -0.49 to 0 Hz	0.01 Hz

Max. differential voltage (dU_{max})

Name:
ConfigOutput13
ConfigOutput13Read

A switch-on command on DO4 is only output if this configured differential voltage percentage based on the synchronization mains' nominal voltage is not exceeded.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 300	For 0.1 to 30% of U_{NomSyn}	0.1%

Max. permitted differential angle (Φ_{Max})

Name:
ConfigOutput14
ConfigOutput14Read

A switch-on command on DO4 is only output if the configured differential angle between the two synchronization mains is not exceeded.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	1 to 600	For 0.1 to 60°	0.1°

Phase rotation of sync mains 1 (dα)

Name:
ConfigOutput15
ConfigOutput15Read

This parameter is used for correcting any phase shifting from upstream transformer vector groups before reaching the mains being synchronized.

This parameter specifies how many degrees the synchronization mains lags behind the mains being synchronized.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 3600	For 0 to 360°	0.1°

Pulse duration of the turn-on delay

Name:
ConfigOutput47 (DO4)
ConfigOutput95 (DO6)
ConfigOutput47Read (DO4)
ConfigOutput95Read (DO6)

The duration of the switch-on pulse can be adjusted for the following switching units.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	40 to 1000	For 0.04 to 1 s	0.001 s

Switching response time of the power switch

Name:
ConfigOutput48 (DO4)
ConfigOutput96 (DO6)
ConfigOutput48Read (DO4)
ConfigOutput96Read (DO6)

The actuation time of the generator power switch corresponds to the lead time of the switch-on command. The switch-on command is executed before the point of synchronization according to the amount of time defined here.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	40 to 300	For 0.04 to 0.3 s	0.001 s

Dead bus voltage ($U_{BminSync}$)

Name:
ConfigOutput58
ConfigOutput58Read

Configurable threshold for dead bus synchronization based on the nominal voltage of the busbar.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of U_{NomBus}	0.1%

2-phase synchronization for commissioning tests

Name:
ConfigOutput93
ConfigOutput93Read

2-phase synchronization for commissioning tests.

The value of this register can be read back.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Synchronization	0	Default: 3-phase synchronization (normal operation)
		1	2-phase synchronization with L1 and L2 (commissioning tests with 2-phase simulation design)
1 - 7	Reserved	0	

Information:

It is only possible to set 2-phase synchronization for commissioning tests with a 2-phase simulation design.

If only 2 phases are connected, then the respective mains must be configured with neutral conductors since a network with a "virtual neutral point" is not possible with 2 phases (see register "ConfigOutput68").

4.26.2.18.3.9 Maximum value buffer and power meter

Pulse value of energy meter output

Name:
ConfigOutput46
ConfigOutput46Read

Output DO2 outputs pulses that occur at a frequency proportional to the measured energy. The frequency of the pulses can be specified. The length of the pulse is 400 ms. The frequency at which the pulses occur should be set so that the duration between two pulses does not exceed 400 ms at the highest possible power. The pulse output's internal meter starts at 0 kWh after a restart. This register has no effect on the "ConfigOutput54" and "ConfigOutput55" registers.

When set to 0, meter output is disabled.

Depending on how the "Power measurement mode" parameter is set in the "ConfigOutput21" register, either the total active power or the active power of the fundamental wave is added together. Changing the parameter "Power measurement mode" during runtime does not cause the internal energy meter to restart.

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 65535	For 0 to 65535 kWh/pulse	1 kWh/pulse

Count value for active energy meter and reactive energy meter

Name:
ConfigOutput94
ConfigOutput94Read

This parameter is used to configure the resolution of the active energy meter and reactive energy meter (default: 100 kWh).

The value of this register can be read back.

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	1 kWh

Maximum value buffer and meter buffer

These registers are used for nonvolatile storage of the maximum value and meter level values. After restarting, the stored maximum values and meter states are loaded back into their registers and the module's internal work meter is reset. It is possible to reset or write to the stored maximum values and meter states using an acyclic register.

The maximum values are recorded by the effective measured values before reaching the configurable filter. The maximum values can be read or written to as acyclic registers.

Maximum phase current

Name:
Reading: ConfigOutput49 (generator I1)
Reading: ConfigOutput50 (generator I2)
Reading: ConfigOutput51 (generator I3)
Writing: ConfigOutput60 (generator I1)
Writing: ConfigOutput61 (generator I2)
Writing: ConfigOutput62 (generator I3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Maximum total active power (supplied power)

Name:
Reading: ConfigOutput52
Writing: ConfigOutput63

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" register, either the total power or the fundamental power is added together or compared.

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 kW

Maximum neutral conductor current

Name:
Reading: ConfigOutput53
Writing: ConfigOutput64

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Active energy counter

Name:
Reading: ConfigOutput54 (delivered (producing))
Reading: ConfigOutput71 (drawn (consuming))
Writing: ConfigOutput66 (delivered (producing))
Writing: ConfigOutput69 (drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94").

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	Default: 100 kWh

Reactive energy counter

Name:
Reading: ConfigOutput55 (reactive energy meter delivered (producing))
Reading: ConfigOutput72 (reactive energy meter drawn (consuming))
Writing: ConfigOutput67 (reactive energy meter delivered (producing))
Writing: ConfigOutput70 (reactive energy meter drawn (consuming))

Depending on the status of the "Power measurement mode" parameter in the "ConfigOutput21" register, either the total power or the fundamental power is added together or compared.

The resolution can be configured (see register "ConfigOutput94").

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	Default: 100 kvarh

4.26.2.18.4 Communication registers

4.26.2.18.4.1 General registers

DigitalOutputPacked01

Name:
DigitalOutputPacked01
DigitalOutput05
DigitalOutput06
ResetGeneratorErrors
ResetMainsErrors
InvertDO5

The module's default configuration is that the generator and mains error bits are reset by the module. If this should be done by the user, then the module needs to be configured accordingly using the following registers.

- Generator error: "ConfigOutput21"
- Network error: "ConfigOutput22"

(data point applied as BOOL)

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalOutput05	0	Reset output 5
		1	Set output 5
1	DigitalOutput06	0	Reset output 6
		1	Set output 6
2	ResetGeneratorErrors	0	Does not reset generator error bits
		1	Resets generator error bits
3	ResetMainsErrors	0	Do not reset mains error bits
		1	Reset mains error bits
4	InvertDO5	0	Do not invert Output 5
		1	Invert output 5 of the mains monitoring function
5 - 7	Reserved	0	

StatusDigitalOutputPacked01

Name:
StatusDigitalOutputPacked01
StatusDigitalOutput01 to StatusDigitalOutput06
StatusInput16 to StatusInput17

(data point applied as BOOL)

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusDigitalOutput01	0	Current state of output 1 = LOW
		1	Current state of output 1 = HIGH
...		...	
5	StatusDigitalOutput06	0	Current state of output 6 = LOW
		1	Current state of output 6 = HIGH
6	StatusInput17	0	Status DO OK
		1	Status DO overload
7	StatusInput16	0	Status 24 V output supply OK
		1	Status 24 V output supply undervoltage

StatusInputPacked01

Name:
StatusInputPacked01
StatusInput01 to StatusInput11
StatusInput31 to StatusInput32
StatusInput18

This register is the error register for the generator mains (error bits are of type BOOL). With regard to bits 9, 11 and 12, please also observe the description of the "Power measurement mode" parameter in the register "ConfigOutput21".

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput01	0	Overvoltage (one phase), OK
		1	Overvoltage (one phase), present
1	StatusInput02	0	Undervoltage (one phase), OK
		1	Undervoltage (one phase), present
2	StatusInput03	0	Over-frequency, OK
		1	Over-frequency, present
3	StatusInput04	0	Under-frequency, OK
		1	Under-frequency, present
4	StatusInput05	0	Voltage asymmetry, OK
		1	Voltage asymmetry, present
5	StatusInput06	0	Current asymmetry, OK
		1	Current asymmetry, present
6	StatusInput07	0	Maximum neutral conductor current, OK
		1	Maximum neutral conductor current exceeded
7	StatusInput08	0	Short circuit-current, OK
		1	Short circuit-current, present
8	StatusInput09	0	Rating-dependent overcurrent OK
		1	Rating-dependent overcurrent occurring
9	StatusInput10	0	Capacitive reactive power (exciter failure), OK
		1	Capacitive reactive power (exciter failure), present
10	StatusInput11	0	Ready, OK
		1	Not ready
11	StatusInput31	0	No generator overload
		1	Generator overload
12	StatusInput32	0	No generator feedback
		1	Generator feedback
13 - 14	Reserved	-	
15	StatusInput18	0	Undervoltage 2 (of a phase) OK
		1	Undervoltage 2 (of a phase) occurring

StatusInput11

The error message "Not ready" is triggered if the X20 I/O supply drops below 18 VDC.

StatusInputPacked02

Name:
StatusInputPacked02
StatusInput24 to StatusInput30
StatusInput33

This register is the error register for the mains (error bits are of type BOOL).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput24	0	Overvoltage (one phase), OK
		1	Overvoltage (one phase), present
1	StatusInput25	0	Undervoltage (one phase), OK
		1	Undervoltage (one phase), present
2	StatusInput26	0	Over-frequency, OK
		1	Over-frequency, present
3	StatusInput27	0	Under-frequency, OK
		1	Under-frequency, present
4	StatusInput28	0	Voltage asymmetry, OK
		1	Voltage asymmetry, present
5	StatusInput29	0	Phase shift monitoring OK
		1	Phase shift error (1/3 of a phase)
6	StatusInput30	0	Df/dt OK
		1	Df/dt error
7	StatusInput33	0	Undervoltage 2 (of a phase) OK
		1	Undervoltage 2 (of a phase) occurring

StatusInput33

The data point is only valid if 2-point mode is configured (see register "ConfigOutput22"). This bit only appears in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

StatusInputPacked03

Name:
StatusInputPacked03
StatusInput12 to StatusInput15
StatusInput19 to StatusInput23

This register is the error register for general error messages (error bits are of type BOOL).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput12	0	All phases of the generator mains OK
		1	Failure of at least one phase of the generator mains
1	StatusInput13	0	All phases of the busbar OK
		1	Failure of at least one phase of the busbar
2	StatusInput14	0	All phases of Sync Mains 1 OK
		1	Failure of at least one phase of Sync Mains 1
3	StatusInput15	0	All phases of Sync Mains 2 OK
		1	Failure of at least one phase of Sync Mains 2
4	StatusInput19	0	Phase sequence of generator voltage OK
		1	Phase sequence of generator voltage incorrect
5	StatusInput20	0	Phase sequence of generator current OK
		1	Phase sequence of generator current incorrect
6	StatusInput21	0	Phase sequence of busbar OK
		1	Phase sequence of busbar incorrect
7	StatusInput22	0	Phase sequence of Sync Mains 1 OK
		1	Phase sequence of Sync Mains 1 incorrect
8	StatusInput23	0	Phase sequence of Sync Mains 2 OK
		1	Phase sequence of Sync Mains 2 incorrect
9 - 15	Reserved	-	

StatusInput12 to StatusInput15: Phase failure is detected if at least one of the phases of the respective terminal fails.

StatusInput19 to StatusInput23 are status bits for detecting a change of rotation.

StatusInputPacked04

Name:
StatusInputPacked04
StatusInput34 to StatusInput37

This register is the error register for the mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Mains configuration / Additional status information" menu option).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput34	0	Overvoltage 2 (of a phase) OK
		1	Overvoltage 2 (of a phase) occurring
1	StatusInput35	0	Underfrequency 2 OK
		1	Underfrequency 2 occurring
2	StatusInput36	0	Overfrequency 2 OK
		1	Overfrequency 2 occurring
3	StatusInput37	0	Microgrid monitoring OK
		1	Microgrid monitoring tripped
4 - 15	Reserved	-	

StatusInputPacked05

Name:
StatusInputPacked05
StatusInput38 to StatusInput40

This register is the error register for the generator mains (error bits are of type BOOL). These bits only appear in the I/O mapping in Automation Studio if the corresponding status information is enabled in the I/O configuration ("Generator mains / Additional status information" menu option).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput38	0	Overvoltage 2 (of a phase) OK
		1	Overvoltage 2 (of a phase) occurring
1	StatusInput39	0	Underfrequency 2 OK
		1	Underfrequency 2 occurring
2	StatusInput40	0	Overfrequency 2 OK
		1	Overfrequency 2 occurring
3 - 15	Reserved	-	

4.26.2.18.4.2 Generator mains measured values

Phase currents of the generator

Name:
AnalogInput01 (I1)
AnalogInput02 (I2)
AnalogInput03 (I3)

Phase currents of the generator

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Neutral conductor current of generator I_n

Name:
AnalogInput05

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Current average of generator I1, I2, I3

Name:
AnalogInput04

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Dynamic current average of generator (I_{m_dyn})

Name:
AnalogInput06

Describes the change to the current average.

The dynamic average is the amount of change (I_{m_diff}) of the current average (sampling time: 10 ms).

This value decays in an e-function.

$I_{m\_diff} > I_{m\_dyn} \rightarrow I_{m\_dyn} = I_{m\_diff}$

$I_{m\_diff} \leq I_{m\_dyn} \rightarrow I_{m\_dyn} = I_{m\_dyn} * 0.98$

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	1 A

Line-to-line voltages of the generator

Name:
AnalogInput07 (UG12)
AnalogInput08 (UG23)
AnalogInput09 (UG31)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Phase voltages of the generator

Name:
AnalogInput10 (UG 1)
AnalogInput11 (UG 2)
AnalogInput12 (UG 3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Voltage average of the generator

Name:
AnalogInput22

Voltage average of the generator UG12, UG23, UG31 (U~3 average)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Filtered generator power values:

Name:
AnalogInput19
AnalogInput20
AnalogInput21

Filtered generator power values:

- Total output (sum of all harmonic frequencies)
- Fundamental frequency power (_H1)

Configuration is explained in the "ConfigOutput21" register.

Data type	Value	Information	Resolution
INT	-32768 to 32767	Total active power P/P_H1	1 kW
	-32768 to 32767	Total reactive power Q/Q_H1	1 kvar
	-32768 to 32767	Total apparent power S/S_H1	1 kVA

Power factor of generator/cos ϕ

Name:
AnalogInput23

The factor is described in the section 4.26.2.17 "Power factor of the generator" and the section for the register "ConfigOutput21".

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	0.001

Frequency of the generator mains

Name:
AnalogInput24

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

Timestamp for generator voltages and currents

These timestamps mark the last positive zero crossing of the generator voltages (L1-N, L2-N, L3-N) and generator currents (I1, I2, I3). They can be used to calculate all the necessary phase ratios.

Calculation of the phase ratios and error handling for the calculations are to be implemented by the user (e.g. period duration monitoring or verification that the voltages are high enough, etc.).

These timestamps only appear in the I/O mapping in Automation Studio if they are enabled in the I/O configuration ("Enable timestamps for generator voltage and current" menu option).

Timestamp of pos. zero crossing of phase voltage

Name:
AnalogInput38 (UG1)
AnalogInput39 (UG2)
AnalogInput40 (UG3)

Time stamp of pos. zero crossing of phase voltage of the respective generator

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	1/4096 µs

Timestamp of pos. zero crossing of phase current

Name:
AnalogInput41 (I1)
AnalogInput42 (I2)
AnalogInput43 (I3)

Time stamp of pos. zero crossing of phase current of the respective generator

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	1/4096 µs

4.26.2.18.4.3 Busbar measured values

Line-to-line voltages of the busbar

Name:
AnalogInput13 (UB12)
AnalogInput14 (UB23)
AnalogInput15 (UB31)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Phase voltages of the busbar

Name:
AnalogInput16 (UB1)
AnalogInput17 (UB2)
AnalogInput18 (UB3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Frequency of busbar

Name:
AnalogInput35

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

4.26.2.18.4.4 Measured value of synchronization mains

(for mains configuration "Sync mains 1 / Sync mains 2")

Line-to-line voltages

Name:
AnalogInput25 (sync mains 1 US1)
AnalogInput26 (sync mains 2 US2)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Frequencies

Name:
AnalogInput27 (sync mains 1)
AnalogInput28 (sync mains 2)

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

4.26.2.18.4.5 Measured value of mains

(for "3-phase mains" configuration)

Line-to-line voltages of mains

Name:
AnalogInput25 (UN12)
AnalogInput31 (UN23)
AnalogInput32 (UN31)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Phase voltages of the generator

Name:
AnalogInput33 (UN1)
AnalogInput34 (UN2)
AnalogInput26 (UN3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Frequency of power mains

Name:
AnalogInput27

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

4.26.2.18.4.6 Generator monitoring

Read unbalanced load meter

Name:
AnalogInput36

This register can be used to track the current state of the unbalanced load meter (see section "Dependent delayed unbalanced load monitoring"). The unbalanced load meter can be reset with an acyclic trigger bit (see register "ConfigOutput23").

Data type	Value	Information	Resolution
UINT	0 to 65535	For 0 to 100%	

Reads the unbalanced load current (I_2)

Name:
AnalogInput37

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

4.26.2.18.4.7 Synchronization

Differential angle between synchronization mains

Name:
AnalogInput29

Angular difference between the mains being synchronized

Specifies how many degrees the sync mains are ahead of the mains being synchronized.

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	0.1°

Differential voltage between synchronization mains

Name:
AnalogInput30

Voltage difference between the mains being synchronized

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

4.26.2.18.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
250 µs

4.26.2.18.6 Minimum I/O update time

The minimum I/O update time for the analog inputs depends on the respective period duration of the measurement signal frequency.

Minimum I/O update time	
At 50 Hz	10 ms

4.26.3 X20CM0985

4.26.3.1 General information

The module has a compact size and combines a power measurement module that has special features with a synchronization unit that is able to meet all demands.

The measurement unit's 3 current inputs are suitable for both X: 1 A and X: 5 A current transformers. Overcurrent resistance and the high resolution of the measurement unit round off its features. For the voltage inputs, the value range can be configured between 480 VAC and 120 VAC.

The area of use includes 4-wire AC networks with a phase voltage up to 480 VAC and 3-wire systems, whereas L2 can be grounded (V-connection). The module can also handle Aron measuring circuits.

The resulting measured values include the pure phase current; line-to-line voltage or phase voltage; the effective, reactive and apparent power parts; the mains frequency; the power factor and much more. In addition, peak values and energy meters are stored on the module in nonvolatile memory. Depending on the configuration, it is also possible to use a digital output as a pulse encoder for an external energy meter.

The synchronization unit doesn't just take the phasing and phase voltage into consideration; integrated intelligence also monitors the rate of change and other parameters, allowing them to influence when the synchronization output is switched. It is also possible to monitor a generator using a large number of additional conditions. A total of 4 voltage inputs provide substantial overall flexibility.

Monitoring functions expand the features of the module. Rating-dependent overcurrent monitoring is included, which utilizes the thermal capacity of the motor/generator to allow short overloads while still providing full protection. The dependent, delayed imbalanced load monitoring used to protect three-phase generator and three-phase networks from imbalanced load can be adapted to the characteristics of different generator types using parameters while taking their special thermal time constants into account.

- Energy measurement for 120 to 480 VAC
- Simultaneous measurement of 2 AC mains networks plus 2 additional voltages
- For multifunctional measurement tasks
- Intelligent mains synchronization unit

Information:

Please refer to section 4.26.2.4 "Safety guidelines" before operating the module.

4.26.3.2 Order data

Model number	Short description	Figure
	Other functions	
X20CM0985	X20 digital and analog mixed module, multi-measurement transducer/ synchronization module, 5 digital outputs, 24 VDC, 0.5 A source, 1 relay, 1 A, changeover contact, 8 analog inputs, ±480 V / 120 V, 16-bit converter resolution, 3 analog inputs 5 A / 1 A AC, 16-bit converter resolution, order terminal blocks 0TB3102-7011, 0TB3104-7011, 0TB3102-7012, 0TB3104-7012 and 2x TB12 separately.	
	Required accessories	
	Terminal blocks

4.26.3.3 Technical data

Product ID	X20CM0985
Short description	
I/O module	X20 energy measurement and synchronization module
General information	
B&R ID code	0x2433
Status indicators	Channel status, operating status, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Analog inputs	Yes, using status LED (measurement range of analog inputs)
Digital outputs	Yes, using status LED and software
Overvoltage category	II [1]
Power consumption	
Bus	1.4 W
Internal I/O	4 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Bus - I/O supply	Yes
Input/Output - Bus	Yes
Digital outputs - Analog inputs	Yes
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [2]	Yes
KC	Yes
GOST-R	Yes
Digital outputs	
Design	FET positive switching
Quantity	5
Nominal voltage	24 VDC
Switching voltage	24 VDC -15% / +20%
Nominal output current	0.1 A
Total nominal current	0.5 A
Connection type	1-wire connections
Output circuit	Source
Output protection	Thermal cutoff for overcurrent and short circuit
Diagnostic status	Output monitoring with 10 ms delay
Leakage current when switched off	5 µA
Residual voltage	<0.3 V at 0.1 A rated current
Peak short circuit current	<2 A
Switching on after overload or short circuit cutoff	Approx. 10 ms, depends on the module temperature
Switching delay	
0 -> 1	<300 µs
1 -> 0	<300 µs
Switching frequency	
Resistive load	Max. 100 Hz
Isolation voltage between channel and bus	500 V_{eff}
Relay outputs	
Quantity	1
Design	Relay / Changeover contact

Table 584: X20CM0985 - Technical data

Product ID	X20CM0985
Nominal voltage	30 VDC / 240 VAC
Rated frequency	DC / 45 to 63 Hz
Switching capacity	
Min.	10 mA / 5 VDC
Max.	30 W / 240 VAC
Nominal output current	1 A at 30 VDC / 1 A at 240 VAC
Actuator supply	External
Switching voltage	Max. 60 VDC / 250 VAC
Switching delay	
0 -> 1	≤10 ms
1 -> 0	≤10 ms
Service life [3]	
Mechanics	Min. 10 x 10^6 ops.
Electrical	Min. 60 x 10^3 ops. (NC) at 1 A Min. 30 x 10^3 ops. (NO) at 1 A
Contact resistance	Max. 100 mΩ
Protective circuit	
Internal	None
External	None
DC	Inverse diode, RC combination or VDR
AC	RC combination or VDR
Isolation voltage	
Contact - Contact	1000 VAC / 1 min
Contact - Coil	4000 VAC / 1 min
Analog input voltage	
Channels	8
Input	120 VAC / 480 VAC
Input type	Single-ended
Digital converter resolution	±15-bit
Conversion time	
50 Hz	20 ms
60 Hz	16.67 ms
Permitted input signal	Max. 132 VAC / 528 VAC
Output format [4]	
±120 VAC	1 LSB = 0x0001 = 5.707 mV
±480 VAC	1 LSB = 0x0001 = 22.787 mV
Output of the digital value during overload	
Above upper limit	0x7FFF
Below lower limit	0x8001
Conversion method	SAR
Input filter	
Cutoff frequency	10 kHz
Slope	60 dB
Maximum gain drift [5]	0.02% per °C
Maximum offset drift [6]	0.003% per °C
Crosstalk between channels	-70 dB
Nonlinearity [6]	≤0.5% at 45 to 65 Hz
Protection against electrical shock	Protective impedance in accordance with IEC 61131-2
Test voltage between channel and bus (type test)	3700 V_{eff}
Output format	INT
Input impedance in signal range	Approx. 3 MΩ
Max. error at 25°C	
Gain	0.09% [5]
Offset	0.03% [6]
Input protection	Overvoltage protection
Analog input current	
Channels	3
Input	1 A / 5 A AC
Input type	Isolated current transformer according to the compensation principle with a magnetic sensor, for connecting an external transformer
Digital converter resolution	±15-bit
Conversion time	
50 Hz	20 ms
60 Hz	16.67 ms
Permitted input signal	Max. 1.5 A / 7.7 A
Output format [4]	
±1 A	1 LSB = 0x0001 = 189.903 µA
±5 A	1 LSB = 0x0001 = 949.513 µA
Output of the digital value during overload	
Above upper limit	0x7FFF
Below lower limit	0x8001
Conversion method	SAR

4.26.3.4 Safety guidelines

General information

Programmable logic controllers, operating and monitoring devices (e.g. industrial PCs, Power Panels, Mobile Panels etc.) as well as the uninterruptible power supplies have all been designed, developed, and produced by B&R for conventional use in industry. They were not designed, developed and manufactured for any use involving serious risks or hazards that could lead to death, injury, serious physical damage or loss of any kind without the implementation of exceptionally stringent safety precautions. In particular, such risks and hazards include the use of these devices to monitor nuclear reactions in nuclear power plants, their use in flight control or flight safety systems as well as in the control of mass transportation systems, medical life support systems or weapons systems.

When using programmable logic controllers or operating/monitoring devices as control systems together with a Soft PLC (e.g. B&R Automation Runtime or comparable product) or Slot PLC (e.g. B&R LS251 or comparable product), safety precautions relevant to industrial control systems (e.g. the provision of safety devices such as emergency stop circuits, etc.) must be observed in accordance with applicable national and international regulations. The same applies for all other devices connected to the system, e.g. drives.

All tasks such as the installation, commissioning and servicing of devices are only permitted to be carried out by qualified personnel. Qualified personnel are those familiar with the transport, mounting, installation, commissioning and operation of devices who also have the appropriate qualifications (e.g. IEC 60364). National accident prevention regulations must be observed.

The safety notices, connection descriptions (type plate and documentation) and limit values listed in the technical data are to be read carefully before installation and commissioning and must be observed.

Intended use

Danger!

Electronic devices are never completely failsafe. If the multi-measurement and synchronization unit fails, the user is responsible for making sure that the motor or generator is brought to a secure state.

Some errors are detected and prevented in the synchronization unit by the system's internal software monitoring. However, when the device is in operation it is always possible for errors, defective components, software errors or configuration mistakes to occur at any time. B&R emphasizes that the multi-measurement and synchronization unit possesses neither a failsafe function nor a redundancy system. For this reason, independent higher-level safety precautions need to be put in place to ensure that personnel and machines are protected.

Grounding the Mounting Rail

For grounding purposes, a good conductive connection between the mounting rail and the metal back wall is required. The mounting rail is to be connected conductively to the back wall. This is achieved by inserting a contact washer with the fastening screw.

Information:

The control cabinet back wall must be connected with GND

4.26.3.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

LED status indicators - Right

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Orange		Output status of the corresponding digital output

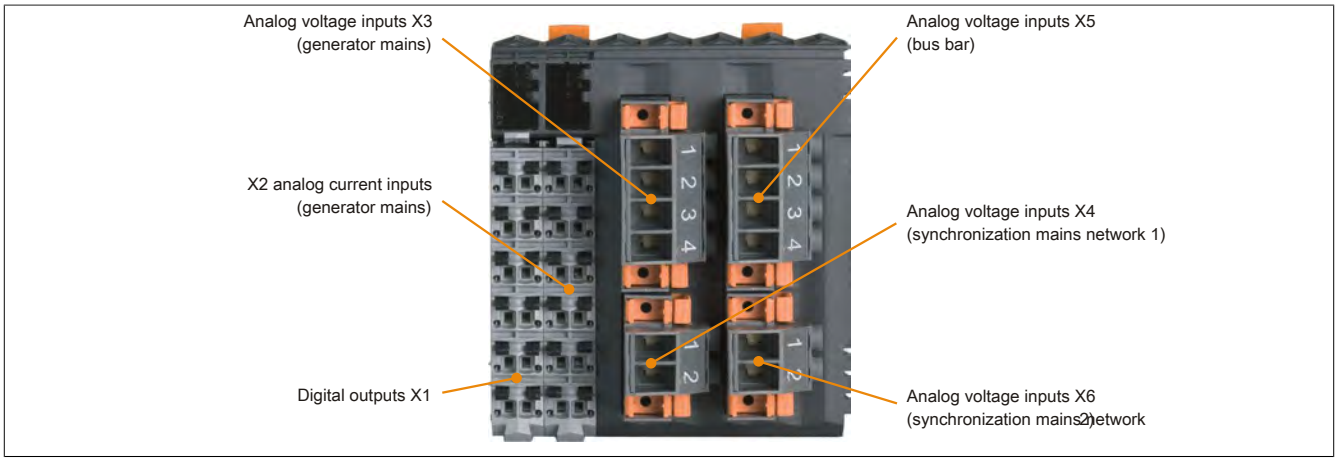
1) Depending on the configuration, a firmware update can take up to several minutes.

Status-LEDs right

Figure	LED[1]	Terminal	Color	Status	Description
	1	X3	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	2	X4	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	3	X5	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	4	X6	Green	On	Measurement range: 120 VAC
			Red	On	Measurement range: 480 VAC
	5	X2	Green	On	Measurement range: 1 A
			Red	On	Measurement range: 5 A

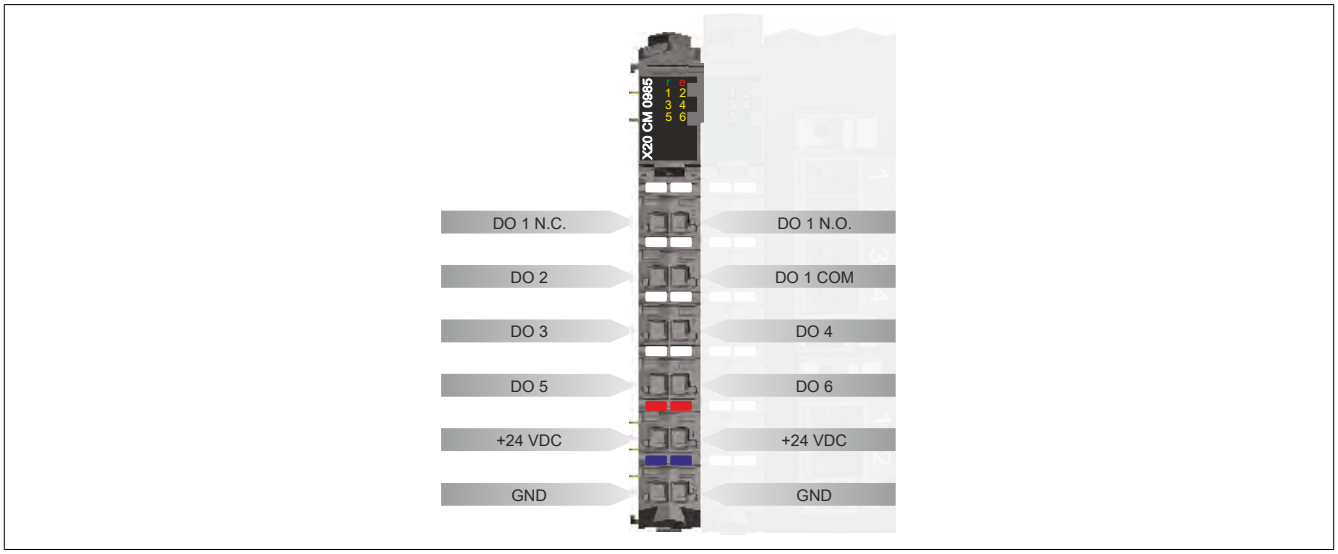
1) LEDs 1 - 5 are green/red dual LEDs.

4.26.3.6 Connection elements



4.26.3.7 Digital outputs X1

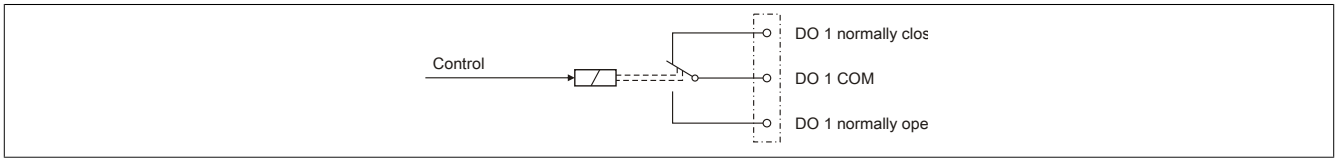
The X1 and X2 terminals can each be keyed differently to prevent them from being inadvertently plugged into the module incorrectly.



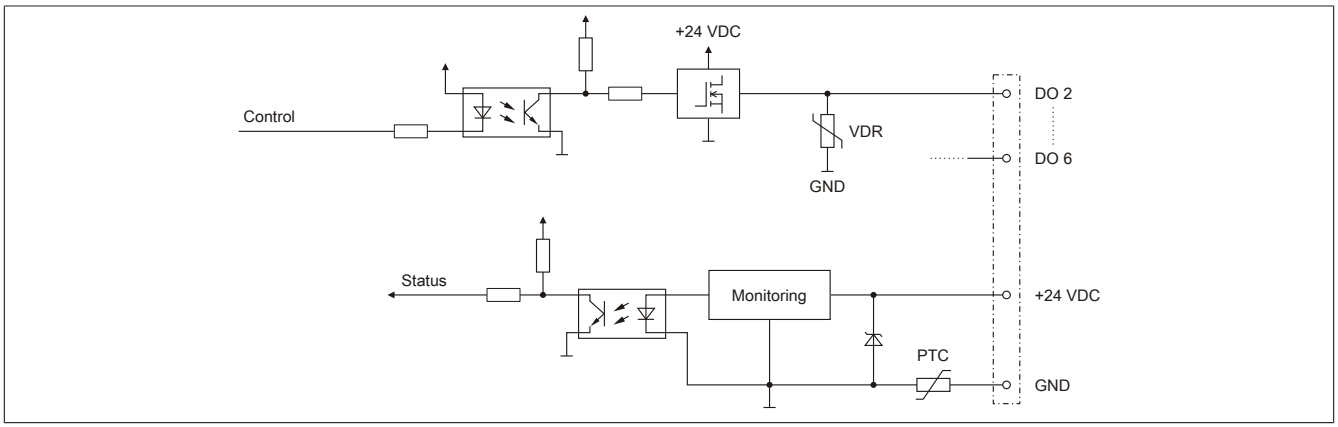
Function description of the digital outputs

Digital output	Description
DO1	This digital output is designed as a changeover contact switch. The monitoring relay allows selective monitoring of: • Overvoltage and undervoltage • Overfrequency and underfrequency • Voltage asymmetry • Current asymmetry • Calculated neutral conductor current (maximum) • Short circuit current • Rating-dependent overcurrent • Limit value of the capacitive reactive power (exciter failure)
DO2	DO2 serves as a meter output. The generated pulses can be recorded by an external energy meter (kWh).
DO3	This output is set when there is no voltage on the bus bar (below the lower limit of the defined parameter). 3-phase monitoring takes place for the bus bar voltage.
DO4	DO4 serves as a synchronization pulse. The power switch is activated by setting this output. The output is deactivated after the configured time has elapsed (exception: "Synchro check" operating mode).
DO5 and DO6	These outputs are freely available to the user.

DO1 - Output circuit diagram



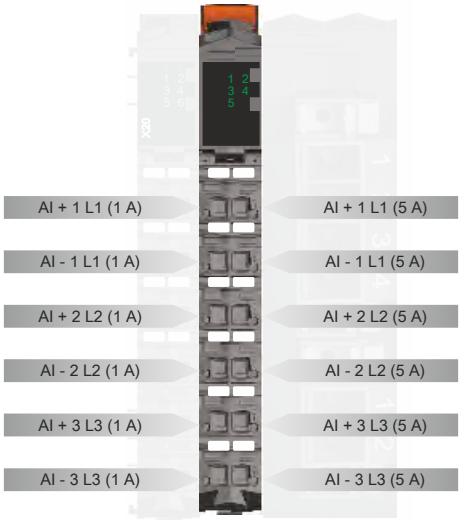
DO2 - DO 6 - Output circuit diagram



4.26.3.8 X2 analog current inputs

The X2 terminal measures the three phase currents of the generator mains using an externally connected current transformer. The measurement range of the current inputs can be configured as 1 A or 5 A.

The X1 and X2 terminals can each be keyed differently to prevent them from being inadvertently plugged into the module incorrectly.

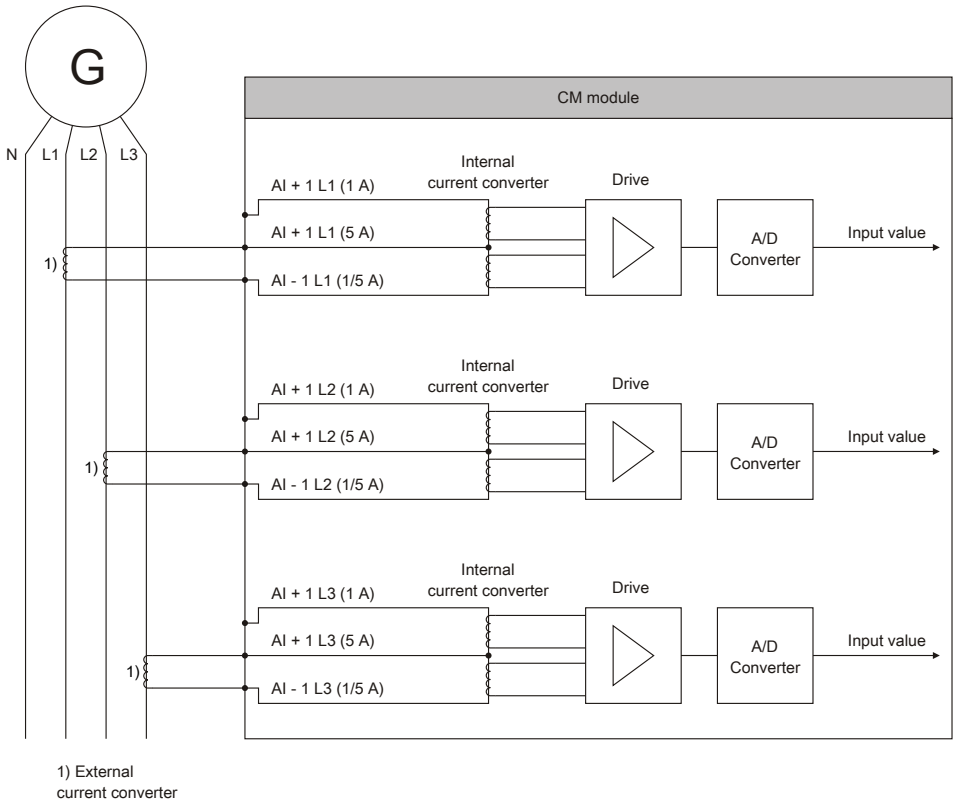


Danger!

Risk of electric shock!

The terminal block must only be allowed to conduct voltage when it is inserted. It must not under any circumstances be removed or inserted when voltage is applied or have voltage applied to it when it is removed.

Input circuit diagram - Analog current inputs

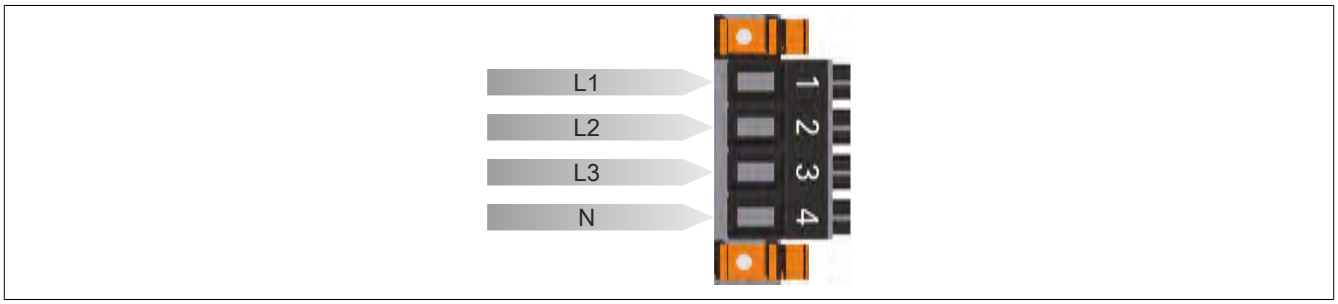


4.26.3.9 X3 and X5 analog voltage inputs

The X3 and X5 terminals are used to measure and monitor the line-to-line and phase voltages of the generator mains and bus bar.

- Terminal X3: Generator mains
- Terminal X5: Bus bar

The X3 and X5 terminals are each keyed differently to prevent them from being inadvertently plugged into the module incorrectly. Section 4.26.2.14 "Releasing the locking clip for terminals X3 - X6" describes how to release the terminal locking clip.

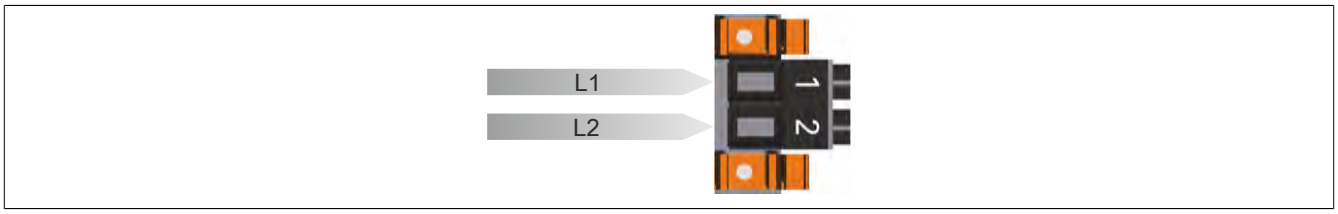


4.26.3.10 X4 and X6 analog voltage inputs

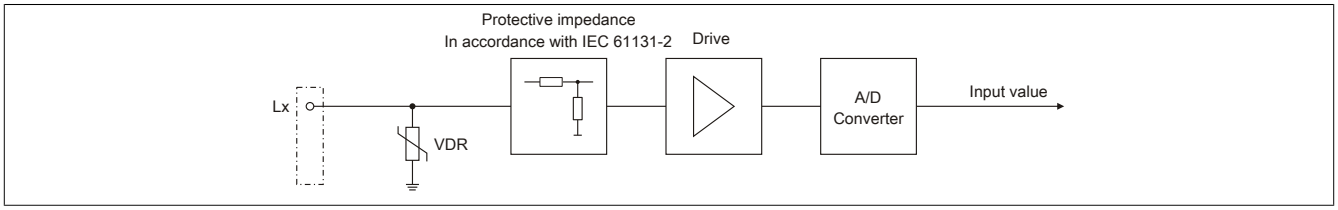
The voltage inputs on the X4 and X6 terminals are used to determine the line-to-line voltages for synchronization between two different mains networks.

- Terminal X4: Synchronization mains network 1
- Terminal X6: Synchronization mains network 2

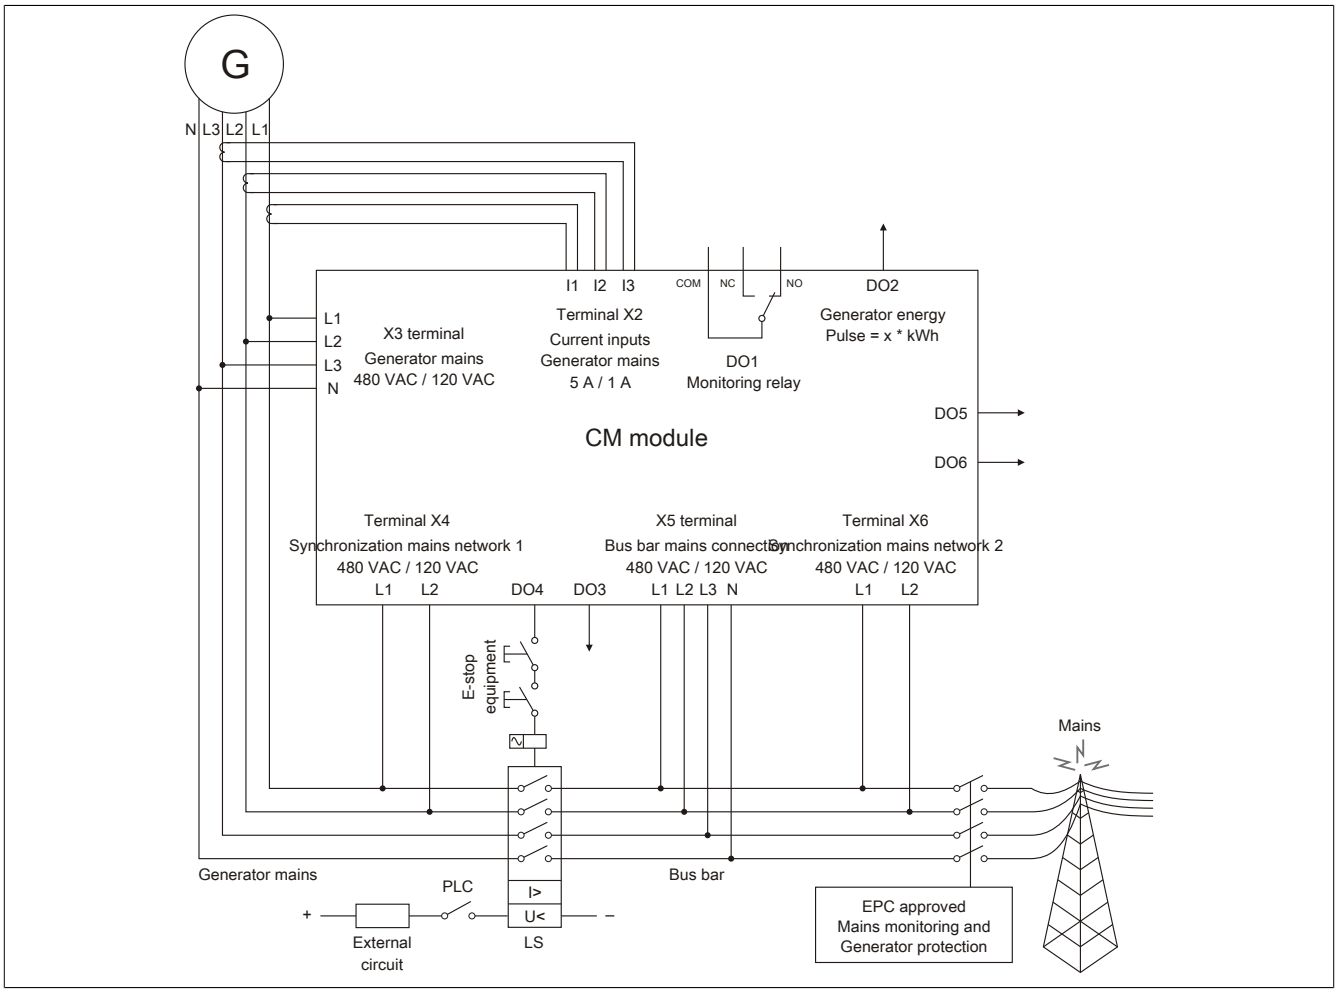
The X4 and X6 terminals are each keyed differently to prevent them from being inadvertently plugged into the module incorrectly. Section 4.26.2.14 "Releasing the locking clip for terminals X3 - X6" describes how to release the terminal locking clip.



Input circuit diagram, analog voltage inputs



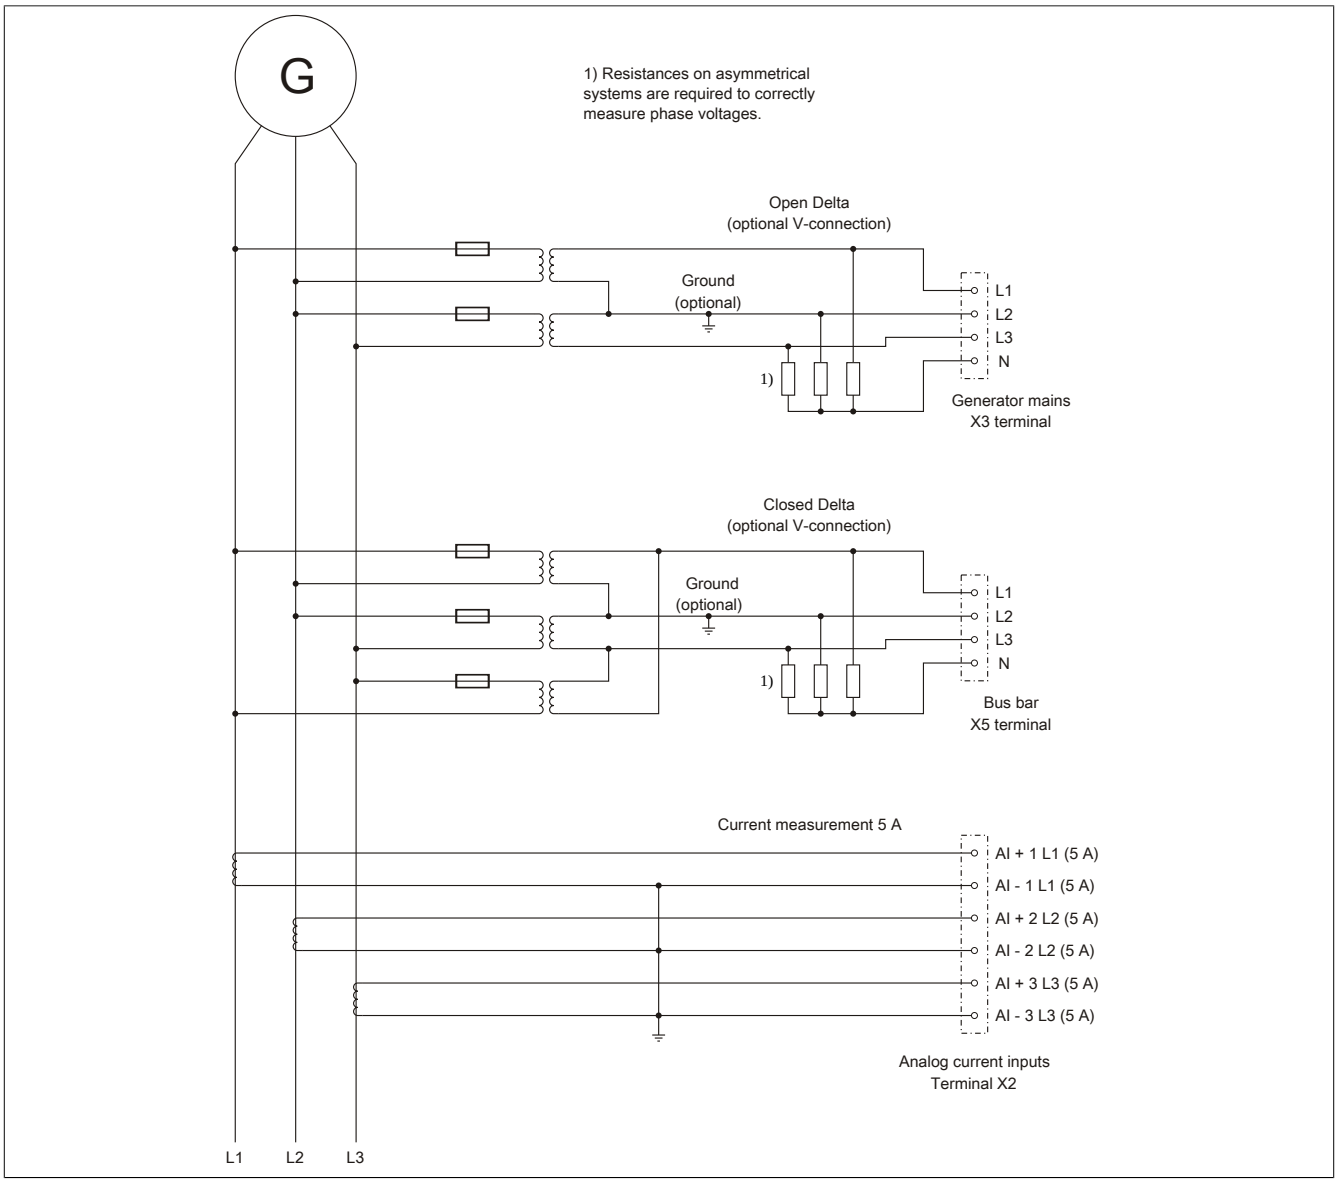
4.26.3.11 Circuit diagram



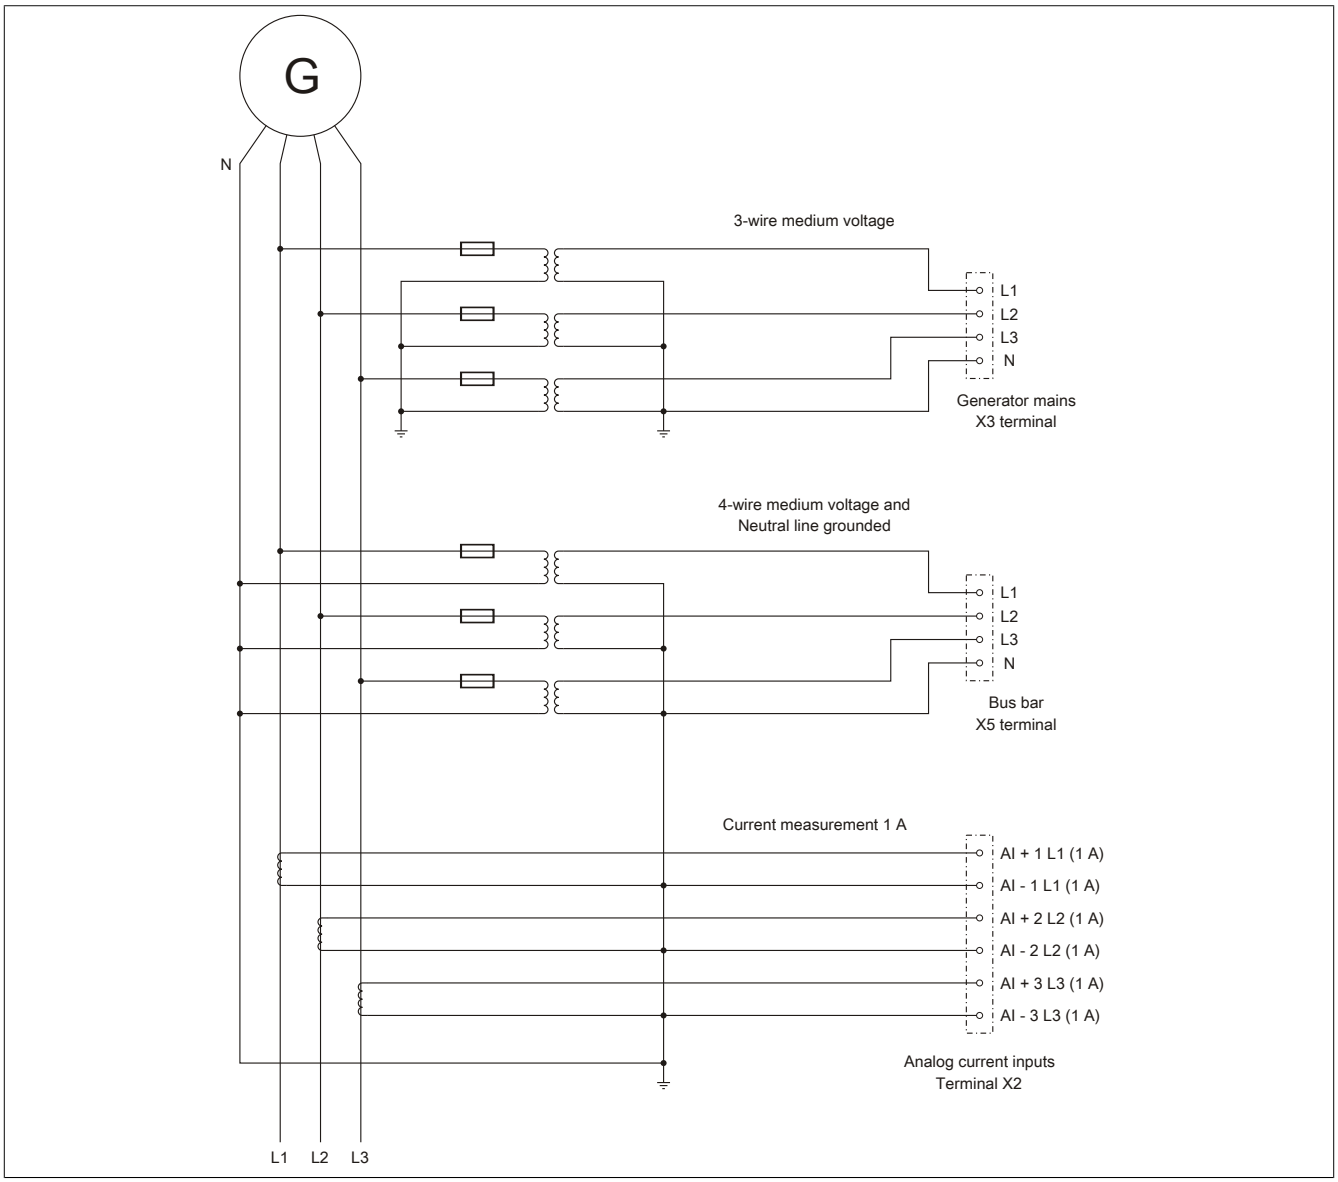
4.26.3.12 Typical connection examples for voltage/current measurement

For power measurement, the X3 terminal must always be used in connection with the X2 terminal! For single-phase measurement, always ensure that current input 1 is used for power measurement if voltage input 1 is being used. Otherwise, accurate power measurement is not possible for this phase!

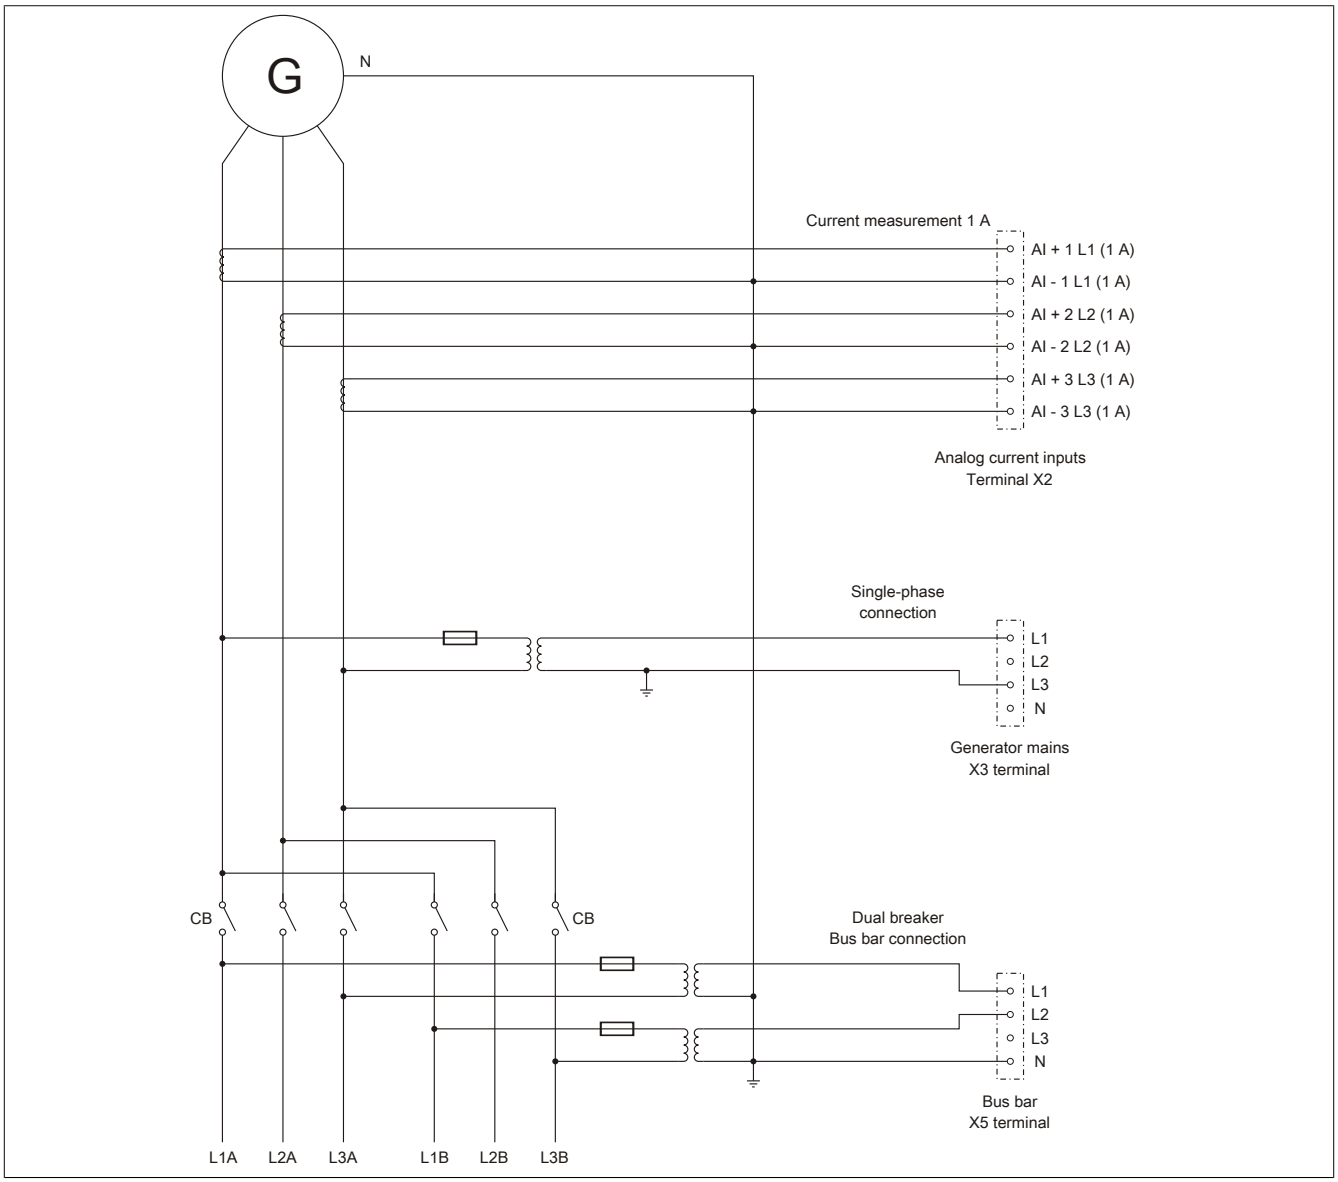
Connection example 1



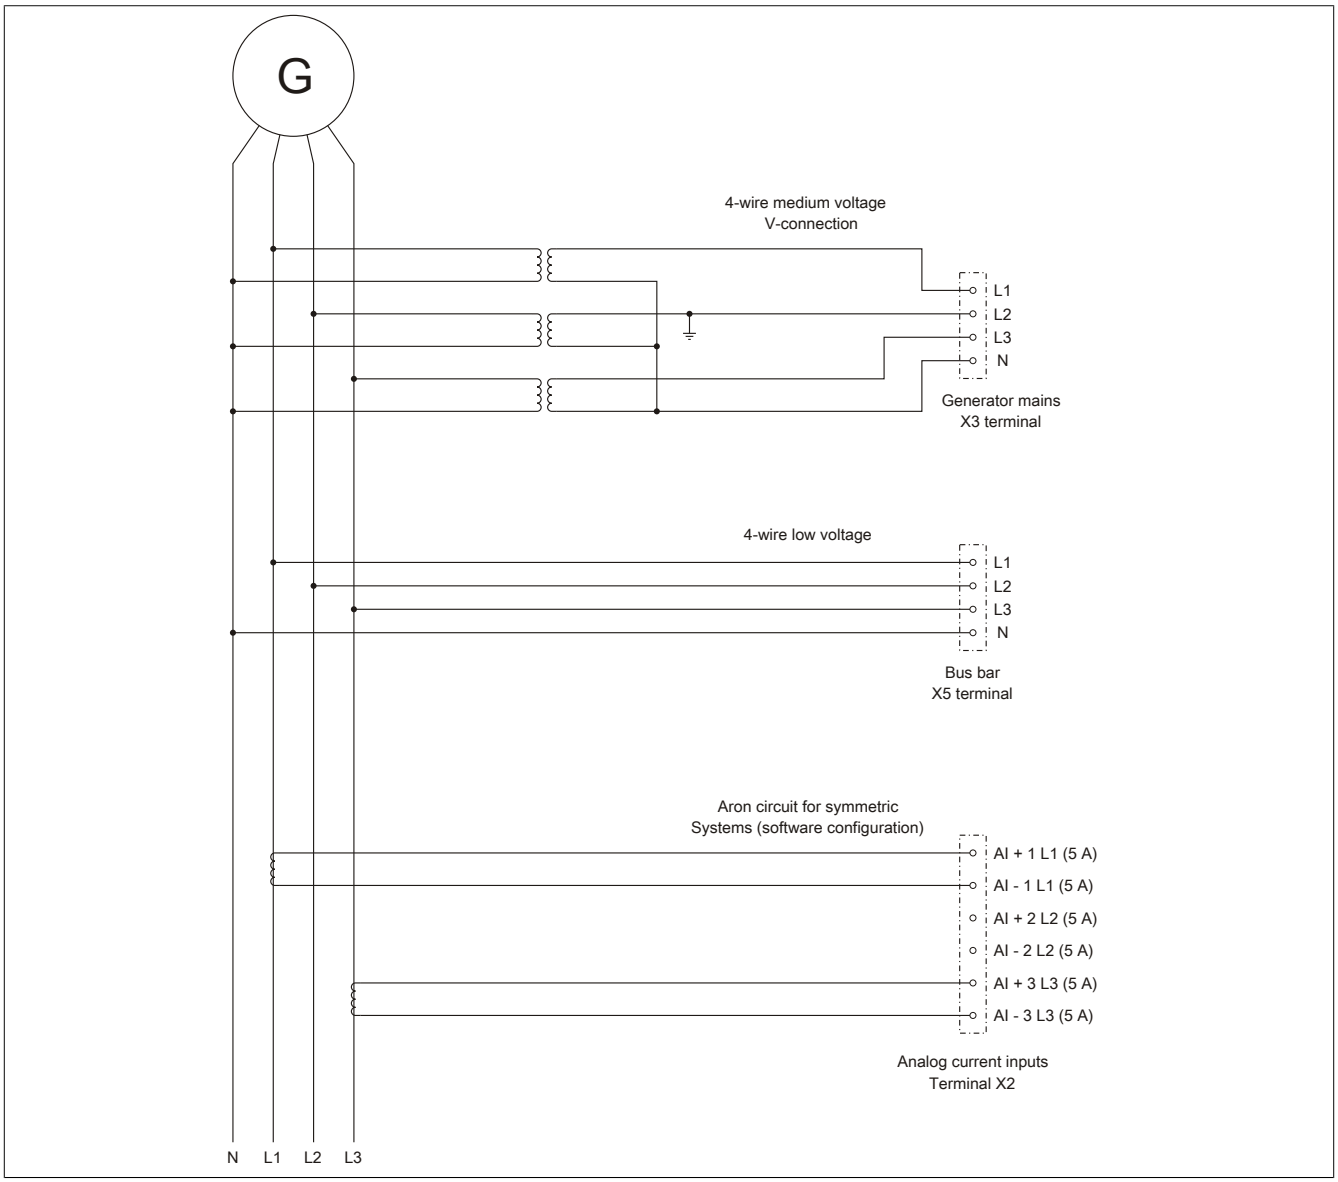
Connection example 2



Connection example 3

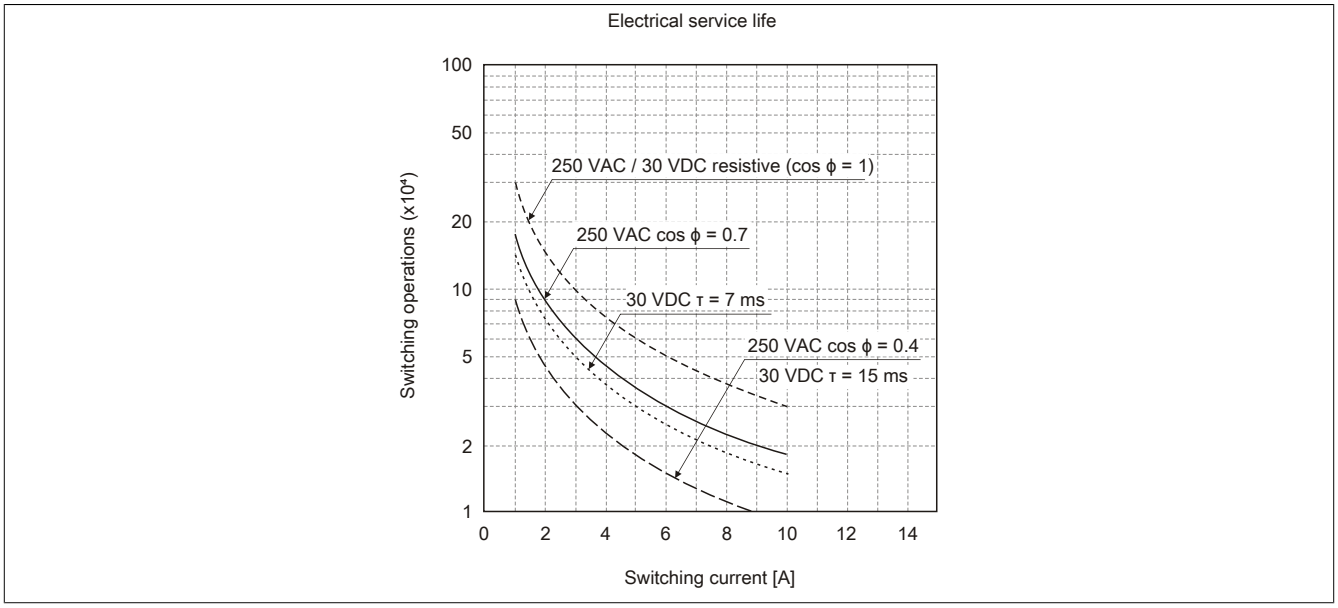


Connection example 4



4.26.3.13 Electrical service life

The electrical service life for the DO1 relay output can be seen in the following diagram.



4.26.3.14 Releasing the locking clip for terminals X3 - X6

Terminals X3 - X6 are equipped with a terminal locking clip. This clip attaches the terminal block securely to the electronic module. This prevents the terminal from accidentally being disconnected.

To release the locking clip, press inwards on the corrugated part of the lever with your fingertip (1) and then slide outwards (2). No additional tools are required for removing the terminal.

Terminals X5 and X6 must be removed first before terminals X3 and X4 can be removed.

4.26.3.15 Synchronization functions

The following three synchronization functions are available on the module:

- Synchronization with slip
- Synchro check
- Switching to voltage-free "dead bus"

Synchronization with slip

The following is valid for synchronization mains 1 and synchronization mains 2:

- 50% < U < 125% of the nominal voltage U_N
- 80% < f < 110% of the nominal frequency f_N

The generator voltage is adjusted to the synchronization voltage with regard to amplitude and frequency. Taking into account the configured phase angle (Δα), a defined transformer vector group and the switching response time, the switch-on command is calculated and transmitted in advance so that the main contacts of the power switch are closed at the point of synchronicity.

Synchronization occurs under the following conditions:

- The "Synchronization selection" command is set using a software application
- The device is ready.
- The configured limit for voltage difference is not exceeded (ΔU_{max}).
- The configured limits for frequency difference are not exceeded (Δf_{max} and Δf_{min}).
- The configured limit for the phase angle (including vector group transformer Δα) is not exceeded (j_{max}).

The actual synchronization is "authorized" if the condition for the phase angle is met the first time and the phase window is exited once. It should be noted that the conditions for voltage and frequency difference do not yet have to be fulfilled this first time.

This means that if the phase difference happens to lie within the phase window when the request is made, it is not necessary to re-enter the window for this "authorization" to take place. In order to abort synchronization when in an "authorized" state, the "Synchronization with slip" command must be reset.

After the synchronization command has been authorized, the synchronization window of all the aforementioned synchronization conditions must be entered again from any phase angle in order to obtain a synchronization impulse in accordance with the switch lead time.

At very low frequencies or equivalent frequencies and in adherence to the conditions described above, synchronization will also take place when entering the synchronization window a second time. The synchronization impulse is only issued at a phase angle = 0°, however.

At low differential frequencies, the switch is not immediately engaged when the phase window is reached. This only occurs when synchronization is possible at the point of synchronicity.

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

Synchro check

In this operating mode, the device can be used to check the synchronization. The DO4 output remains set as long as the following conditions are met:

- The "Enable Synchro Check" command is set using software.
- The device is ready.
- The configured limit for voltage difference is not exceeded (ΔU_{max}).
- The configured limits for frequency difference are not exceeded (Δf_{max} and Δf_{min}).
- The defined limit for the phase angle is not exceeded (ϕ_{max}).

DO4 stays at High as long as all conditions are met.

Switching to voltage-free "dead bus"

The switch-on command for the power switch is output without synchronization if the following conditions have been met:

- The "Enable Dead Bus" command is set using software.
- The device is ready.
- The bus bar does not have voltage applied: $U_B < U_{Bmin}$ as a percentage of U_{NomBus}

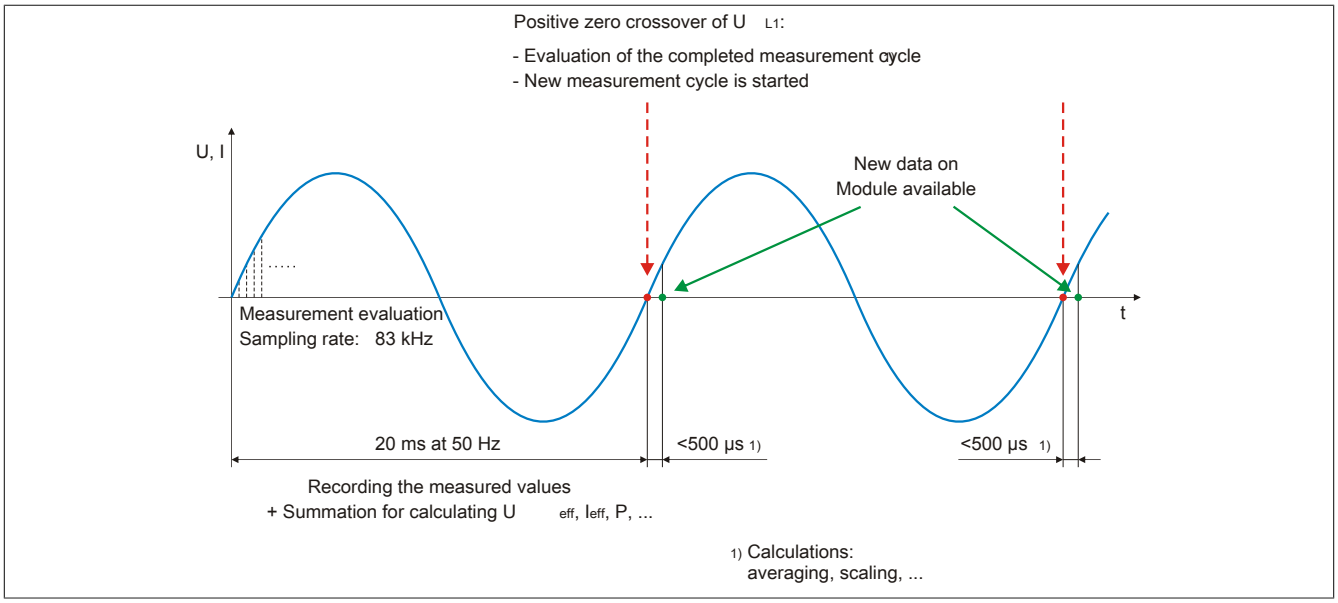
U_B ...	Bus bar phase voltage
U_{Bmin} ...	Minimum bus bar voltage
U_{NomBus} ...	Bus bar nominal voltage

- The generator voltage and frequency can be any valid value.

DO4 changes its state from Low to High when all conditions are met. It changes back from High to Low after the configured pulse duration has elapsed.

4.26.3.16 Measurement functions

Timing diagram



Measured parameters for generator mains (X3)

- Phase currents
- Current average
- Dynamic current average
- Neutral current
- Line-to-line voltages
- Phase voltages
- Voltage average
- Total apparent power
- Total reactive power
- Total active power
- Active power factor
- Frequency

Measured parameters between synchronization mains networks

- Differential angle
- Differential voltage

Rating-dependent overcurrent

Rating-dependent overcurrent monitoring is in accordance with the specifications of IEC 255-8 "Electrical relay; Relay for protecting against thermal overload (overload relay)" and IEC 255-17 "Electrical relay; Relay for protecting against the thermal overload of motors (overload relay for motors).

Dependent delayed imbalanced load monitoring

Dependent delayed imbalanced load monitoring protects against imbalanced loads in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An imbalanced load can be caused by uneven current distribution in the mains due to imbalanced load, asymmetrical short circuits, line interruptions or switching operations. Imbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An imbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an imbalanced load occurs, the characteristics that trigger imbalanced load protection should be adapted to the thermal characteristics of the generator. Imbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

Short circuit current monitoring

If overcurrent or a short circuit occurs and the limit value is exceeded, the error message "Overcurrent / Short circuit" is signaled after the configured time delay has passed.

Voltage asymmetry monitoring

The trigger value, which is adjustable by percentage, is always based on the respective average voltage of the linked generator voltages. This value defines the maximum permitted deviation of one of the three differential voltages between the three monitored, interlinked phase voltages.

If this value is exceeded in either direction, the error notification "Asymmetrical voltage" is indicated after the configured time delay has passed.

Bus bar voltage measurement and zero voltage monitoring

3-phase monitoring takes place for the bus bar voltage. The measured values are represented as phase-to-phase and phase-to-neutral values. The D03 output is set when there is no voltage (below the lower dead bus limit) on the bus bar (X5 terminal).

This monitoring can be used to determine which synchronization function should be used.

Synchronization function	Bus bar voltage measurement
Dead bus	No voltage is being supplied to the bus bar or the value is below the lower limit parameter. Output DO3 is set.
Synchronization with slip	The voltage measured on the bus bar is above the defined parameter value. Output DO3 is not set.

Exciter failure

The reactive power monitoring can be used to protect a generator against operating in the impermissible range. The capacitive reactive power monitor offers protection against under-excitation (exciter failure). If the lower limit is exceeded (in the negative direction), the error message "Exciter failure" is signaled after the configured time delay has passed.

4.26.3.17 Register description

4.26.3.17.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.3.17.2 Function model 0 - default

1) The offset specifies the position of the register within the CAN object.

4.26.3.17.3.1 CAN I/O bus controller

The module occupies 8 analog logical slots on CAN-I/O.

4.26.3.17.4 Configuration registers

4.26.3.17.4.1 Generator mains

Nominal voltage of generator mains (U_{NomGen})

Name:
ConfigOutput02

This is needed for converting the percentages based on this nominal value into physical units.

Data type	Value	Information	Resolution
UINT	70 to 65000	Corresponds to 70 to 65000 V	1 V

Nominal current of generator mains (I_{Nom})

Name:
ConfigOutput04

This is needed for converting the percentages based on this nominal value into physical units.

Data type	Value	Information	Resolution
UINT	0 to 65000	Corresponds to 0 to 65000 A	1 A

Multiplier for generator mains

Name:
ConfigOutput06

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

The value 100 corresponds to a multiplication factor of 1 (measured value not changed).

Data type	Value	Information	Resolution
UINT	1 to 65535	Corresponds to 0.01 to 655.35	0.01

Multiplier for current transformer

Name:
ConfigOutput09

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

Data type	Value	Information	Resolution
UINT	1 to 65535	Corresponds to 1 to 65535	1

Overvoltage limit of generator mains (U_{max})

Name:
ConfigOutput16

If the value of one of the linked generator voltages exceeds the value set here, then the "Overvoltage" error message (register "StatusInputPacked04") is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 2000	Corresponds to 0 to 200% of U_{NomGen}	0.1%

Nominal voltage range of generator mains

Name:
ConfigOutput20

Can be toggled between 100 and 400 V.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Voltage	0	100 V
		1	400 V
1 - 7	Reserved	-	

Nominal current range of the generator mains

Name:
ConfigOutput24

Can be toggled between 1 and 5 A.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Current range	0	1 A
		1	5 A
1 - 7	Reserved	-	

Aron circuit

Name:
ConfigOutput25

Switch to power measurement principle of Aron circuit.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Aron circuit	0	Disabled: Three-phase supply with neutral line
		1	Enabled: Three-phase supply without neutral line
1 - 7	Reserved	-	

Undervoltage limit of generator mains (U_{min})

Name:
ConfigOutput27

If the value of one of the linked generator voltages falls below the value set here, then the "Undervoltage" error message (register "Error register") is indicated after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 2000	Corresponds to 0 to 200% of U_{NomGen}	0.1%

Low-pass filter for total power ratings

Name:
ConfigOutput41

Parameter for the response time of the low-pass filter of the total power values P, Q and S. The maximum total power values are recorded independently of this without being filtered.

This parameter is used as a delay element so that current or voltage fluctuations have less effect on how the calculated power values are represented. The damping behavior of the low-pass filter acts in accordance with the configurable time constant of a decaying e-function.

Data type	Value	Information	Resolution
UINT	0 to 300	Corresponds to 0 to 300 ms	1 ms

4.26.3.17.4.2 Generator monitoring

Nominal frequency (f_{Nom})

Name:
ConfigOutput10

This is needed for converting the percentages based on this nominal value into physical units.

Data type	Value	Information	Resolution
UINT	480 to 620	corresponds to 48 to 62 Hz.	0.1 Hz

Response time for generator overvoltage (U_{max})

Name:
ConfigOutput26

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	Corresponds to 0.5 to 10 s	0.1 s

Response time for generator undervoltage (U_{min})

Name:
ConfigOutput28

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	Corresponds to 0.5 to 10 s	0.1 s

Generator over-frequency (f_{max})

Name:
ConfigOutput29

If the value of the generator frequency exceeds the percentage of the nominal frequency set here, then the error message "Overfrequency" is indicated (register "Error register") and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for generator over-frequency (f_{max})

Name:
ConfigOutput30

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 for 10 s	0.1 s

Generator under-frequency (f_{min})

Name:
ConfigOutput31

If the value of the generator frequency falls below the percentage of the nominal frequency set here, then the error message "Underfrequency" is indicated (register "Error register") and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 2000	For 0 to 200% of f_{Nom}	0.1%

Response time for generator under-frequency (f_{min})

Name:
ConfigOutput32

The error is only triggered if the response value is exceeded in the negative direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Generator voltage asymmetry (U_{as})

Name:
ConfigOutput33

The trigger value, which is adjustable by percentage, is always based on the respective average voltage of the linked generator voltages. If the value of the voltage difference exceeds or falls below the value set here, then the "Voltage asymmetry" error message is indicated (register "Error register") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 300	For 0 to 30% of U~3average	0.1%

Response time for generator voltage asymmetry (U_{as})

Name:
ConfigOutput34

This error is triggered only if the response value is exceeded without interruption (in either the positive or negative direction) for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Load time constant for current asymmetry

Name:
ConfigOutput35

The dependent delayed unbalanced load monitoring function continually monitors the AC currents coming from the main current converters and continually calculates the present unbalanced load current. This is compared with the threshold value, which is calculated using the load time constants. If this threshold value is exceeded, the error message "Current asymmetry" is indicated (register "Error register") and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.1 to 6553.5 s	0.1 s

Dependent delayed unbalanced load monitoring

Unbalanced load monitoring protects against unbalanced load in three-phase generators and three-phase mains. Parameters can be changed to make it possible to match the trigger characteristics to different generator types while taking their special thermal time constants into consideration.

An unbalanced load can be caused by uneven current distribution in the mains due to unbalanced load, asymmetrical short circuits, line interruptions or switching operations. Unbalanced loads result in reverse system currents in the stator, which causes harmonics with an uneven ordinal number in the stator winding and harmonics with an even ordinal number in the rotor winding. The rotor is at particular risk here because the harmonic waves place an additional load on the rotor winding and induce eddy currents in the rotor's solid iron, which may melt the metal or destroy the metallic structure.

An unbalanced load can be permissible within certain limits, however, when accounting for the thermal load limit of the generator. To avoid premature failure of the generator when an unbalanced load occurs, the characteristics that trigger unbalanced load protection should be adapted to the thermal characteristics of the generator. Unbalanced load protection can also be triggered by external errors in the mains caused by asymmetric short circuits.

When unbalanced load protection is tripped can be calculated using the following formula:

Operating mode	Formula
Short-term operation	$t = \frac{K1}{\frac{2}{(\frac{I_2}{I_{Nom}}) - 0.08^2}}$
Continuous operation	$\frac{I_2}{I_{Nom}} \leq 0.08 \rightarrow t = \infty$

Key	
t	Calculated tripping time
K1	Valid load time constant for the generator [s]
I_2	Calculated inverse current / unbalanced load current [A]
I_{Nom}	Nominal current for the generator [A]

To calculate the tripping time instant, the scan duration of the measurement system (i.e. 20 ms for 50 Hz voltage) is divided by the calculated trigger time, and the results are continually added up. With short-term operation, the value of the summands increases; with continuous operation, it decreases. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

Information:

The boundary between continuous operation and short-term operation is always 0.08 for calculations.

When the generator is at a standstill, the summand is neither reset nor is its value reduced.

Maximum limit of neutral conductor current

Name:
ConfigOutput36

Configurable limit for the neutral conductor current. If the value is exceeded, then the error message "Maximum neutral conductor current" is indicated (register "Error register") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of I_{Nom}	0.1%

Response time for neutral conductor current monitor

Name:
ConfigOutput37

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

Short circuit current

Name:
ConfigOutput38

If the value of the generator current exceeds the percentage based on the converter's nominal current set here, then the error message "Short circuit current" is indicated (register "Error register") and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	1000 to 5000	For 100 to 500% of I_{Nom}	0.1%

Response time for short circuit current

Name:
ConfigOutput39

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	4 to 30	For 0.04 to 0.3 s	0.01 s

Rating-dependent overcurrent

Name:
ConfigOutput42

The response value percentage is based on the nominal current of the generator. If the response value is exceeded, then the error message "Rating-dependent overcurrent" is indicated (register "Error register") and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
UINT	1000 to 2000	For 100 to 200% of I_{Nom}	0.1%

Rating-dependent overcurrent monitoring

A generator that is operated at its nominal current I_{Nom} normally reaches about half of its maximum thermal load. Operating it above the rated current I_{Nom} result in additional warming, which is permitted until the maximum temperature is reached. The highest permissible continuous temperature is determined by the class of the insulation material used in the generator.

Based on the settings and the current measurement, the device forms an internal model based on an I^2t characteristic curve of the generator temperature. This allows the heat capacity of the generator to be completely utilized for short overloads while at the same time providing full protection. The configurable parameters for determining the machine model include the nominal current I_{Nom} of the generator and the time multiplier.

Integration coefficient for rating-dependent overcurrent (iths)

Name:
ConfigOutput43

To calculate the tripping time instant, the sampling duration of the measurement system is divided by the calculated trigger time (t). The results are continually added up. If the summand reaches the value 1 (100%), then the max. permitted value has been reached. The summand is limited between 0 and 1.

Data type	Value	Information	Resolution
UINT	1 to 20	For 0.1 to 2	0.1

For a constant overcurrent, the trigger characteristic curve can be calculated based on the following formula:

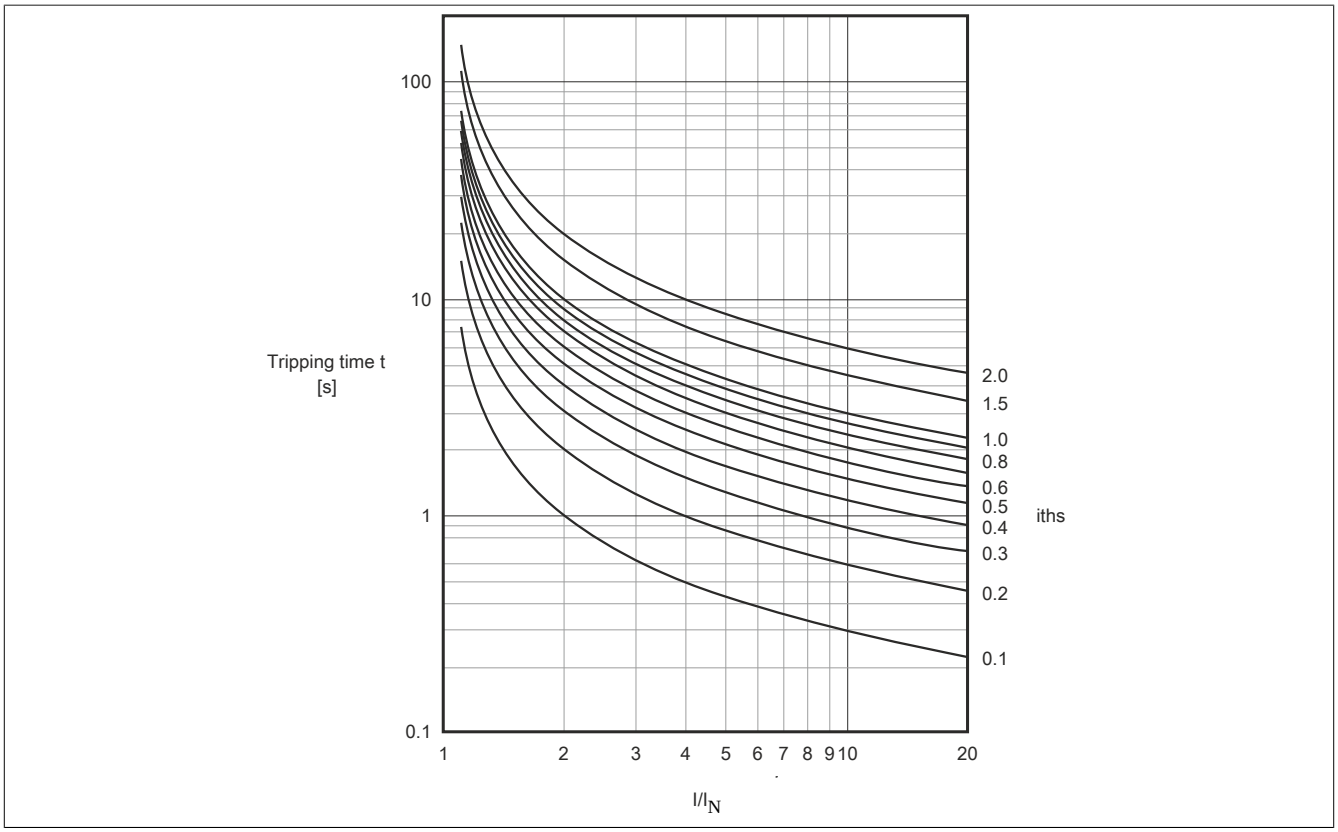
$$t = \frac{0.14}{(\frac{I}{I_N})^{0.02} - 1} * iths$$

Key:

t	Tripping time [s]
I	The highest value of the 3 phase currents [A]
I_N	Rating-dependent overcurrent [A] (0.5 to 2 * I_{Nom})
iths	Integration coefficient (0.1 to 2)

The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Trigger characteristic curve in accordance with IEC 255-4 (normal, inverse)



The monitor function can be reset by restarting the module or by falling below the overcurrent value so that the results of the continuous addition decrease according to the formula.

Capacitive reactive power

Name:
ConfigOutput44

The capacitive reactive power for the generator is monitored to determine if it falls below the defined response value. In this way, monitoring the capacitive reactive power can be used to detect exciter failure. If the response value is fallen below, then the error message "Capacitive reactive power" is indicated (register "Error register") after the delay time has passed and, if configured, the DO1 monitoring relay is switched.

Data type	Value	Information	Resolution
INT	-32768 to 32767	For -32768 to 32767 kvar	1 kvar

Response time for reactive power monitoring

Name:
ConfigOutput45

The error is only triggered if the response value is exceeded in the positive direction without interruption for as long as is specified in this register.

Data type	Value	Information	Resolution
UINT	5 to 100	For 0.5 to 10 s	0.1 s

DO1 function

Name:
ConfigOutput57

This digital output can be set after the defined response time has elapsed depending on the assignment of the generator mains' monitoring variables (X3).

The monitoring variables can be assigned to this input either individually or with additional monitoring variables using an OR connective. This makes it possible to set the relay when there are multiple monitoring variables.

The following monitoring functions can be assigned to the monitoring relay using this register:

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Overvoltage (of a phase)	0	Do not assign function
		1	Assign function
1	Undervoltage (or a phase)	0	Do not assign function
		1	Assign function
2	Overfrequency	0	Do not assign function
		1	Assign function
3	Underfrequency	0	Do not assign function
		1	Assign function
4	Voltage asymmetry	0	Do not assign function
		1	Assign function
5	Current asymmetry (unbalanced load)	0	Do not assign function
		1	Assign function
6	Neutral conductor current, maximum	0	Do not assign function
		1	Assign function
7	Short circuit current	0	Do not assign function
		1	Assign function
8	Rating-dependent overcurrent	0	Do not assign function
		1	Assign function
9	Capacitive reactive power (exciter failure)	0	Do not assign function
		1	Assign function
10	Ready	0	Do not assign function
		1	Assign function
11 - 15	Reserved	0	

Information:

The minimum pulse duration when addressing a monitoring function on the error bit via X2X as well as on the relay is 500 ms.

4.26.3.17.4.3 Busbar

Busbar nominal voltage (U_{NomBus})

Name:
ConfigOutput03

This is needed for converting the percentages based on this nominal value into physical units.

Data type	Value	Information	Resolution
UINT	70 to 65000	For 70 to 65000 V	1 V

Multiplier for busbar

Name:
ConfigOutput05

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 thus means a multiplier factor of 1 (measured value not changed).

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.01 to 655.35	0.01

Nominal voltage range of busbar

Name:
ConfigOutput21

Can be toggled between 100 and 400 V.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Voltage	0	100 V
		1	400 V
1 - 7	Reserved	-	

Minimum busbar voltage (U_{Bmin})

Name:
ConfigOutput40

Configurable threshold for zero voltage monitoring of the busbar based on its nominal voltage. DO3 is set if the value falls below the configured threshold.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of U_{NomBus}	0.1%

4.26.3.17.4.4 Synchronization

Synchronization mode

Name:
ConfigOutput
ConfigOutput17 to ConfigOutput19

If multiple mode bits are set at the same time, then no mode will be selected (type BOOL).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	ConfigOutput17	0	Sync mode ≠ Slip
		1	Sync mode = Slip
1	ConfigOutput18	0	Sync mode ≠ Check
		1	Sync mode = Check
2	ConfigOutput19	0	Sync mode ≠ Dead bus
		1	Sync Mode = Dead bus
3 - 7	Reserved	-	

Nominal voltage of synchronization mains (U_{NomSyn})

Name:
ConfigOutput01

This is needed for converting the percentages based on this nominal value into physical units.

Data type	Value	Information	Resolution
UINT	70 to 65000	For 70 to 65000 V	1 V

Multiplier for synchronization mains

Name:
ConfigOutput07 (mains 1)
ConfigOutput08 (mains 2)

This is used for converting the measured value into a physical value. The multiplier is applied to the respective input value.

100 means a multiplier factor of 1 (measured value not changed).

Data type	Value	Information	Resolution
UINT	1 to 65535	For 0.01 to 655.35	0.01

Max. differential frequency (df_{max})

Name:
ConfigOutput11

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded. This value specifies the upper frequency (positive value corresponds to positive slip → generator frequency is greater than the busbar frequency when synchronizing).

Data type	Value	Information	Resolution
UINT	2 to 49	For 0.02 to 0.49 Hz	0.01 Hz

Min. differential frequency (df_{min})

Name:
ConfigOutput12

A switch-on command on DO4 is only output if this configured differential frequency is not exceeded in the negative direction. This value specifies the lower frequency (negative value corresponds to negative slip → generator frequency is less than the busbar frequency when synchronizing).

Data type	Value	Information	Resolution
INT	-49 to 0	For -0.49 to 0 Hz	0.01 Hz

Max. differential voltage (dU_{max})

Name:
ConfigOutput13

A switch-on command on DO4 is only output if this configured differential voltage percentage based on the synchronization mains' nominal voltage is not exceeded.

Data type	Value	Information	Resolution
UINT	1 to 300	For 0.1 to 30% of U_{NomSyn}	0.1%

Max. permitted differential angle (ϕ_{Max})

Name:
ConfigOutput14

A switch-on command on DO4 is only output if the configured differential angle between the two synchronization mains is not exceeded.

Data type	Value	Information	Resolution
UINT	1 to 600	For 0.1 to 60°	0.1°

Phase rotation of sync mains 1 (dα)

Name:
ConfigOutput15

This parameter is used for correcting any phase shifting from upstream transformer vector groups before reaching the mains being synchronized.

This parameter specifies how many degrees the synchronization mains lags behind the mains being synchronized.

Data type	Value	Information	Resolution
UINT	0 to 3600	For 0 to 360°	0.1°

Nominal voltage range of synchronization mains

Name:
ConfigOutput22 (mains 1)
ConfigOutput23 (mains 2)

Can be toggled between 100 and 400 V.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Voltage	0	100 V
		1	400 V
1 - 7	Reserved	-	

Pulse duration of the turn-on delay

Name:
ConfigOutput47

The duration of the switch-on pulse can be adjusted for the following switching units. The time set here is valid for the switch-on pulse for DO4.

Data type	Value	Information	Resolution
UINT	40 to 500	For 0.04 to 0.5 s	0.001 s

Switching response time of the power switch

Name:
ConfigOutput48

The actuation time of the generator power switch corresponds to the lead time of the switch-on command. The switch-on command is executed before the point of synchronization according to the amount of time defined here.

Data type	Value	Information	Resolution
UINT	40 to 300	For 0.04 to 0.3 s	0.001 s

Synchronization configuration

Name:
ConfigOutput56

Parameter for configuring which mains or voltages should be synchronized with each other.

This configuration makes it possible to synchronize the AC mains on terminal X4 either with terminal X3, X5 or X6. In each case, synchronization mains 1 (X4) is the network to which synchronization takes place.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Synchronization	00	X4 - X6: Synchronization mains 1 - Synchronization mains 2
		01	X4 - X5: Synchronization mains 1 - Busbar
		10	X4 - X3: Synchronization mains 1 - Generator
		11	Reserved
2 - 15	Reserved	-	

Dead bus voltage

Name:
ConfigOutput58

Configurable threshold for dead bus synchronization based on the nominal voltage of the busbar.

Data type	Value	Information	Resolution
UINT	0 to 1000	For 0 to 100% of U_{NomBus}	0.1%

4.26.3.17.4.5 Maximum value buffer and power meter

Pulse value of energy meter output

Name:
ConfigOutput46

Output DO2 outputs pulses that occur at a frequency proportional to the measured energy. The frequency of the pulses can be specified. The length of the pulse is 400 ms. The frequency at which the pulses occur should be set so that the duration between two pulses does not exceed 400 ms at the highest possible power. The pulse output's internal meter starts at 0 kWh after a restart. This register has no effect on the "ConfigOutput54" and "ConfigOutput55" registers.

Data type	Value	Information	Resolution
UINT	0 to 65535	For 0 to 65535 kWh/pulse	1 kWh/pulse

Maximum value buffer and meter buffer

These registers are used for nonvolatile storage of the maximum value and meter level values. After restarting, the stored maximum values and meter states are loaded back into their registers and the module's internal work meter is reset. It is possible to reset or write to the stored maximum values and meter states using an acyclic register.

The maximum values are recorded by the effective measured values before reaching the configurable filter. The maximum values can be read or written to as acyclic registers.

Maximum phase current

Name:
Reading: ConfigOutput49 (generator I1)
Reading: ConfigOutput50 (generator I2)
Reading: ConfigOutput51 (generator I3)
Reset: ConfigOutput60 (generator I1)
Reset: ConfigOutput61 (generator I2)
Reset: ConfigOutput62 (generator I3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Maximum total active power

Name:
Reading: ConfigOutput52
Reset: ConfigOutput63

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 kW

Maximum neutral conductor current

Name:
Reading: ConfigOutput53
Reset: ConfigOutput64

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Active energy counter

Name:
Reading: ConfigOutput54
Writing: ConfigOutput66

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	100 kWh

Reactive energy counter

Name:
Reading: ConfigOutput55
Writing: ConfigOutput67

Data type	Value	Information	Resolution
DINT	-2,147,483,648 to 2,147,483,647	-	100 kvarh

4.26.3.17.5 Communication registers

4.26.3.17.5.1 General registers

Digital outputs

Name:
DigitalOutput
DigitalOutput05
DigitalOutput06

(data point applied as BOOL)

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalOutput05	0	Reset output 5
		1	Set output 5
1	DigitalOutput06	0	Reset output 6
		1	Set output 6

Status of digital outputs

Name:
StatusDigitalOutput01 to StatusDigitalOutput06
StatusInput16 to StatusInput17

(data point applied as BOOL)

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusDigitalOutput01	0	Current state of output 1 = LOW
		1	Current state of output 1 = HIGH
1 - 7	Reserved	-	
8	StatusDigitalOutput02	0	Current state of output 2 = LOW
		1	Current state of output 2 = HIGH
...		...	
12	StatusDigitalOutput06	0	Current state of output 6 = LOW
		1	Current state of output 6 = HIGH
13	Reserved	-	
14	StatusInput17	0	Status DO OK
		1	Status DO overload
15	StatusInput16	0	Status 24 V output supply OK
		1	Status 24 V output supply undervoltage

Error registers

Name:
StatusInput18
StatusInput01 to StatusInput15

This register contains status inputs (type BOOL).

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusInput01	0	Overvoltage (one phase), OK
		1	Overvoltage (one phase), present
1	StatusInput02	0	Undervoltage (one phase), OK
		1	Undervoltage (one phase), present
2	StatusInput03	0	Over-frequency, OK
		1	Over-frequency, present
3	StatusInput04	0	Under-frequency, OK
		1	Under-frequency, present
4	StatusInput05	0	Voltage asymmetry, OK
		1	Voltage asymmetry, present
5	StatusInput06	0	Current asymmetry, OK
		1	Current asymmetry, present
6	StatusInput07	0	Maximum neutral conductor current, OK
		1	Maximum neutral conductor current exceeded
7	StatusInput08	0	Short circuit-current, OK
		1	Short circuit-current, present
8	StatusInput09	0	Rating-dependent overcurrent OK
		1	Rating-dependent overcurrent occurring
9	StatusInput10	0	Capacitive reactive power (exciter failure), OK
		1	Capacitive reactive power (exciter failure), present
10	StatusInput11	0	Ready, OK
		1	Not ready
11	StatusInput12	0	Generator mains phase 1 OK
		1	Failure of generator mains phase 1
12	StatusInput13	0	Busbar phase 1 OK
		1	Busbar phase 1 failure
13	StatusInput14	0	Phase 1 sync mains 1 OK
		1	Phase 1 sync mains 1 failure
15	StatusInput15	0	Phase 1 sync mains 2 OK
		1	Phase 1 sync mains 2 failure
15	Reserved	-	

StatusInput11

The error message "Not ready" is triggered if the X20 I/O supply drops below 18 VDC.

StatusInput

(StatusInput12 to StatusInput 14)

Phase failure is detected if phase 1 of the respective terminal fails.

If this error occurs, it will mean losses in measurement precision.

4.26.3.17.5.2 Generator mains measured values

Phase currents of the generator

Name:
AnalogInput01 (I1)
AnalogInput02 (I2)
AnalogInput03 (I3)

Phase currents of the generator

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Current average of generator I1, I2, I3

Name:
AnalogInput04

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Neutral conductor current of generator I_n

Name:
AnalogInput05

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 A

Dynamic current average of generator (I_{m_dyn})

Name:
AnalogInput06

Describes the change to the current average.

The dynamic average is the amount of change (I_{m_diff}) of the current average (sampling time: 10 ms).

This value decays in an e-function.

$I_{m\_diff} > I_{m\_dyn} \rightarrow I_{m\_dyn} = I_{m\_diff}$

$I_{m\_diff} \leq I_{m\_dyn} \rightarrow I_{m\_dyn} = I_{m\_dyn} * 0.98$

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	1 A

Line-to-line voltages of the generator

Name:
AnalogInput07 (UG12)
AnalogInput08 (UG23)
AnalogInput09 (UG31)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Phase voltages of the generator

Name:
AnalogInput10 (UG 1)
AnalogInput11 (UG 2)
AnalogInput12 (UG 3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Generator power: Total active power P

Name:
AnalogInput19

Filtered generator power values:

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 kW

Generator power: Total reactive power Q

Name:
AnalogInput20

Filtered generator power values:

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 kvar

Generator power: Total apparent power S

Name:
AnalogInput21

Filtered generator power values:

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 kVA

Voltage average of the generator

Name:
AnalogInput22

Voltage average of the generator UG12, UG23, UG31 (U~3 average)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Power factor of generator/cos ϕ

Name:
AnalogInput23

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	0.001

Frequency of the generator mains

Name:
AnalogInput24

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

4.26.3.17.5.3 Busbar measured values

Line-to-line voltages of the busbar

Name:
AnalogInput13 (UB12)
AnalogInput14 (UB23)
AnalogInput15 (UB31)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Phase voltages of the busbar

Name:
AnalogInput16 (UB1)
AnalogInput17 (UB2)
AnalogInput18 (UB3)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

4.26.3.17.5.4 Synchronization mains measured values

Line-to-line voltages

Name:
AnalogInput25 (sync mains 1 US1)
AnalogInput26 (sync mains 2 US2)

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

Frequencies

Name:
AnalogInput27 (sync mains 1)
AnalogInput28 (sync mains 2)

Data type	Value	Information	Resolution
UINT	0 to 65,535	-	0.01 Hz

Differential angle between synchronization mains

Name:
AnalogInput29

Angular difference between the mains being synchronized

Specifies how many degrees the sync mains are ahead of the mains being synchronized.

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	0.1°

Differential voltage between synchronization mains

Name:
AnalogInput30

Voltage difference between the mains being synchronized

Data type	Value	Information	Resolution
INT	-32768 to 32767	-	1 V

4.26.3.17.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
≥ 250 µs

4.26.3.17.7 Minimum I/O update time

The minimum I/O update time for the analog inputs depends on the respective period duration of the measurement signal frequency.

Minimum I/O update time	
At 50 Hz	20 ms

Table 585: X20CM4810 - Order data

4.26.4.2 Technical data

Information:

The X20CM4810 module is only supported by Automation Studio 3.0.90.x and Automation Runtime versions >= J3.09, J4.01 and O4.02.

4.26.4.2.1 Technical data

Product ID	X20CM4810
Short description	
I/O module	X20 4-channel analog input module for vibration measurement and analysis of condition monitoring tasks
General information	
Isolation voltage between channel and bus	500 V_{eff}
Nominal voltage	24 VDC ±20%
B&R ID code	0xC8F9
Status indicators	Run, error, vibration inputs 1 to 4
Diagnostics	
Module run/error	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	2.5 W
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
GOST-R	Yes
Analog inputs	
Quantity	4
Input type	IEPE sensor: Acceleration
Digital converter resolution	24-bit

Table 586: X20CM4810 - Technical data

Product ID	X20CM4810
Open line detection	
Per channel	Yes
At minimum supply voltage [1]	17 V (or higher) for more than 1 ms
At nominal supply voltage [2]	21.3 V (or higher) for more than 1 ms
At maximum supply voltage [3]	25.5 V (or higher) for more than 1 ms
Permitted input signal	±10 VAC
Conversion procedure	Sigma Delta
Type	Vibration input
Sampling frequency	51.5625 kHz
Input high pass cutoff frequency	34 mHz
Input low pass cutoff frequency	19.75 kHz
Downsampling	200 Hz, 500 Hz, 1 kHz, 2 kHz, 5 kHz, 10 kHz (configurable)
Frequency resolution of the spectrums	0.0629 Hz, 0.1574 Hz, 0.3147 Hz, 0.6294 Hz, 1.5736 Hz, 3.1471 Hz
Sensor supply	IEPE, 5 mA constant current source (4.9 - 5.5 mA), can be switched off for each channel
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at altitudes above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 50°C
Vertical installation	-25 to 45°C
Derating	See section "Derating"
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM31 bus module separately
Spacing	25 $^{+0.2}$ mm

1) Input voltage: 19.2 V
2) Input voltage: 24 V
3) Input voltage: 28.8 V

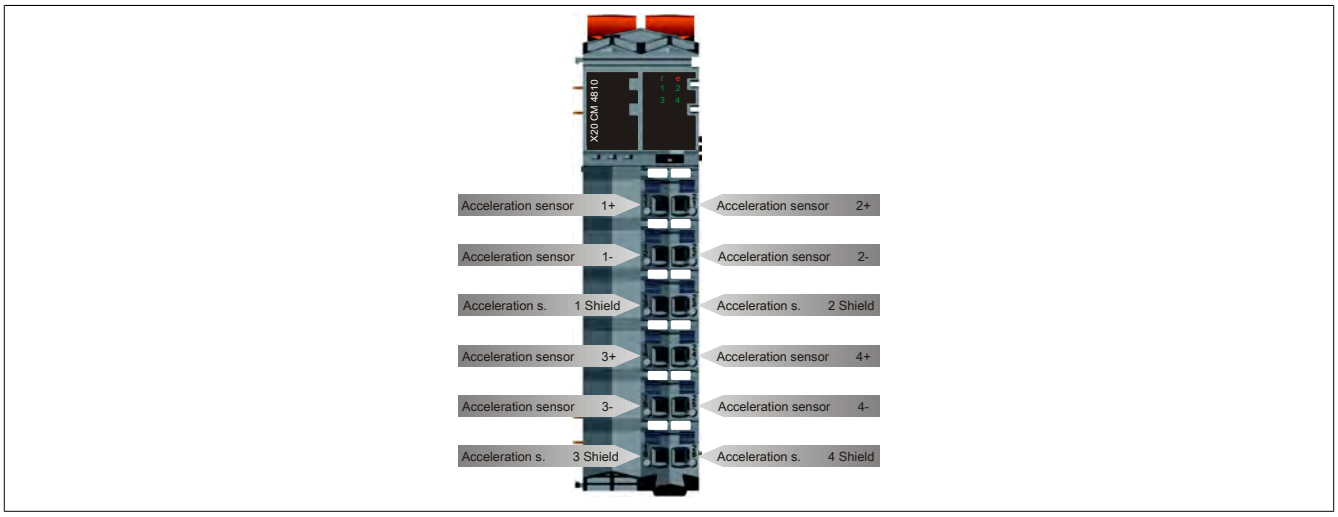
4.26.4.2.2 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	Reset mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	Module supply not connected or everything OK
			On	Warning, error or reset status
	e + r	Red on and green single flash		Invalid firmware
	1 - 4	Green	On	Status of the respective acceleration sensor (no open circuit)

1) Depending on the configuration, a firmware update can take up to several minutes.

4.26.4.2.3 Pinout



4.26.4.2.4 Shielding

There are two ways to shield the cable for the acceleration sensors:

- Shielding possibilities on the terminal block. (Contact "Acceleration sensor 1 - 4 shield")
- X20 shielding on the bus module. (See the "Shielding" chapter in the X20 system user's manual)

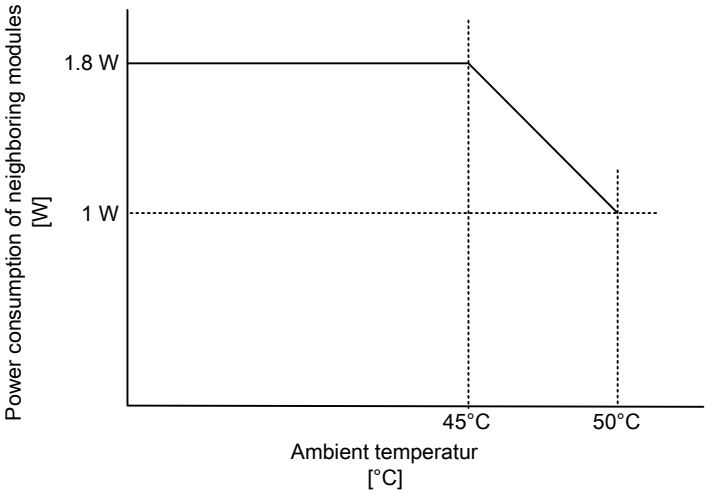
Shielding via the terminal block is perfectly sufficient for environments with no special EMC requirements.

However, if the X20CM4810 is used in an environment with special EMC requirements and high frequency disturbances, both options should be used together.

4.26.4.2.5 Derating

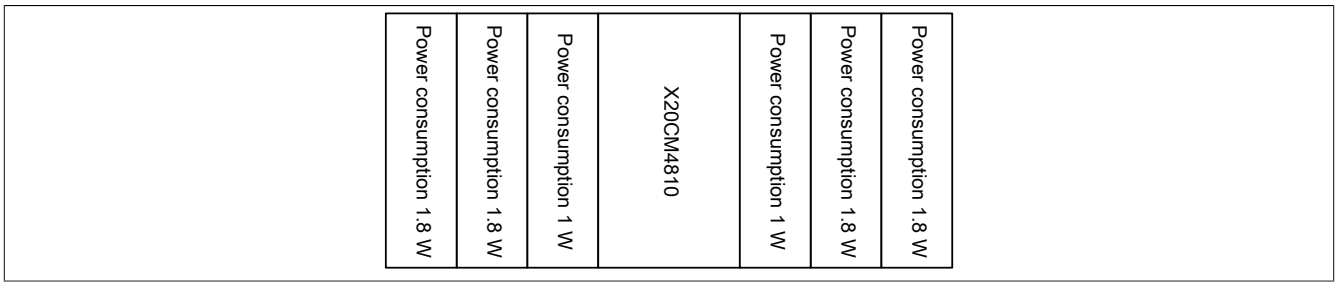
Horizontal installation

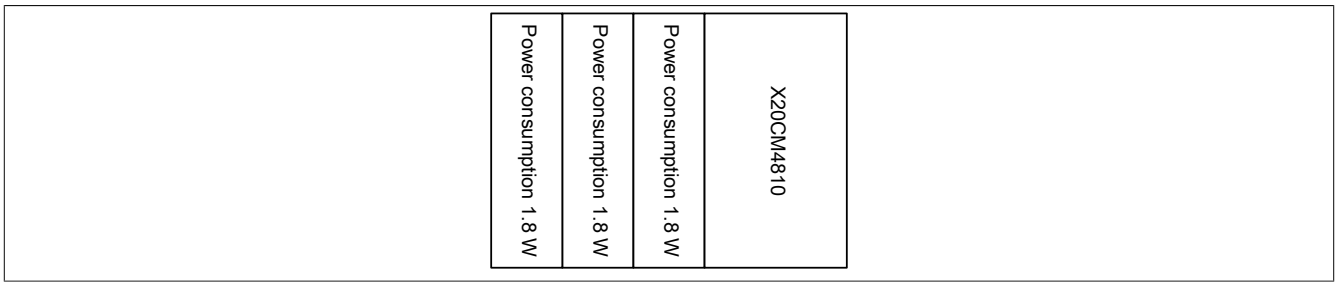
At ambient temperatures higher than 45°C, the X20CM4810 requires power derating:

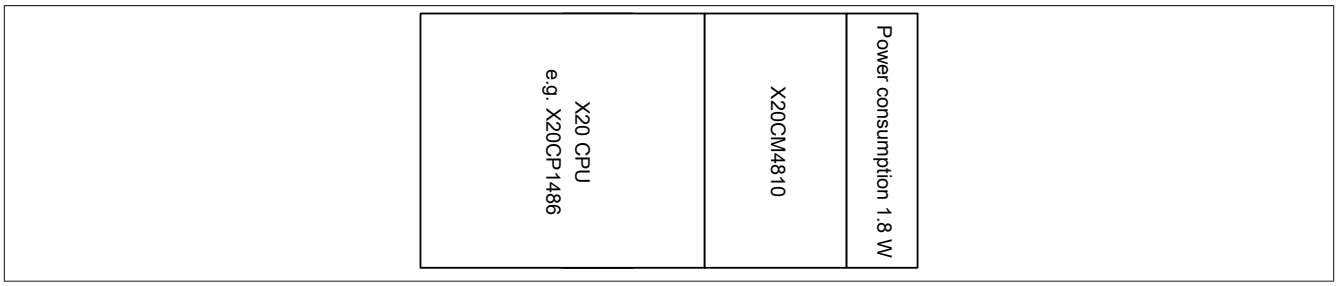


If the X20CM4810 is to be operated with ambient temperatures up to 50°C, then the neighboring modules must not consume more than 1 W.

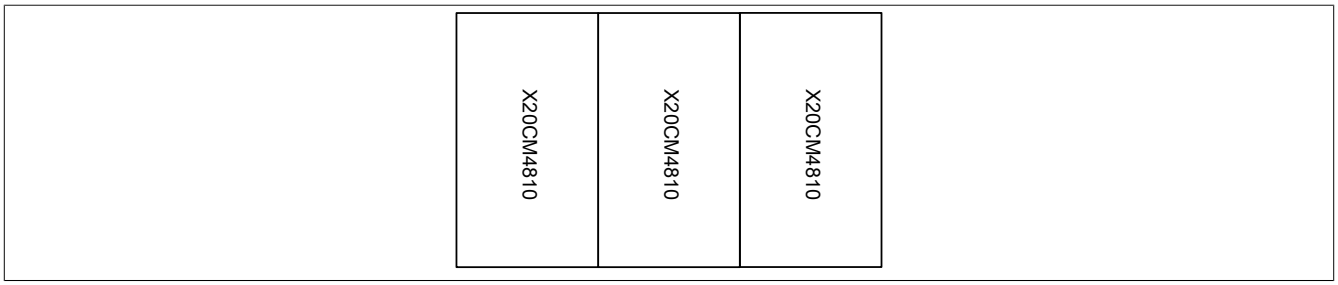
Example: ambient temperature up to 50°C



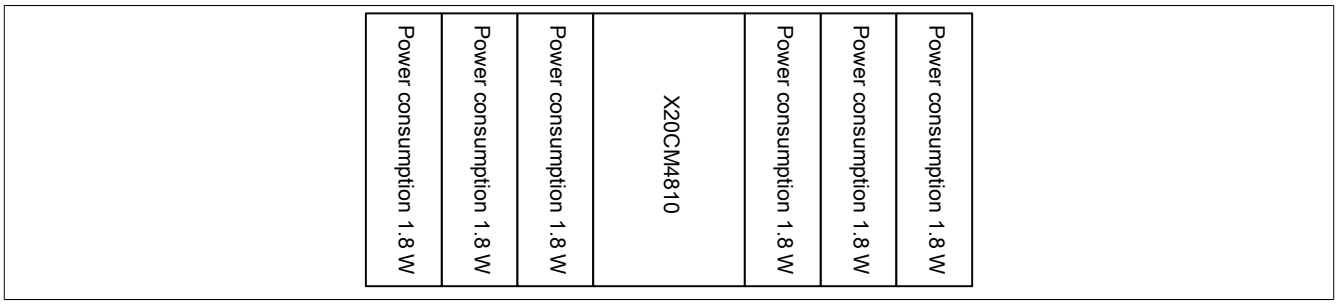




X20 double-width modules are an exception. It is also possible, for example, to place multiple X20CM4810 modules next to one another.

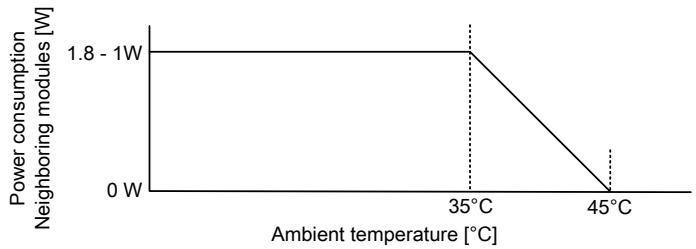


Example: ambient temperature up to 45°C



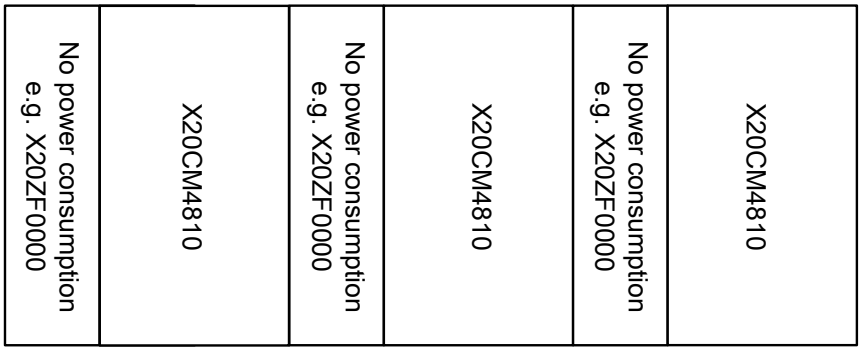
Vertical installation

At ambient temperatures higher than 35°C, the X20CM4810 requires power derating:

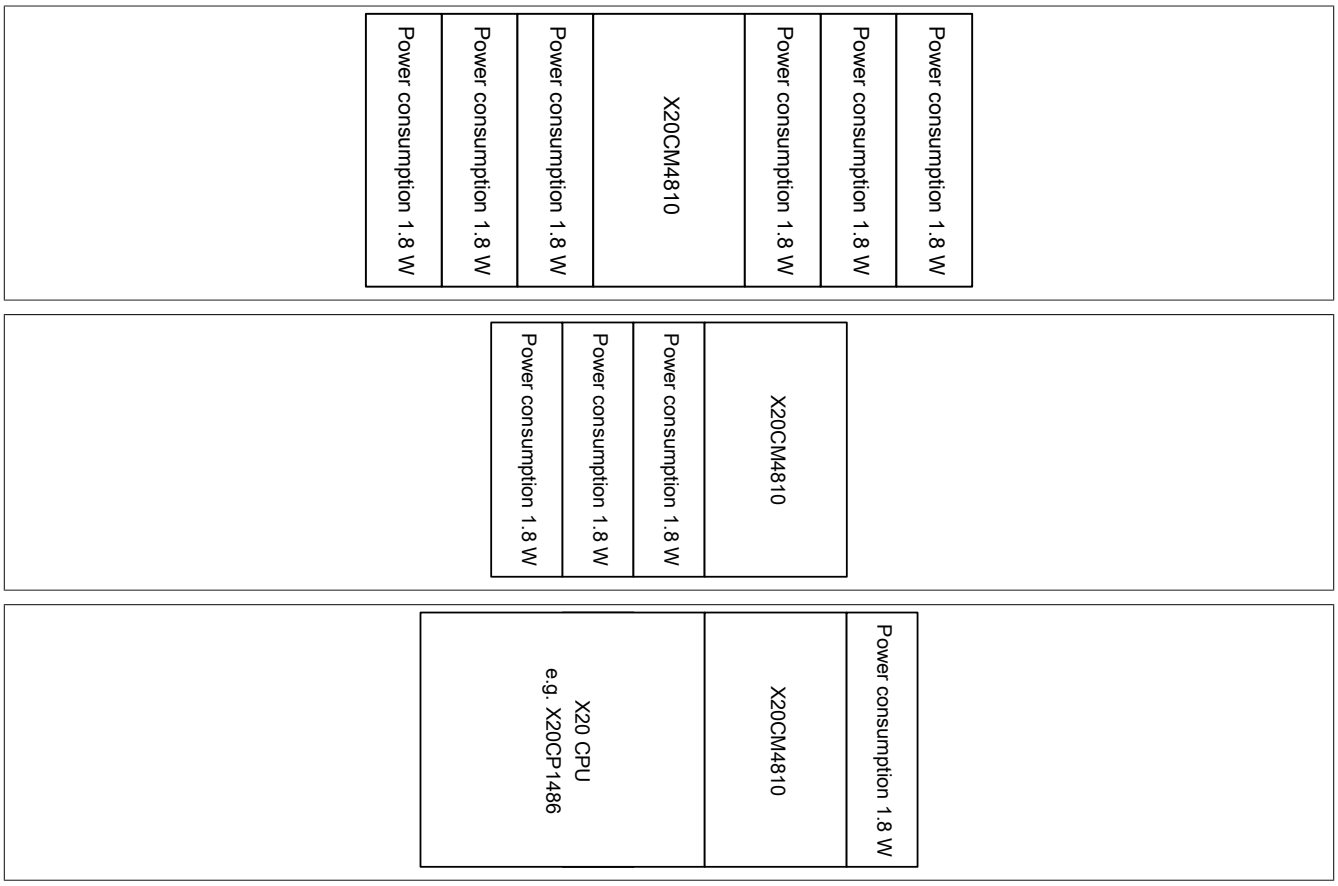


If the X20CM4810 is to be operated with ambient temperatures up to 45°C, then the neighboring modules must not consume power.

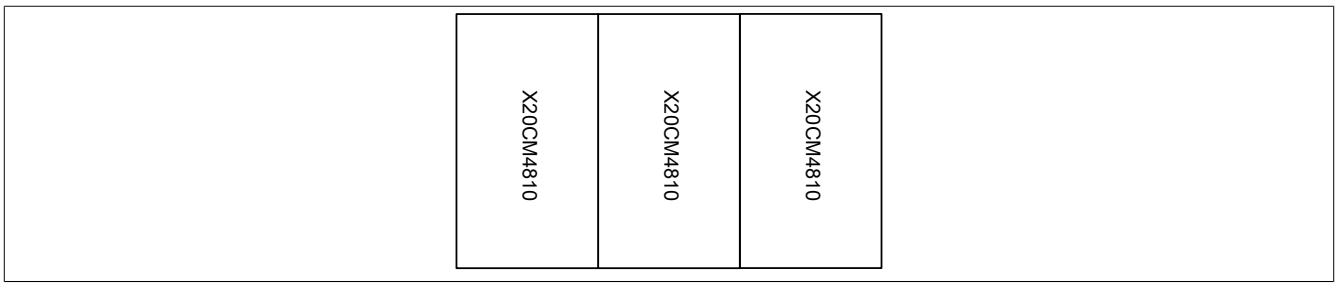
Example: ambient temperature up to 45°C



Example: ambient temperature up to 35°C



X20 double-width modules are an exception. For example, multiple neighboring X20CM4810 modules can be operated up to an ambient temperature of 30°C.



4.26.4.2.6 Gain curve

The following diagram shows a typical gain curve for the X20CM4810 module.

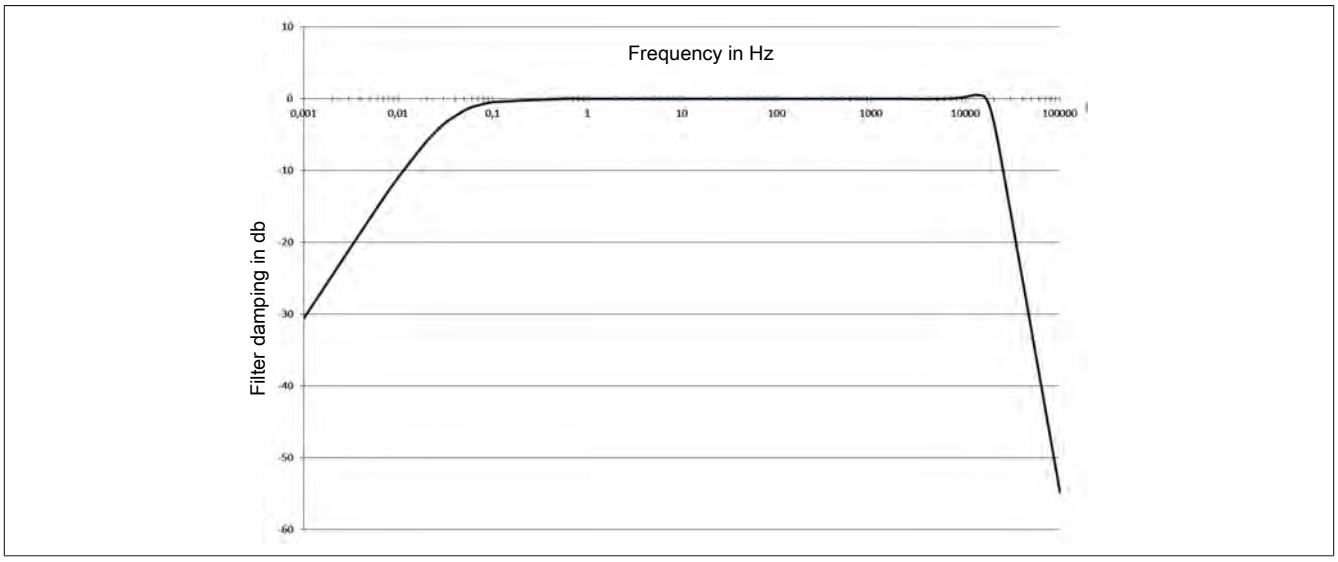


Figure 400: Typical gain curve

4.26.4.2.7 Signal generation

The following signals and characteristic values are calculated from the acceleration sensor's input signal:

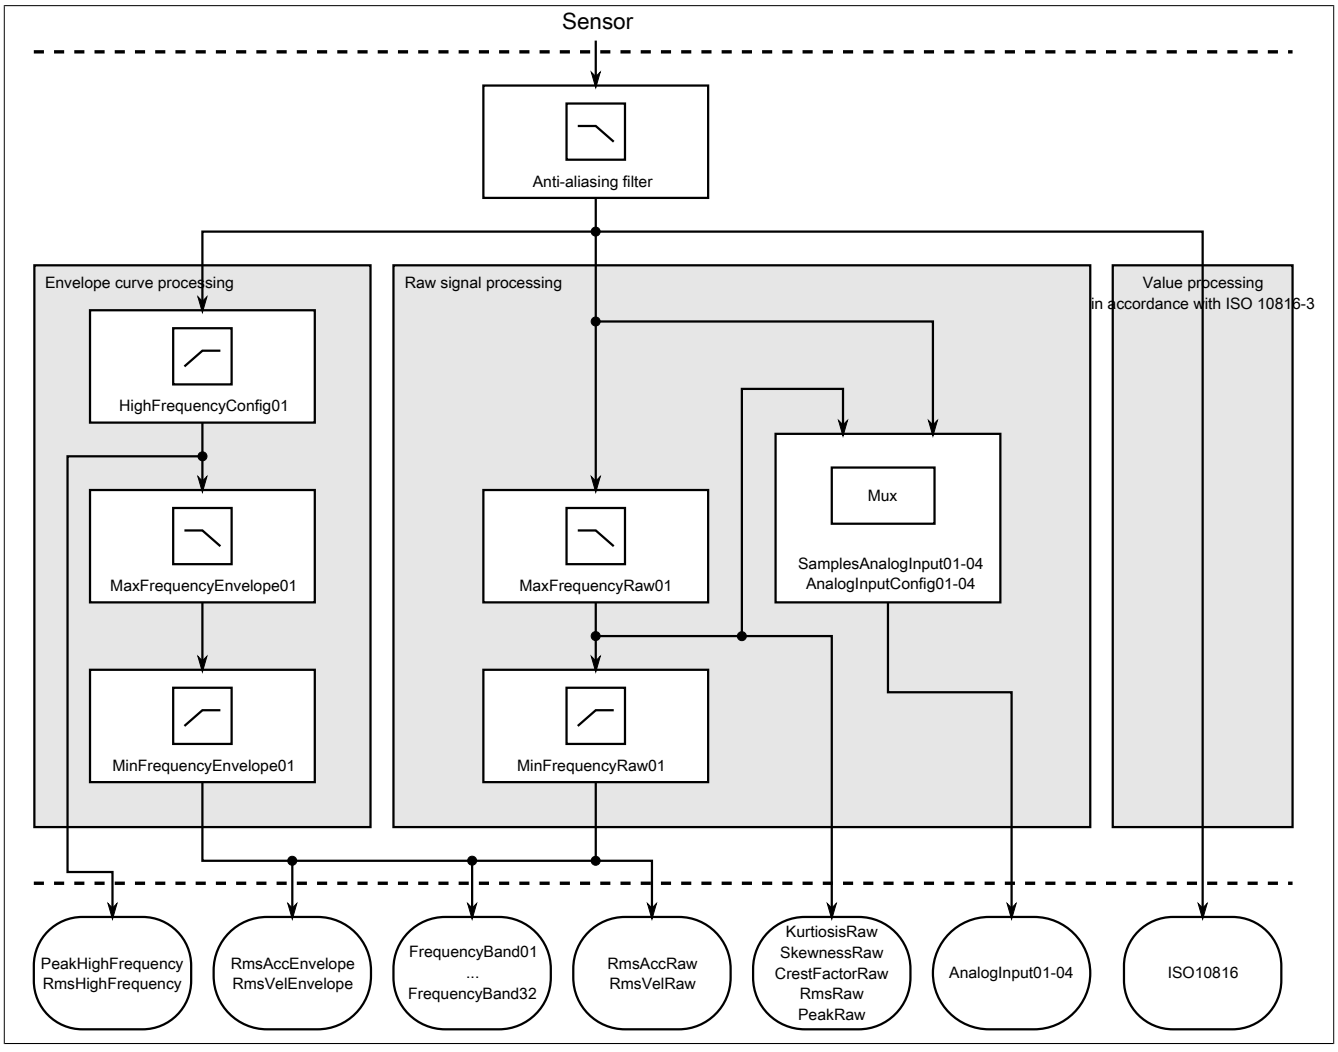

Figure 401: Signal generation in the module

4.26.4.2.8 Filter configuration

The X20CM4810 has a number of configurable filters.

There is an adjustable high-pass filter for the whole module that can be configured using "HighFrequencyConfig01". Possible settings are 500 Hz, 1 kHz and 2 kHz. This high-pass affects all high-frequency and envelope characteristic values of all module channels.

In addition, there are two adjustable low pass filters per channel.

- For the raw signal. This filter is configured using "MaxFrequencyRaw01". Possible settings are 200 Hz, 500 Hz, 1 kHz, 2 kHz, 5 kHz and 10 kHz.
- For the envelope signal. This filter is configured using "MaxFrequencyEnvelope01". Possible settings are 200 Hz, 500 Hz, 1 kHz and 2 kHz.

These low-pass filters affect all calculated characteristic values of the respective signal, i.e. the raw or envelope signal. They can be used to increase the frequency resolution of the FFT. When calculating characteristic values in AnalogInput, however, it is possible to select whether the characteristic values should be calculated directly from the input signal or from the low-pass filtered raw signal.

4.26.4.2.9 Frequency bands

It is possible to individually configure up to 32 frequency bands where the effective value (RMS) or the noise of a quadrant is calculated.

Configuration:

Parameter	Settings		
Enable	Off | RMS | Noise		
Channel	1 | 2 | 3 | 4		
Source	Raw acceleration signal | Raw velocity signal | Enveloped acceleration signal | Enveloped velocity signal		
Calculation of harmonics (RMS only)	Yes | No		
Rotation-dependent (RMS only)	On	Selects the data point for velocity ("ActSpeed01-04")	[1/100 Hz]
		Standardized damage frequency at 60 rpm	[1/100]
		± Width of the frequency band (tolerance band)	[1/100 Hz]
	Off	Lower frequency	[1/4 Hz]
		Upper frequency	[1/4 Hz]
Quadrant (noise only)	1 Quadrant | 2nd Quadrant | 3rd Quadrant | 4th Quadrant		

4.26.4.2.10 Characteristic values

The following condition parameters can be read from the X20CM4810 module for each channel:

Characteristic values	Description
"PeakHighFrequency"	Absolute maximum of the high-frequency portions of the input signal. The high-pass filter can be configured with the "HighFrequencyConfig01" register.
"CrestFactorHighFrequency"[1]	Ratio of the maximum amount to the RMS value ("Crest factor") of the high-frequency portions ("PeakHighFrequency" and "RmsHighFrequency") of the input signal
"Vdi3832KtHighFrequency"[1]	Ratio between the reference values and the currently measured values of the high-frequency portions of the input signal in accordance with the VDI 3832 guideline
"PeakRaw"	Peak value (absolute) of the input signal up to the maximum frequency ("MaxFrequencyRaw01") of the channel
"CrestFactorRaw"	Crest factor (peak-to-average power ratio) of the input signal up to the maximum frequency ("MaxFrequencyRaw01") of the channel
"SkewnessRaw"	Skewness (third statistical moment) of the input signal up to the maximum frequency ("MaxFrequencyRaw01")
"KurtosisRaw"	Peakedness, fourth statistical moment (kurtosis) of the input signal up to the maximum frequency ("MaxFrequencyRaw01") of the channel
"Vdi3832KtRaw"[1]	Ratio between the reference values and the currently measured values of the input signal in accordance with the VDI 3832 guideline
"RmsHighFrequency"	RMS value of the high-frequency portions of the input signal. The high-pass filter can be configured with the "HighFrequencyConfig01" register.
"RmsRaw"	RMS value of the input signal up to the maximum frequency ("MaxFrequencyRaw01") of the channel
"RmsAccRaw"	RMS value of the acceleration of the input signal from the configured minimum frequency ("MinFrequencyRaw01") up to the configured maximum frequency ("MaxFrequencyRaw01") of the channel
"RmsVelRaw"	RMS value of the speed of the input signal from the configured minimum frequency ("MinFrequencyRaw01") up to the configured maximum frequency ("MaxFrequencyRaw01") of the channel[2]
"ISO10816"	Effective value of the velocity in the frequency domain 10 Hz to 1 kHz in accordance with ISO 10816
"RmsAccEnvelope"	RMS value of the acceleration of the envelope from the configured minimum frequency ("MinFrequencyEnvelope01") up to the configured maximum frequency ("MaxFrequencyEnvelope01") of the channel
"RmsVelEnvelope"	RMS value of the speed of the envelope from the configured minimum frequency ("MinFrequencyEnvelope01") up to the configured maximum frequency ("MaxFrequencyEnvelope01") of the channel[2]

Table 587: Characteristic values

1) Only available in Function model 0 - Standard
2) Only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

4.26.4.2.11 Characteristic value format

Characteristic value	Format	Unit
"ActSpeed01-04"	REAL	Hz
"AnalogInput01-04"	REAL	mg or 1 when crest
"PeakHighFrequency01-04"	REAL	mg
"RmsHighFrequency01-04"	REAL	mg
CrestFactorHighFrequency01-04[1)]	REAL	1
Vdi3832KtHighFrequency01-04[1)]	REAL	1
"RmsAccEnvelope01-04"	REAL	mg
"RmsVelEnvelope01-04"	REAL	mm/s
"RmsAccRaw01-04"	REAL	mg
"RmsVelRaw01-04"	REAL	mm/s
"PeakRaw01-04"	REAL	mg
"RmsRaw01-04"	REAL	mg
"CrestFactorRaw01-04"	REAL	1
"SkewnessRaw01-04"	REAL	1
"KurtosisRaw01-04"	REAL	1
Vdi3832KtRaw01-04[1)]	REAL	1
"Iso10816_01-04"	REAL	mm/s
"FrequencyBand01-32"	REAL	mg or mm/s depending on the configuration

Table 588: Characteristic values after preparation by Automation Runtime in the standard function model

1) Additional characteristic value provided by Automation Runtime.

Characteristic value	Format	Resolution and unit	Value on overflow
"ActSpeed01-04"	UINT	0.01 Hz	
"AnalogInput01-04"	INT	AnalogInputScale/32768	32767 or -32768 (cap)
"PeakHighFrequency01-04"	24-bit unsigned	1/65536 g	16777215
"RmsHighFrequency01-04"	24-bit unsigned	1/65536 g	16777215
"RmsAccEnvelope01-04"	24-bit unsigned	0.001 g	16777215
"RmsVelEnvelope01-04"	24-bit unsigned	0.001 mm/s	16777215
"RmsAccRaw01-04"	24-bit unsigned	0.001 g	16777215
"RmsVelRaw01-04"	24-bit unsigned	0.001 mm/s	16777215
"PeakRaw01-04"	24-bit unsigned	1/65536 g	16777215
"RmsRaw01-04"	24-bit unsigned	1/65536 g	16777215
"CrestFactorRaw01-04"	24-bit unsigned	0.001	16777215
"SkewnessRaw01-04"	24-bit signed	0.001	8388607
"KurtosisRaw01-04"	24-bit signed	0.001	8388607
"Iso10816_01-04"	24-bit unsigned	0.001 mm/s	16777215
"FrequencyBand01-32" (configured as RMS)	24-bit unsigned	0.001 g or 0.001 mm/s depending on the configuration	16777215
"FrequencyBand01-32" (configured as noise)	24-bit unsigned	1/65536 g or 1/65536 mm/s depending on the configuration	16777215

Table 589: X20CM4810 characteristic values

4.26.4.3 General information about the module

4.26.4.3.1 X20CM4810 settling time

The input high-pass cut-off frequency of the AC voltage input (limit frequency of 34 MHz) means that a certain amount of settling time is required after changing the DC offset of the pending signal.

- Settling time of approximately 30 seconds at 100 mV/g sensor sensitivity and a 24 V supply voltage with an accuracy of 0.4 g
- Settling time of approximately 60 seconds at 100 mV/g sensor sensitivity and a 24 V supply voltage with an accuracy of 0.001 g
- The respective settling time must be allowed to pass in order to achieve accurate measurement results when an open line occurs. Because of this, all characteristic values and analog input values are set to 0 by the module during the first 30 seconds after a restart or wire breakage.

4.26.4.3.2 Sensor sensitivity

The X20CM4810 always assumes a 100 mV/g acceleration sensor on the input. When using Function model 0 - Standard, it is possible to configure a different sensor sensitivity directly in the function library.

If a different function model is used, for example an SGC controller or bus coupler, any conversion to a different sensitivity must be performed manually.

Example

Factor = 100 / (sensor sensitivity in mV/g)

All characteristic values and values must be multiplied by the calculated factor. This also applies to the analog characteristic values if the characteristic value calculation is enabled as well as for uploaded time signals and amplitude spectra. Exempt from this are all characteristic values without any units, such as "KurtosisRaw", "CrestFactorRaw" and "SkewnessRaw". See section 4.26.4.2.11 "Characteristic value format" on page 2602.

4.26.4.3.3 Information about FlatStream

When using FlatStream in Function model 0 - Standard and Function model 1 - Fast master, the following must be noted. The X20CM4810 changes the values in the FlatStream in every X2X Link cycle. To avoid missing anything in the task, it is important to select a task cycle that is either the same speed and synchronous to the module's bus or faster. This also applies to fieldbus connections between the CPU and bus coupler.

The maximum bus cycle time of 10 ms must not be exceeded since it is not possible to guarantee that the data calculated by the module every 300 ms will be fully transferred on the bus.

4.26.4.3.4 Information about using a SG4 CPU

The X20CM4810 calculates all characteristic values up to "Vdi3832KtRaw", "Vdi3832KtHighFrequency" and "CrestFactorHighFrequency" independently every 300 ms. Automation Runtime facilitates the handling of the module for the user (characteristic value upload), scales the characteristic values to the sensor resolution and also calculates the characteristic values specified above.

4.26.4.3.5 Calculating the velocity signal automatically

The X20CM4810 module can calculate the velocity signal from the signal provided by the acceleration sensor. This calculation is disabled by default since it can reduce the accuracy of the acceleration signal.

Reason

When converting from acceleration to velocity, low frequency portions become very large. As a result, the autogain is decreased by a few levels, which then further degrades accuracy.

If this calculation is not enabled, 0 is output for all characteristic values calculated on the velocity spectrum. The characteristic value "ISO10816" is not affected by this.

4.26.4.3.6 Information about AutogainDelay and overflow

The X20CM4810 automatically adjusts the measurement signal dynamically (autogain) to ensure that it is measured with the highest possible accuracy. This adjustment is made in multiple steps. Each step amplifies the input signal more than the last. If the signal was very small for a long time and a impact suddenly occurs, an overflow may occur with some calculated characteristic values. This is indicated by the overflow bit for the respective channel (Overflow01-04) being set and the affected module characteristic values being set to their maximum. See section 4.26.4.2.11 "Characteristic value format" on page 2602.

With Function model 0 - Standard, there are also the additional data points "OverflowCharacteristicValues01-04" and "OverflowFrequencyBands01". These are automatically generated by Automation Runtime and directly indicate the overflow status of the individual characteristic values and frequency bands.

If an overflow occurs or if an internal threshold is exceeded, the autogain for the next measurement is reduced by one level. If no overflow occurs for a certain number of measurements (adjustable by "AutogainDelay01"), or the signal stays below the internal threshold, the autogain is increased by one level again.

If overflows are occurring frequently, increasing AutogainDelay may help.

4.26.4.3.7 Important information when using a B&R Compact CPU or fieldbus CPU

Due to the size of the firmware for the X20CM4810 module, only CPUs with sufficient ROM (> 1MB) are supported. (X20CP0292 or X20XC0292)

4.26.4.3.8 Firmware update time

Updates to the firmware can take some time due to the size of the files.

The following firmware update times can be expected depending on the configured bus cycle time:

Bus cycle time	Update time
400 µs	Approx. 3 min
2 ms	Approx. 15 min

Table 590: Firmware update time

4.26.4.4 Condition monitoring / Oscillation analyses

4.26.4.4.1 General information

System availability is one of the most important criteria in machine operation. For this reason, increasing and ensuring this availability over the long term is a primary objective of the system operator.

Unplanned stoppages and the resulting loss of production can lead to substantial costs. The implementation of condition monitoring has proven to be a very good method for supporting anticipatory maintenance.

4.26.4.4.1.1 What is condition monitoring?

Condition monitoring involves recording the status of the machines at regular intervals by measuring important values in order to recognize impending problems in the system. The goal is to recognize imminent damage early enough so that a faulty machine part can be repaired or replaced before it leads to consequential damage or a partial or complete breakdown of the system.

The specific purpose of condition monitoring is to collect and process sensor data (e.g. oscillations, temperatures, lubricant conditions, pressures, flows) that can be used to assess the overall condition of the system.

Deviations from normal process or system conditions are caused by defects, which can occur for a variety of reasons. If corresponding countermeasures are not taken, this can quickly lead to a malfunction and breakdown of the system. Monitoring the sources of defects through the analysis of machine parameters can make it possible to recognize malfunctions as early as possible in order to take preventive action. Possible responses can include, for example, an error message or warning to the operator or an automated action for fault clearance and prevention of damage all the way up to automatic shutdown.

The integration and systematic implementation of condition monitoring provides many advantages:

- System components are only repaired or replaced when actually necessary. Potential defects are recognized early on in operation.
- Reliability can be significantly increased by integrating condition monitoring into the process.

Bathtub / Deterioration curve

The operating performance of every mechanical component changes over the course of operation, with each component becoming defective at some point. It is crucial to recognize such a change before the component can no longer fulfill its function. This behavior can be demonstrated using a "bathtub curve", which indicates the probable failure rate over time.

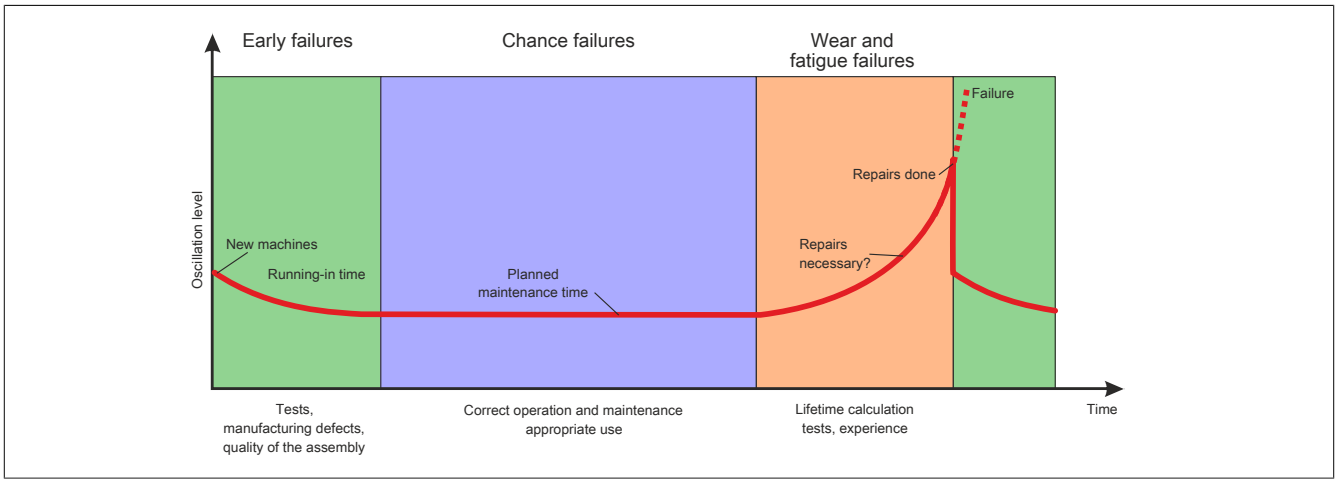

Figure 402: Bathtub curve illustrating the three typical phases

Each component is subject to the regularities of this curve, with a typical trend emerging as a result.

- **Area 1 (early failures)** is characterized by a decreasing failure rate. Early failures are caused almost exclusively by errors in assembly or construction. Nevertheless, particular care and quality during manufacturing and initial operation significantly reduces the failure rate at the beginning. This area also explains the increased failure performance after an intervention in a system that functions well.
- During continuous operation in **Area 2 (chance failures)**, the failure rate is almost consistent. These chance failures are fundamentally difficult to ascertain and, most importantly, not easily influenced. Operating and maintenance errors contribute towards an increase in the failure rate in this region.
- The failure rate increases dramatically in **Area 3 (wear and failure due to fatigue)**. Wear and fatigue failures are primarily characterized by damage that progresses slowly over time.

The trend provides valuable information about the failure probability of the parameters measured by condition monitoring. This usually behaves like the bathtub curve, i.e. an increase in the characteristic value signifies a change in the system. The characteristic values can be synchronized with the operating parameters through the integration of automation technology. Assessing curve performance and incorporating operating parameters makes it possible to identify the best time to perform service work depending on condition.

In addition, oscillations are often representative of the condition of a machine or component. They are a good indication of wear or damage. One example of this is roller bearings. Surface damage (pitting) leads to increased oscillations in the bearing housing, which can then be measured and analyzed. An increase in oscillations during operation indicates damage and/or increased wear. By constantly observing this condition, deviations from normal operation can be recognized immediately.

Damage development and the damage chain

Explaining damage development with a roller bearing example

The majority of bearing damage develops slowly and usually without being noticed. In many cases, it is only once the damage is more advanced that irregular running and unusual operating noises indicate bearing damage. This points to material fatigue, e.g. chipping or altered radial clearance through wear.
If the damage is so advanced that it can be detected without measuring equipment, spontaneous failures such as blockages and breakage of the bearing housing components often occur.

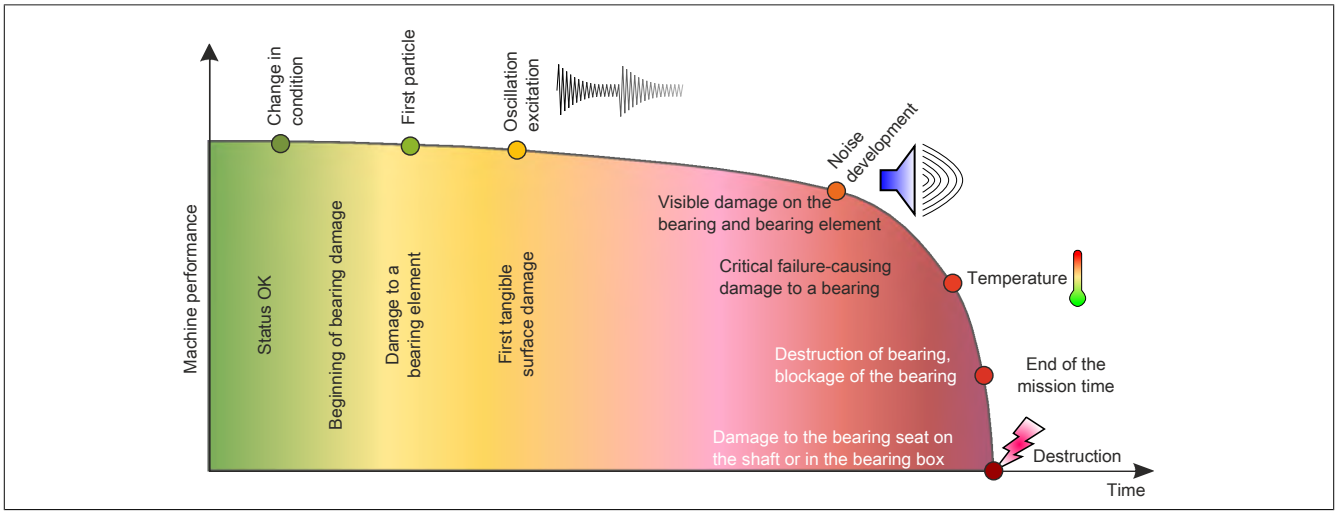

Figure 403: Illustration of the damage chain and the development of damage over time

The damage chain illustrated in the image above presents condition monitoring as an important tool in the condition-oriented operation and maintenance of a system.

It is possible to draw conclusions about the condition of the machine or its components from the parameters recorded by the sensors. Deterioration of the condition of components or system parts becomes apparent through the detection and observation of their condition, the consideration of the trend and, if necessary, through the detailed analysis of the measurement data obtained. Based on this, targeted measures can be put in place for maintenance.

Condition monitoring is a suitable option under the following conditions:

- Measurable parameters that correlate with a failure need to be identified and selected.
- The failure cannot be prevented by redesign or altered usage.

- Events lead to failures that occur randomly.
- Sufficient warning time must be given in advance before a function fails.

The consideration of the condition monitoring "tool" must not only be limited to the recognition of operating conditions, but should be integrated into the general asset management strategy as a component of this. In order to manage this, all types of condition monitoring and industrial diagnostics should be integrated into an overall strategy.

For a failure-oriented operational mode ("reactive maintenance"), components are only replaced if they can no longer fulfill their function. For a planned operational mode ("preventive maintenance"), components are replaced at a certain point in time – regardless of their current condition.

For state-oriented maintenance, the area where maintenance is planned can be significantly isolated while reducing the risk of failure at the same time.

	Advantages	Disadvantages
Reactive maintenance	- Utilization of the wear reserve - No costs during the period of use	- Unexpected failure - Consequential damage - High downtime costs - Low operational safety
Preventive maintenance	- Can be planned well	- No utilization of the wear reserve - Increased risk of failure after maintenance - Repair costs
State-oriented maintenance	- Early recognition of problems - Downtime can be planned - Utilization of the wear reserve - High operational safety - Avoidance of consequential damage	- Dealing with the issue - Investment costs

Table 591: Comparison of the advantages and disadvantages of standard maintenance strategies

4.26.4.4.1.2 Conventional condition monitoring

- There exists a lot of measurement and process data that is not currently used for condition monitoring (CM). Links and correlations with process parameters and further CM parameters can often be made possible only with considerable expenditure.
- CM systems are implemented as "isolated applications". In such cases condition monitoring is performed by standalone sensor and measurement systems with standalone hardware and software
- The range of different systems can lead to significant problems in the on-site operation of the system. Different software solutions make it more difficult since there is separate hardware and a separate user interface for each CM method and each CM tool.
- In many cases, necessary expert knowledge specific to a system is not available. The complexity of some configuration tools exceeds the user's existing expertise.

Using the X20CM4810 together with B&R standard modules has the following advantages:

- Easy exchange of process data and condition monitoring data
- Easy integration of parameters in the overall process
- Modular construction

4.26.4.4.1.3 Overview of condition monitoring methods

Method	Brief description of operation	Available signals / interfaces
Determination of the condition of coolants and lubricants Visual assessment, filtration, ferrography, magnet detection, spectroscopy, radioactive trace analysis	Quantitative examination of wear products (filtering, magnetic catches, ferrography, spectral oil analysis, particle counting) that are obtained from the lubricant oil or coolant fluid Regular taking of samples according to a defined time schedule or according to operating hours Quantitative comparison of the samples	Using suitable measurement systems, these condition monitoring methods can be processed in the B&R system using analog/digital inputs or bus coupler modules.
Thermal diagnostics Temperature sensors, thermometry, infrared measurement technology	Recording of temperatures through sensors with different physical modes of action Recording of temperature distribution through detection of infrared radiation	
Acoustic emission analysis Airborne sound measurement pulse analysis, pulse density fluctuation analysis, sound pressure measurement, acoustic emission location	Airborne sound measurement from infrasound to ultrasound using a microphone Multidimensional microphone structure for emission source location Recognition of microdamage (cracks) etc. through the measurement of acoustic emissions of transient waves with high frequencies	
Vibration measurement Structure-borne sound measurement, FFT analyses, order analyses, modal analyses	Vibroacoustic diagnostics Measurement of the structure-borne sound at bearing positions or structures with accelerometers, analysis and evaluation	
Electrical parameters, motor current analysis, insulation resistance measurement	Compilation of electro-technical parameters and analysis with regard to condition monitoring	These condition monitoring methods can be processed in the B&R system using analog/digital inputs, bus coupler modules or B&R drive systems (different functions from system to system).

4.26.4.4.2 Oscillation measurement technology

4.26.4.4.2.1 Sensor technology

Oscillation sensors convert the mechanical oscillations of the machines being measured into an electrical signal.

For the most part, structure-borne sound, i.e. the sound that spreads through a solid object, is measured. The three oscillation magnitudes correlate mathematically to the integration or differentiation of the basic variables. Oscillation velocity is calculated through integration from the oscillation acceleration; oscillation displacement is calculated through integration from the oscillation velocity.

The acceleration measured within the scope of the condition monitoring is typically measured with piezoelectric sensors. The oscillation sensors being used utilize the piezoelectric properties of quartz or certain ceramics. The actual measured value is a force that is proportional to the acceleration.

The piezoelectric effect involves a charge separation when a force acts on the piezoelectric material. This is in proportion to the force and is consequently proportional to the acceleration. Piezoelectric quartz or piezoelectric ceramic is used as the piezoelectric material. The output signal is an electrical charge that is specified in pC (picocoulombs). A charging amplifier is necessary in order to convert the charge into a voltage signal.

The **I**ntegrated **E**lectronics **P**iezo **E**lectric (IEPE) technology used in B&R sensors strengthens the signal directly in the sensor and emits it as a low-resistance voltage signal. The sensitivity is specified in mV/g where g represents the gravity of the earth.

$1g = 9.81\ m/s^2$

Information:

Piezoelectric sensors cannot measure static magnitudes.

Basic design

The piezoelectric crystal is jammed between the seismic mass and the foundation with what is known as a compression mode sensor. Through the acceleration that occurs, the force that is acting upon the crystal increases or decreases. The bigger the implemented seismic mass, the bigger the output signal.

Sensors of this type can be constructed with a very high rigidity and therefore have a correspondingly high resonant frequency.

Magnitudes of influence on the sensors

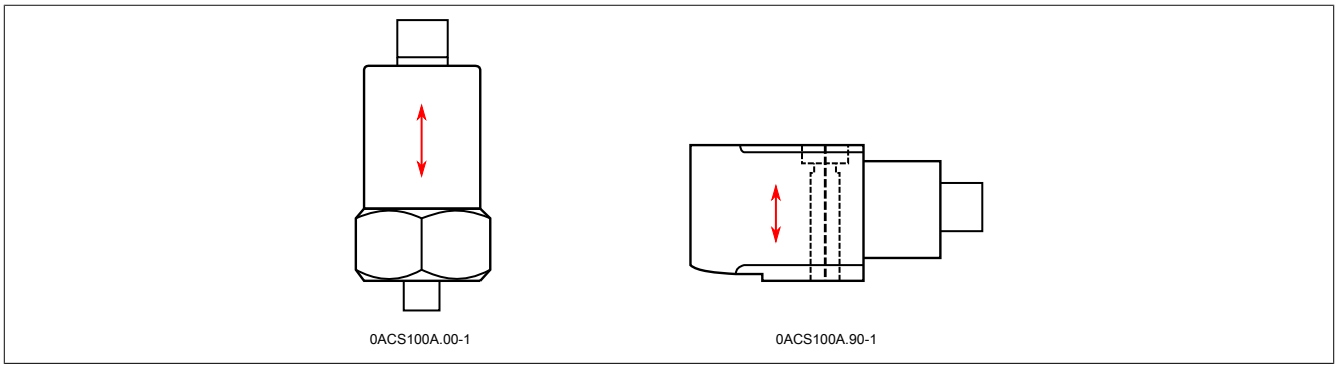
Mounting direction - Preferred direction

Oscillation sensors can be fitted at any location. The installation position usually results from the measuring task itself. Nevertheless, oscillation sensors have a preferred measurement direction that is usually indicated on the housing of the sensor.

Of course, oscillations in cross direction to the installation position also act upon the sensor. These can be compensated as much as possible through appropriate constructive measures and suitable selection of the piezoelectric crystal.

Installation position

The 0ACS100A.00-1 oscillation sensor from B&R is designed to measure the longitudinal axis; the 0ACS100A.90-1 sensor is designed to measure the lateral axis.



Cross-sensitivity

Oscillations in all directions act upon the sensor. The sensor should ideally transfer oscillations in its main direction, i.e. in the direction of the sensor. Oscillations that deviate from this main direction are still registered by the sensor, however, and transferred to the overall signal at different strengths depending on its type.

Cables

When transferring a signal over a connector, errors such as noise, ground loops and contortions may occur. This influence is particularly important in the transfer of charges since system noise is a function of the cable's capacity. When using IEPE technology, the sensor produces a high voltage signal with a low source impedance due to its internal electronics.
As a result, this technology is well suited for signal transmission over long lines.

The supply unit provides constant current to supply the IEPE electronics in the sensor. The maximum frequency that can be transferred via the test lead without considerable loss depends on the length of the cable, the cable capacity and the ratio between the output amplitude and the constant current.

Information:

Maximum cable length when using the 0ACCxxx0.01-1 cable from B&R: 20 m.

Temperature influence

All piezoelectric materials also have a distinct pyroelectric effect. This describes the change in the electric polarization of ferroelectric materials as a result of a change in temperature. This effect is undesirable since it often leads to charge separations in the oscillation measurement. These arise from the change in temperature and not through the mechanical vibrations occurring in the measured object.

This effect can be limited by the design, however. The interferences are grouped together in the interference transfer factor for temperature changes.

Temperature drift:

The values specified in the sensor's technical data have been determined as a step response to a change in temperature for the lower electrical limit frequency f_u = 1 Hz.

Changes in temperature, in particular, cause interference in the low frequency domain below f = 10 Hz since this is generally a low frequency event.

Interference

A backlash on the sensors occurs near electromechanical machines such as motors and generators due to electromagnetic alternating fields, the associated induction and magnetostriction. This backlash is very low, however, due to the screening concept used and the use of IEPE technology.

This effect is specified in the interference transfer factor. It is determined by a magnetic flow density of 0.01 T and a frequency of 50 Hz.

Information:

B&R sensors have an isolated base. When using sensors from other manufacturers, it is important to pay attention to isolation/screening in order to minimize interference. This allows interference frequencies with single and double mains frequency.

Linearity

The piezoelectric sensor is linear over long distances of the frequency response.

Frequency response

The frequency response of the sensor is determined by its mechanical construction. The seismic mass and the rigidity of the inner structure is crucial here, as is its construction.

The sensitivity is linear in other areas of the frequency response. The frequency response only increases significantly when near the resonant frequency. Since misinterpretations can occur in proximity to the resonant frequency, the resonant frequency must be correspondingly high.

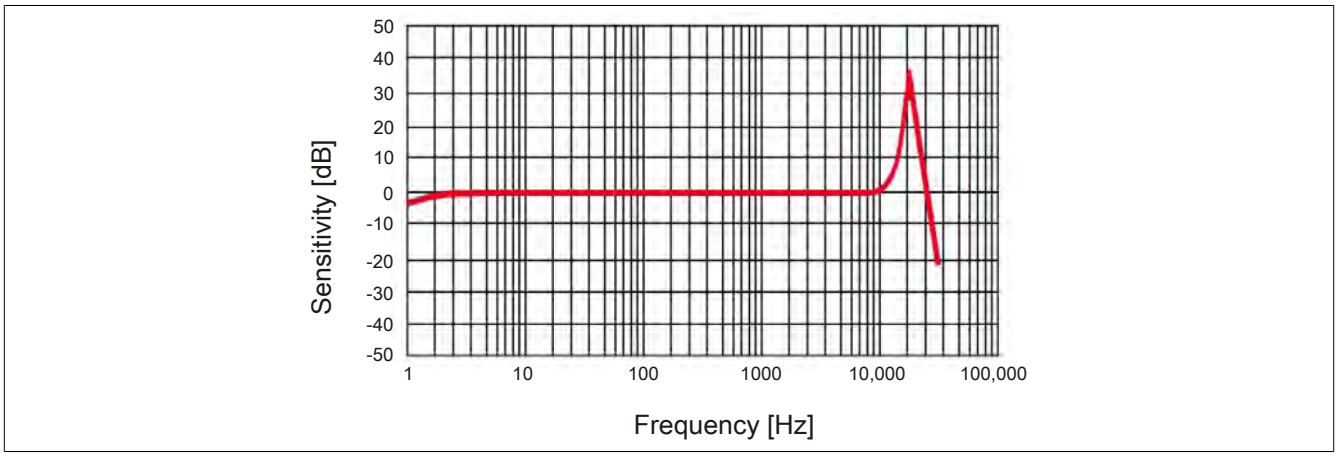


Figure 404: Frequency response of 0ACS100A.00-1 and 0ACS100A.90-1 sensors from B&R

Installing sensors

Sensors can be connected to object to be measured using various methods. How the sensors are installed on the measurement object is crucial for the quality of the overall measurement.
In order to transfer all frequency portions to be measured to the sensor accordingly, very good coupling of the sensor to the mechanical component is necessary.

Machine parts may be subject to temperature-related expansion and deformation, with the result that the sensor no longer has its whole measurement surface available. This affects the quality of the measurement.

Figure 405: Temperature deformation of a machine part (excessive deformation shown)

Information:

For optimal measurement, the base surface of the sensor must be flat and the sensor must be fully supported.

In order to increase the quality of the measurement accordingly, a fixed connection to the measurement object is necessary. Cover plates and plastic parts are therefore not suitable for the attaching sensors.

The following methods are available for installing sensors:

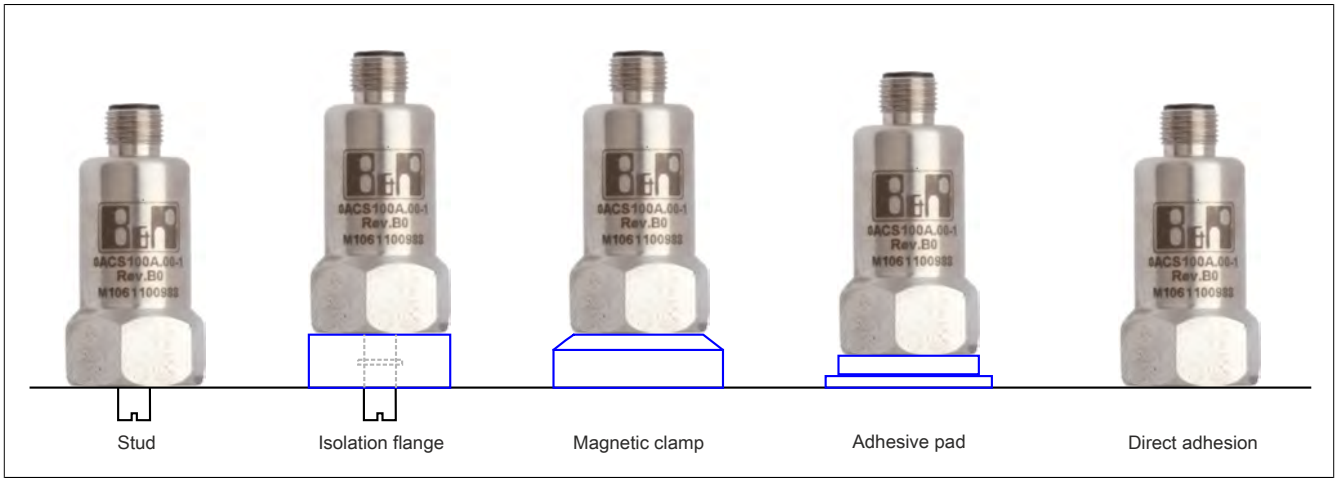

Figure 406: Overview of installation methods

Of all of the mounting methods, fastening by means of a screw is preferable due to the low attenuation between the sensor and the measurement surface.

Typical sensor installation is performed by screwing the sensor to the measurement object with what are called studs (supplied with the sensor). Studs are specially-made setscrews made from special materials that facilitate the optimal transfer of vibrations.

If the mounting location is well prepared and the sensor is screwed on correctly, frequencies of up to approximately 10 kHz can be transferred without significant loss.

Information:

To ensure measurements of sufficient quality, B&R recommends mounting the sensor with a screw.

Ground loops can occur at great distances. If necessary, isolated mounting must be performed using an isolated adhesive mounting plate.

The resonant frequency is reduced by additional elements such as an isolation flange, collar screw, magnetic clamp and probe tip positioned between the coupling surfaces. The coupling becomes softer using these elements. These differences can be clearly seen in the frequency response diagram
Different frequency responses of the relative voltage transfer factor are illustrated in the image below.

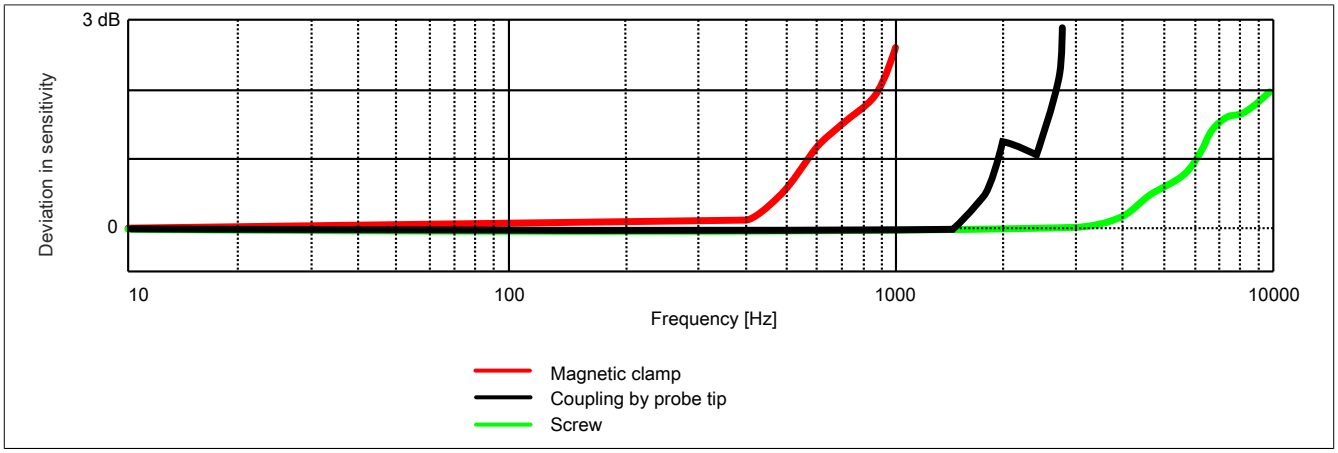

Figure 407: Attenuation of the different types of sensor mounting

The choice of mounting is influenced by the resonance frequency and temperature. The following table shows how strongly these influences impact on the different mounting methods.

	Resonant frequency	Temperature
Stud	●	●
Instant adhesive	●	●
Beeswax	◐	○
Double-sided adhesive tape	○	◐
Magnetic clamp	◐	●
Probe tip	○	○

Effects on the installation methods:

● High ◐ Medium ○ Low

Table 592: Overview of installation methods

Installation procedure

Depending on the conditions of the location, sensors can be screwed directly onto the surface of the object to be measured.

STEP 1: As smooth and flat a surface as possible is needed to mount the sensors. The size needed depends on the sensor and can be found in its data sheet.

For a vertical installation position: "Dimensions" on page 2732
For a horizontal installation position: "Dimensions" on page 2734

STEP 2: An M8 blind hole is needed to attach the B&R sensor.

STEP 3: To further improve the transfer performance, a thin layer of silicone grease can be applied between the object surface and the sensor mounting surface. The sensor should then be pressed on briefly so that any excess grease is pushed out. This is not an essential part of the application and is only useful when measuring particularly high frequencies.

STEP 4: The sensor should be tightened by approx. 8 Nm when using the M8x1 screw thread. If necessary, the sensor can be protected against loosening using an adhesive.

Sensor positioning

To ensure optimal detection and measurement of frequencies propagating from a point of damage, sensor positioning plays an important role. The ideal position for mounting a sensor on a structure is often difficult to reach and is not always necessary. Since sound waves propagate throughout the entire structure, the damage frequencies are measured with varying intensity or amplitude (green arrow). If a flexible connection is used, a valid measurement is no longer possible (red arrow).

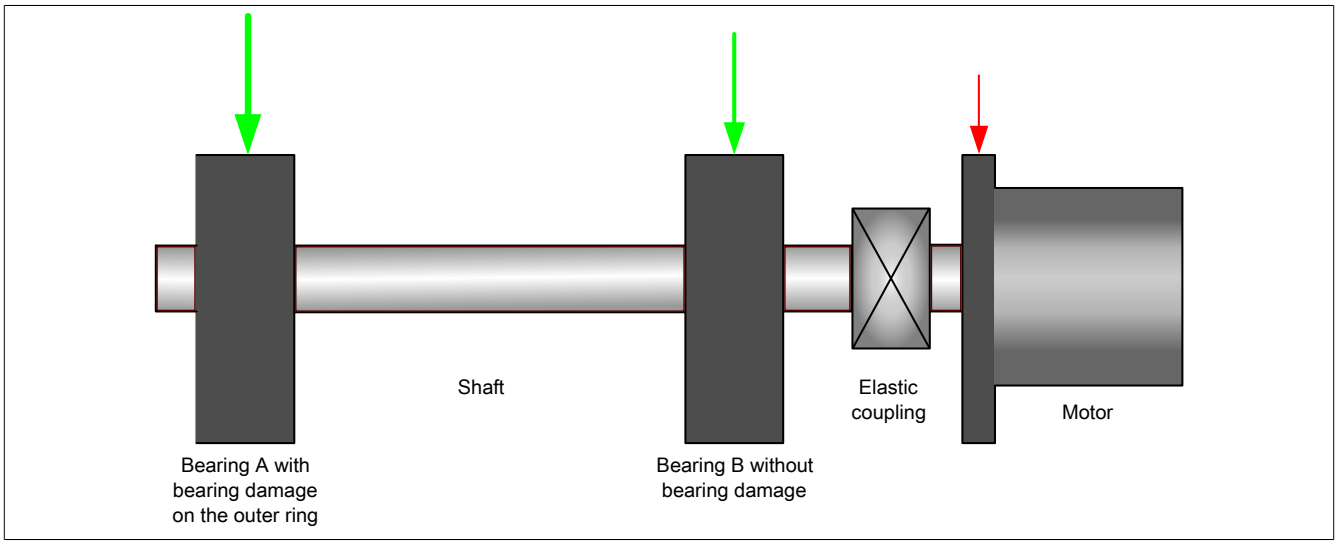

Figure 408: Suitable and unsuitable sensor attachments

4.26.4.4.2.2 Oscillations - Overview of measuring structure-borne sound

Oscillations

Mechanical oscillations

Oscillations are forms of movement that occur very frequently in nature. Harmonic oscillation is the third basic type of form of movement alongside uniform movement and uniform accelerating movement. An oscillation or vibration is a cyclical, i.e. repetitive simultaneous movement of a structure in its rest or equilibrium position.

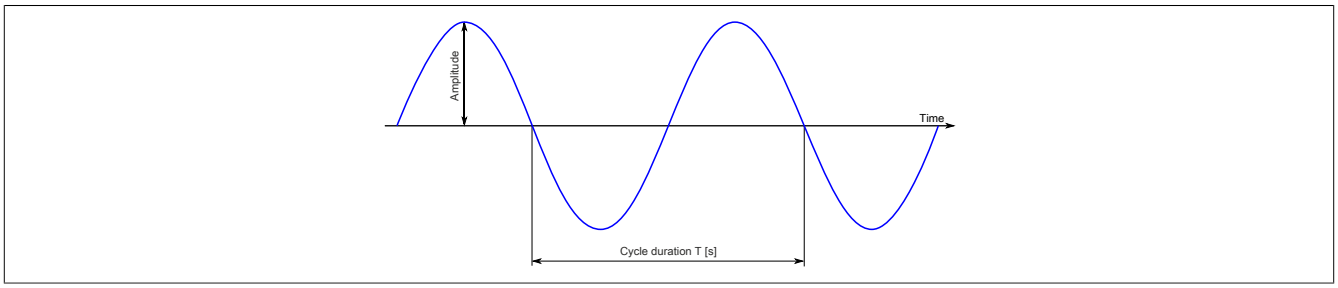

Figure 409: Illustration of a basic oscillation

If a fixed medium is stimulated by an impact, structure-borne sound spreads throughout it. This consists of additional frequencies which are determined by the shape of the structure and the material it is made from (e.g. gong or concrete block).

A portion of the structure-borne sound energy is converted into airborne sound through the surrounding atmosphere.

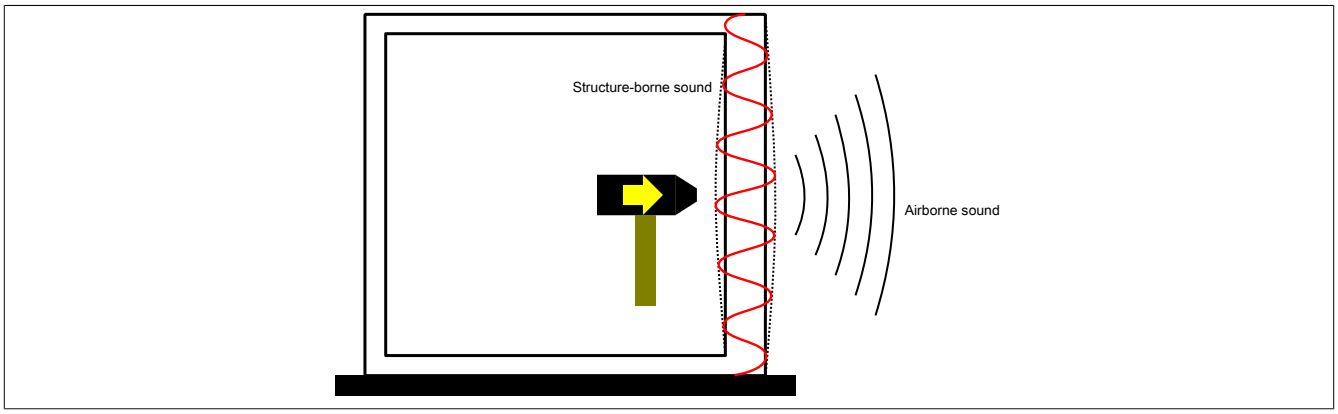

Figure 410: Propagation of structure-borne sound

Resonant frequency

Every machine has what are known as resonant frequencies. These must be observed during operation since with these frequencies the amplitude of the oscillation increases dramatically, putting strain on the mechanical components. If harmonic oscillations occur for a long time in proximity to the resonant frequency, this can lead to a so-called "resonance catastrophe", which causes the destruction of the affected part.

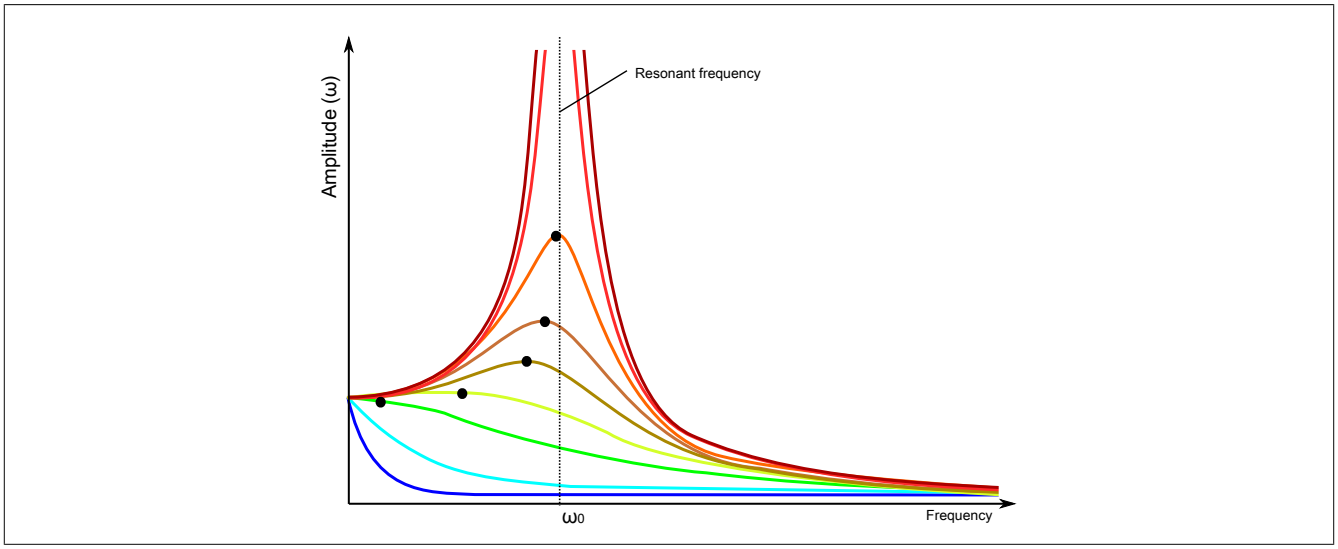

Figure 411: Increase of the amplitude in proximity to the resonant frequency

The measurement and subsequent analysis of the mechanical oscillations on stationary and rotating parts of machines, support structures and pipelines has become accepted as technically possible with practically applicable monitoring procedures.

Mechanical oscillations are a good parameter for detecting initial defects and damage and can be used for machine diagnostics.

The consequence of stress is always damage. If cyclical stress occur, it can be identified by its excitation frequency and intensity.

There are numerous overlapping causes for oscillations. The size (amplitude) of the oscillation depends on several factors such as attenuation through joints or grease, the rigidity of the component, the housing and foundations, and much more.

The absolute bearing oscillation is measured on the housing of the machine and involves the movements of the housing in relation to a fixed reference point in the room.

Causes of oscillations:

Imbalance

In accordance with DIN ISO 1925[1)], an imbalance is present in a rotating system if forces or oscillation movements are transferred to the bearing as a consequence of imbalanced centrifuges.

Imbalances on a rotating structure not only cause forces on the bearing and foundations, but also oscillations in the machine. These oscillations have a harmonic nature, with the excitation frequency corresponding to the rotary frequency of the unbalanced rotor.

Alignment errors

The main function of coupling is to connect two shafts in order to achieve a statically determinate overall system. In addition to transferring torque, couplings also offset misalignment (radial, axial, angular) to a certain extent. If the misalignment exceeds the ability of the coupling to compensate, however, additional stress such as increased bearing forces, shaft deformations and axial forces occur on the machine components involved.

Oscillations have a harmonic nature and are bound to the rotary frequency of the misaligned shafts and the multiples of this frequency. Misalignment can be measured using the rotary frequency of the misaligned part or its harmonic oscillations.

Shocks

Foreign objects as well as loose or colliding parts can cause shocks between rotating and stationary parts. These shocks repeat periodically once or several times each time the shaft revolves.

The frequency of these shock repetitions corresponds to the rotary frequency of the shaft or its harmonic frequency.

Roller bearing damage

Most bearing damage results from changes on the surface (pitting). By rolling over the damaged area on the inner ring, outer ring, cage or rolling element, pulse-shaped shocks occur that make the bearing structure and its components vibrate.

Each of these shocks appears in the oscillation signal through the typical course of a shock sequence. Characteristic values can be obtained from these measurements that give an indication of the condition of the bearing.

The excitation frequency on the inner ring, outer ring, cage and roller bearing damage is specified by the bearing manufacturer.

Magnetic induction

The rotating magnetic field causes counterforces in the stator of the machine. This electric magnetic stimulation often causes oscillations on the electric motors that are hard to detect.

Inverters also often lead to an inference of oscillations, the cause of which is of an electrical magnetic nature.

Effects

Machines and systems with moving parts cause mechanical oscillations. The effects on the immediate location and surrounding area include tremors and structure-borne sound, often creating a disturbing noise development.

Increased vibrations can lead to malfunctions in the machine, particularly in measurement and control devices. If this causes the measuring equipment to resonate as well, incorrect measurements will result and manufacturing quality will suffer.

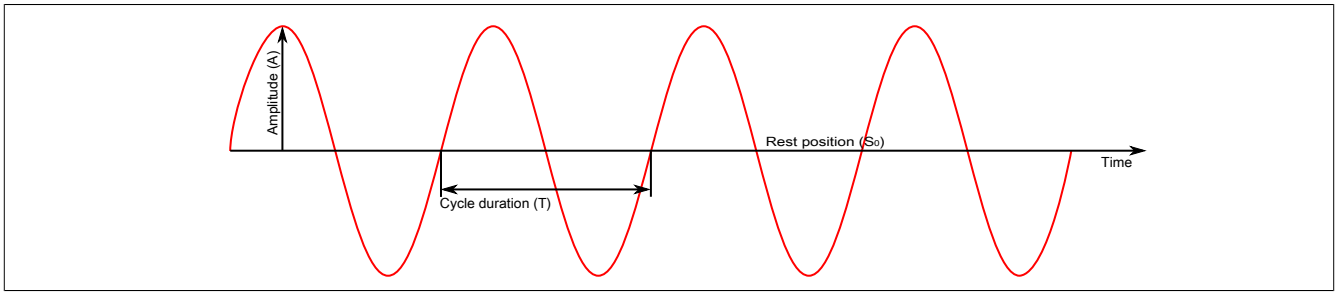
In addition, stress will develop on the components of the machine. Unwanted vibrations lead to increased wear with partly plastic distortion of components and increased crack formation all the way up to failure.

Noticeable oscillations are felt through the equilibrium organ and sense of touch. It can impair working performance and well-being, even leading to health damage.

[1)] DIN ISO 1925: Issue: 1996-11 Mechanical oscillations - Balancing technology - Terms (ISO 1925:1990 + AMD 1:1995)

Oscillation parameters

Parameter	Explanation	Symbol	Formula
Rest position	The structure's undisplaced position	s_0	
Amplitude	The greatest displacement from the rest position	A	
Period duration	Minimal time span for a complete oscillation after which a structure has reached its initial position and initial speed again	T	
Frequency	Number of oscillations per unit of time	f	f = 1 / T
Angular velocity	Change of angle in the radian measure over time	ω	ω = 2 * π * f



Large mechanical oscillations

An oscillation consists path (s), velocity (v) and acceleration (α) values.

These three values have a consistent relationship with one another and can be converted from one to the other using simple calculations.

The B&R sensors measure oscillation acceleration. The unit is m/s^2, although acceleration is often specified in the unit g ($1g = 9.81\ m/s^2$) for the earth's acceleration.

For some diagnostics, however, the oscillation velocity or displacement is more significant. The acceleration can then be passed converted to the oscillation velocity through integration. The path can be calculated from the acceleration by using integration twice.

Displacement

$$s = \hat{s} \cdot \sin(\omega t + \varphi)$$

Oscillation velocity

$$v = \frac{ds}{dt} = \hat{s} \cdot \omega \cdot \cos(\omega t + \varphi)$$

Oscillation acceleration

$$\alpha = \frac{d^2s}{dt^2} = \frac{dv}{dt} = -\hat{s} \cdot \omega^2 \cdot \sin(\omega t + \varphi)$$

Converting from one value to the other through Integration or differentiation

Table 593: Mathematical relationship

Information:

Displacement is not calculated by the X20CM4810.

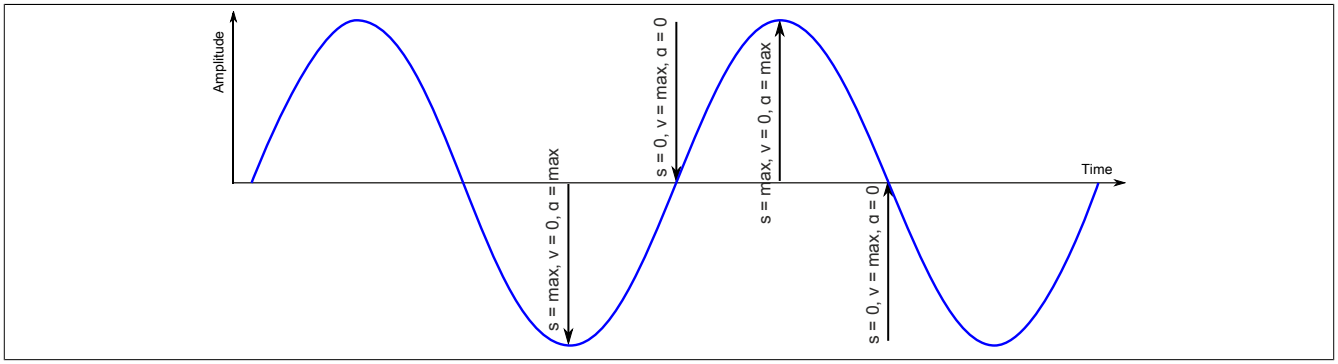


Figure 412: The s-v-a relationship

A harmonic oscillation can be clearly described by its amplitude, frequency and phase angle.

- The amplitude in the path, velocity or acceleration indicates the instantaneous value.
- The frequency describes how often an oscillation changes within one second. In oscillation diagnostics, this plays an important role since many frequencies can be assigned to one cause.
- The phase angle refers to the starting point of the oscillation. This is usually not that important since in most cases several oscillations are present.

Fast Fourier transforms (FFT)

Oscillation signals generally consist of a number of oscillations that occur simultaneously and overlap. Individual frequencies are not directly evident from a timing diagram.

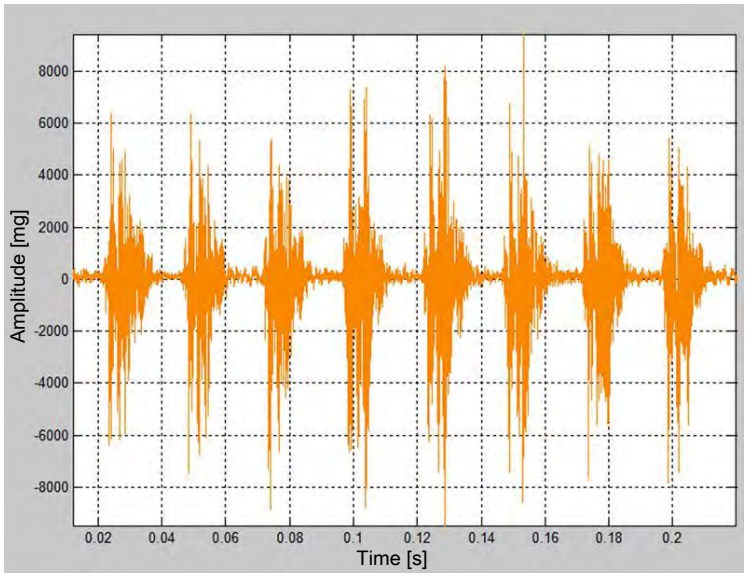

Figure 413: Timing diagram of an oscillation

Calculating a line spectrum is suitable for analyzing a mixture of oscillations of different frequencies where each participating oscillation and their frequencies and amplitudes are represented by a single line.

Within the scope of condition monitoring, spectra are a valuable aid in finding the cause of a failure. Many frequencies can be traced back to individual components so that damaged components can be identified.

Adding sinusoidal oscillations to generate a signal

The following figures show how a square wave signal is created by overlapping sinusoidal oscillations.

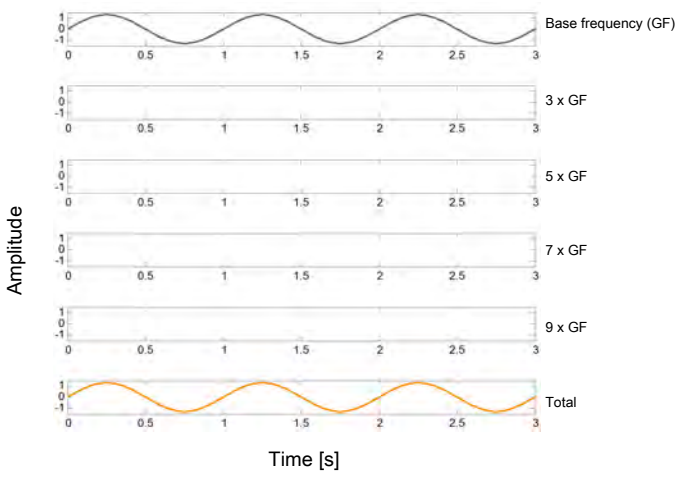

Figure 414: Pure sinusoidal oscillation

Sinusoidal oscillation with 1 hertz and an amplitude of 1.

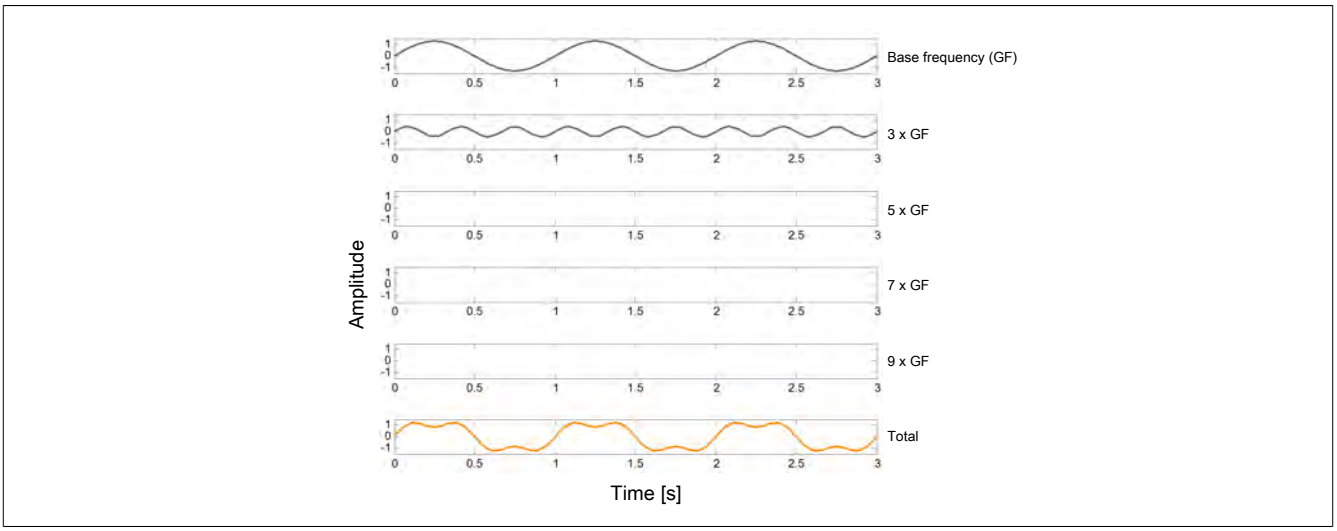

Figure 415: Sinusoidal oscillation with one harmonic

Sinusoidal oscillation with 1 hertz and an amplitude of 1 and sinusoidal oscillation with 3x the base frequency, i.e. 3 hertz and a lower amplitude.

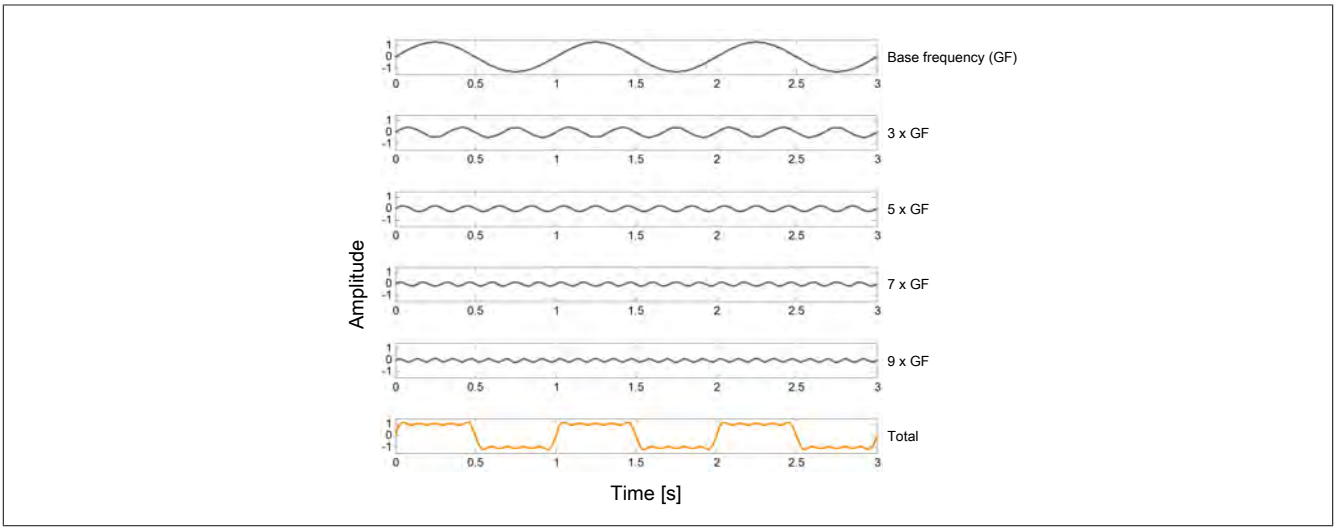

Figure 416: Sinusoidal oscillation with several harmonics

Sinusoidal oscillation with 1 hertz and an amplitude of 1 and sinusoidal oscillation with 3x the base frequency and a lower amplitude, and others with 5x 7x and 9x the base frequency.

General description

The Fourier transform is the basic principle of frequency analysis. Using mathematical approaches, this process brings the time signal waveform into the frequency representation (spectrum). Probably the most well-known concept in connection with signal processing and frequency analysis is the fast Fourier transform, or FFT.

The fast Fourier transform assumes that each harmonic oscillation can be broken down into any number of sinusoidal and cosinusoidal waves, the sum of which reproduces the original oscillation. Linked individual waves are "broken down" again accordingly.

If this procedure is then applied to a single sine signal with a constant frequency, a single line is shown in the frequency spectrum.

In order to be able to evaluate single partial oscillations into amplitude and frequency, the digitized time signal is converted into a frequency spectrum. In addition, a small extract is taken from the signal; this is known as the time window.

Using the FFT algorithm, the frequency spectrum is calculated from this so that each involved oscillation and its associated frequencies and amplitudes is shown as a single line in the line spectrum.

Information about using FFT

Window functions

Depending on the signal structure and boundary conditions, discontinuities may occur at the time window limits of the extract taken. These reflect partial oscillations that do not exist at all in reality.

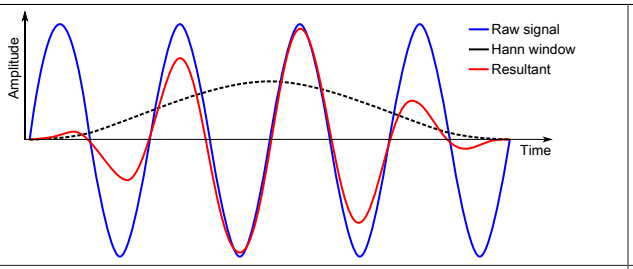
These discontinuities arise if the period of the sampling does not correspond to an integral multiple of the period of the time signal. This occurs with practically every real measured signal since this is composed of a number of signals with different period durations.

Window functions are used to suppress these discontinuities. This is done by multiplying the input signal with the window function and supplying the Fourier transform with the resulting signal.

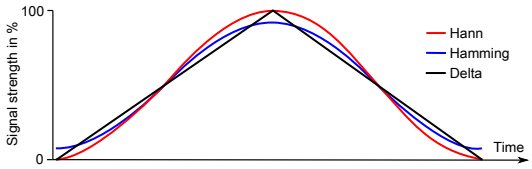
Common window functions are:

- Triangular window
- Hann window
- Hamming window

All of these functions share the fact that they approach zero at the edges, so the periodic continuation now no longer has any jump discontinuities.



Time signal with Hann window



Comparing window functions

Information:

Only the Hann window is used in the X20CM4810 module.

Sampling

Scanning or sampling refers to the recording of an analog value at certain intervals.

At the respective point in time, the precise voltage level of the signal is recorded and stored. The distance Δt (Delta t) between the recording points is called the sampling interval. If the inverse value is formed from the sampling rate, this results in the sampling frequency.

Sampling an analog signal once per second corresponds to a sampling rate of 1 Hz; sampling once per ms corresponds to a rate of 1 kHz.

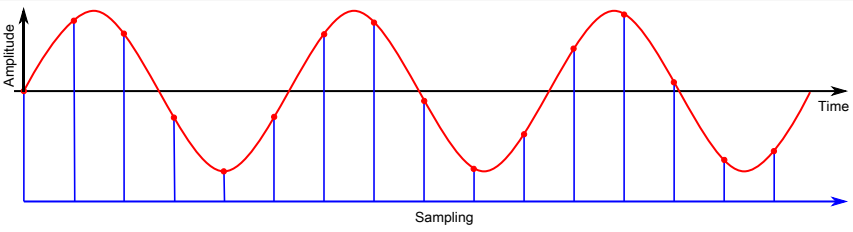


Figure 417: Sampling of a curve

If the sampling rate is many times higher than the theoretically required sampling frequency, it is called "oversampling". The reduction of the sampling rate to the required rate is called "downsampling".

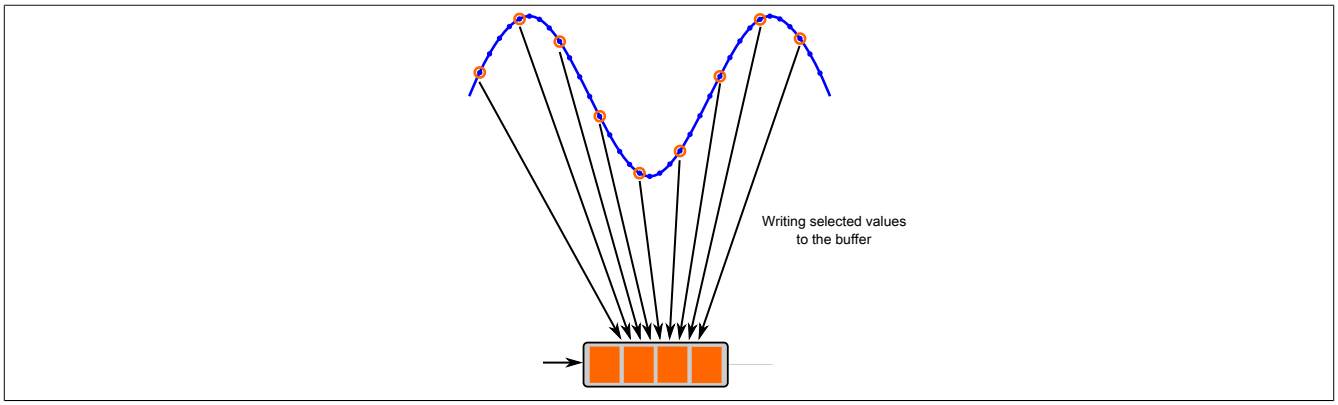
Using FFT for a signal with a multiple frequency of the sampling frequency results in only a single line on the spectrum.

Normally, however, frequency analysis is used on signals where the frequency is unknown. In other words, there is an arbitrary, periodic signal composed of various oscillations with different frequencies. As a result, no whole number frequencies of the oscillations being measured can be used as the sampling frequency. This causes additional lines to appear on the spectrum.

Depending on the resolution selected, the lines manifest themselves in different ways on the spectrum.

Buffer storage

The values that have been sampled are stored in the module's internal buffer. A copy of these values is transmitted every 300 ms.



The size of the buffer is constant and can store 8192 measurement values. This results in the ratio between the sampling frequency and the duration of measurement.

Duration of measurement = Buffer size / Sampling frequency

Since the values stored are dependent on the configured sampling frequency and not the hardware-based sampling frequency, not all values that are measured are stored. At a measurement duration of 318 ms, every second value is stored; at a duration of 15.9 ms, every hundredth value is stored.

These are indirectly adjustable using the registers "MaxFrequencyEnvelope01" and "MaxFrequencyRaw01"

Aliasing effect

The input signal is sampled at regular intervals. If the sampling rate used is too low, the input signal will be sampled incorrectly and a flawed image of the oscillation will occur. This undesirable phenomenon is called the aliasing effect.

To avoid such false results, the requirements of the theorem known as Nyquist's sampling theorem must be fulfilled in the sampling. This sampling theorem describes the necessary frequency ratio between the sampling and the signal and states that the sampling frequency must be more than double the maximum frequency of the measured signal.

Example of incorrect sampling

Sine wave with 4 kHz sampled at 6kHz. The red wave shows the sine wave measuring 2 kHz, which is a result of the sampling being too low.

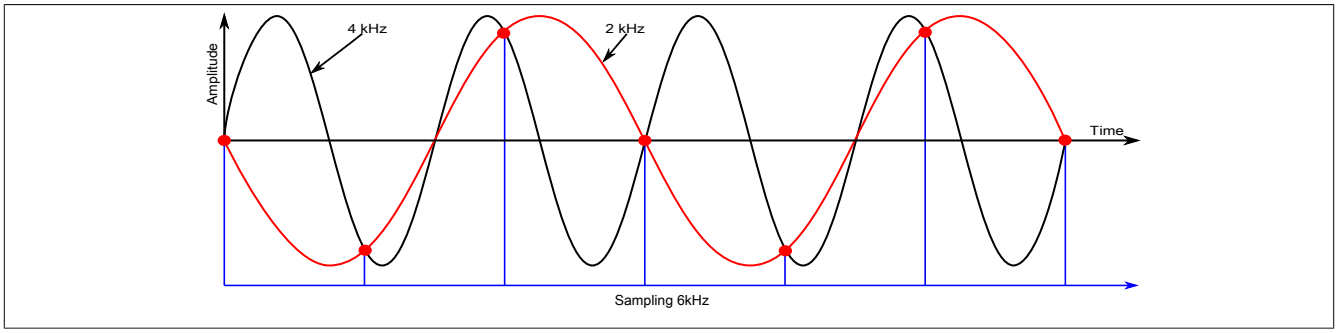


Figure 418: Incorrect sampling with 6 kHz and 4 kHz

Information:

The X20CM4810 module ensures that Nyquist's sampling theorem is always fulfilled.

In the X20CM4810 module, a sampling rate of 51.5625 is used to achieve a signal of 10 kHz.

Resolution

Resolution refers to the difference between two two adjacent measurement data points. This specifies the size of the distance between two lines along both the horizontal ("Time signal" or "Frequency spectrum") and vertical axis ("Quantization" of the amplitude).

An important factor affecting the quality of the resolution is the relationship between the number of measurement data points and the sampled frequency. The larger this ratio, the more accurately the measured signals correspond to the actual amplitude information. For example, 10,000 samplings of a 10 kHz signal yield a 10x more accurate amplitude characteristic than of a 100 kHz signal.

Information:

On the X20CM4810, a MaxFrequency of 200 Hz results in a distance of 0.0629 Hz between two lines.

Time signal

The resolution can be identified in the time signal from the distance between two adjacent measurement points.

Example

A "MaxFrequencyRaw" of 2 kHz is used in this example.

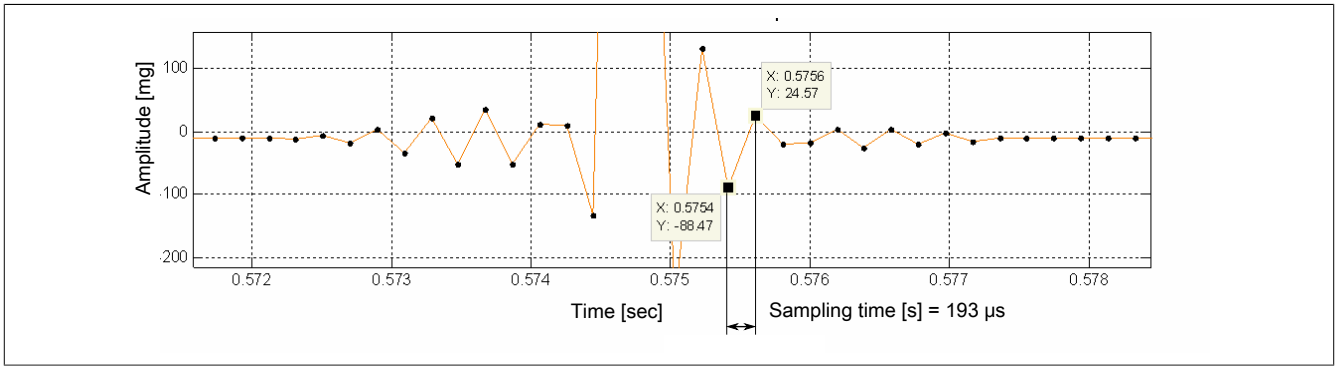

Figure 419: Time signal from a module with corresponding resolution

Frequency spectrum

The resolution in the frequency spectrum indicates the distance between the individual frequency lines (spectral lines) that can still be evaluated.

Example

Frequency spectrum at a MaxFrequency of 2 kHz.

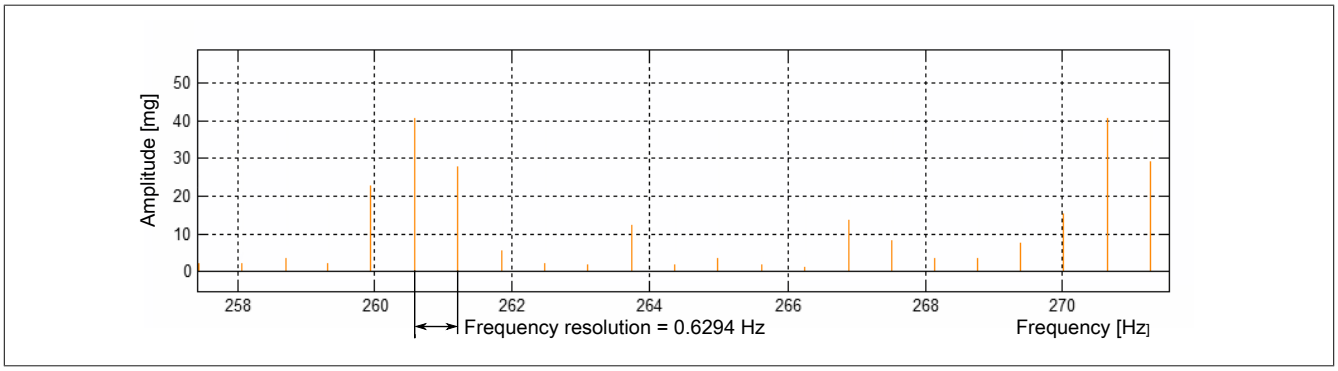

Figure 420: Frequency spectrum from the module

Quantization

To process the analog signal, an analog-to-digital converter (AD converter) is required. An AD converter can only measure voltage in stages, however. This is known as quantum voltage. The area to be measured is therefore quantized.

In an AD converter, the digital resolution depicts the number of levels there are in the quantization. This determines the accuracy and sensitivity with which a previously analog level value is depicted. The more available levels there are, the better the discrete signal received and the higher the sensitivity of the vibration measurement.

The resolution indicates how many varying digital values an analog signal can be converted into. The resolution is expressed in bits. "N-bit" means" 2^n", i.e. 2 to the power of n quantization levels are available.

8-bit resolution	256 level values
16-bit resolution	65,536 level values
24-bit resolution	16,777,216 level values

Example

At a sensor measurement range of ±50 g, the smallest distinguishable level is 5.96046E-06 (0.00000596046 g and 5.96 µg).

This resolution is much higher than the resolution of standard industrial sensors. This is in the range of 350 µg, representing a difference of a factor of 70.

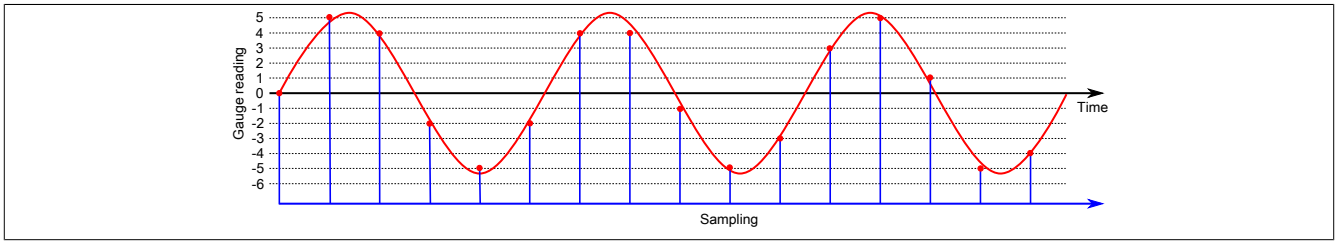

Figure 421: Quantization error at low resolution

Information:

The X20CM4810 module has 24-bit resolution.

Measurement time

The measurement time is dependent on the maximum frequency. See "MaxFrequencyEnvelope01" for the envelope characteristic values and "MaxFrequencyRaw01" for the raw values.

Maximum frequency	Sample frequency	Measurement time
10000 Hz	25781 Hz	0.3178 s
5000 Hz	12891 Hz	0.6355 s
2000 Hz	5156 Hz	1.5888 s
1000 Hz	2578 Hz	3.1775 s
500 Hz	1289 Hz	6.3550 s
200 Hz	516 Hz	15.8875 s

Table 594: Overview of possible measurement times.

Envelope

There are two main causes of oscillation.

1. Oscillations

Imbalance and problems with alignment lead to predominantly harmonic, sinusoidal oscillations.

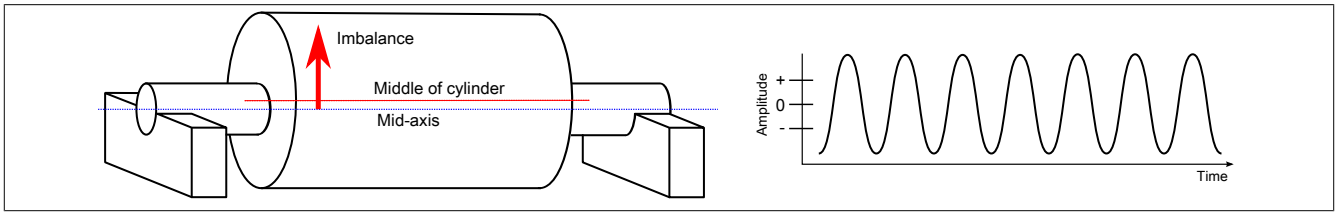

Figure 422: Imbalance - Harmonic oscillation

2 Impacts

Many types of machine damage can result in oscillations that cause the structure of the machine or adjacent machine parts to vibrate at their natural frequency. Impact-related causes of this are a result of corrosion, a rotor brushing up against the machine housing or roller bearing/gearing damage to the gears.

In the case of roller bearing damage, impact occurs when either the rolling elements roll over damage on the inner or outer track or when one of the rolling elements themselves is damaged.

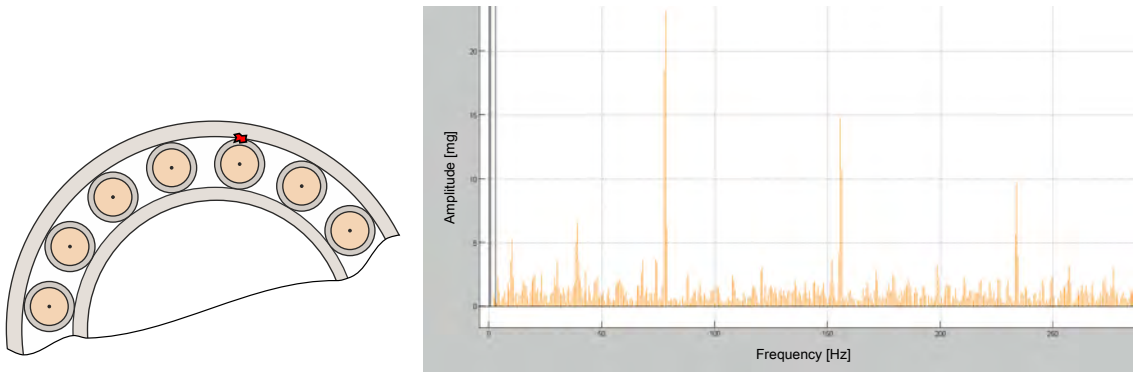

Figure 423: Bearing damage - FFT of envelope signal

This kind of impact can be compared to a clapper hitting a bell. If the bell is struck twice a second, it vibrates at its natural frequency and not 2 Hz. The natural frequency is determined by the constructive design and material properties. As with any sound boxes, mounting also factors into this.

If the damage is to the roller bearing track, every shock pulse will lead to a corresponding reaction in the vibrating system. It is only practical of course to measure the sum of all pulses, i.e. the total signal.

In the case of damage to roller bearings, the bearing rings are the first to start vibrating.

Oscillations are transmitted to the machine as waves and can be measured on the machine's surface. Naturally, it is a requirement that a path is available for the sound to be transmitted, i.e. no sound-absorbing limiting processes such as air, rubber etc. are present.

This signal can be measured on the surfaces of the machine by means of an acceleration sensor. The signal is made up of a variety of oscillations and impacts that overlap each other. When considering the time signal in this way, it is easy to see that allocating individual frequencies is impossible.

Using a Fast Fourier transform, this time signal can be converted to give the natural frequency of the system. These are in the high-frequency range. The rotor frequency and its harmonic frequency are clearly identifiable as the dominant frequency portion.

The rollover frequencies of the roller bearings are between 15 and 70 Hz at a speed of approximately 600 rpm, depending on the bearing.

In particular, shock pulses of a lower intensity, as they are when damage first begins, can barely be noticed or assessed. It is only when there is advanced damage to bearings that signal peaks can be clearly observed.

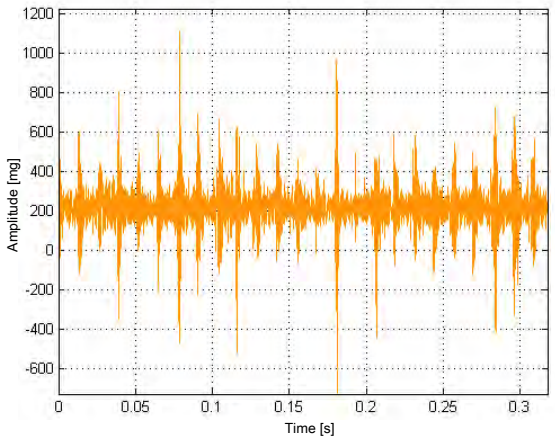

Figure 424: Advanced bearing damage at 600 rpm

To make the actual result, or shock sequence, clearly visible, it is obviously not enough to simply provide the amplitude spectrum. It is much more important that the process of convolution that took place when the signal occurred be appropriately reversed so as to separate the excitation function from the natural frequency. This is what envelope analysis provides.

An amplitude-modulated signal is made up of a high-frequency carrier signal in a low-frequency wanted signal. The amplitude of the carrier signal changes depending on the wanted signal. In the receiver, the wanted signal is extracted from the carrier signal by the formation of the envelope curve (demodulation).

In the case of machine resonances caused by periodic impacts, the machine resonances can be viewed as the carrier signal and the low-pass-filtered shock pulses can be viewed as the low-frequency modulation signal. Demodulation results in the shock pulses being extracted from the resonance frequencies.

Envelope analysis

Normally in an envelope analysis, the frequency spectrum of the envelope signal is evaluated. The frequency spectrum of the low-pass-filtered, aligned, amplitude-modulated sinusoidal oscillation is trivial since it relates to only one sinusoidal oscillation. Suppressing the steady component gives a frequency spectrum that exhibits only one increased amplitude at the frequency of the low-frequency sinusoidal oscillation.

The envelope signal of the periodically peaked excited machine resonance shows mostly increased amplitudes in the shock pulse repetition rate and its multiples.

The envelope analysis is therefore a method for differentiating between harmonic causes (imbalance, orientation) and impact-related causes (roller bearing damage, gearing damage, etc.).

Conversely, it must be stated that harmonic causes in an envelope spectrum cannot be determined accordingly.

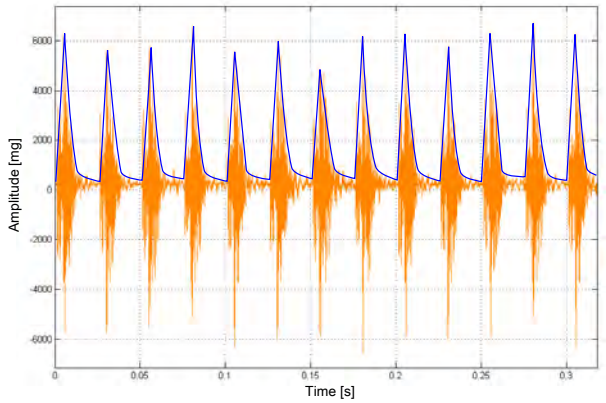

Figure 425: Time signal with envelope

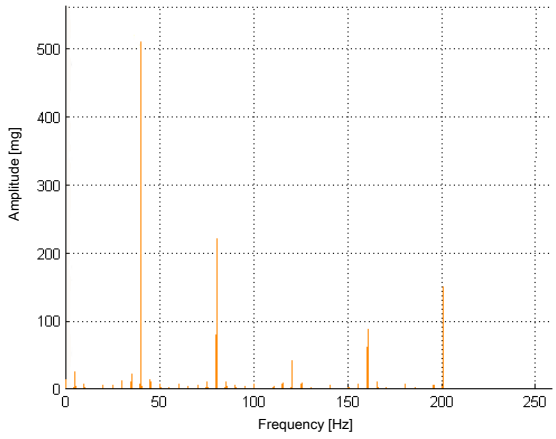

Figure 426: Resulting frequency spectrum

Displacement, velocity and acceleration

Sensors can record oscillation acceleration, oscillation velocity or oscillation displacement. Regardless of the physical size that the sensor records, the oscillation can be represented as acceleration, velocity or displacement since:

$$s = \int v dt = \iint a dt^2, \text{ or } \qquad a = \frac{dv}{dt} = \frac{d^2 s}{dt^2}$$

Where:

- s = Oscillation displacement
- v = Oscillation velocity
- a = Oscillation acceleration
- t = Time

Acceleration is proportional to the force. In contrast, the velocity is an indication of the energy.

The practical implication is that frequency has an influence when converting from one physical size to another. For a sinusoidal oscillation, the following applies:

$$s = \frac{a}{(2 \cdot \pi \cdot f)^2} \qquad v = \frac{a}{2 \cdot \pi \cdot f}$$

The frequency is in the denominator. As a result, high-frequency signal portions are underestimated when using oscillation velocity in comparison with oscillation acceleration. This effect is squared with the application of oscillation displacement.

Since oscillation velocity is calculated through integration from the oscillation acceleration and oscillation displacement is calculated through integration from the oscillation velocity, the mathematical relationship is easily identifiable.

4.26.4.4.2.3 Determining the limit - Alarm philosophy

A fundamental statement can be made by comparing the characteristic values with predefined limit values.

Characteristic values are calculated from the measured signals, which are representative of the status of the system at the given measurement point.

Norms can be used in part to determine alarm limits. In addition, limits can be set based on the machine's history and the experience of the operator.

Comparison with references and norms

For certain machines and systems, limits are fixed by norms. With the exception of ISO 10816, these give little information for assessing the actual status of the machine.

Manufacturer's limits

A few machine manufacturers give limits for permissible oscillations and other relevant factors for assessing the status of the machine.

These are based partly on calculations as well as the knowledge and experience of the manufacturers of these systems.

The limit values provided by the manufacturer should be used when making assessments.

Operator's limits - Experience-based values

Operators draw on their own experience when assessing the status of the machine. Long-term observation of the characteristic values and the machine's history can provide relevant values based on experience.

The limits ascertained from this can vary significantly from limits set by norms and those prescribed by the manufacturer of the machines.

This assessment is only possible when operators have considerable experience with oscillations in the machine and are in a position to differentiate between positive and negative characteristics.

Measuring the broadband values (see 4.26.4.4.3.1 "Characteristic values" on page 2629) is one well suited way to find limits. Some of the characteristics on which limits depend include:

- The location of the damage
- The location of the sensor
- The speed of the moving parts of the machine
- The load on the machine parts
- Etc.

Assessing the trend

In many cases, not enough is known about the actual behavior of a machine during operation, in particular when there is damage.

To make a reliable statement about its condition, the chronological sequence of the characteristic values (characteristic value trend) must also be used when making the assessment.

In the progression of the trend, the "Normal condition" is the starting point. The reference level (normal level) is the level of the characteristic value as set in the normal condition.

Changes in the trend are observed with the normal condition as the starting point. When there is damage, the relevant characteristic values in each case generally increase, although a decrease can also be an indication of a problem in the system.

In order to assess trends accurately, it is essential that the characteristic values of the oscillations are always recorded under the same operating conditions and always classified in the same way. In particular, the speed and load ratio, where applicable, have a strong effect on the characteristic values. Increases in trends under differing operating conditions cannot necessarily be a sign of a change in the actual condition. In many cases, trend observation can assist in monitoring the condition of the machine and bearings.

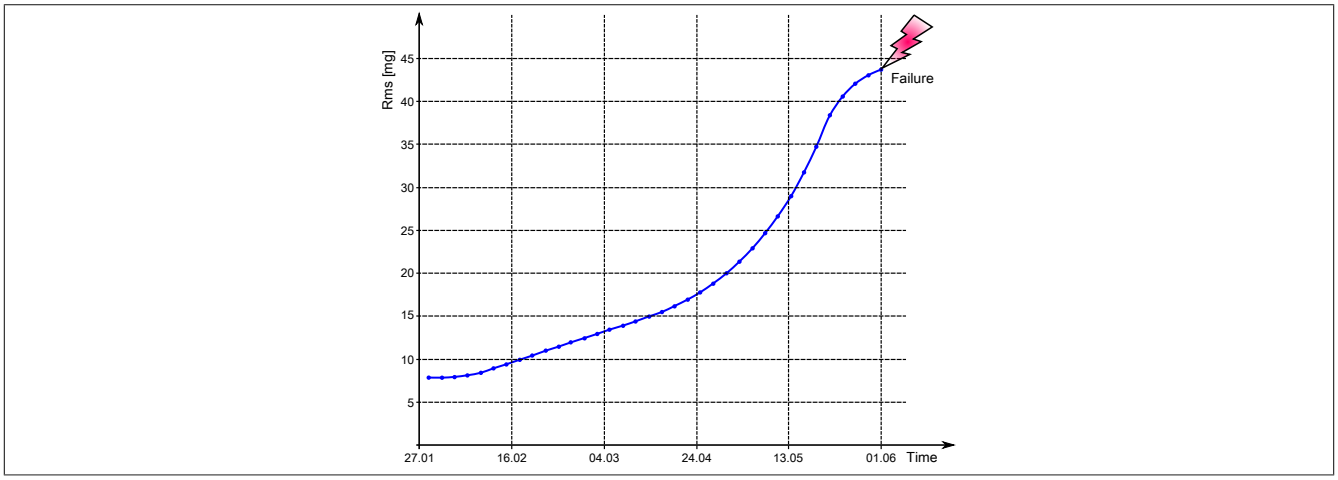

Figure 427: Typical trend progression

The first and second derivatives of the damage progression trend line can provide good information about how badly a component is damaged.

Example

This example will use the first and second derivative to determine the best time for repairs. The maximum service life will be taken into account when selecting a time to perform a replacement. The possibility of lowered production quality is not taken into consideration.

Various times for performing a replacement can be selected by referring to the trend progression.

- k1 = First increase. Very conservative, service life is wasted.
- k2 = Second increase. Good compromise between conservative and optimal.
- k3 = Drop in second derivative. Optimal utilization of service life.

Information:

This example of derivative usage should not be used in your own applications.

First derivative

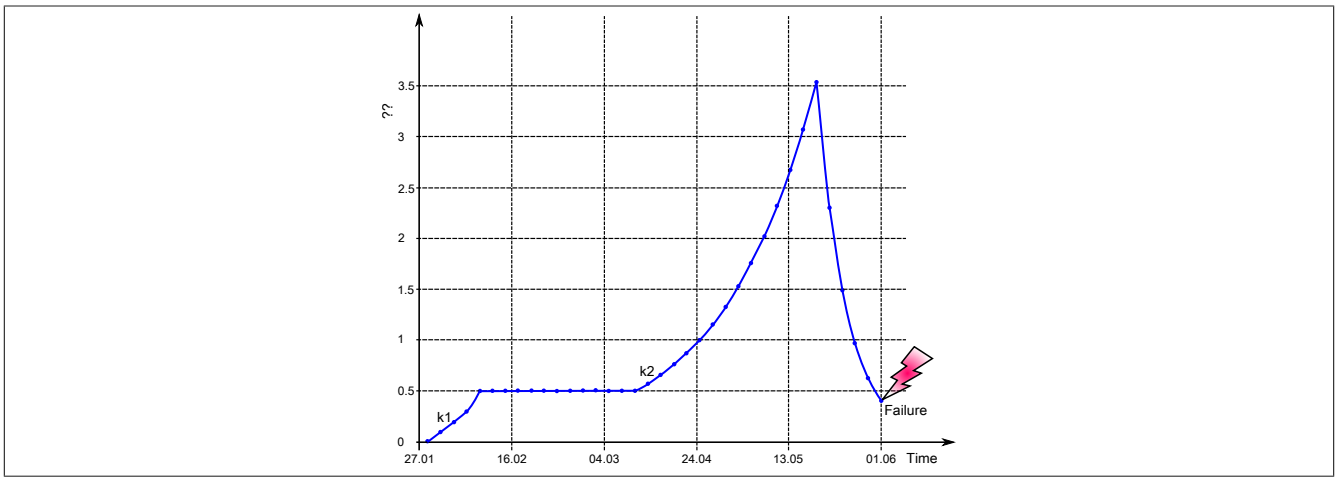

Figure 428: First derivative of the trend progression

Second derivative

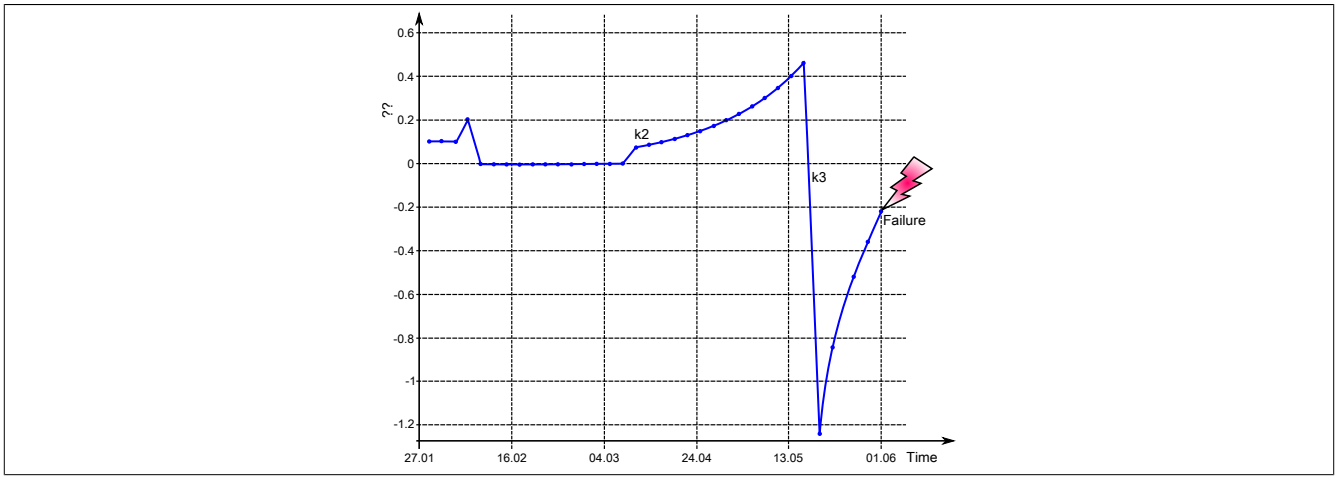

Figure 429: Second derivative of the trend progression

Dynamic speed change

With the FFT calculation in the X20CM4810 module, it is assumed that the lines do not shift during the calculation of a buffer. This is only the case when the system speed is constant.

In the case of dynamic speed, narrow-band frequencies cannot be used to monitor or analyze damaged frequencies since these do not give valid results. The following diagrams show the effect that such a change in speed during an FFT calculation can have.

Example

The speed of a wave changes from 100 Hz to 200 Hz.

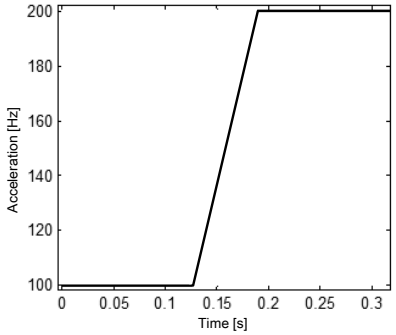

Figure 430: Speed profile

Changing the speed of a wave (within a buffer measuring length, damage is simulated with the speed frequency)

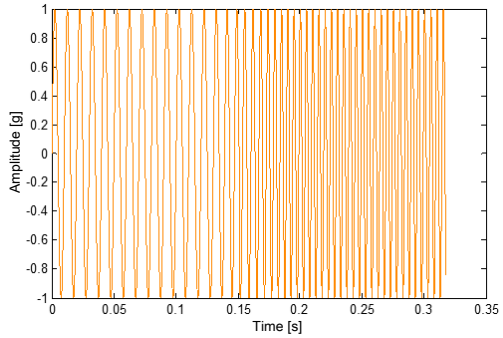

Figure 431: Time signal

Change in the time signal

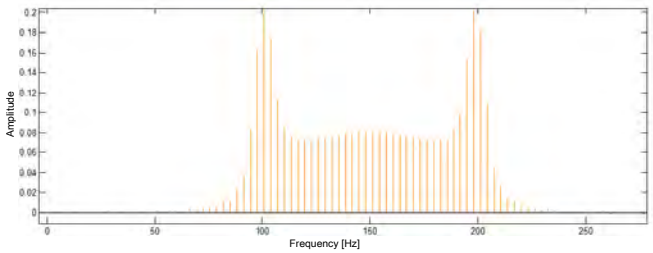

Figure 432: Result in the frequency spectrum

Resulting spectrum calculated from the time signal

Possible approaches to measuring in a dynamic system

- **Best solution:** Adopting separate measurements for trend analysis where the speed can be kept constant for the duration of measuring.
- If a measurement cannot be taken at constant speed, an assessment of the machine condition can be made using the characteristic values or a broadband frequency (in this example, this would be 80 to 220 Hz).

4.26.4.4.3 Practical applications of damage recognition

It is possible to gain good insight into the condition of a machine or system by measuring the parameters associated with errors. This parameter data is used by different algorithms in the module to even calculate the characteristic values. This method of forming characteristic values occurs continually and automatically. It requires little technical knowledge and is easy to use and implement. Damage and flawed conditions can therefore no longer be overlooked.

Selecting suitable characteristic values and assessing them over a longer time frame is the basis for effective and successful monitoring of a machine, a process known as "trending". It enables multiple aggregates to be monitored with a relatively low need for technical measuring and a low demand on staff.

When integrating condition monitoring into automation systems, simply setting basic limits as a warning is not enough. Instead, logical correlations with other parameters such as load or speed, or even the shape of the trend curve, are also required.

Characteristic values are thus gathered and compared with norms or values taken from available experience over a long period of time. This trend progression can be used to make a good assessment of the machine's condition. The trend development of this factor indicates whether the condition is worsening, i.e. if damage is beginning to occur.

Recording the measurement values in a diagram shows the status of the characteristic values at the default warning and alarm thresholds. If these thresholds are exceeded (and only then), oscillation diagnostics gives the cause of the error so that appropriate maintenance measures can be taken.

4.26.4.4.3.1 Characteristic values

The following matrix shows the relationship between potential failures and the suitability of the characteristic values provided in the module. The potential failures refer to the individual application possibilities.

This assessment is based on an estimation of typical applications.

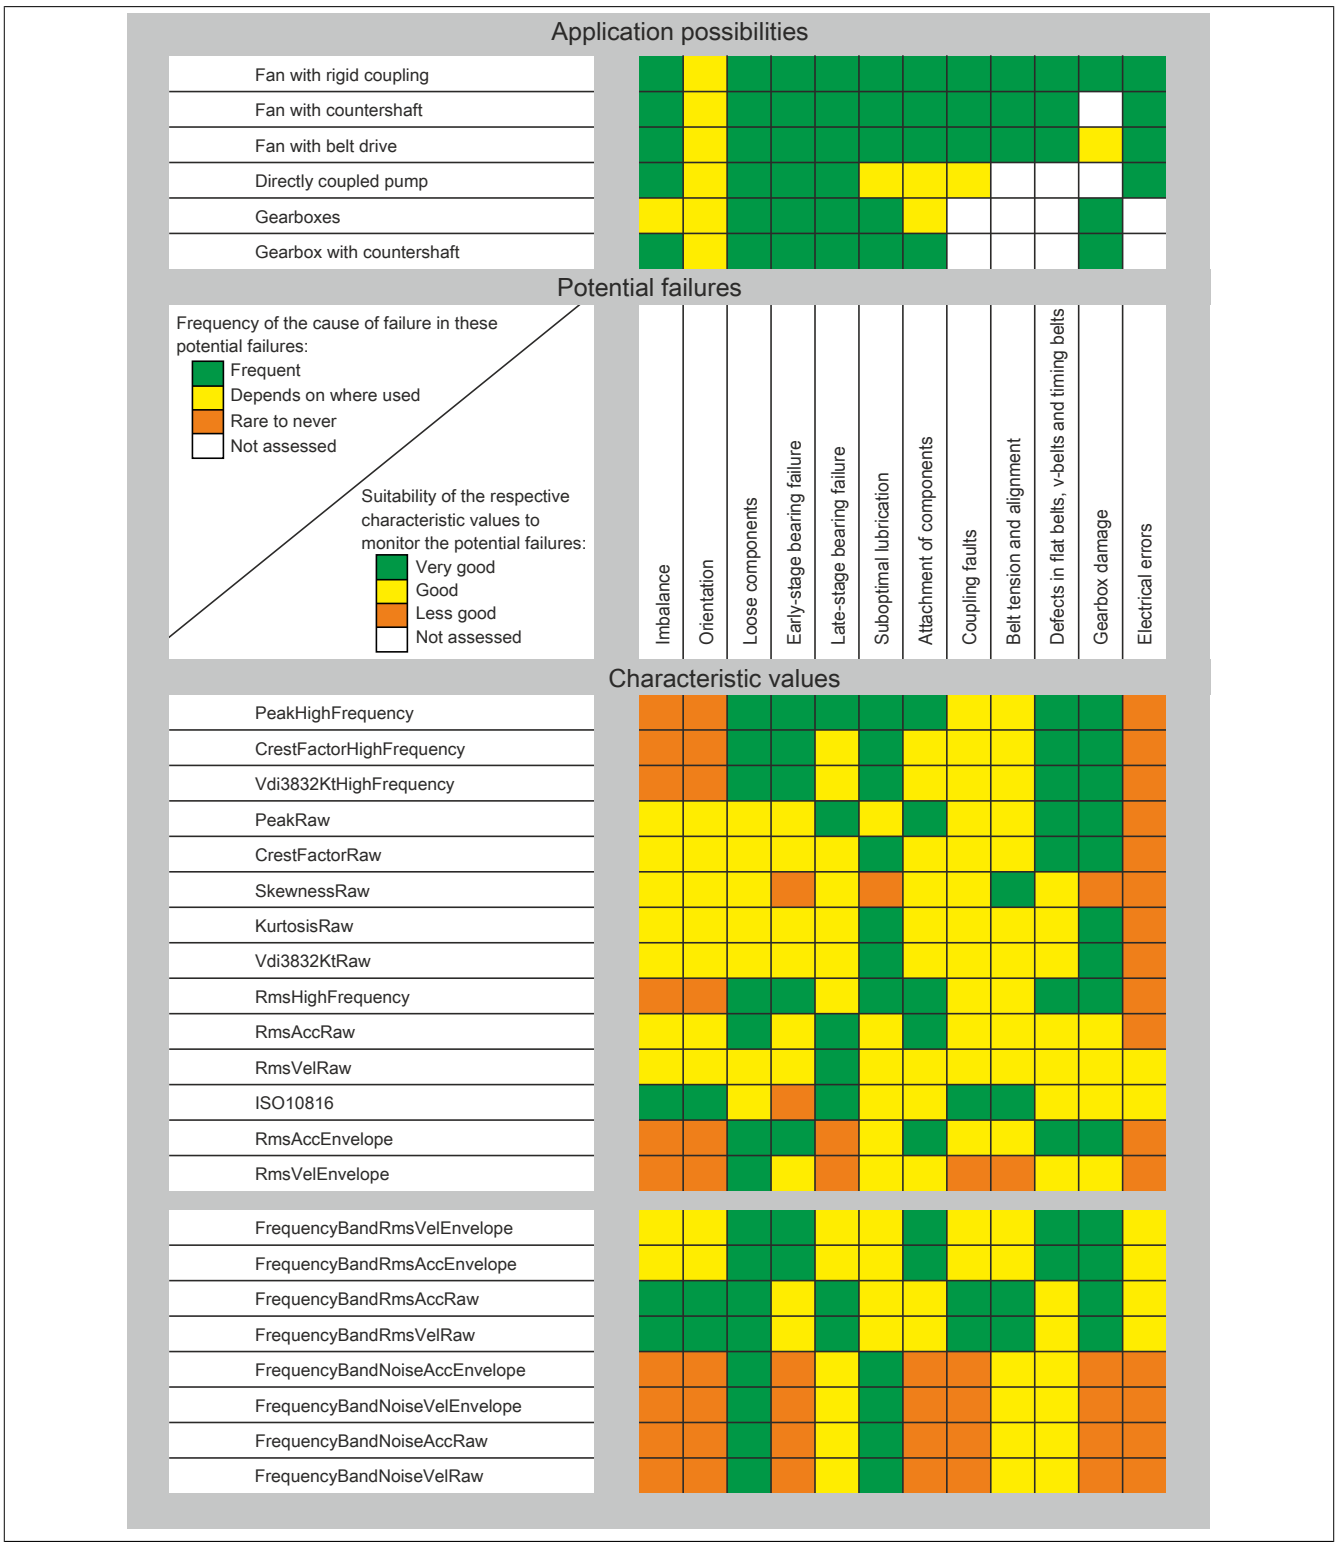

Figure 433: Relationship between potential failures, characteristic values and application possibilities

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Description of individual characteristic values

Sum of maximum value

The maximum value is often also referred to as the peak value.

The peak value of a mechanical oscillation signal indicate the maximum sum of individual impacts that come from the ambient noise. Different types of damage give rise to strong impacts, which show up in the peak value.

PeakHighFrequency

Maximum sum formed from the high-frequency portions of the input signal of the oscillation acceleration in the frequency range between "HighFrequencyConfig01" (500 Hz – 2 kHz) and 10 kHz.

Example: Loose components in the motors

PeakRaw

Maximum sum formed from the raw signal of the oscillation acceleration up until the configured maximum frequency ("MaxFrequencyRaw01") of the channel.

Example: Late-stage bearing damage

RMS value

The RMS value is also known as the quadratic mean, or the root-mean-square. Along with the amplitude, it also takes the energy content of the oscillation into consideration and is the mathematical background for many characteristic values of assessment.

If the RMS is calculated to be above the oscillation velocity, this can be referred to as oscillation speed. In the RMS value, everything contributing to the oscillation is added up. The high oscillation amplitudes of an imbalance are the same as the low oscillation level of bearing damage that is just beginning to occur.

If the RMS value is measured broadly, changes in individual elements contributing to the oscillation can be masked by the message. Early and reliable detection of damage, e.g. due to defects in roller bearings, is only conditionally possible.

ISO10816

The RMS value from the raw signal of the oscillation velocity in a frequency range from 10 Hz to 1 kHz according to ISO 10816.

This broad characteristic value is often used in the assessment of the machine condition since assessment limits are specified for this characteristic value in the standard. These depend on the type of machine and type of installation (rigid or non-rigid). The characteristic value limits for a pre-warning or a warning are given according to their defined classification.

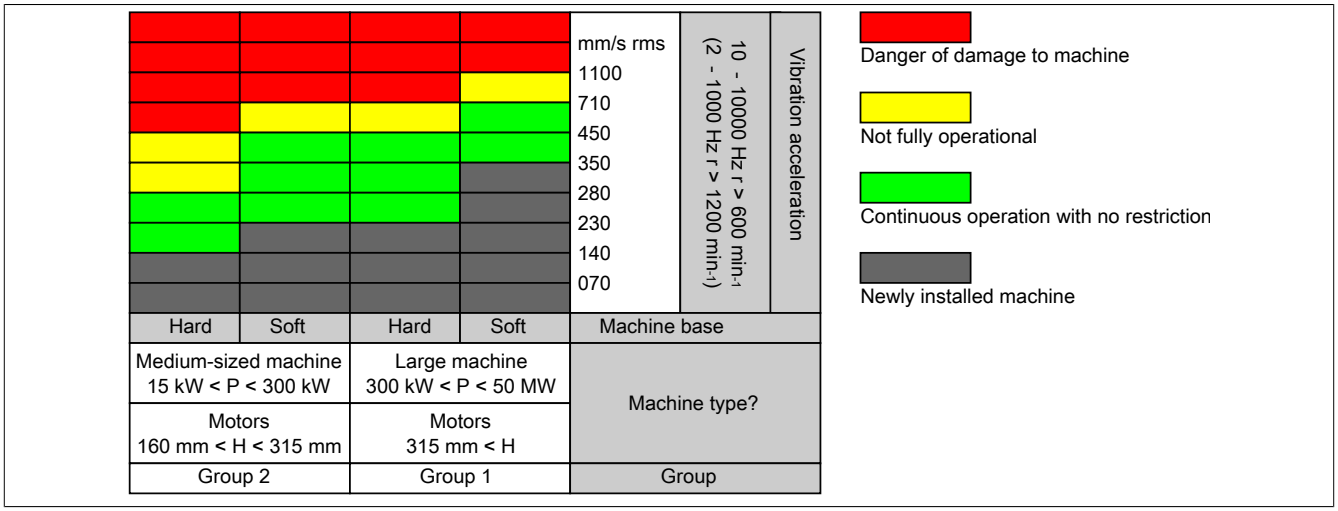

Figure 434: DIN assessment scheme

If the machine condition is in order, this characteristic value is low. If damage occurs, then this value increases severely. If the RMS is assessed in the range of the oscillation velocity, lower frequency portions such as drive speed (and associated imbalance and/or misalignment) that are emphasized more and reflected more heavily in the characteristic value.

Example: Wave imbalance

RmsAccEnvelope

The RMS value formed from the envelope signal of the oscillation acceleration from the configured minimum frequency ("MinFrequencyEnvelope01") to the maximum frequency ("MaxFrequencyEnvelope01") of the channel.

Example: Impact of components on fans

RmsAccRaw

The RMS value formed from the raw signal of the oscillation acceleration from the configured minimum frequency ("MinFrequencyRaw01") to the maximum frequency ("MaxFrequencyRaw01") of the respective channel.

Example: Loose components in pumps

RmsHighFrequency

The RMS value formed from the high-frequency portions of the input signal of the oscillation acceleration in the frequency range between "HighFrequencyConfig01" (500 Hz – 2 kHz) and 10 kHz.

Example: Early-stage bearing damage to electric motors

RmsRaw

The RMS formed from the raw signal of the oscillation acceleration up until the configured maximum frequency ("MaxFrequencyRaw01") of the respective channel.

Example: Loose components in pumps

RmsVelEnvelope

The RMS value formed from the envelope signal of the oscillation acceleration from the configured minimum frequency ("MinFrequencyEnvelope01") to the maximum frequency ("MaxFrequencyEnvelope01") of the channel.

This characteristic value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Loose components in gears

RmsVelRaw

The RMS value formed from the raw signal of the oscillation velocity from the configured minimum frequency ("MinFrequencyRaw01") to the maximum frequency ("MaxFrequencyRaw01") of the respective channel.

This characteristic value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Late stage bearing damage to fans

Crest factor

The crest factor is defined as a the quotient derived from the peak value and the RMS value. In a sinusoidal oscillation, this factor amounts to √2. This value is also known in electrical engineering as the crest factor.

In a bearing that is operating normally, the factor is also approximately the sum of √2 of the crest factor. If the condition of the bearing deteriorates, individual impacts affect the peak value and consequently raise the crest factor. If pronounced defects are then compounded by overall wear, the RMS value in increased further. In the worst case, the crest factor can remained unchanged or even sink again, even despite increasing damage.

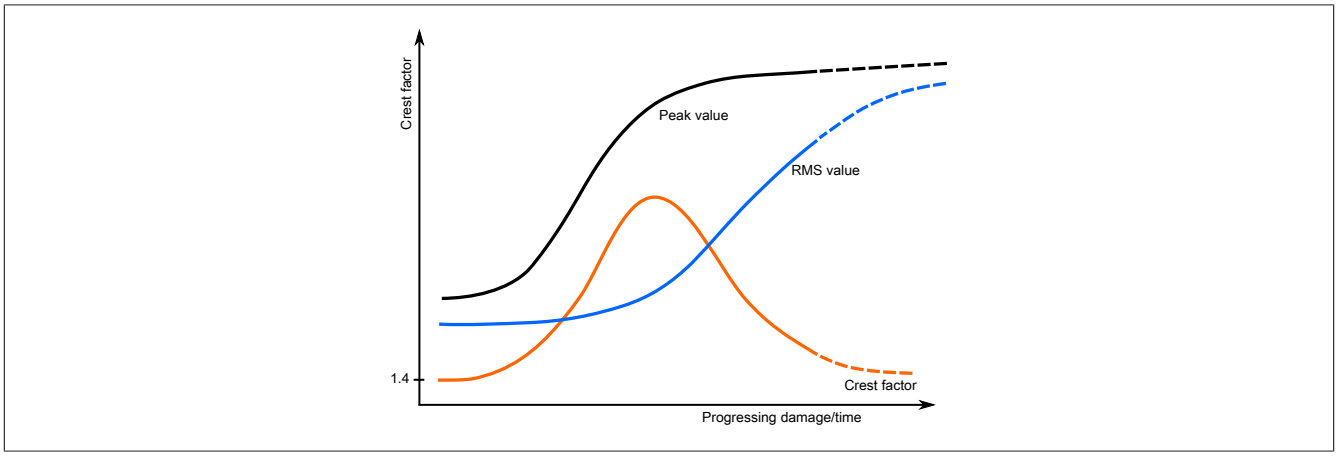

Figure 435: Relationship between the RMS value and peak value

Information:

When a recording of the crest factor is made, the peak and RMS values should also be recorded

CrestFactorHighFrequency

This crest factor is the ratio of the maximum amount to the RMS value formed from the high-frequency portions of the input signal ("PeakHighFrequency" and "RmsHighFrequency") of the oscillation acceleration in the frequency range between "HighFrequencyConfig01" (500 Hz – 2 kHz) and 10 kHz.

Example: Early stage bearing damage to pumps

CrestFactorRaw

This crest factor is the ratio of the maximum amount to the RMS value formed from the raw signal of the oscillation acceleration to the configured maximum frequency ("MaxFrequencyRaw01") of the respective channel.

Example: Notification of suboptimal lubrication of gears

K(t) value

The K(t) is described in the VDI 3832 guideline and is calculated from the RMS value and the peak value of a broadband time signal of the oscillation acceleration.

This ratio correlates to the reference values. The reference values should be measured by the operator shortly after the running-in time. These values can be classified as "System OK" and are therefore the initial values.

The K(t) value decreases with progressive wear. This allows it to be classified into three groups:

- Undamaged
- Early damage
- Pronounced damage

The advantage of the K(t) value is that does not change much, even when damage is severe.

$$K(t) = \frac{a_{RMS}(0) \cdot a_p(0)}{a_{RMS}(t): \; a_p(t):}$$

The following applies:

Formula symbols	Description	Characteristic value in the module
$a_{rms}(0)$	RMS value of the reference value	RmsHighFrequencyRef01-04 RmsRawRef
$a_p(0)$	Maximum value of the reference value	PeakHighFrequencyRef PeakRawRef
$a_{rms}(t)$	Current RMS value	RmsHighFrequency RmsRaw
$a_p(t)$	Current maximum value	PeakHighFrequency ReakRaw

Example

Possible progression of the (K/t) characteristic value

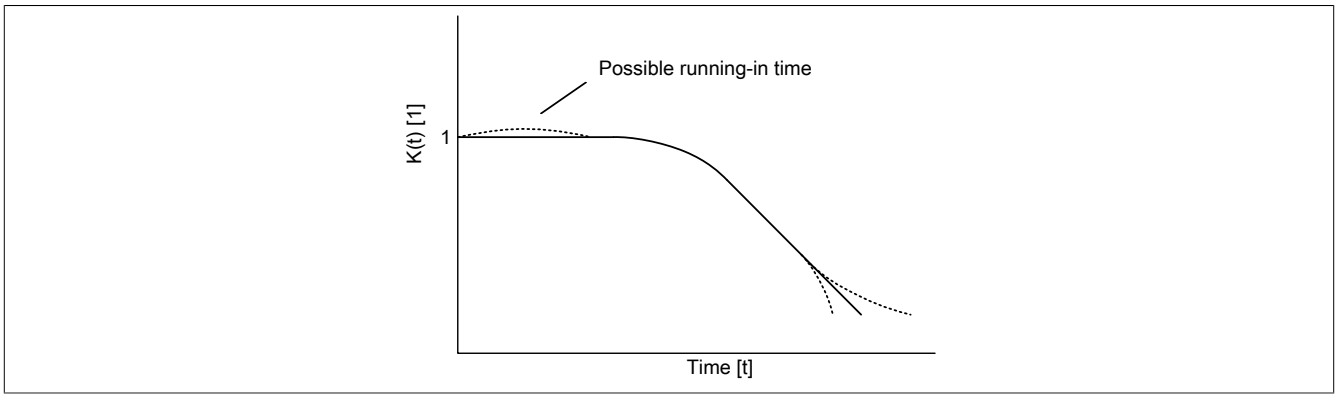

Figure 436: K(t) value progression

Vdi3832KtHighFrequency

K(t) value according to the VDI 3832 guideline formed from the high-frequency portions of the input signal ("PeakHighFrequency" and "RmsHighFrequency") of the oscillation acceleration in the frequency range between "HighFrequencyConfig01" (500 Hz – 2 kHz) and 10 kHz.

Example: Gear damage

Vdi3832KtRaw

K(t) value according to the VDI 3832 guideline formed from the raw signal of the oscillation acceleration up to the configured maximum frequency ("MaxFrequencyRaw01") of the respective channel.

Example: Suboptimal lubrication of electric motors

Kurtosis

Kurtosis is an effective characteristic value for assessing the number of peaks in a signal. Kurtosis (peakedness, fourth statistical moment) is defined as the ratio of two statistical characteristic values/processes.

Kurtosis is a type of weighted "Crest factor". The signal peaks are valued higher than the "signal noise" (also called the carpet value) due to the fourth power of the integral. Not only is the RMS value also used, but the entire signal progression as well. This increases the informational value of this characteristic value.

Information:

Kurtosis is standardized at zero in the X20CM4810 module.

A kurtosis factor of less than two is typical of a machine in good condition.

KurtosisRaw

The kurtosis factor formed from the raw signal of the oscillation acceleration up until the configured maximum frequency ("MaxFrequencyRaw01") of the respective channel.

Example: Suboptimal lubrication of fans

Skewness factor

The skewness factor (skewness, third statistical moment) specifies the degree of a signal's asymmetry in reference to its standard distribution. The lower the skewness, the more evenly distributed the signal. A signal with a high skewness factor has a much larger amplitude in the assessment range.

A symmetrically distributed signal has a skewness factor of 0. Depending on the direction of the slant, the skewness can be positive or negative. A considerable slant means approximately a skewness factor of ±1.

A large kurtosis factor combined with a large skewness factor indicates electrostatic discharge.

SkewnessRaw

Skewness factor formed from the raw signal of the oscillation acceleration up until the configured maximum frequency ("MaxFrequencyRaw01") of the channel.

Example: Determining the belt tension and belt alignment in flat belts and V-belts

Description of frequency bands

For the early detection of damage and problems, it is often useful to monitor individual frequency bands. A selective RMS value can be used as the characteristic value for these frequency bands.

Possibilities:

- "Broadband RMS"
- "Speed-dependent RMS"
- "Noise"

Up to 32 different frequency bands can be defined. The center frequency and the frequency intervals are defined in terms of the upper and lower limits. It is important to note that the format varies slightly depending on the configuration (see section 4.26.4.2.11 "Characteristic value format" on page 2602).

Speed-dependent RMS	
	Frequency broadband is formed from the speed frequency ± the frequency interval. 1) Speed frequency: "FrequencyBandxxDmgFreq60Rpm" * "ActSpeed" 2) Frequency interval: "FrequencyBandxxTolerance"
Non speed-dependent RMS	
	Frequency bandwidth is formed of the lower and upper frequency band limits. 1) Lower frequency band limit: "FrequencyBandxxLowerFrequency" 2) Upper frequency band limit: "FrequencyBandxxUpperFrequency"

Restricting the frequency range allows certain errors to be identified easily.

One example of this is imbalance. This is clearly shown by an increase in the frequency line for speed. Forming a selective characteristic value for the speed frequency can thus improve classification.

Selective characteristic values can also be formed for RMS values formed from the envelope.

Damage to the outer ring is shown more clearly in the increase of the frequency known as the bearing damage frequency. Damage to the outer ring is shown in the increase of the component of the outer ring damage frequency.

This bearing damage frequency is generally available from the bearing manufacturer.

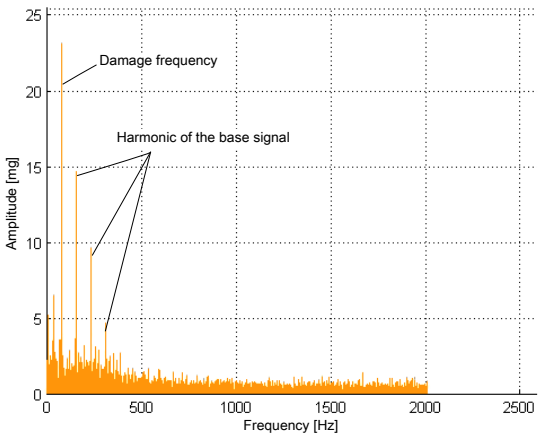

Figure 437: Selective characteristic value for outer ring damage

Bearing damage on the outer ring can be found early by the parameters of a characteristic value with a frequency range that encompasses the damage frequency.

If frequencies are entered that are outside the minimum and maximum signal frequency for the selected channel, then only the domains between the minimum and maximum frequency will be analyzed.

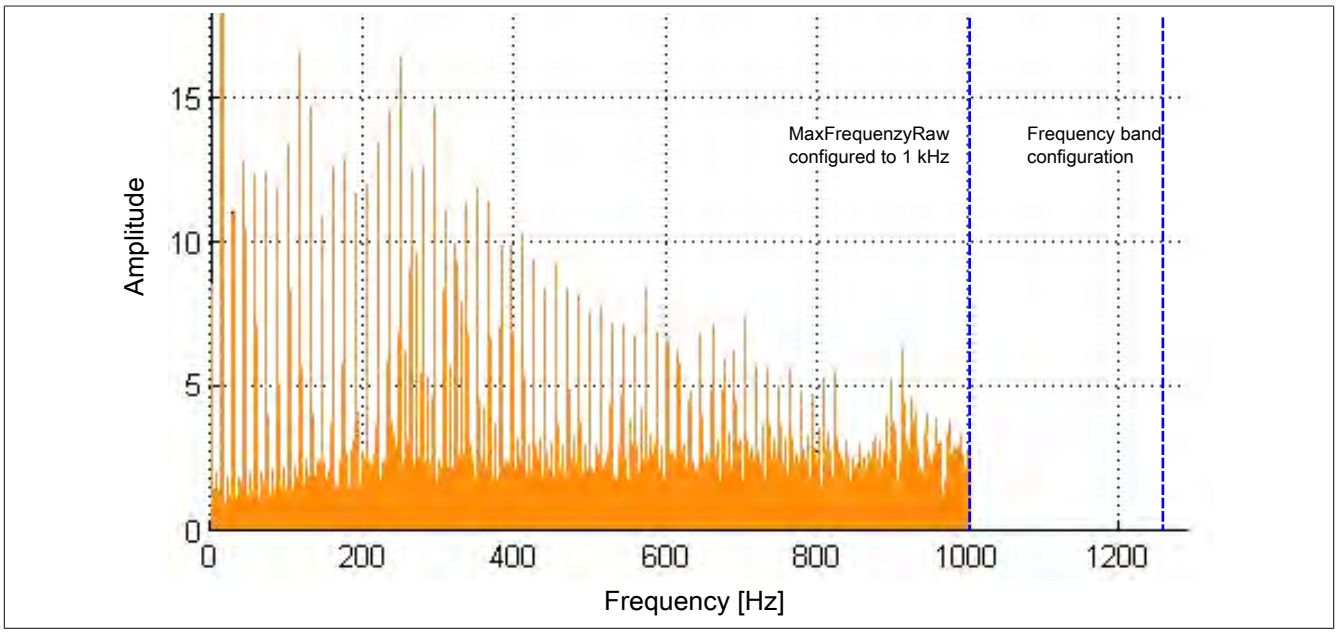

Figure 438: Restricting the frequency band evaluation

Two neighboring lines (samples) in the spectrum that are already outside the set window (one above and one below the window) will be partially included in the calculation depending on their distance from the window.

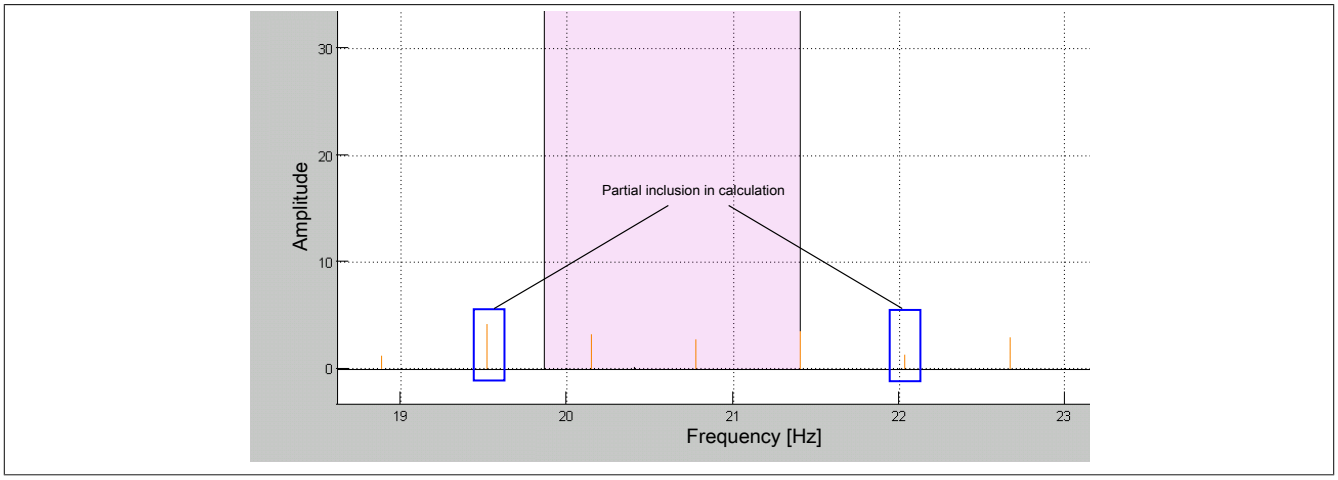

Figure 439: Partial inclusion of marginal lines in the calculation

Guidelines for configuring the frequency bands

- The total range of the frequency band is at least 2 * 0.005 * max. drive frequency [Hz].
- The upper and lower frequency limits must not be less than 0.005 * max. drive frequency [Hz] from the desired average frequency.
  Example
  At a maximum drive frequency of 50 Hz, a frequency band should be set at 10 Hz.
  10 Hz ± (0.005 * 50 Hz) = At least 9.75 Hz lower and 10.25 Hz upper frequency band limits
- Depending on the MaxFrequency selected, a least three lines should be configured within each frequency band.
- The first lines to the left and right of the configured frequency band are included proportionally based on their distance from the frequency band (see image above).

Broadband RMS

In this configuration, the RMS value of the configured signal and channel in the frequency band is calculated. The value is calculated from the minimum frequency ("FrequencyBandXXLowerFrequency") to the maximum frequency ("FrequencyBandXXUpperFrequency"). The minimum and maximum frequency can be entered here in increments of 0.25 Hz.

Any channel for any frequency band can be selected.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (whole number multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by 1, 2, 3, etc.) until the maximum frequency of the configured signal and channel is reached.

Speed-dependent RMS

In this configuration, the RMS value is calculated in a movable window. There are 4 speed inputs for this ("ActSpeed01-04" in 0.01 Hz). One of the 4 speeds can be selected for each of the 32 frequency bands. In addition, the standardized damage frequency at 60 rpm ("FrequencyBandXXDmgFreq60rpm") and a tolerance ("FrequencyBandXXTolerance") must be configured. These can be configured separately for each frequency band.

The window in which the RMS is calculated is determined as follows:

Minimum frequency = (speed * standardized damage frequency at 60 rpm) – tolerance

Maximum frequency = (speed * standardized damage frequency at 60 rpm) + tolerance

The standardized damage frequency and tolerance can be entered here in increments of 0.01 Hz.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (whole number multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by *1, *2, *3, etc.) until the maximum frequency of the set signal and channel is reached.

Useful information

If a fixed frequency band is needed in which the minimum frequency ("FrequencyBandXXLowerFrequency") and maximum frequency ("FrequencyBandXXUpperFrequency") must be set with a higher precision than 0.25 Hz, then a speed-dependent frequency band with a fixed speed can be used.

Noise

In this configuration, the noise from a quadrant of the respective signal on the selected channel that is within the frequency band is calculated.

To do this, the configured maximum frequency of the signal on the selected channel is divided by 4. This results in 4 quadrants. A configuration can then be used to select one of the 4 quadrants in which the noise should be determined.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

This configuration allows slippage to be effectively measured, for example. The higher the friction, the more noise that is created.

Configuration options

Each of the 32 frequency bands can be configured to one of the following characteristic values.

FrequencyBandRmsVelEnvelope

The RMS value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

This frequency band is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Defects in toothed belts

FrequencyBandRmsAccEnvelope

The RMS value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

Example: Gear damage

FrequencyBandNoiseAccRaw

The noise value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

Example: Imbalance of toothed belts

FrequencyBandNoiseVelRaw

The noise value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

This frequency band is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Imbalance of toothed belts

FrequencyBandNoiseAccEnvelope

The noise value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

Example: Imbalance of toothed belts

FrequencyBandNoiseVelEnvelope

The noise value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

This frequency band is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Imbalance of toothed belts

FrequencyBandNoiseAccRaw

The noise value formed from the envelope signal of the oscillation acceleration in a freely selectable frequency range.

Example: Imbalance of toothed belts

FrequencyBandRmsVelRaw

The RMS value formed from the raw signal of the oscillation velocity in a freely selectable frequency range.

This frequency band is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Example: Imbalance of toothed belts

4.26.4.4.3.2 Potential failures

The direct effect on the oscillation behavior is dependent on the type and extent of damage. For this reason, it must be assessed individually.

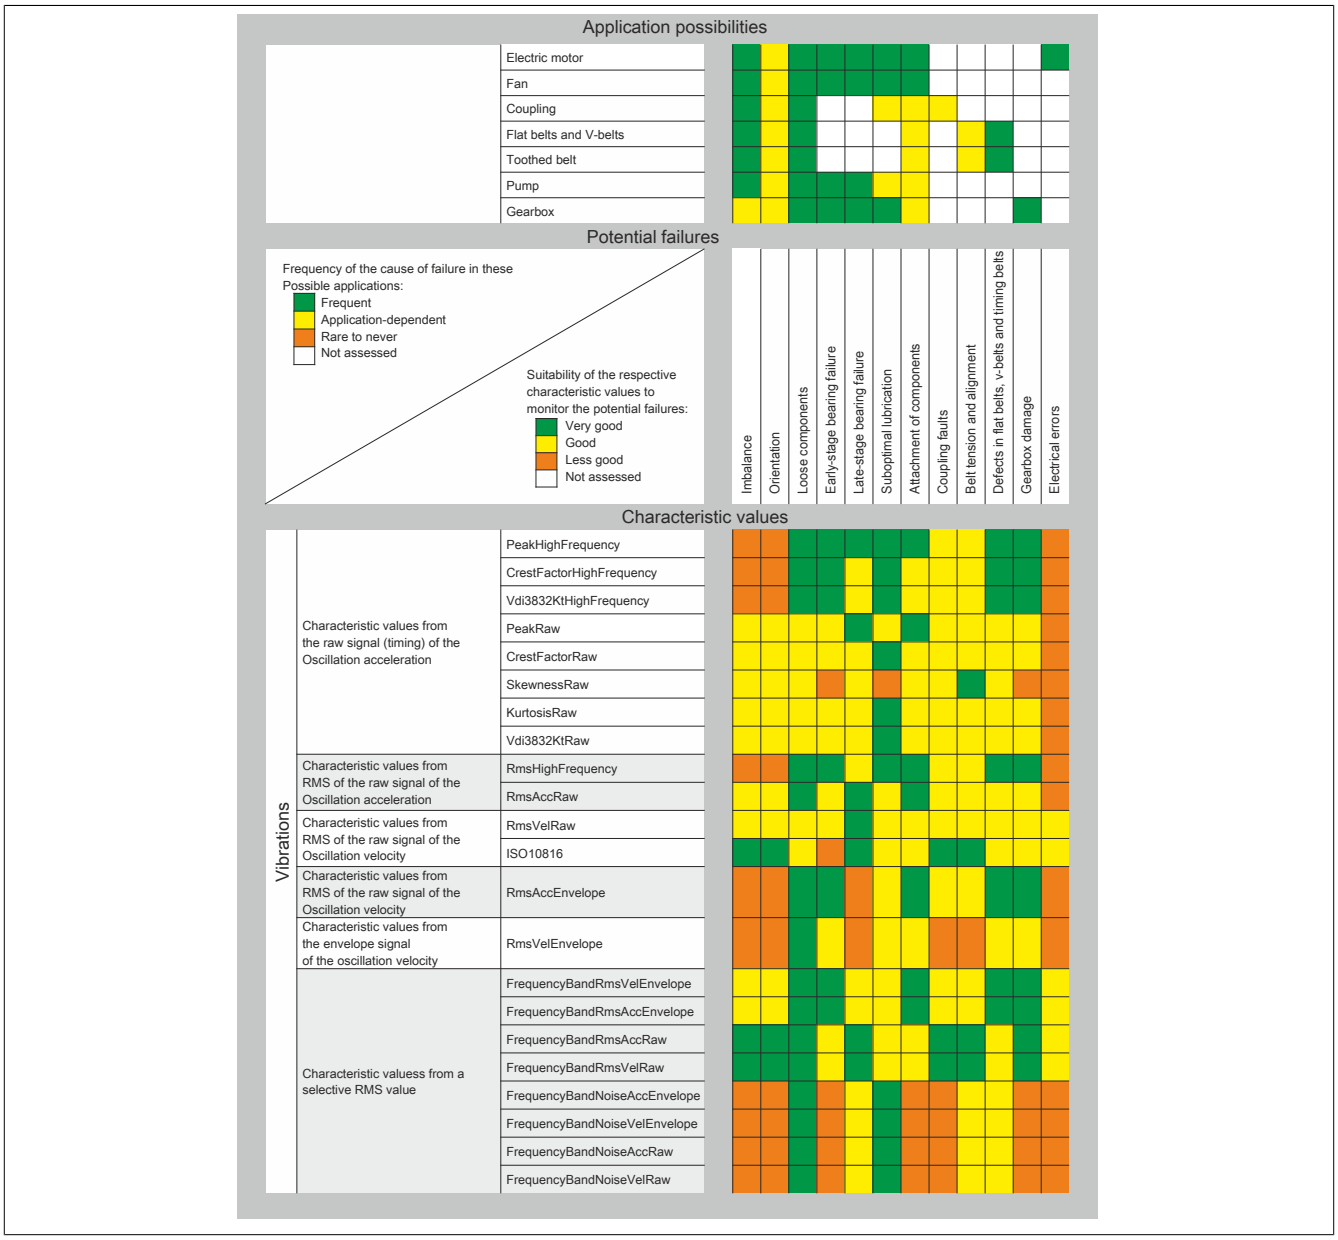

Figure 440: Overview of application possibilities, characteristic values and potential failures

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Imbalance

The term imbalance refers to rotating bodies with a mass that is not rotationally symmetrical. In other words, the center is not on the axis of rotation

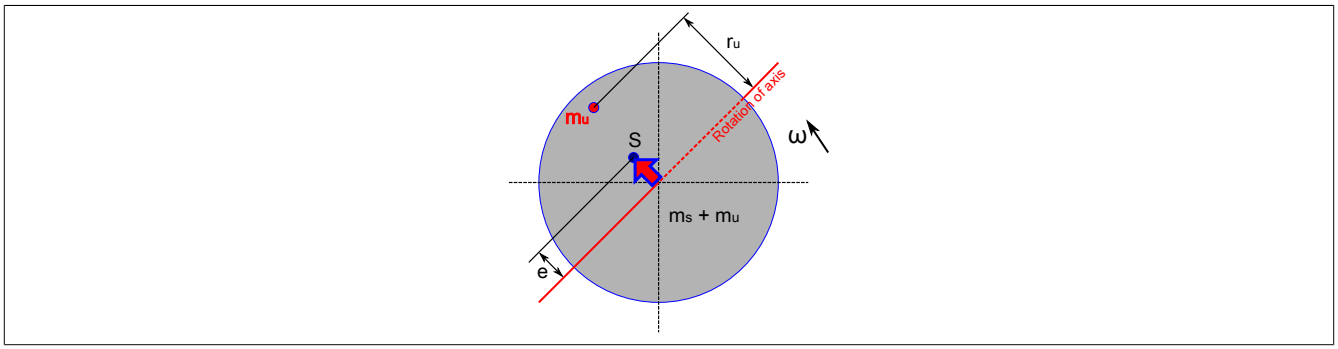

Figure 441: Representative sketch of an imbalance

Imbalance leads to vibrations and increased wear, particularly at high speeds, which is why counterweights are applied to compensate for this as counterbalance. In practice, it is never possible to fully compensate for this, meaning each rotating body always has residual imbalance.

The centrifugal force caused by imbalance is dependent on the square speed and thus has a more significant effect at higher speeds (higher speed frequency). On a spectrum, therefore, the frequency line denoting speed is significantly higher.

Failure mode	Frequency in the raw signal spectrum	Frequency in the envelope spectrum	Comment
Imbalance	1 x fn	-	Only severe imbalance causes peaks in the speed that show up in the envelope spectrum.

Table 595: Frequency of imbalance

fn ... Nominal speed

The X20CM4810 module can only measure the intensity of the imbalance, not its position on the wave. For this reason, it cannot be used for balancing.

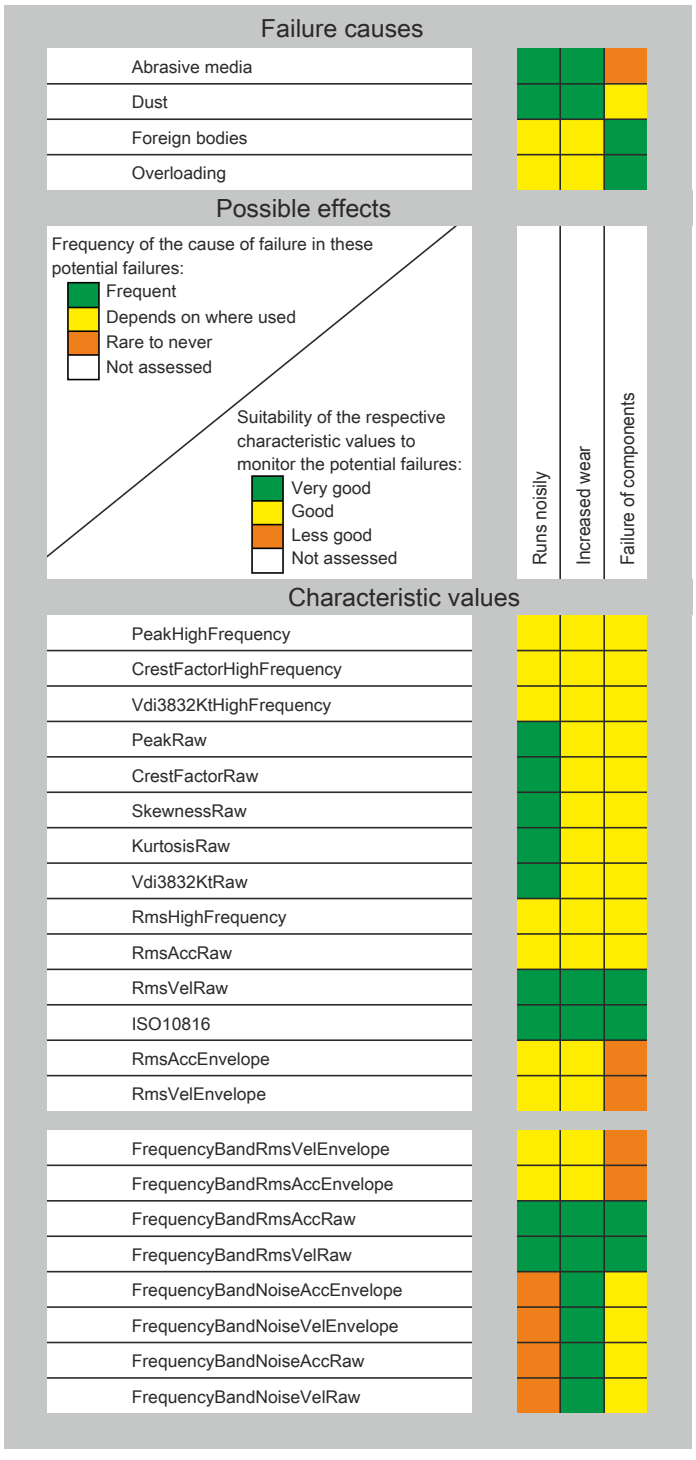

Figure 442: Failure causes and effects of imbalance

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Misalignment

During operation, a number of different factors can cause machine parts to fail to align or stop aligning with each other.

Shafts should rotate around a linear axis at the coupling positions, so that the restoring forces at the coupling position and the loading forces in the bearings are kept as low as possible. Misalignment causes increased vibrations and wear.

Misalignment usually consists of a parallel and an angular misalignment. In the event of a severe parallel misalignment, the frequency portions increase sharply at twice the speed.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Misalignment in coupling	1 x fn, 2 x fn (sometimes 3 x fn, 4 x fn)	-	With a parallel misalignment, usually only "1 x fn" occurs.

Table 596: Frequency of misalignment

fn ... Nominal speed

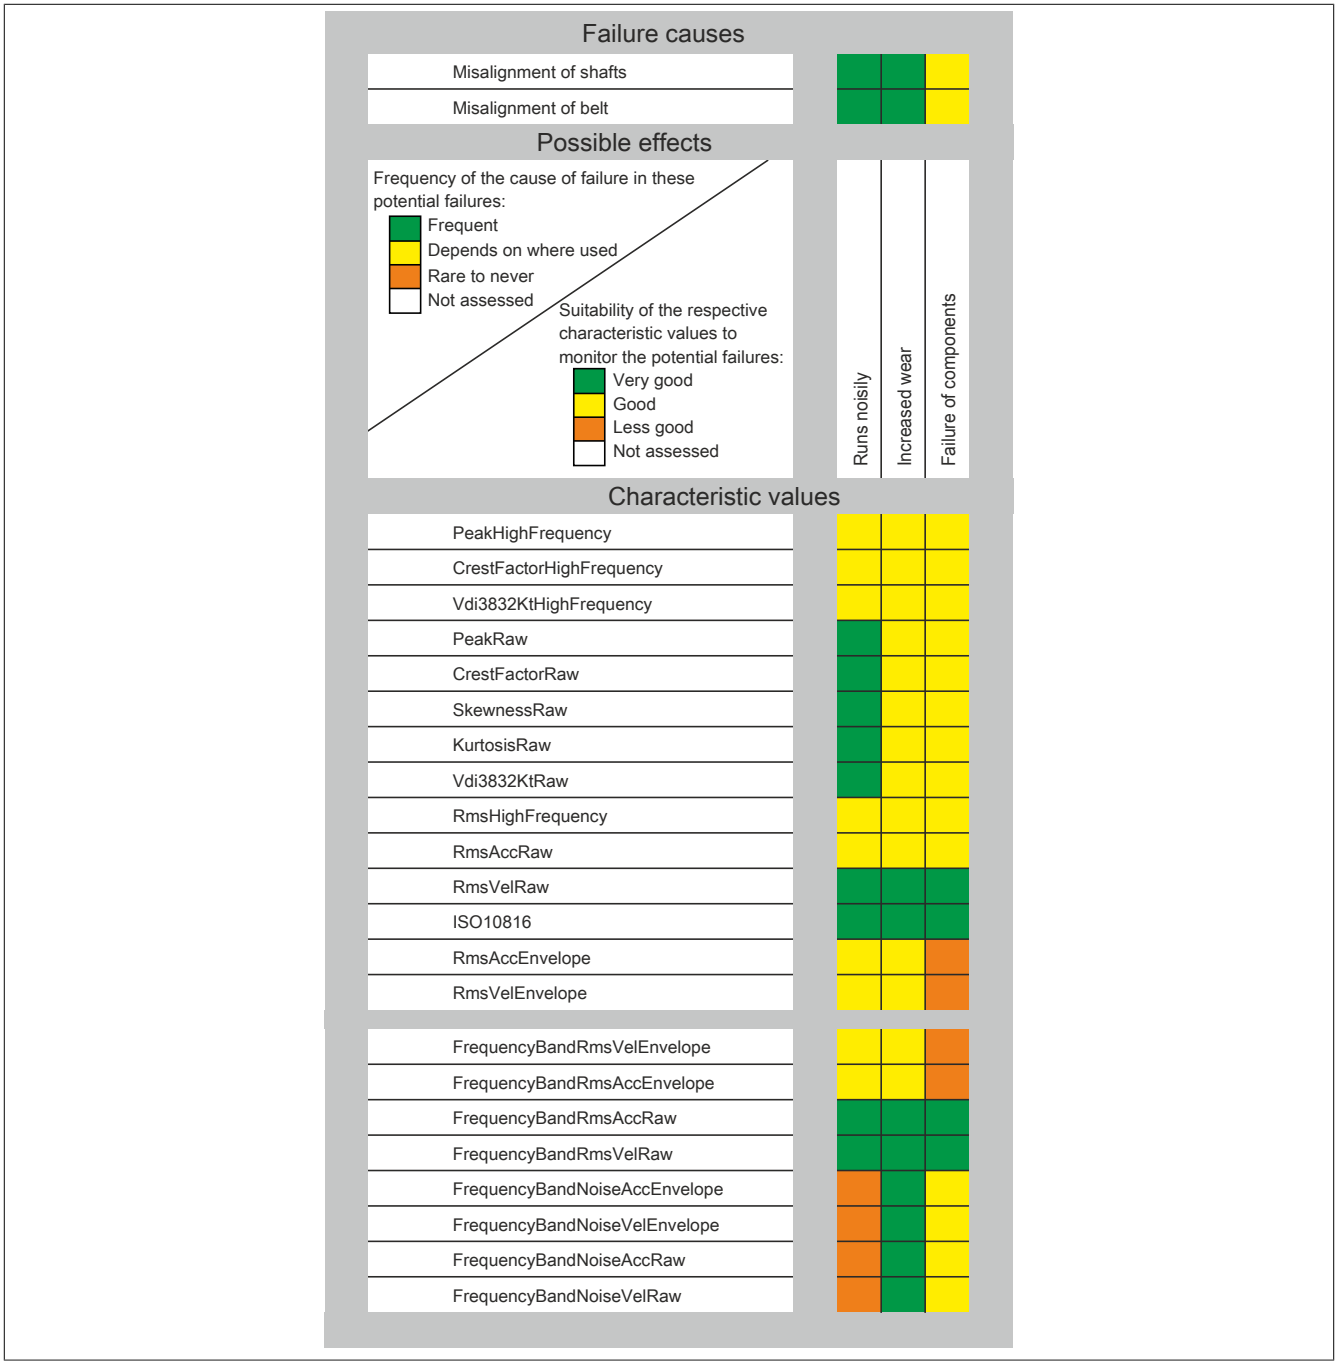

Figure 443: Failure causes and effects of an alignment failure

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Belt damage

Belts often cause various problems during operation. A belt can be damaged if the tension is too low or too high or if the belt is incorrectly aligned. If the damaged belt part rolls over the pulley, this causes impacts that can be measured.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Defective belt	1 x fr, 2 x fr, 3 x fr ...	1 x fn1, 1 x fn2, 1 x fr	Belt frequencies usually occur in both spectra.

Table 597: Frequency of failure indicators on belt drives

fr ... Belt drive speed
fn1 ...
fn2 ...

Poorly aligned or incorrectly tensioned belts can also cause severe stress on the bearing points. The increased vibration also causes heavier wear on belts and pulleys.

The vibrations are clearly identifiable at the bearing points.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Misalignment of belt	1 x fn, 2 x fn 1 x fr	1 x fn	If the belts strike against the pulley laterally, impacts can also occur with speed and belt frequency.

Table 598: Frequency of failure indicators on poorly aligned belt drives

fn ... Nominal speed
fr ... Belt drive speed

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Toothed belt damage	1 x frn	1 x frn, 1 x fzn	The tooth meshing frequencies in combination with the respective speed are clearly visible.

Table 599: Frequency of failure indicators on poorly aligned timing belts

frn ...
fzn ... Tooth meshing frequency

Flat belts and V-belts

With flat belts and V-belts, torque is transferred between the belt and the pulley through the contact surface. Belt drives are not particularly sensitive to alignment. If the deviation is too high, they can nevertheless cause oscillations to occur and, above all, increase the level of wear and energy consumption.

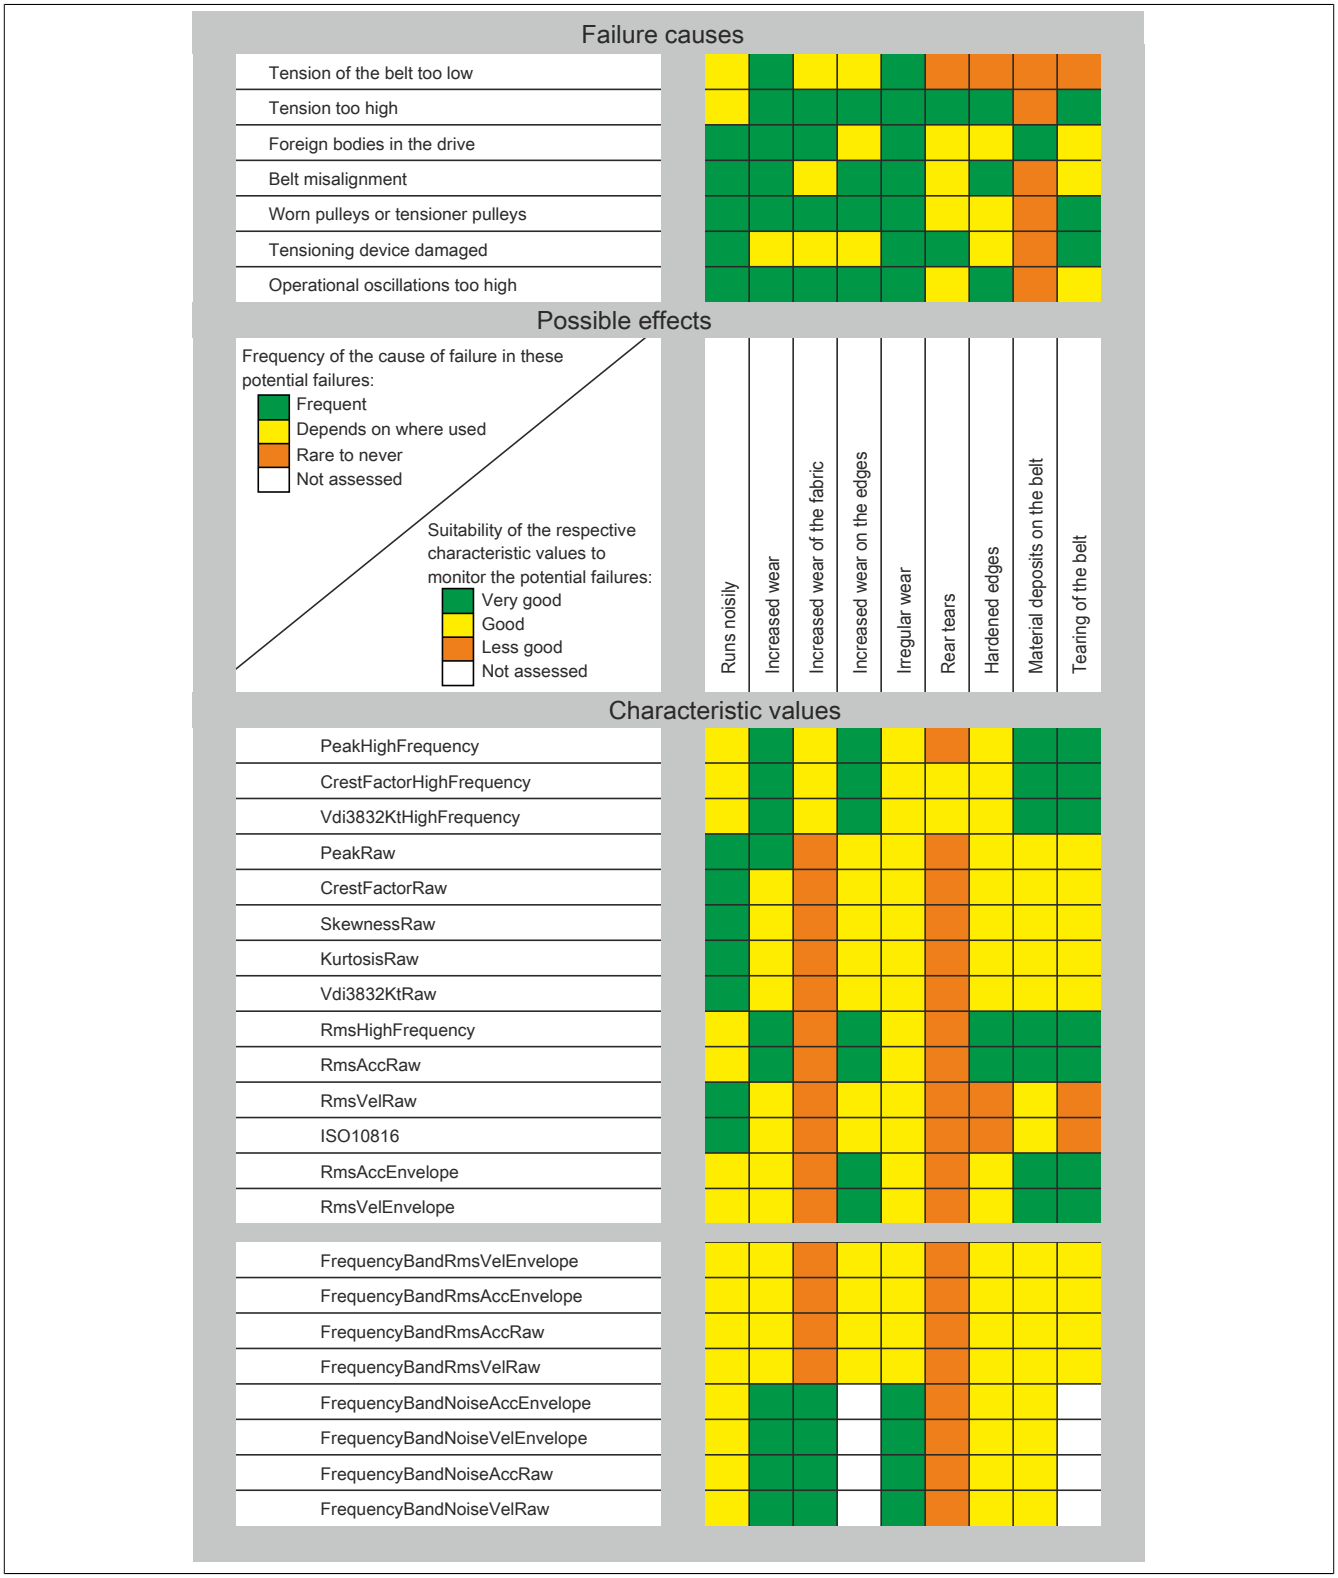

Figure 444: Failure causes and effects of belt damage in flat belts and V-belts

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Toothed belt

With toothed belts, torque is transferred via the meshing of the teeth. In addition to the already known failure causes, there are also the failures caused by the toothing.

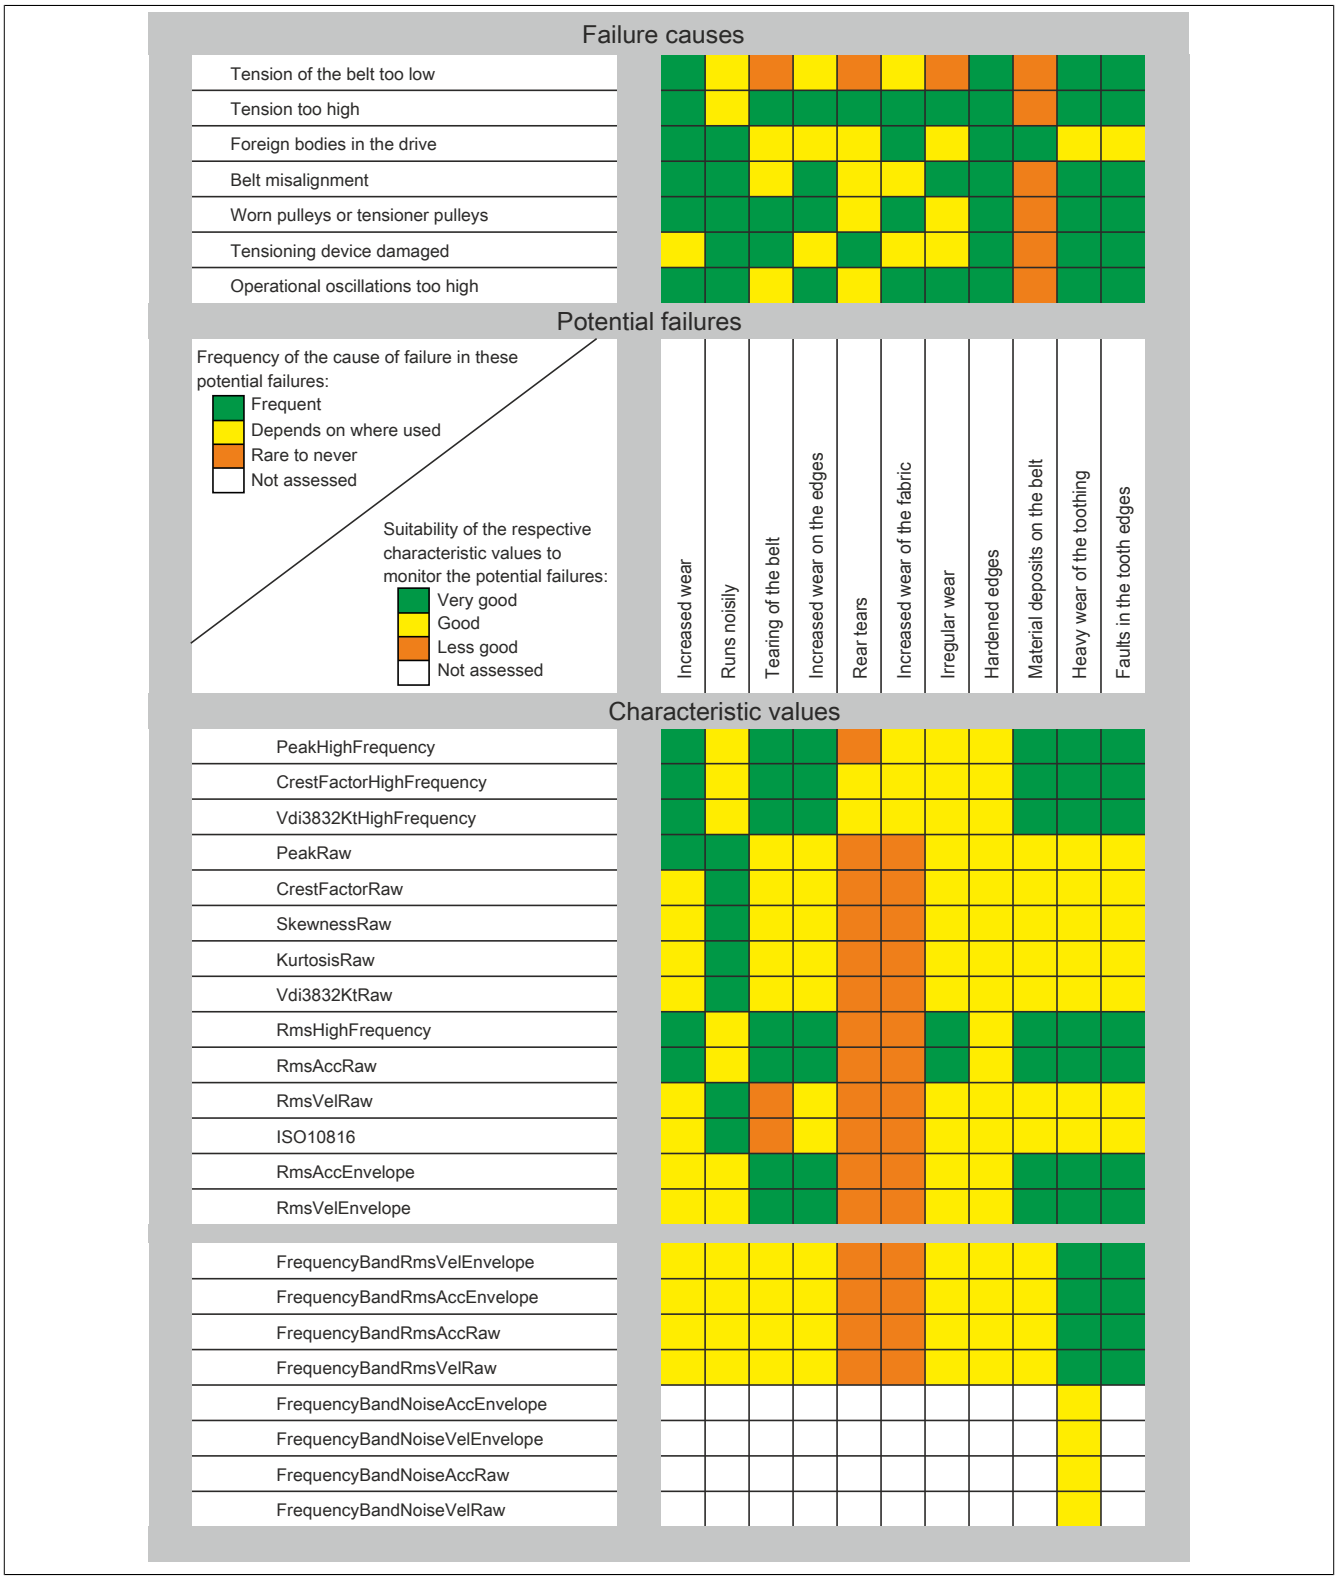

Figure 445: Frequency of failure indicators on toothed belts

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Loose parts, parts striking each other

If individual parts in the machine are loose, they can cause unwanted oscillations. When individual parts strike housings or attachment parts, these appear very similar. As a result, the two causes of damage cannot be analyzed separately.

In addition, components strike their counterparts on each revolution. This in turn causes the attachment parts to vibrate at their natural frequency. Envelope analysis can be used to separate the causes of impact.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Loose parts, parts striking each other	(1 x fn)	1 x fn	There is usually one strike per revolution. If an envelope occurs for the load, a double frequency can be seen.

Table 600: Frequency of failure indicators for loose or impacting components

fn ... Nominal speed

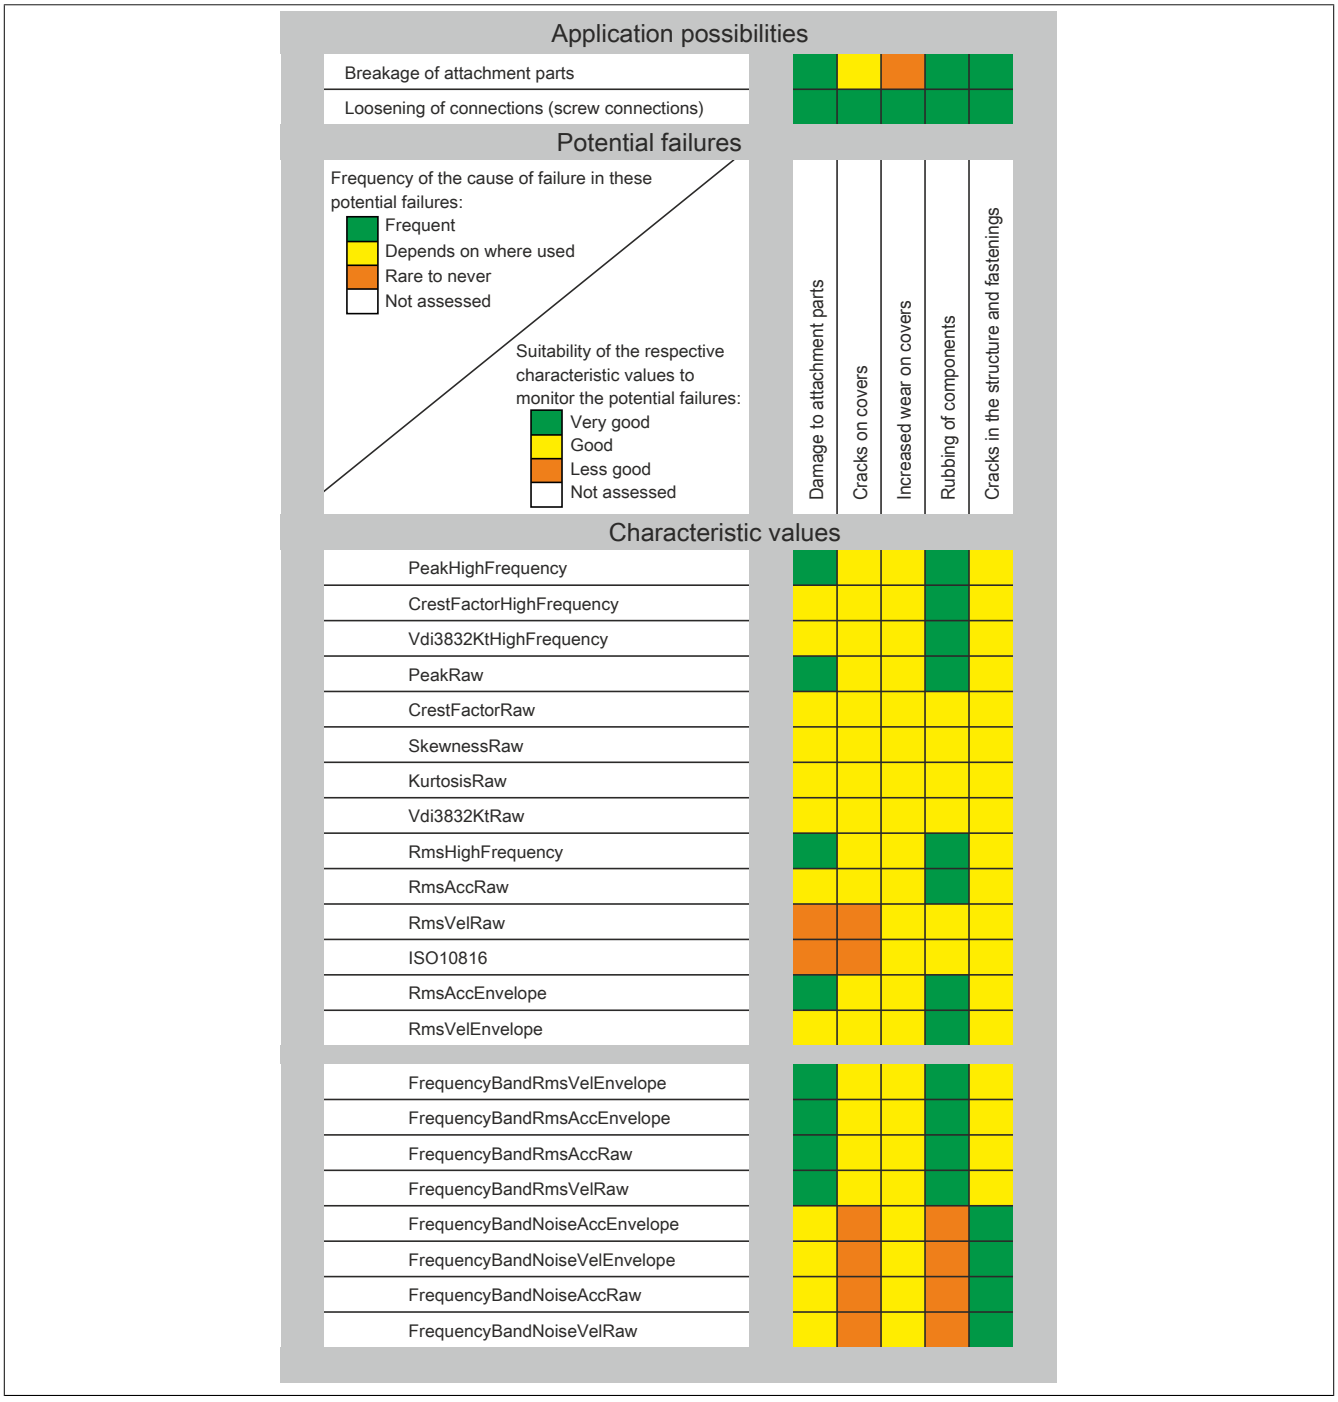

Figure 446: Failure causes and effects of belt damage

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Slide bearing damage

In a structure-borne sound measurement, the typical damage frequencies for a slide bearing do not manifest themselves until a very late stage. For this reason, this method is less suitable for early detection.

Roller bearing damage

Many types of bearing damage are caused by imprecisions in the bearing surface such as material damage or micro-cracks. These pits are rolled over by the roller elements and cause impacts on the roller bearing and its attachment parts.

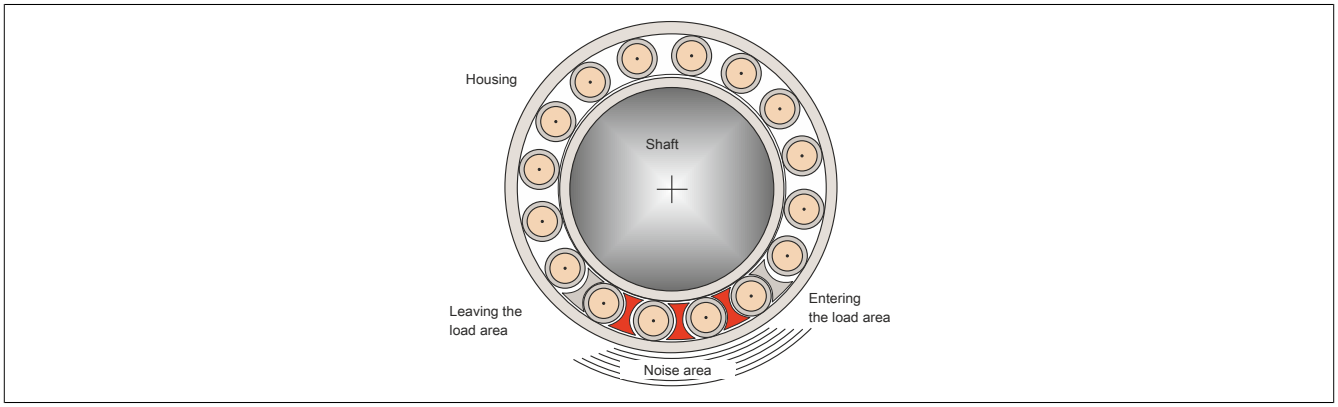

Figure 447: Roll-over processes in the bearing

The mechanism is very similar to the striking of a bell. The clapper strikes the body of the bell, and the bell starts vibrating at its natural frequency.

In the case of the bearing, each time the roller moves over the damaged area it is like the striking of the clapper, and the roller parts and attachment parts start to vibrate.

These very small oscillations can be measured as a modulation or superposition of the excitation frequency on the surface of the bearing.

Appropriate analysis methods such as formation of the envelope can separate the superposition to make the roll-over frequencies of the bearing clearly discernible.

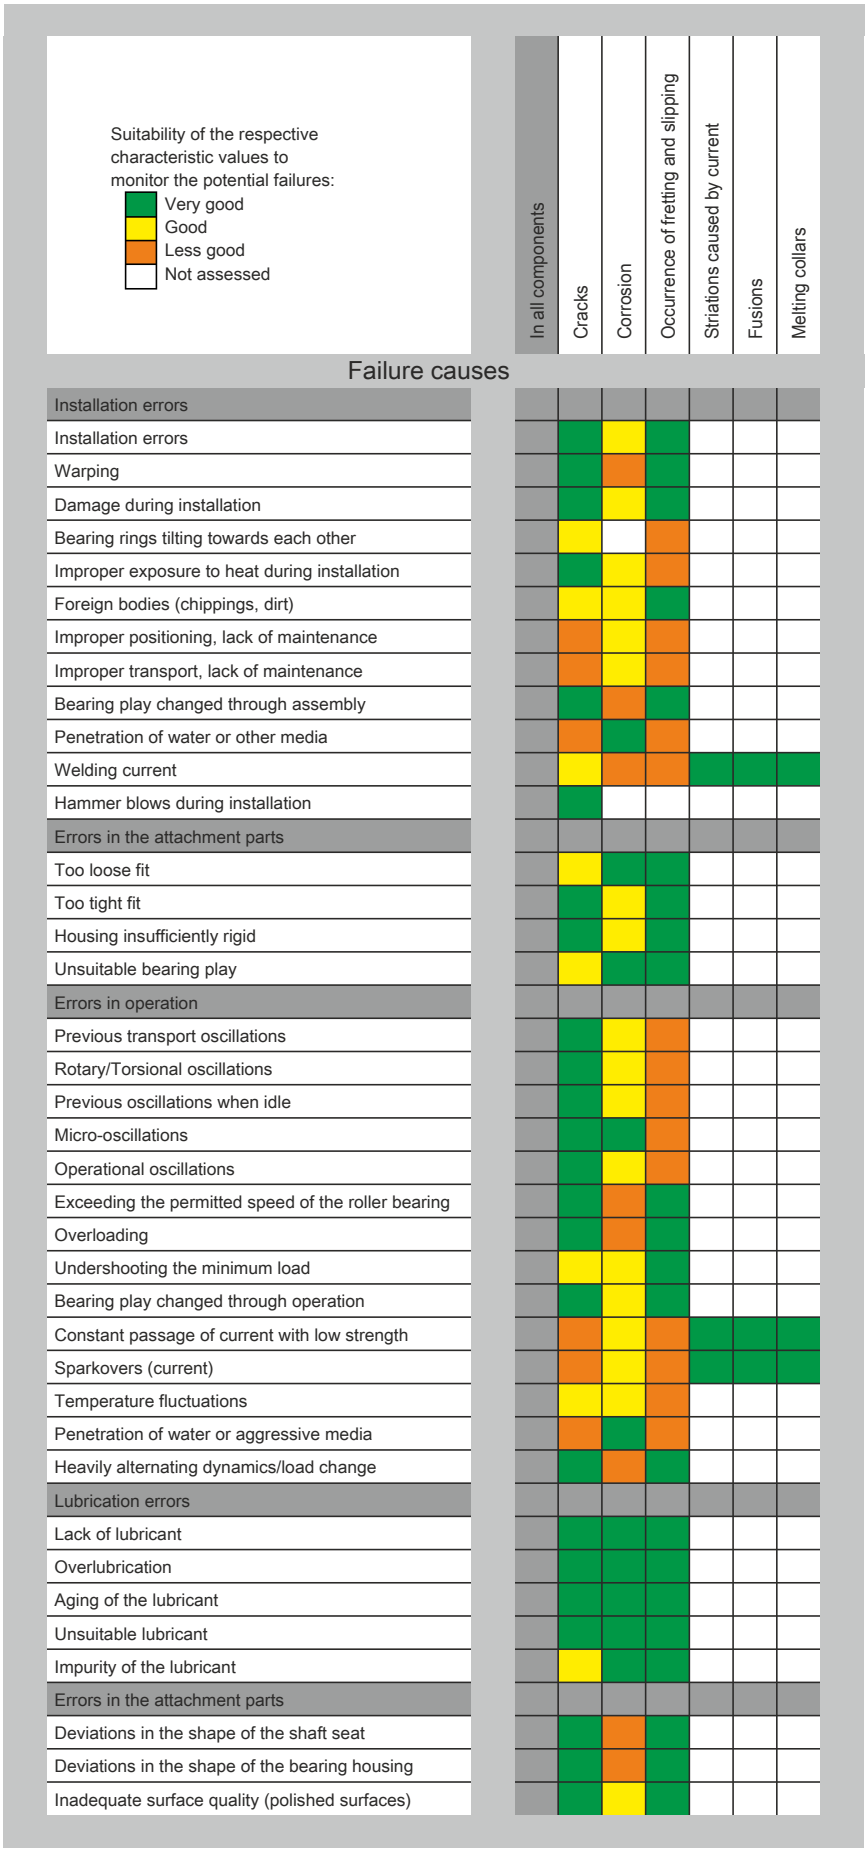

Figure 448: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

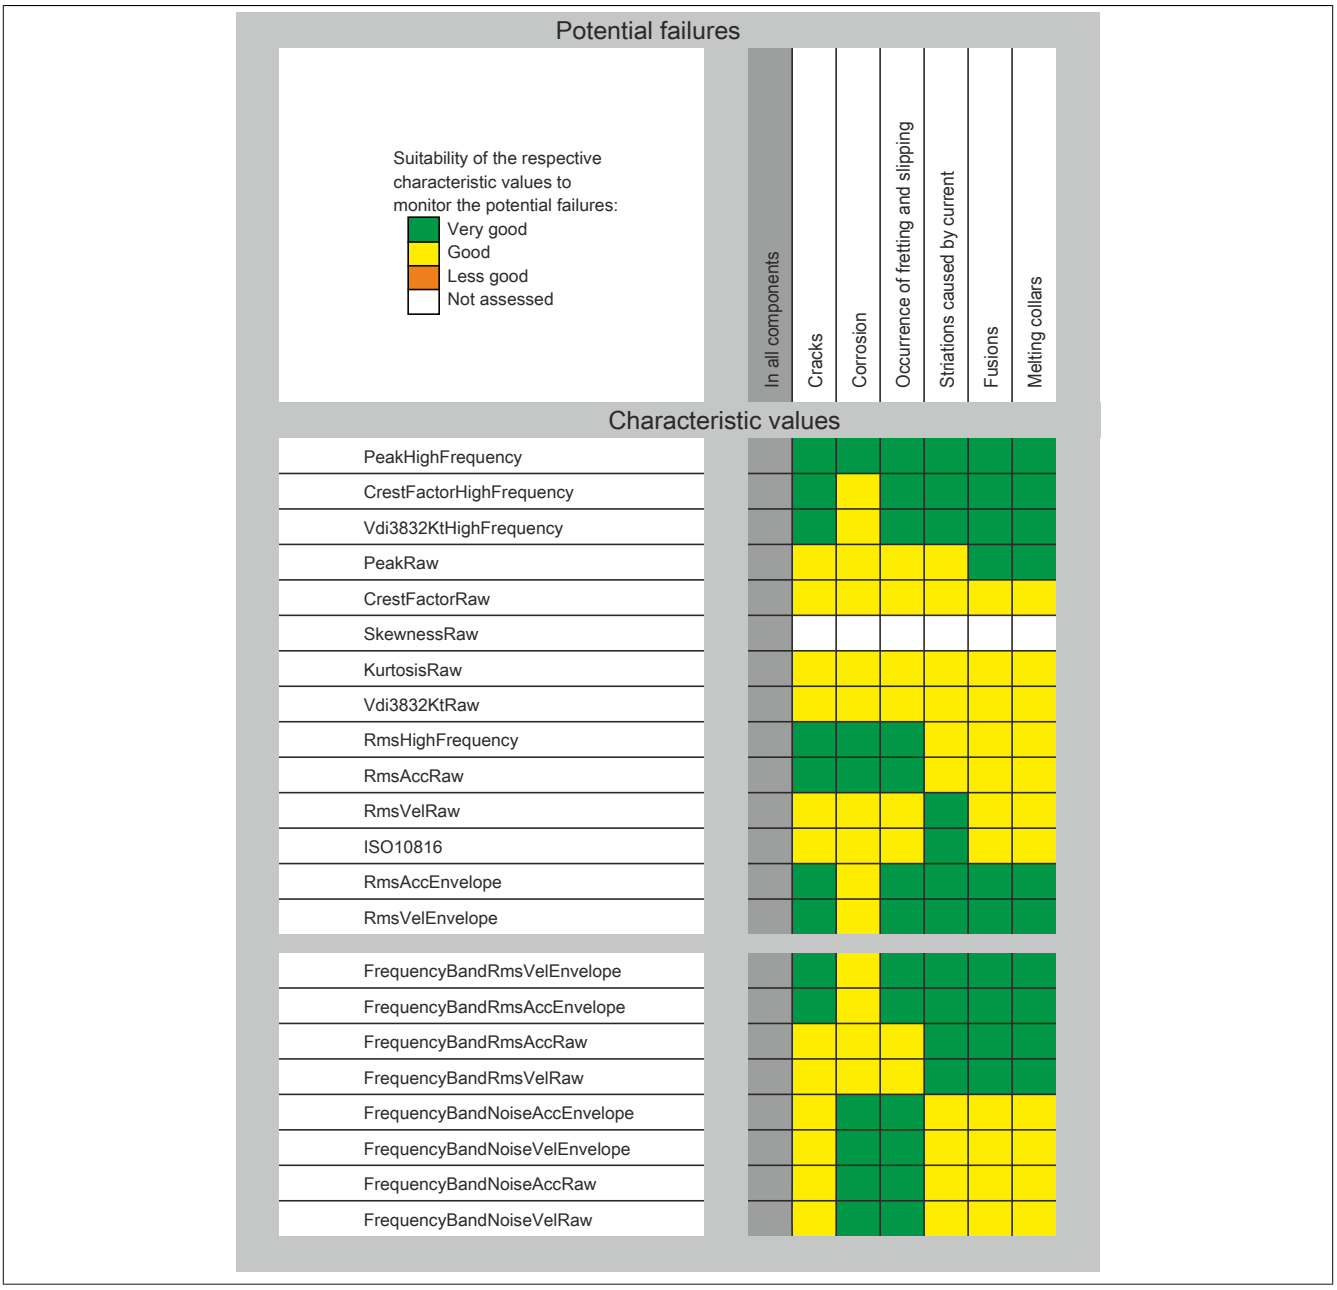

Figure 449: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Typical outer and inner ring damage

Outer ring damage

In most cases the outer ring remains stationary while the inner ring turns. This gives a clearly defined fixed load zone. Most damage occurs in this load zone. If pitting or other surface damage forms, vibrations occur when the roller element moves over it that can be measured on the housing components.

Outer ring damage is manifested in the envelope spectrum as follows:

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Outer ring damage	(1 x fa)	1 x fa, 2 x fa, 3 x fa ...	With advanced damage, the outer ring frequencies can also be seen in the raw signal spectrum

Table 601: Frequency of outer ring damage

fa ... Frequency of the outer ring damage

Inner ring damage

Any inner ring damage that occurs travels with the rotating shaft. Due to the different rotary speeds of the revolving roller elements and the inner ring, pronounced modulations occur. As a result, inner ring damage frequencies are usually shown with sidebands in the spectrum.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Inner ring damage	(1 x fi)	i x fi ± i x fn	Inner ring damage generally appears based on modulation with pronounced sidebands for the speed.

Table 602: Frequency of inner ring damage

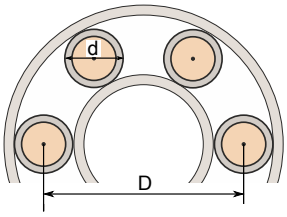
fi ... Frequency of the inner ring damage
fn ... Nominal speed

Calculating damage frequencies

Details of bearing damage frequencies are normally provided by the manufacturer and can be found in the data sheets for the bearings.

They can also be calculated easily using the following values:

N	Speed in rpm
n_b	Number of roller elements
d	Diameter of roller elements
β_c	Pressure angle
D	Roller ring diameter



Formula for calculating the inner ring damage frequency

$$fi = \frac{n_b \cdot N}{2 \cdot 60} \cdot \left[1 + \frac{d}{D} \cdot \cos \beta_c\right]$$

Figure 450: Calculation of the inner ring damage frequency

fi ... Inner ring damage frequency

Formula for calculating the outer ring damage frequency

$$fa = \frac{n_b \cdot N}{2 \cdot 60} \cdot \left[1 - \frac{d}{D} \cdot \cos \beta_c\right]$$

Figure 451: Calculation of the outer ring damage frequency

fa ... Outer ring damage frequency

Formula for calculating the roller element damage frequency

Damage impacting the individual pitch line:

$$few = \frac{1}{2} \cdot \frac{D \cdot N}{d \cdot 60} \cdot \left[1 - \left(\frac{d}{D} \cdot \cos \beta_c\right)^2\right]$$

Figure 452: Calculating the damage frequency on one roller element

few ... Damage frequency of the individual roller element

Damage impacting both pitch lines:

$$f_W = \frac{D \cdot N}{d \cdot 60} \cdot \left[1 - \left(\frac{d}{D} \cdot \cos \beta_c\right)^2\right]$$

Figure 453: Calculating the damage frequency on both roller elements

fw ... Damage frequency of both roller elements

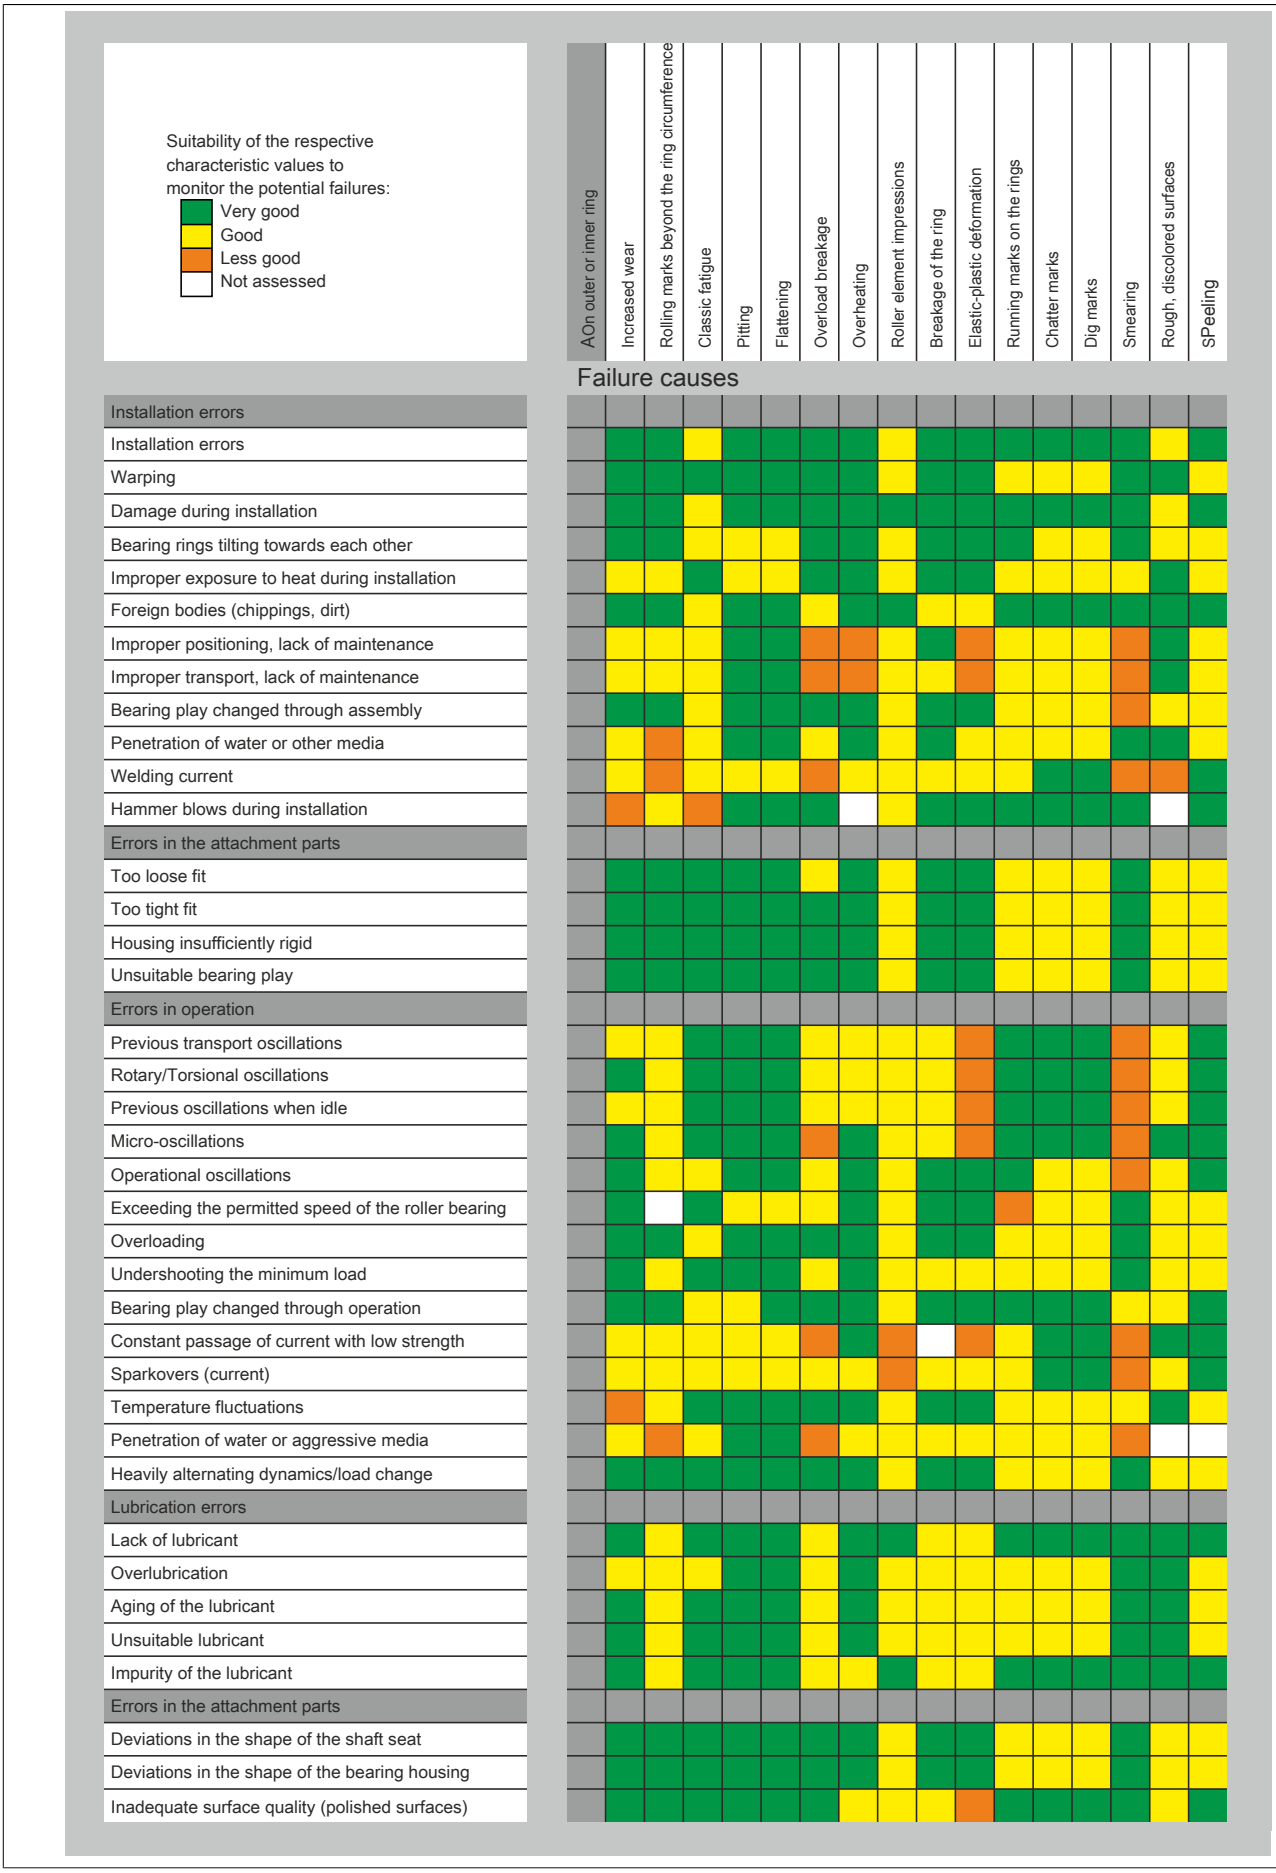


Figure 454: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

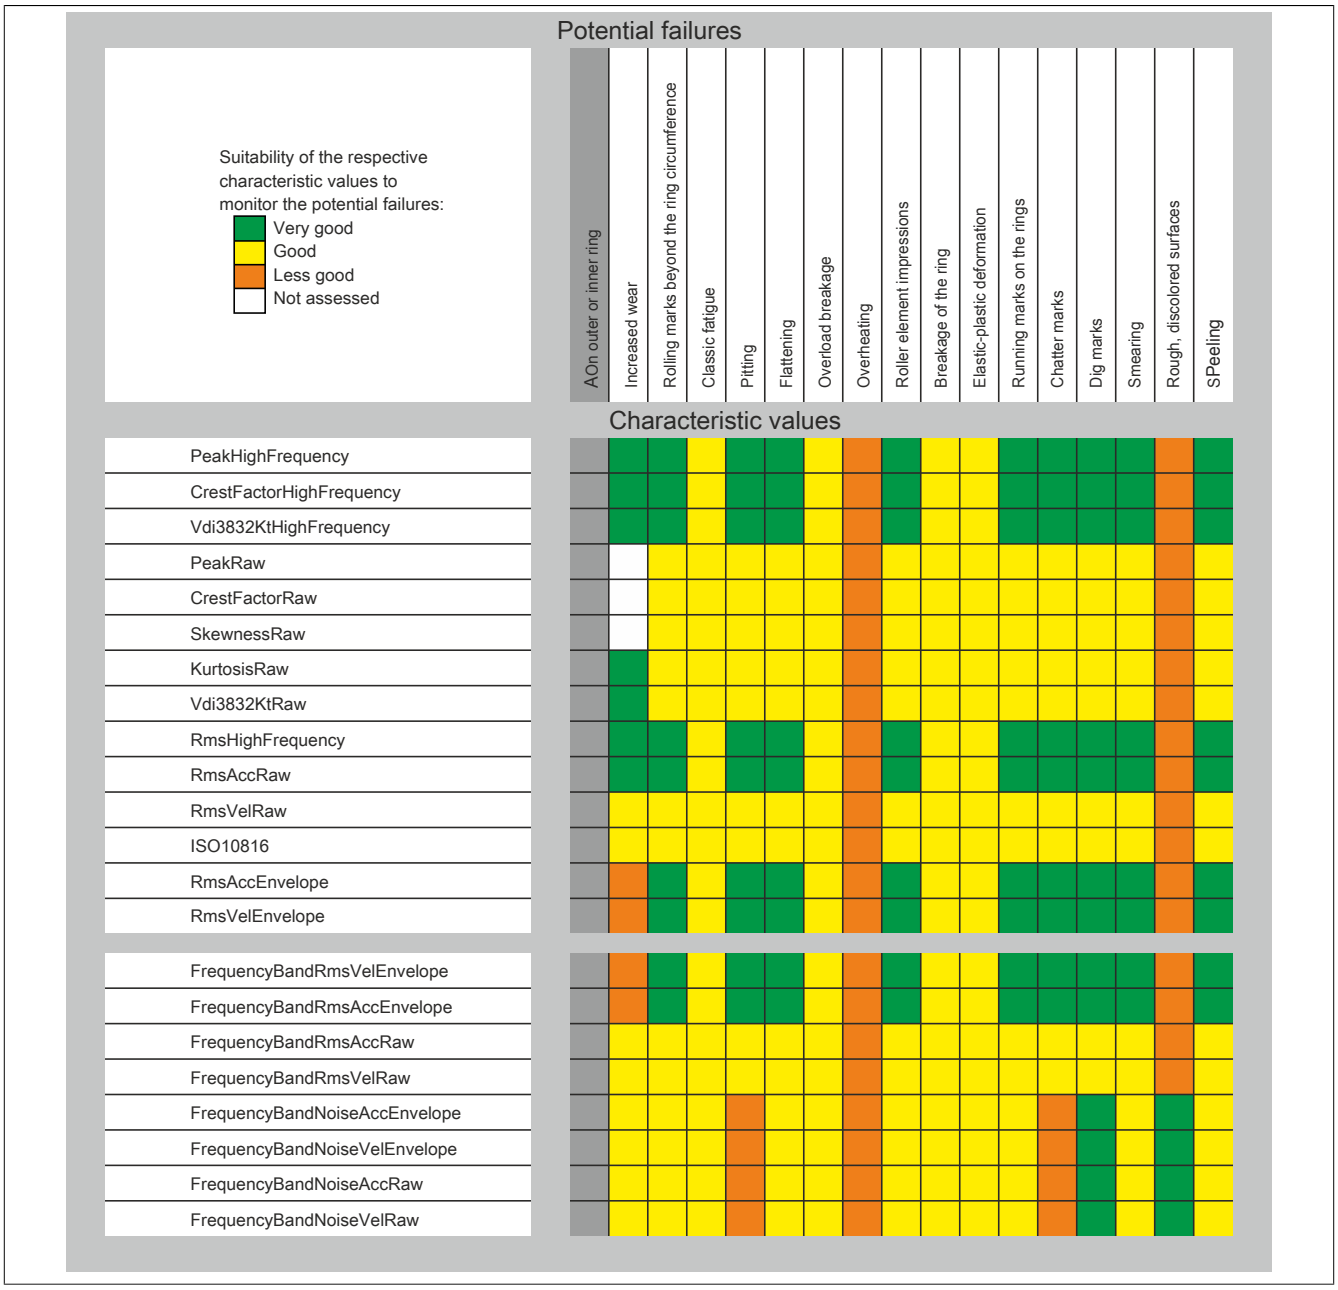

Figure 455: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Typical cage and roller element damage

Cage damage

Cage frequencies often occur in electric motors, especially where bearings with increased bearing play are used. If this is not used, oscillation of the cage often occurs, which is evidenced by increased running noise.

Roller element damage

Roller element damage without outer or inner ring damage is extremely rare. The individual indicators are therefore listed for example purposes only.

If the roller element is damaged, an impact occurs either on the inner ring, outer ring, or both. Roller element damage can therefore be detected by the roll-over frequency or double the roll-over frequency. For this reason, the harmonic should be included in the characteristic value calculation where possible to detect roller element damage.

For the failure mode, see "Typical outer and inner ring damage" on page 2650

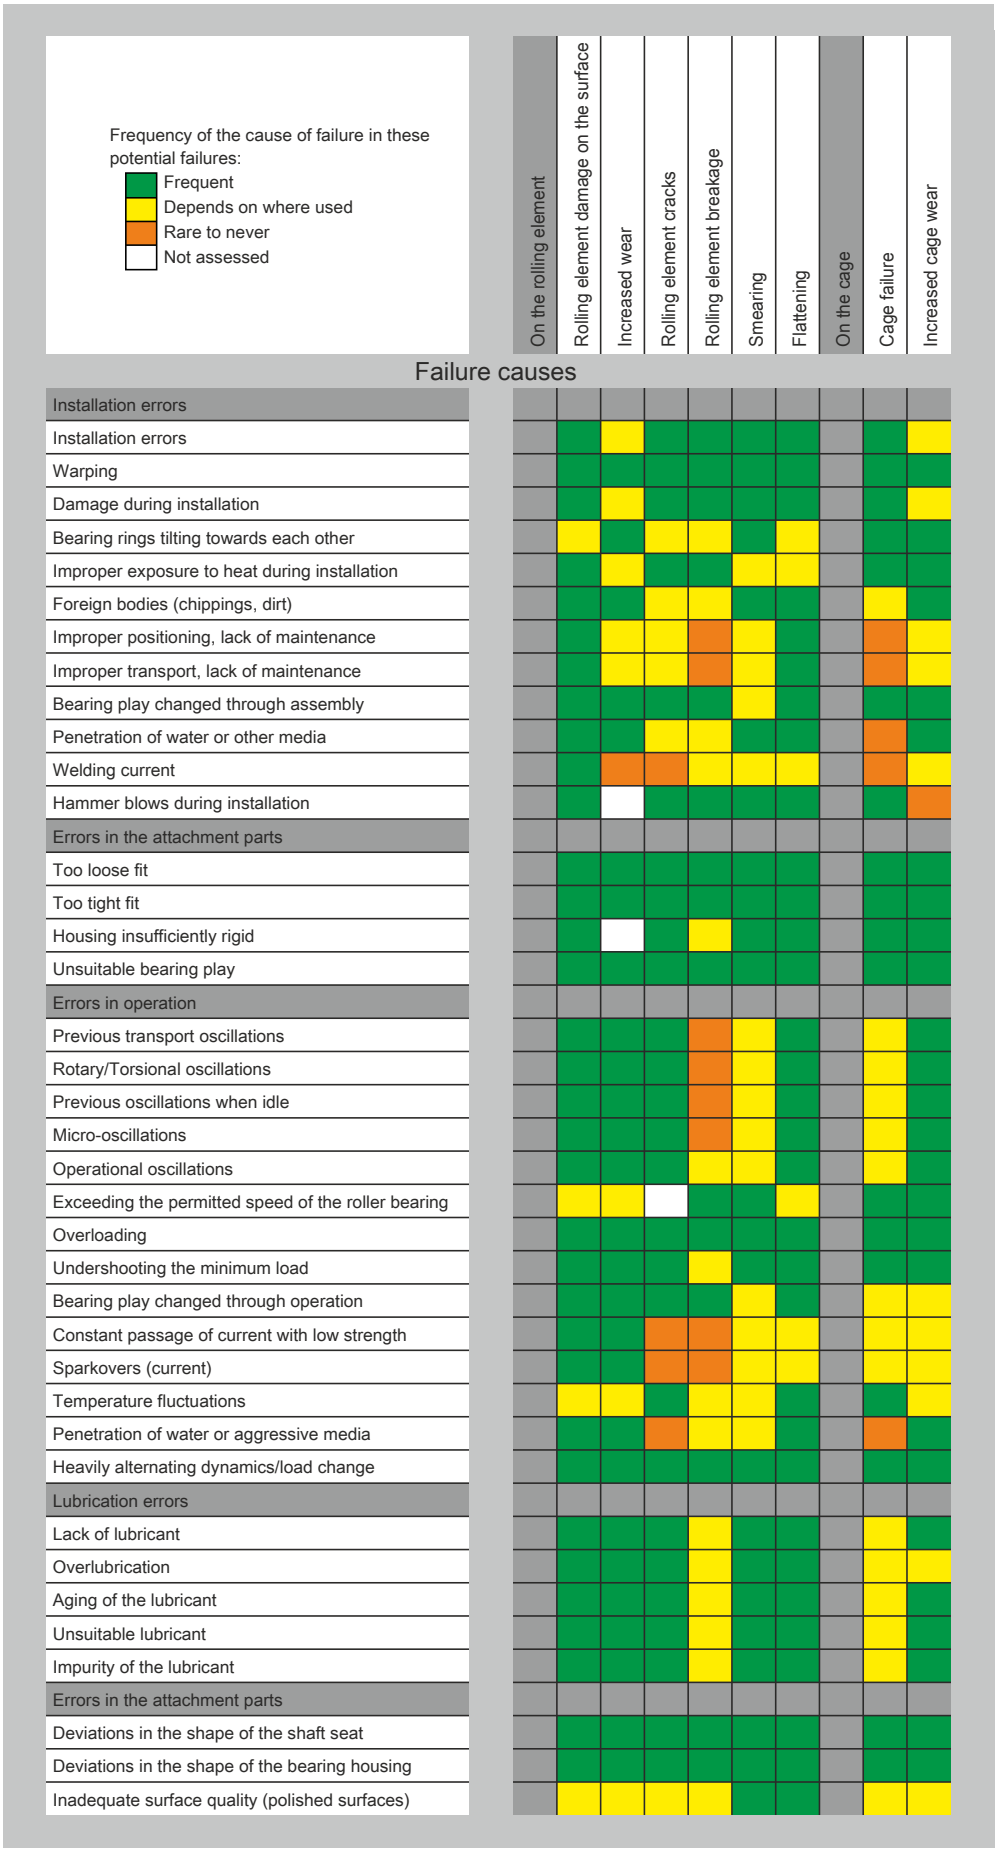

Figure 456: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

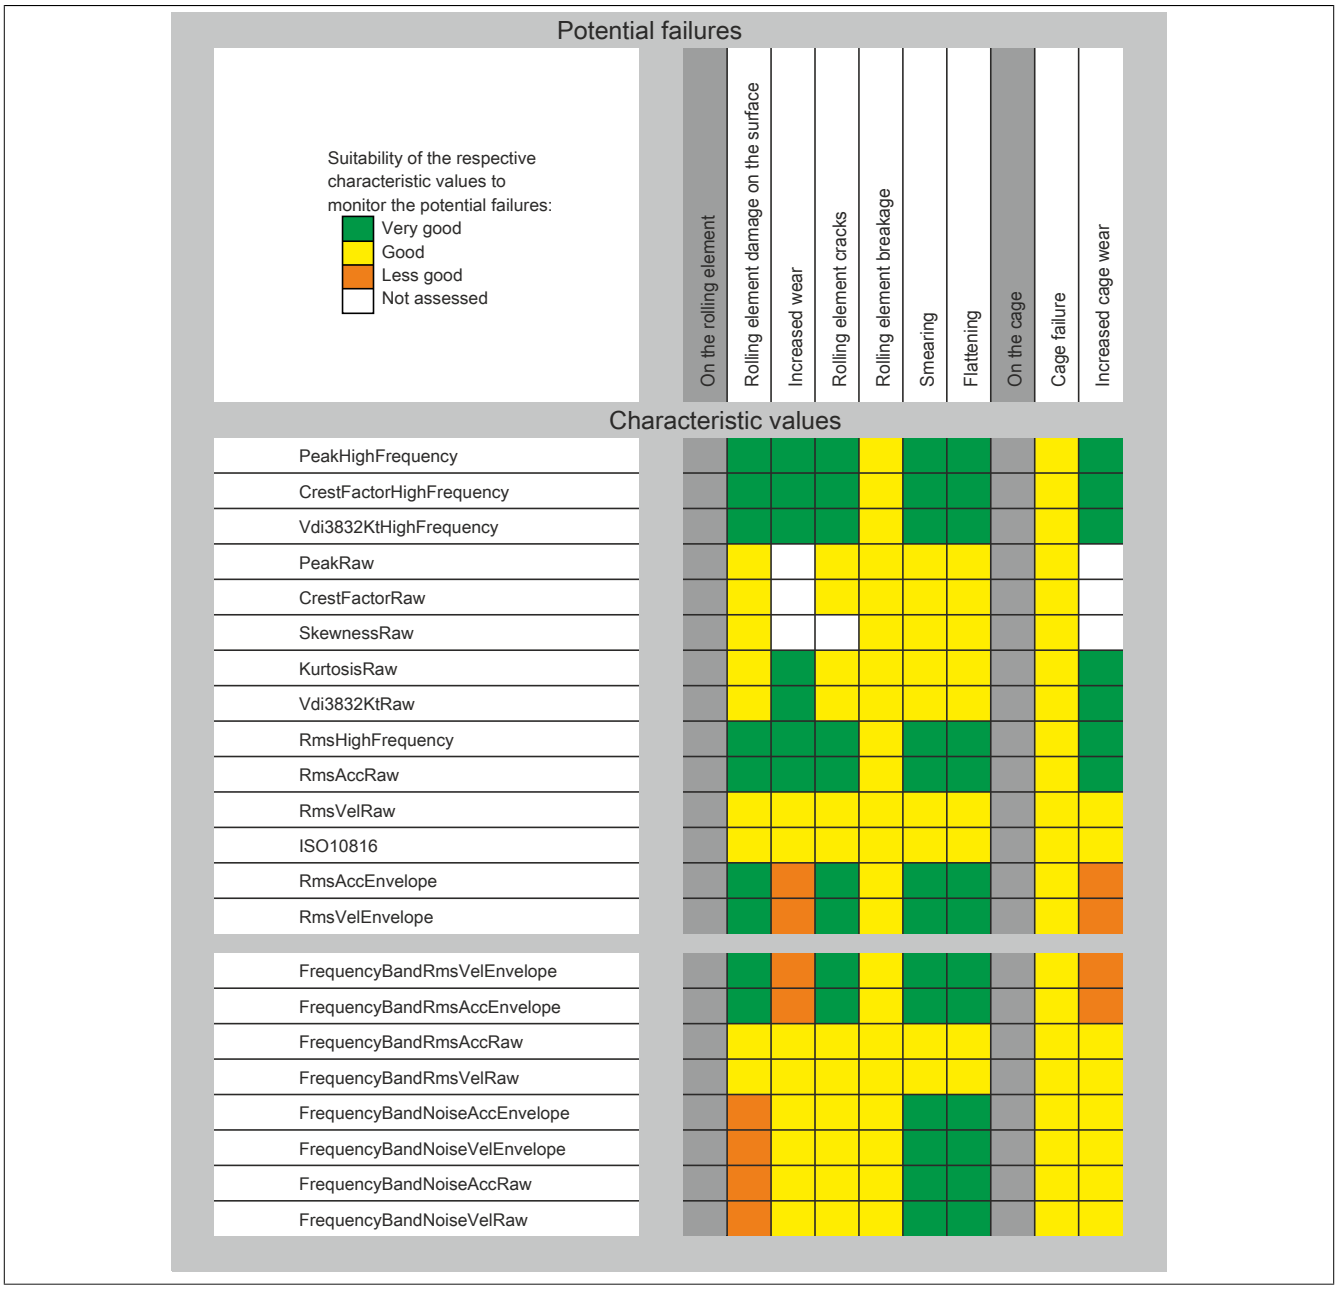

Figure 457: Frequency of failure indicators on roller bearings

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Gear damage

DIN 3979 provides a description of gear errors and defects. The most common errors in individual gearboxes are described below.

The complexity of the machine dynamics must be taken into consideration in individual applications.

Translation: The conversion of the speed ratio must always be considered in relation to the gear ratio. The frequencies on the gearwheels are always based on the speed of the respective axis.

Manufacturing defects

Oscillations due to manufacturing always occur in a gearbox. Typical manufacturing defects are pitch errors, profile deviations, concentricity and spacing errors.

Depending on the gearwheel pairing, these individual defects can intensify or become less intense depending on how the defects affect each other. The interplay of the individual defects is also responsible for the overall oscillation behavior.

Pitch error is a frequently occurring defect and is used as an example here. Depending on whether the pitch error is positive or negative, it is intensified or compensated by an existing load. The effects on the oscillation behavior depend very much on the rigidity of the gearwheel. If there is a pitch error, a shock occurs that can be measured effectively.

In addition to pitch errors, all form and dimensional gear errors lead to oscillations.

Outer ring damage is manifested in the envelope spectrum as follows:

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Meshing frequencies	1 x fz	1 x fz	Gear frequencies depend on the respective geometric ratios of the wheels but can be precisely calculated in any case.

Table 603: Frequency of a typical toothing error

fz ... Tooth meshing frequency

Defects caused by wear

If form and dimensional deviations occur during operation, observing the trend can lead to an appropriate level of confidence when performing diagnostics.

Failure mode	Frequency in raw signal spectrum	Frequency in envelope spectrum	Comment
Deterioration	1 x fz	1 x fz ± i x fn	Geometric errors increasingly appear additionally with sidebands for the tooth meshing frequency.

Table 604: Frequency of defects caused by wear

fz ... Tooth meshing frequency
fn ... Nominal speed

Wobbling

If the toothed belt axis and the rotation axis are not parallel, the phenomenon called wobbling occurs. This causes two flank errors per revolution. Depending on the position, there is one transmission on the inner edge and one on the outer edge of the toothed wheel.

The doubled speed frequency is clearly evident in the frequency spectrum.

Failure mode	Frequency in the raw signal spectrum	Frequency in the envelope spectrum	Comment
Wobbling	1 x fn, 2 x fn	1 x fz, 2 x fz	Wobbling movements manifest as doubled speed frequency and are usually accompanied by sidebands.

Table 605: Frequency of a typical toothing error

fn ... Nominal speed
fz ... Tooth meshing frequency

Cyclic running errors and axial distance errors

In DIN 3960, axial distance errors are defined as a deviation between the target/actual value.

An error in the distance between the axes causes a change in the contact of both toothed wheels. The so-called overlap ratio is negatively affected.

Even small pitch errors lead to a noise increase in the gearbox. Superposition with the previously mentioned errors often cause a frequency to form with various different frequency portions. Interpretation must be checked on a case-by-case basis

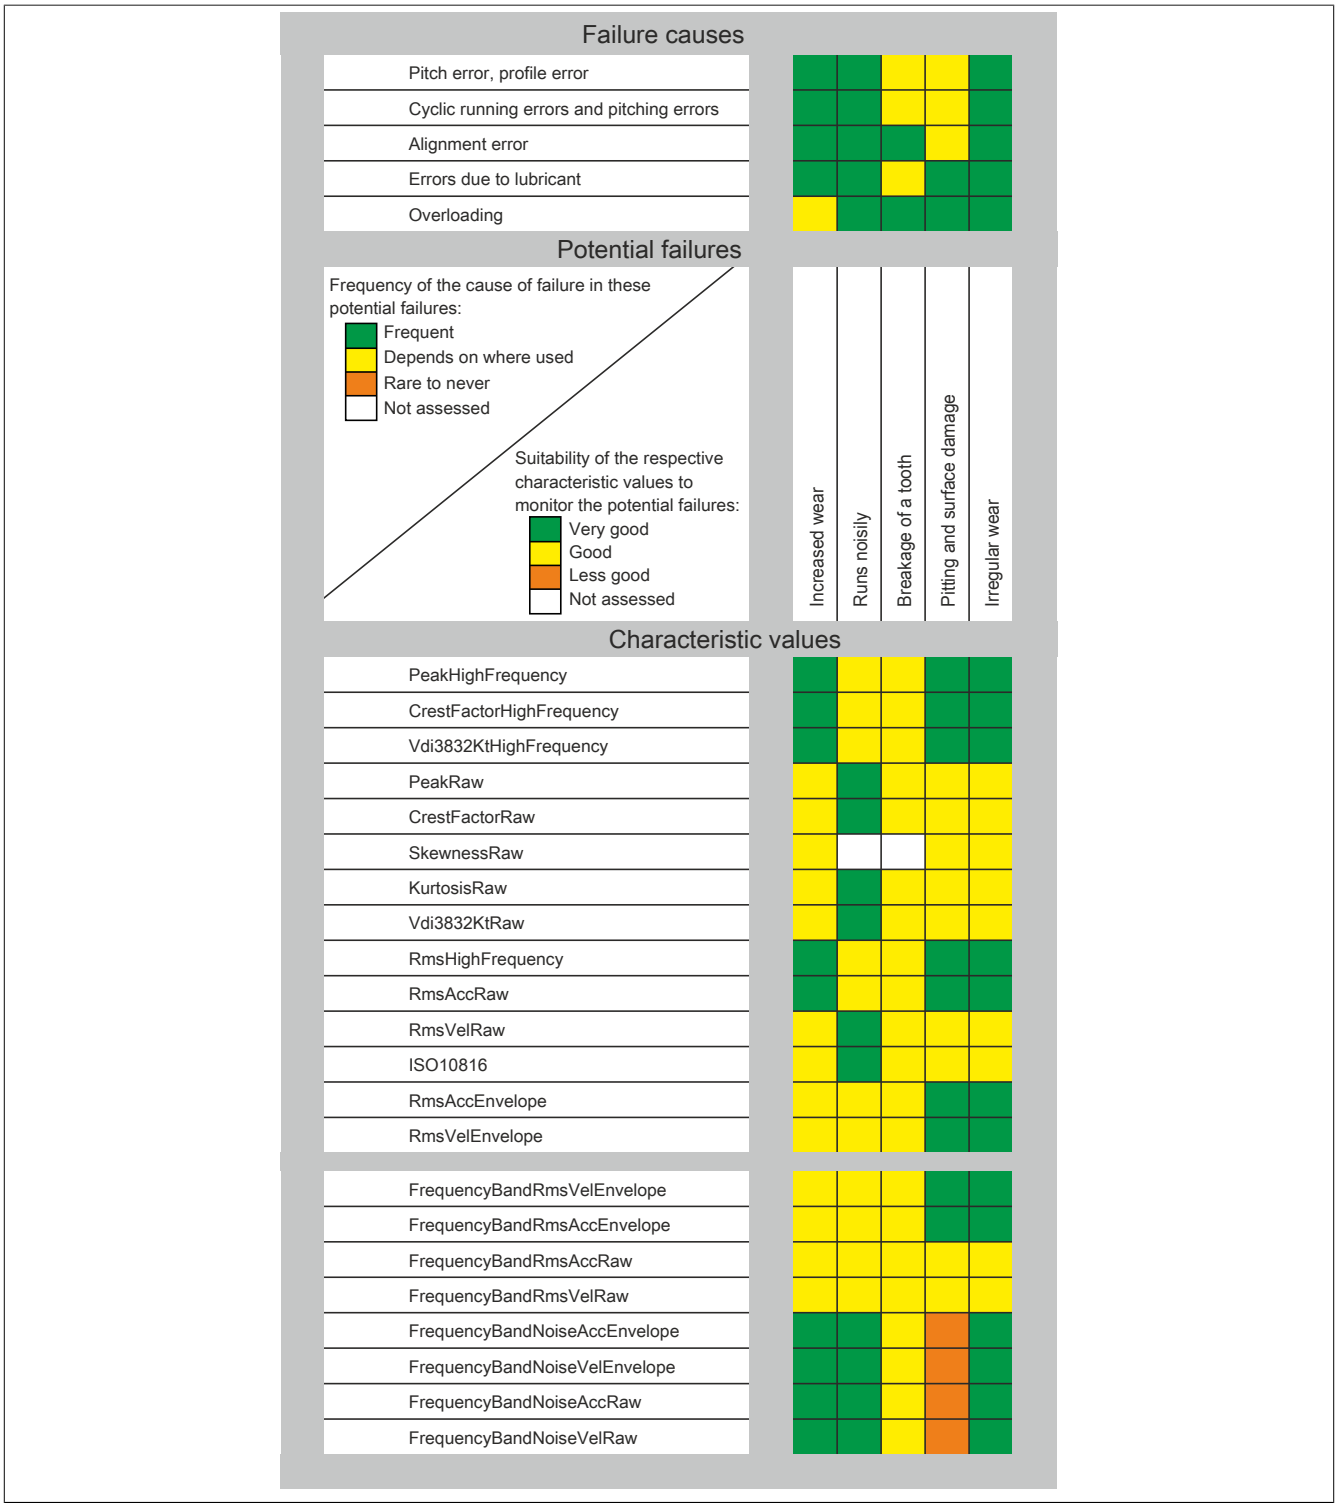

Figure 458: Frequency of failure indicators for gearbox damage

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Electrical errors

Occasionally, bridges in the rotor bars or short circuit rings occur. They occur as a result of overloading as well as aging and the ongoing oscillation load. This leads to a very uneven distribution of the induction current in the rotor.

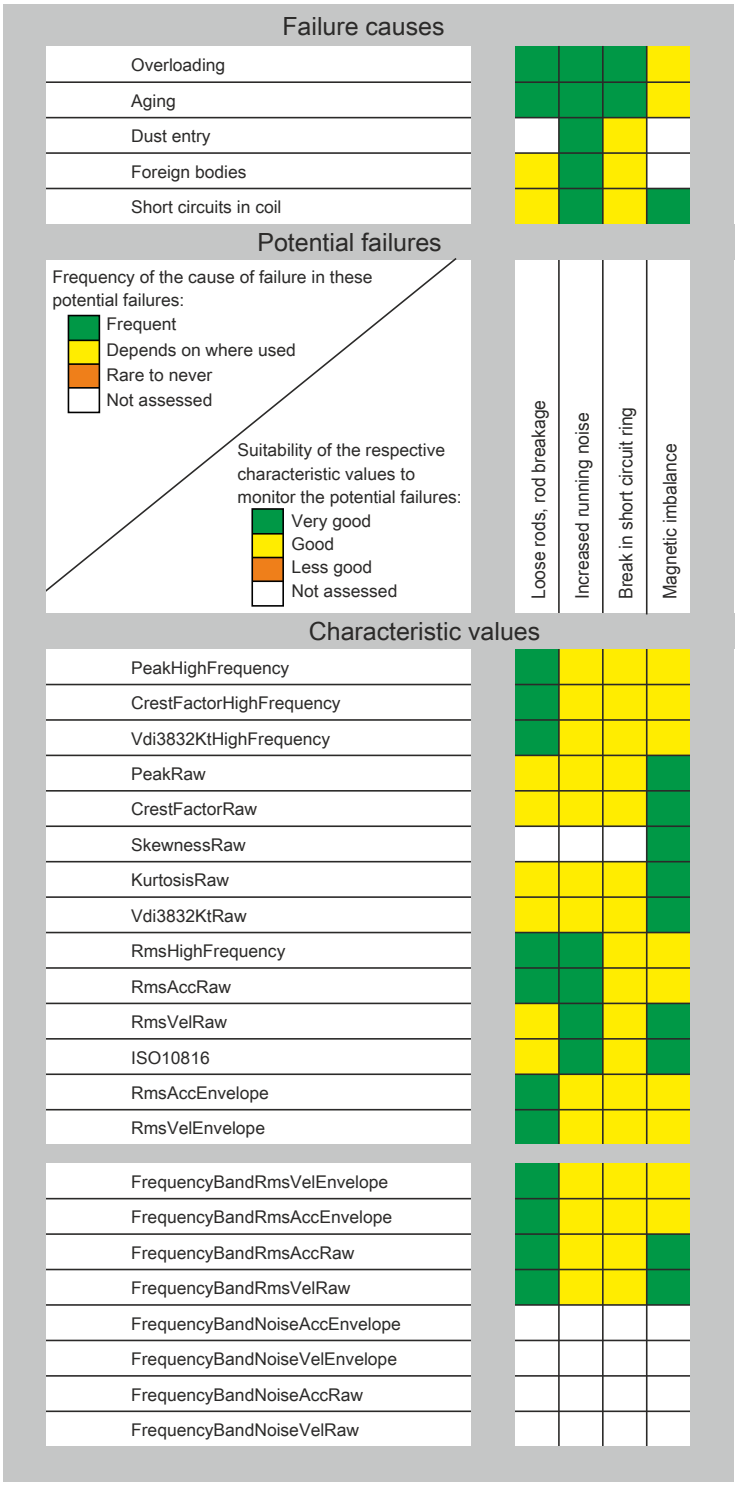

Figure 459: Electrical errors

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

4.26.4.4.3.3 Typical applications of damage recognition

The examples listed in the following are typical application cases and should provide assistance during integration. Detailed planning of usage must still be carried out for each individual case, however.

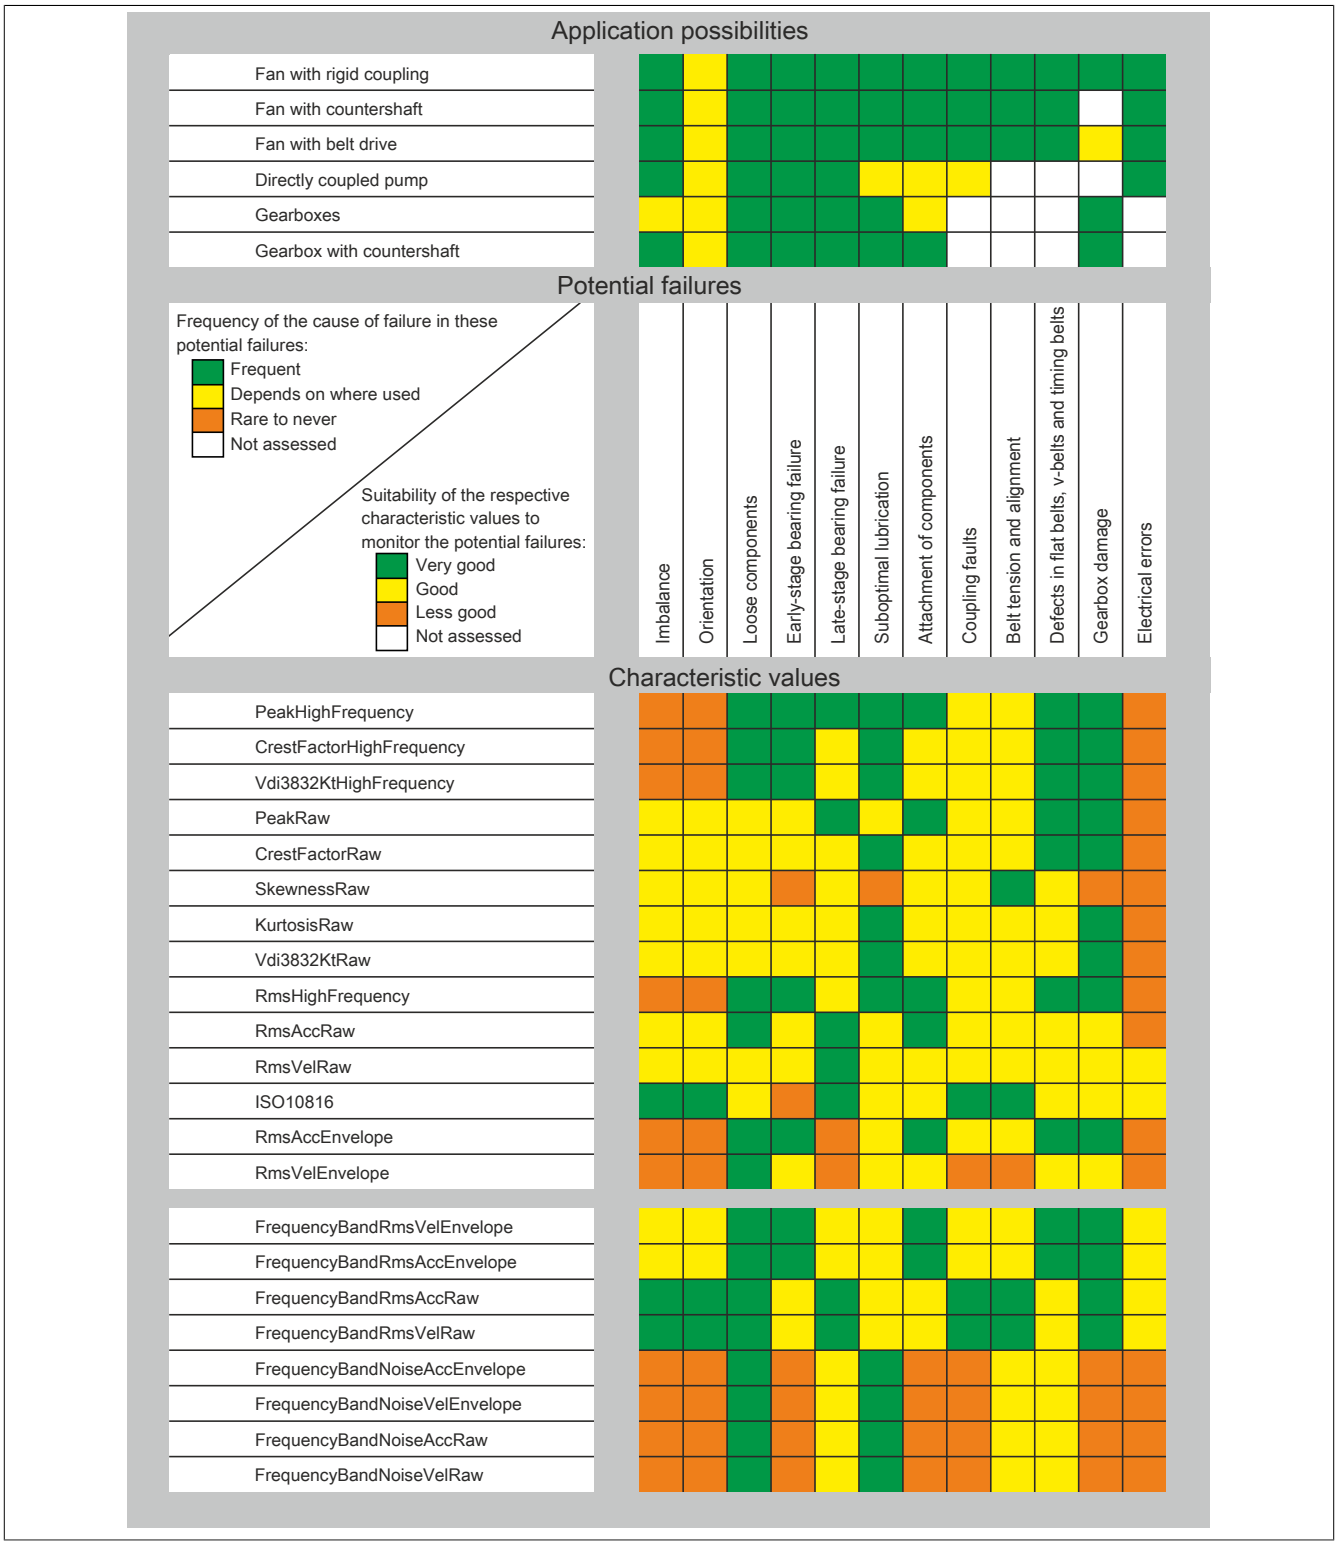

Figure 460: Typical applications of damage recognition

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Fan with rigid coupling

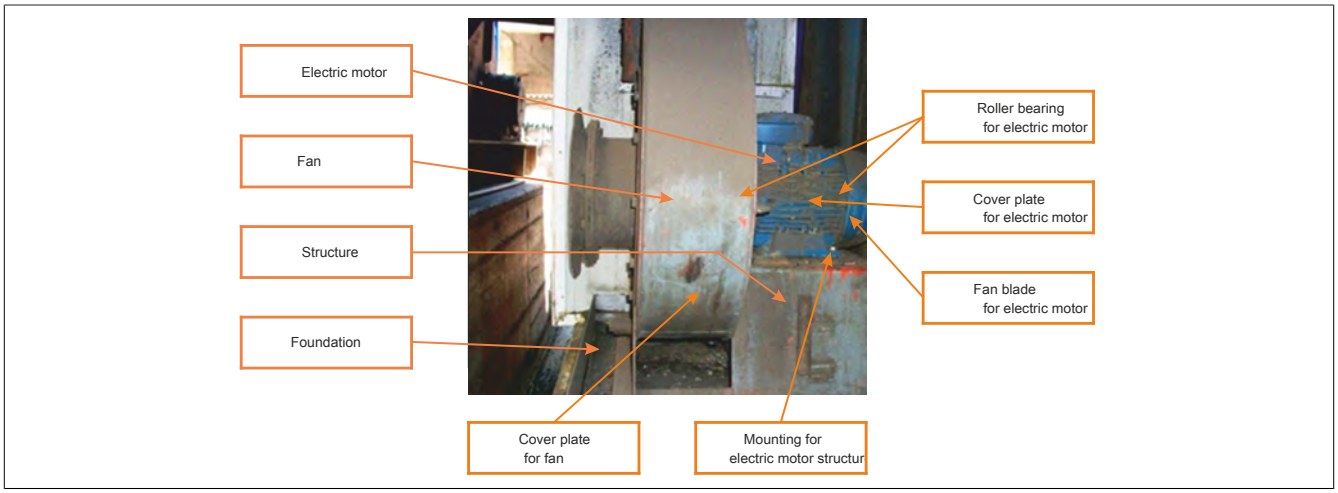

Figure 461: Drive unit with fan

Condition monitoring solution:

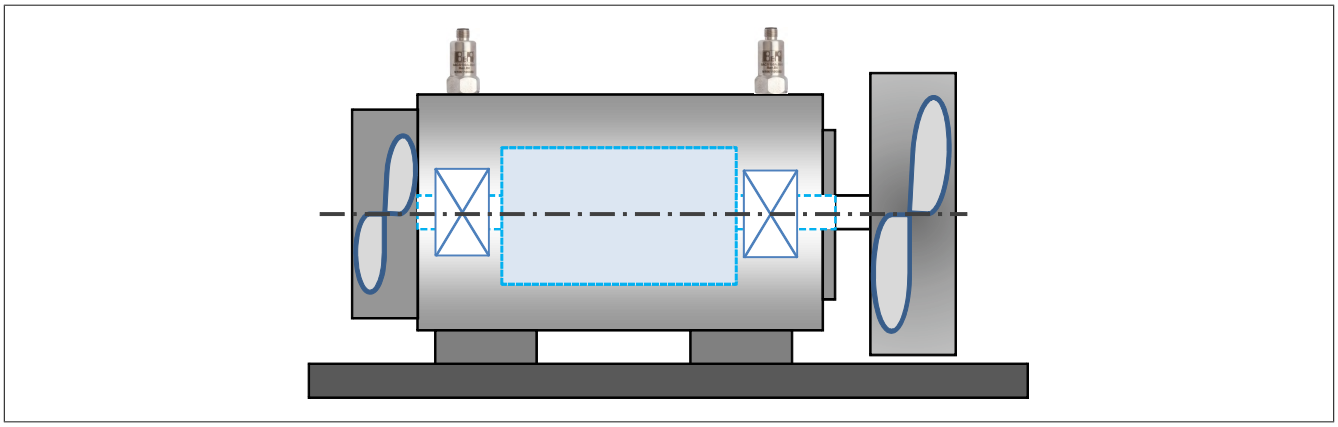

Figure 462: System diagram - Drive unit with fan

Sensor usage:

Number of sensors	Usually 2 sensors. One sensor is sufficient for smaller drive units.
Sensor installation	Preferably vertical. Horizontal installation is also possible, if necessary.

Frequent problems

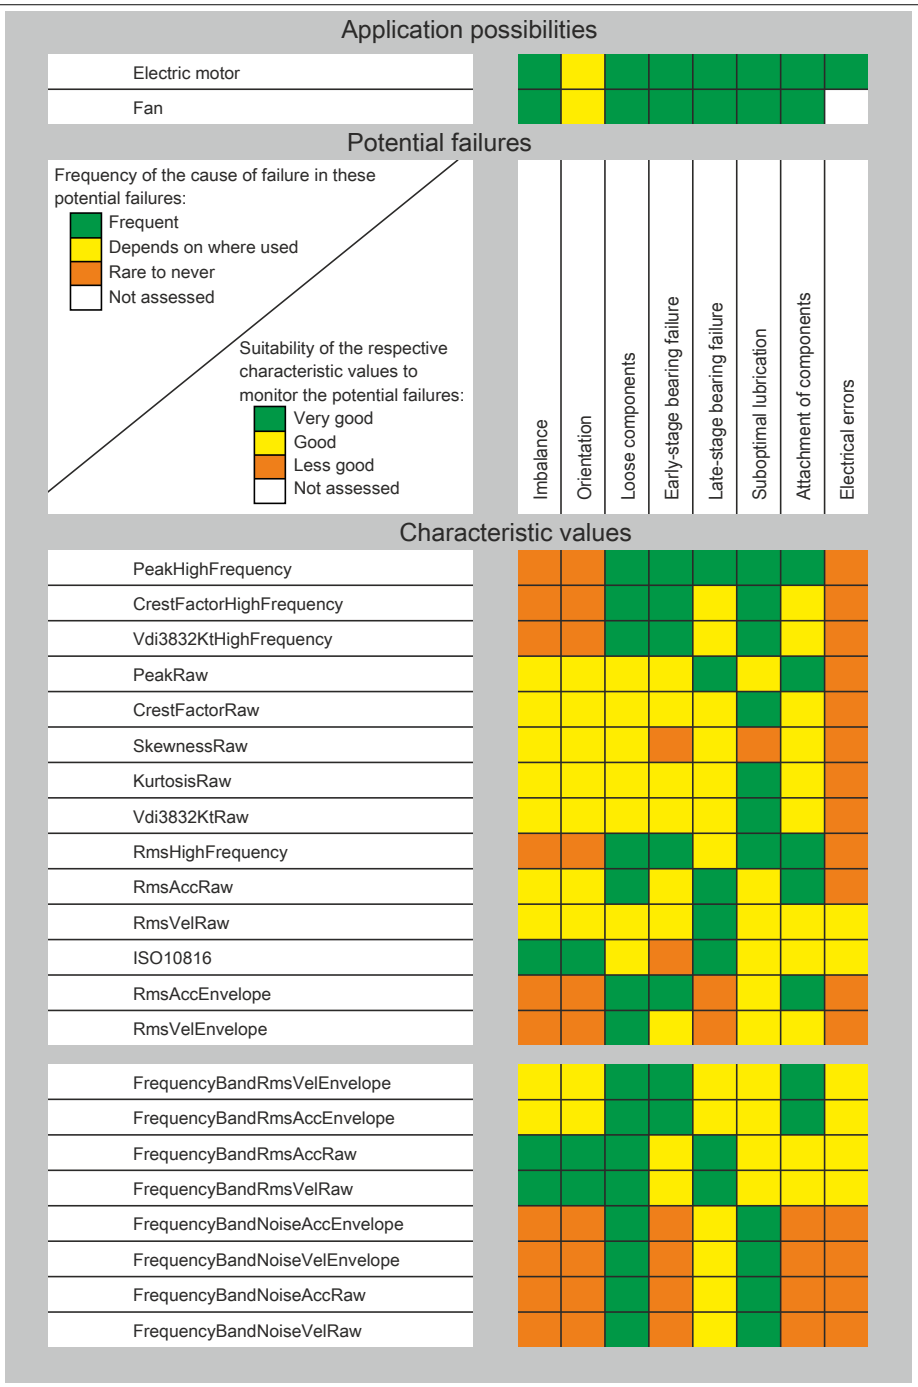

Figure 463: Fan with rigid coupling - Frequent problems

For the meaning of individual characteristic values, see "Characteristic values" and "Configuration options"

Fan with countershaft

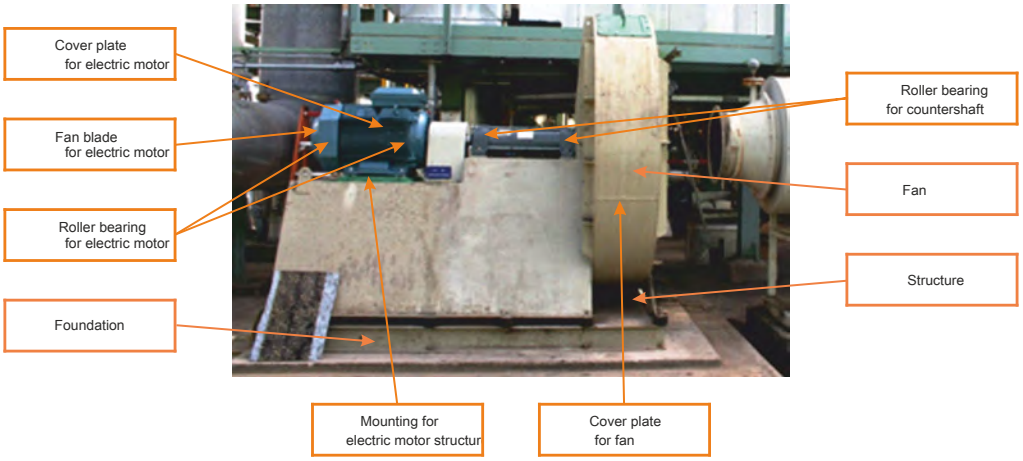

Figure 464: Drive unit with fan

Condition monitoring solution:

4.26.4.5 Register description

4.26.4.5.1 Function models

A function model specifies the storage model used, i.e. which registers are available for the application. Only these registers are processed in the module during each cycle and transferred cyclically or acyclically via the bus.

The function model is used to determine the module's functionality. The following options are available:

- Standard (SG4)
- Fast master (SGC and bus coupler)
- Slow master (SGC and bus coupler)
- CANIOBusController (CANIO bus coupler)

4.26.4.5.2 Function model 0 - Standard

Automation Runtime support

This is the default function model for the X20CM4810. The calculated module characteristic values are streamed from the module via FlatStream every 300 ms and prepared for the user by Automation Runtime. If the streamed data is not collected by the next transfer, the measured characteristic values are lost. For this reason, the maximum cycle time must be observed for an error-free evaluation.

Analog inputs are provided as cyclic data points.

To help the user, all of the module's characteristic values – such as FlatStream handling for characteristic values, unit scaling and so on – are prepared in this function model using Automation Runtime and then made available to the user.

With this function model it is also possible to use an additional FlatStream to read data buffers (time signal and FFT spectrum) from the module.

The AsVib function library is available for this application.

In this function model, the X20CM4810 can only be configured using the I/O configuration. Registers may not be reconfigured asynchronously.

Features provided by Automation Runtime support:

- **"DataToggleBit01":** This bit changes its value whenever new characteristic values are loaded from the module.
- **"OverflowAnalogInput01-04":** Indicates whether a signal is pending on the input that is larger than the configured AnalogInputScale.
  Important! This is always based on a 100 mV/g sensor.
- **"OverflowCharacteristicValues01-04":** This register contains an overflow indicator bit for each characteristic value of the respective channel.
- **"OverflowFrequencyBands01"**: This register contains an overflow indicator bit for each frequency band.
- **"ActSpeed01-04"**: The module always expects a value in 0.01 Hz resolution on these data points. Automation Runtime support allows the the user to specify can state the current speed directly in Hz in the "standard" function model.
- **"SensitivitySensor01-04"**: The X20CM4810 module expects a 100 mV/g sensor on the input by default. When using other sensors, the sensor resolution can be specified in mV/g for each channel on these data points. All cyclical characteristic values are then automatically scaled to the correct sensor resolution by Automation Runtime. If this parameter is changed, then the next measurement indicated by "DataToggleBit01" is invalid.
- **"AnalogInput01-04":** The analog input is automatically scaled to the sensor resolution and with the defined AnalogInputScale. It is then made available to the user in mg. This scaling does not apply to the "Crest factor" since it is a non-dimensional value.
- **Characteristic values and frequency bands:** All characteristic values and frequency bands calculated by the X20CM4810 are flat and can be connected directly in the I/O mapping. They are already scaled to the correct sensor resolution and will be displayed in mg or mm/s or as non-dimensional values (kurtosis, crest factor, skewness and Vdi3832) depending on the characteristic value.
- **Additional characteristic values:** In addition to the characteristic values calculated by the module, the following characteristic values are also provided automatically via Automation Runtime:

- **Vdi3832KtRaw01-04:** Requires PeakRawRef and RmsRawRef as reference values and outputs the reference values used in the calculation to PeakRawRefCalculated and RmsRawRefCalulated.
- **CrestFactorHighFrequency01-04:** Ratio of the maximum amount to the RMS value ("Crest factor") of the high-frequency portions ("PeakHighFrequency" and "RmsHighFrequency") of the input signal.
- **Vdi3832KtHighFrequency01-04:** Requires PeakHighFrequencyRef and RmsHighFrequencyRef as reference values and outputs the reference values used in the calculated to PeakHighFrequencyRefCalculated and RmsHighFrequencyRefCalulated.

- **"DataConsistentWithLockedBuffers01"**: If the data buffers on the module are locked to prevent uploading, this bit is used to indicate the time at which all characteristic values and frequency bands are consistent with the locked buffers on the module.

4.26.4.5.3 Function model 1 - Fast master

The characteristic values calculated by the module are streamed to the master every 300 ms via FlatStream. If the streamed data is not collected by the next transfer, the measured characteristic values are lost. For this reason, the maximum cycle time must be observed for an error-free evaluation.

With this function model, it is also possible to use an additional FlatStream to read data buffers (time signal and FFT spectrum) from the module.

Analog inputs are provided as cyclic data points. The AsVib library provides support for the user when using SGC CPUs.

This function model can only be used on **Ethernet-based masters**. However, it must be ensured that FlatStream handling is implemented on the master and that the module changes the data in the FlatStream in every X2X cycle.

4.26.4.5.3.1 Register of function model 1 - Fast master

Register	Name	Data type	Read		Write

4.26.4.5.4 Function model 2 - Slow master

This function model was developed specifically for operating the X20CM4810 with "slow masters" and for conserving resources on the PLC.

With this function model, it is not possible to upload data buffers from the module.

Analog inputs are provided as cyclic data points.

Characteristic values are calculated by the module every 300 ms and can only be read via acyclical access. In order to keep all characteristic values consistent with one another, they can be locked as they are read (RequestDataLock01). This function model does not allow for seamless measurements, however, although minimum and maximum functionality can be used for seamless recording. See 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705

This function model is recommended for all slow buses and masters. It is important to note that asynchronous register access must be implemented on the master if a B&R master is not being used.

4.26.4.5.5 Function model 254 - Bus controller

This function model can only be used with a CANIO bus controller. It includes the same functionality as Function model 2 - Slow master.

Differences:

- The order of cyclical registers is different on the bus for reasons of consistency.
- Since the AnalogInputToggleBit01-04 data points cannot be consistently transferred to the "AnalogInput01-04" data points, they are not available in this function model. The user must watch for changes in the value of the data points "AnalogInput01-04" in order to determine whether a new value is available.

1) The offset specifies the position of the register within the CAN object.

4.26.4.5.6 Module registers - General information

4.26.4.5.6.1 AnalogInput function

General information

Each of the four acceleration sensor inputs on the X20CM4810 can also be used directly as an analog input with various special functions ("AnalogInput01-04").

The resolution of the analog input can be set using the configuration ("AnalogInputScale01"). The lower the maximum value, the higher the resolution of the data point and vice versa. When the maximum value is exceeded, the data point is limited to the respective maximum (positive or negative).

A toggle bit (AnalogInputToggleBit01-04) signals when a new value has been transferred.

The following functions are available:

- Normal AnalogInput function
- Characteristic value calculation in continuous mode with enable (continuous mode)
- Characteristic value calculation in trigger mode (single shot)

AnalogInput

The last 8 measured values before the X2X cycle are always averaged and transferred on the bus. Here, the direct input signal (raw signal max. 10 kHz) with a sampling frequency of 25.781 kHz is always used and is not offset-adjusted.

Characteristic value calculation in AnalogInput

It is possible to display the following characteristic values directly in AnalogInput. In this case, it is necessary to check the configured scale.

- Average
- Peak value (absolute)
- RMS
- Crest factor

Two signals are available to calculate the configured characteristic values:

- Raw input signal filtered to 10 kHz with a sampling frequency of 25.781 kHz and without calculating the average (offset adjustment)
- Raw signal filtered to the maximum frequency with a sampling frequency that is dependent on the "MaxFrequencyRaw01" configuration and with an average calculation (offset adjustment) from the last 8192 samples.

Similarly, the registers ("SamplesAnalogInput") can be used to specify how many of the values (samples) are to be calculated for the relevant parameter. The time between 2 samples depends on the maximum frequency.

2 modes are available:

- Continuous mode with enable (continuous mode)
- Trigger mode (single shot)

Continuous mode with enable (continuous mode)

This mode offers the following advantages:

- When the parameters are configured correctly, nothing can be overlooked.
- Using "enable", measurement in the module can be started after an event or events can be hidden.
- The toggle bit toggles with every new value.

The following must be taken into consideration for the configuration:

- In order to guarantee seamless measurement, the sample time (number of samples * sample rate) must be longer than the X2X cycle (see section "SamplesAnalogInput" on page 2687).
- If a shorter sample time than the X2X Link cycle is configured, the last complete measurement is always transferred.

Information:

Values are lost here. The measured values cannot be transferred to the bus because multiple values are calculated in each X2X Link cycle.

Trigger mode (single shot)

This mode offers the following advantages:

- Only one measurement is taken at a time.
- The trigger is edge-sensitive, so it can be retriggered in each X2X Link cycle.
- The toggle bit toggles with every new value.

The following must be taken into consideration for the configuration:

- A new trigger will be ignored during an ongoing measurement. The runtime on the bus can cause retriggering before the toggle bit has changed.
- If a shorter sample time than the X2X Link cycle is configured, then the first complete measurement is always transferred.
- In trigger mode, values are lost because the measurement values are recorded asynchronously to the X2X Link and cannot be synchronized continually.
- The trigger results in temporary synchronization with X2X Link.

AnalogInput01-04

Depending on the configuration this data point contains:

- The actual input value of the associated input averaged over the last 8 samples
- Or the characteristic value to be calculated using the configured number of samples

The value in the data point is scaled according to the configuration "AnalogInputScale01".

If scaling the value takes it outside of the permitted value range for INT, then it will be limited to the minimum or maximum INT value. The overflow bit for the corresponding channel is not set in this case.

Information:

In Function model 0 - Standard, Automation Runtime automatically scales the analog input to mg or non-dimensional values (crest factor) while taking SensitivitySensor and AnalogInputScale into account. If the value of the analog input without sensor scaling exceeds the value range of the AnalogInputscale of 100 mV/g, then the corresponding AnalogInputOverflow bit is used.

AnalogInputConfig01

Register for configuring the characteristic value calculation in "AnalogInput01-04". This is only needed if "SamplesAnalogInput" of the respective channel is greater than 0.

Bit	Description
15	Signal source for characteristic value calculation AnalogInput04. For possible values, see signal source AnalogInput01.
14	Signal source for characteristic value calculation AnalogInput03. For possible values, see signal source AnalogInput01.
13	Signal source for characteristic value calculation AnalogInput02. For possible values, see signal source AnalogInput01.
12	Signal source for characteristic value calculation AnalogInput01 **Value** / **Description** 1 – Raw signal filtered to 10 kHz without calculating the average 0 – Raw signal filtered to the maximum frequency of the raw signal with calculation of the average value for the last 8192 samples
11	Trigger mode for AnalogInput04 (0 = Continuous with enable, 1 = Once with trigger)
10	Trigger mode for AnalogInput03 (0 = Continuous with enable, 1 = Once with trigger)
9	Trigger mode for AnalogInput02 (0 = Continuous with enable, 1 = Once with trigger)
8	Trigger mode for AnalogInput01 (0 = Continuous with enable, 1 = Once with trigger)
7-6	Value to be calculated in AnalogInput04. For possible values, see value to be calculated for AnalogInput01.
5-4	Value to be calculated in AnalogInput03. For possible values, see value to be calculated for AnalogInput01.
3-2	Value to be calculated in AnalogInput02. For possible values, see value to be calculated for AnalogInput01.
1-0	Value to be calculated in AnalogInput01 **Value** / **Description** 3 – Crest factor 2 – RMS value 1 – Peak value 0 – Average

Table 606: AnalogInputConfig01

AnalogInputConfig01Read

Register for reading the current AnalogInput01 configuration.

AnalogInputControlByte01

The control register for "AnalogInput01-04" is only functional if the respective "SamplesAnalogInput" configuration register is greater than 0.

The configuration in "AnalogInputConfig01" of each channel determines whether the respective bit is an enable or a trigger bit.

Bit	Description
15-4	Reserved = 0
3	AnalogInputControl04 for the parameter calculation by AnalogInput04
2	AnalogInputControl03 for the parameter calculation by AnalogInput03
1	AnalogInputControl02 for the parameter calculation by AnalogInput02
0	AnalogInputControl01 for the parameter calculation by AnalogInput01

Table 607: AnalogInputControlByte01

AnalogInputControl01-04 in continuous mode:

Bit to start the continuous characteristic value calculation of "AnalogInput01-04".

0 = Characteristic value calculation off

1 = Continuous calculation

If this bit = 1, then the characteristic value configured in "AnalogInputConfig01" for the respective channel is calculated continuously. The number of samples configured in "SamplesAnalogInput" is used. The calculated value is displayed in "AnalogInput01-04" with the scaling of the respective channel configured in "AnalogInputScale01". The value of AnalogInputToggleBit01-04 changes each time a new calculation takes place.

AnalogInputControl01-04 in single-shot mode:

Bit to start a new characteristic value calculation of "AnalogInput01-04". Every edge starts a new calculation provided the previous one is already completed.

If the value of this bit changes, then the characteristic value configured in "AnalogInputConfig01" for the respective channel is calculated. The number of samples configured in "SamplesAnalogInput" is used. The calculated value is displayed in "AnalogInput01-04" with the scaling of the respective channel configured in "AnalogInputScale01". The value of AnalogInputToggleBit01-04 changes each time a new calculation takes place.

AnalogInputSamples

Name:
AnalogInputSamples01 to AnalogInputSamples04

If Bit 15 of the corresponding SamplesAnalogInput register is 1, then this register is used cyclically to set the number of samples for parameter calculation.

Information:

If the register is changed during an active measurement, then the current measurement is discarded (AnalogInputToggleBit0X is not toggled). Keep an eye out for this, particularly with Enable in continuous mode.

Data type	Value
UINT	See bit structure.

Bit structure:

Data type	Value	Description
	> 8191	Invalid
	8191 to 1	Characteristic value calculation active for the respective channel in the corresponding analog input
	0	Invalid

The time between 2 samples depends on MaxFrequencyRaw:

Maximum frequency	Sample time (time between 2 samples)
10000 Hz	38.79 µs
5000 Hz	77.58 µs
2000 Hz	193.94 µs
1000 Hz	387.88 µs
500 Hz	775.76 µs
200 Hz	1939.39 µs

Table 608: Overview of the sample time at the maximum frequency of the raw signal

AnalogInputScale01

This register can be used to specify the scale of the four analog inputs ("AnalogInput01-04"). If the actual value is greater than the value configured in this register, the respective register for the analog input ("AnalogInput01-04") is limited to the positive maximum (32767).

For example, if ±128 is configured for AnalogInput04, then the 16 bits represent a value range of ±128 g or without units if the crest factor has been calculated.

Information:

The configured scaling value is always based on a 100 mV/g sensor. Any sensor that has a different sensor resolution must be reflected in the configuration.

Bit	Description
15-12	Scaling for AnalogInput04. For possible values, see AnalogInput01.
11-8	Scaling for AnalogInput03. For possible values, see AnalogInput01.
7-4	Scaling for AnalogInput02. For possible values, see AnalogInput01.
3-0	Scaling for AnalogInput01

Value	Description
15 - 9	Invalid
8	±128
7	±64
6	±32
5	±16
4	±8
3	±4
2	±2
1	±1
0	Invalid

Table 609: AnalogInputScale01

AnalogInputScale01Read

This register can be used to read the scale of the analog inputs ("AnalogInput01-04").

SamplesAnalogInput

Name:
SamplesAnalogInput01 to SamplesAnalogInput04

If the corresponding SamplesAnalogInput register is equal to 0, then the "AnalogInput01-04" data points will provide the current input value for the analog input.

If the SamplesAnalogInput register is greater than 0, the characteristic value configured in "AnalogInputConfig01" for the respective channel is calculated. For this, the number of samples configured in this register will be used and displayed in the corresponding AnalogInput with the configured scaling.

Data type	Value	Description
UINT	Bit 15	0 = The samples are set cyclically via the register AnalogInputSamples01 - 04
		1 = The samples are configured using the register AnalogInputSamples01 - 04
	> 8191	Invalid
	8191 to 1	Characteristic value calculation active for the respective channel in the corresponding analog input
	0	Characteristic value calculation not active for the respective channel in the corresponding analog input

Table 610: SamplesAnalogInput01-04

If Bit 15 of the SamplesAnalogInput is 1, then the parameter configured in "AnalogInputConfig01" is also calculated. However, the number of samples set cyclically in the AnalogInputSamples register will be used and displayed in the corresponding AnalogInput with the configured scaling.

The time between 2 samples depends on MaxFrequencyRaw:

Maximum frequency	Sample time (time between 2 samples)
10000 Hz	38.79 µs
5000 Hz	77.58 µs
2000 Hz	193.94 µs
1000 Hz	387.88 µs
500 Hz	775.76 µs
200 Hz	1939.39 µs

Table 611: Overview of the sample time at the maximum frequency of the raw signal

SamplesAnalogInputRead

Name:
SamplesAnalogInput01Read to SamplesAnalogInput04Read

Register for reading the current "SamplesAnalogInput" configuration.

Data type	Value
UINT	0 to 65535

4.26.4.5.6.2 Frequency bands

General information

The X20CM4810 has 32 frequency bands that can be configured as needed. It is important to note that the format varies depending on the configuration (see section 4.26.4.2.11 "Characteristic value format" on page 2602). The following functions are available:

- "Broadband RMS"
- "Speed-dependent RMS"
- "Noise"

If frequencies are entered that are outside the minimum and maximum signal frequency for the selected channel, then only the domains between the minimum and maximum frequency will be analyzed.

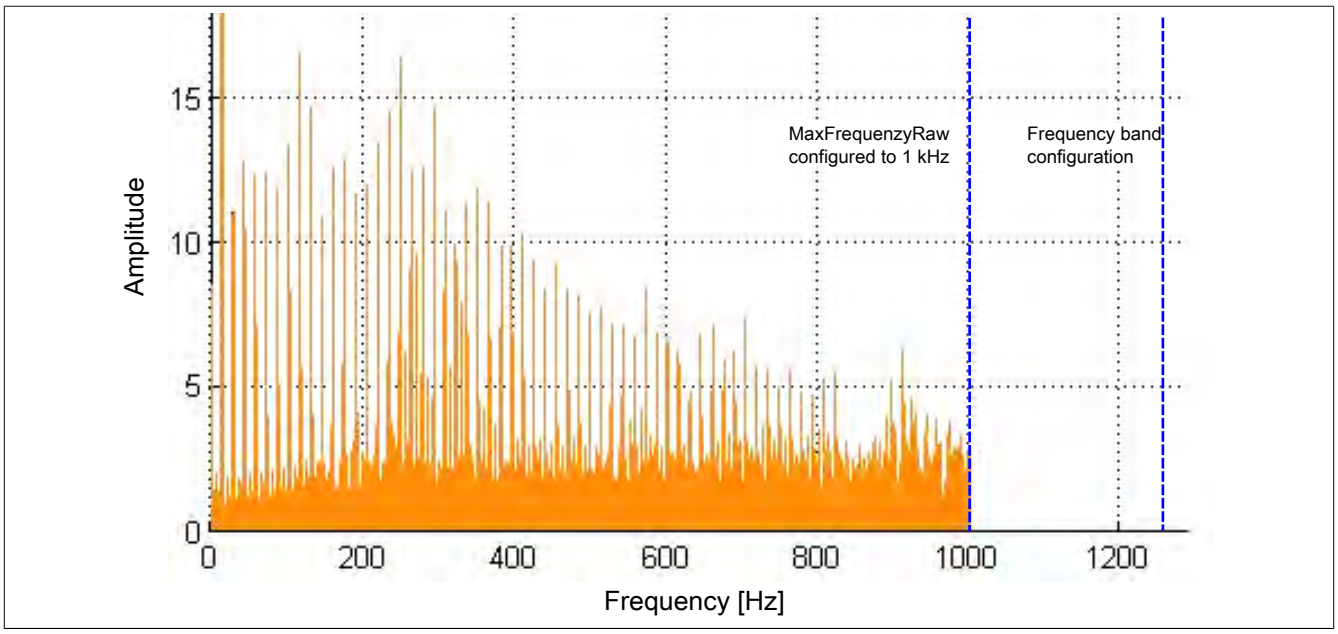

Figure 480: Restricting the frequency band evaluation

Two neighboring lines (samples) in the spectrum that are already outside the set window (one above and one below the window) will be partially included in the calculation depending on their distance from the window.

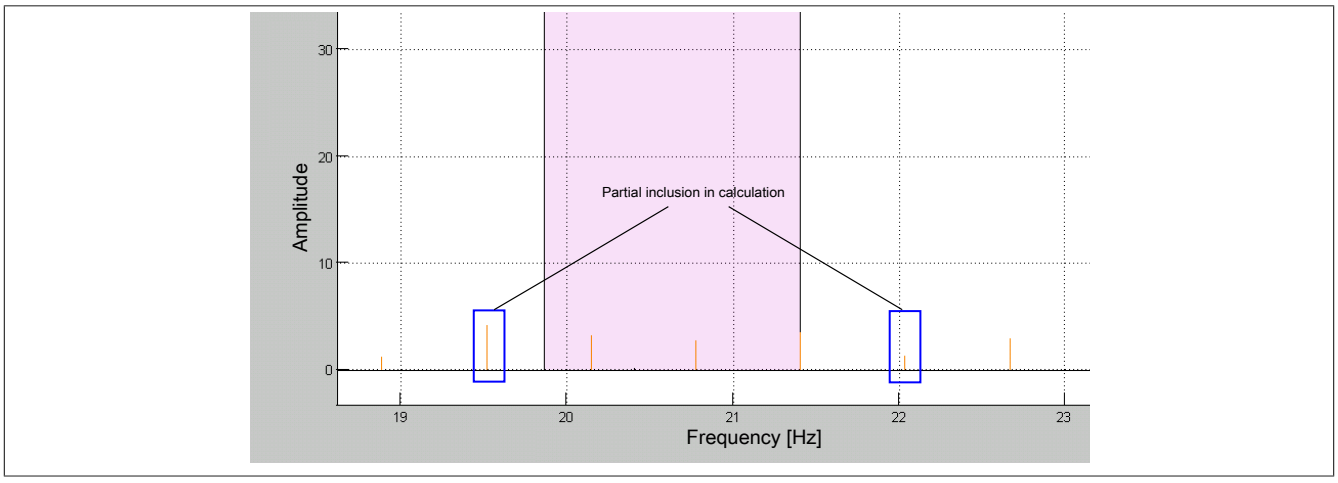

Figure 481: Partial inclusion of marginal lines in the calculation

Guidelines for configuring the frequency bands

- The total range of the frequency band is at least 2 * 0.005 * max. drive frequency [Hz].
- The upper and lower frequency limits must not be less than 0.005 * max. drive frequency [Hz] from the desired average frequency.
  Example
  At a maximum drive frequency of 50 Hz, a frequency band should be set at 10 Hz.
  10 Hz ± (0.005 * 50 Hz) = At least 9.75 Hz lower and 10.25 Hz upper frequency band limits
- Depending on the MaxFrequency selected, a least three lines should be configured within each frequency band.
- The first lines to the left and right of the configured frequency band are included proportionally based on their distance from the frequency band (see image above).

Broadband RMS

In this configuration, the RMS value of the configured signal and channel in the frequency band is calculated. The value is calculated from the minimum frequency ("FrequencyBandXXLowerFrequency") to the maximum frequency ("FrequencyBandXXUpperFrequency"). The minimum and maximum frequency can be entered here in increments of 0.25 Hz.

Any channel for any frequency band can be selected.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (whole number multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by 1, 2, 3, etc.) until the maximum frequency of the configured signal and channel is reached.

Speed-dependent RMS

In this configuration, the RMS value is calculated in a movable window. There are 4 speed inputs for this ("ActSpeed01-04" in 0.01 Hz). One of the 4 speeds can be selected for each of the 32 frequency bands. In addition, the standardized damage frequency at 60 rpm ("FrequencyBandXXDmgFreq60rpm") and a tolerance ("FrequencyBandXXTolerance") must be configured. These can be configured separately for each frequency band.

The window in which the RMS is calculated is determined as follows:

Minimum frequency = (speed * standardized damage frequency at 60 rpm) – tolerance

Maximum frequency = (speed * standardized damage frequency at 60 rpm) + tolerance

The standardized damage frequency and tolerance can be entered here in increments of 0.01 Hz.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

The harmonic frequencies (whole number multiples) of the window can also be included in the calculation. Here, the width of the window is simply retained and the mean frequency of the window is multiplied (by *1, *2, *3, etc.) until the maximum frequency of the set signal and channel is reached.

Useful information

If a fixed frequency band is needed in which the minimum frequency ("FrequencyBandXXLowerFrequency") and maximum frequency ("FrequencyBandXXUpperFrequency") must be set with a higher precision than 0.25 Hz, then a speed-dependent frequency band with a fixed speed can be used.

Noise

In this configuration, the noise from a quadrant of the respective signal on the selected channel that is within the frequency band is calculated.

To do this, the configured maximum frequency of the signal on the selected channel is divided by 4. This results in 4 quadrants. A configuration can then be used to select one of the 4 quadrants in which the noise should be determined.

The following signals can be selected for each channel:

- Raw acceleration signal
- Raw velocity signal. Equal to 0 if the speed calculation is disabled.
- Enveloped acceleration signal
- Enveloped velocity signal. Equal to 0 if the speed calculation is disabled.

This configuration allows slippage to be effectively measured, for example. The higher the friction, the more noise that is created.

ActSpeed01-04

Data point for the current speed to calculate FrequencyBands01-32 as long as they have been configured as being speed-dependent.

The current speed must be specified in 1/100 Hz. In Function model 0 - Standard, Automation Runtime handles this. The current speed is defined in hertz.

If the 4 different speed data points are not sufficient, e.g. for several different gear ratios, the speed ratio can also be included when calculating the standardized damage frequency for the frequency band ("FrequencyBand-DmgFreq60rpm").

FrequencyBandConfig

Name:
FrequencyBand01Config to FrequencyBand32Config

General configuration of individual frequency bands.

Each frequency band can be calculated on any channel with any of the four speed data points ("ActSpeed01-04").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description
15	Reserved = 0
14-13	Selects the quadrant to calculate the noise **Value** / **Description** 3 – 4 quadrant from 3/4 MaxFrequency to MaxFrequency of the respective signal (raw signal or envelope signal) on the channel 2 – 3 quadrant from 1/2 MaxFrequency to 3/4 MaxFrequency of the respective signal (raw signal or envelope signal) on the channel 1 – 2 quadrant from 1/4 MaxFrequency to 1/2 MaxFrequency of the respective signal (raw signal or envelope signal) on the channel 0 – 1 quadrant from MinFrequency to 1/4 MaxFrequency of the respective signal (raw signal or envelope signal) on the channel
12	Enables noise calculation instead of RMS (0 = Off, 1 = On) As soon as this is enabled, the speed-dependent and harmonic settings are ignored.
11-8	Selects which ActSpeed data point should be used for the calculation if the frequency band is speed-dependent **Value** / **Description** 15 - 4 – Invalid 3 – ActSpeed04 2 – ActSpeed03 1 – ActSpeed02 0 – ActSpeed01
7	Includes harmonic frequencies in the calculation (0 = Off, 1 = On) If enabled, all harmonic frequencies up to the maximum frequency are included in the calculation. **Information:** **The harmonic frequencies can also include frequency portions that are the result of damage at other positions. This can lead to a misinterpretation of the measurement.**
6	Speed-dependent (0 = Off, 1 = On) If enabled, the ActSpeed data point is used with the entered FrequencyBandDmgFreq60rpm and the configured FrequencyBandTolerance to calculate the frequency band. If disabled, then FrequencyBandLowerFrequency and FrequencyBandUpperFrequency are used to calculate the frequency band.
5-4	Selects the signal for calculating the frequency band **Value** / **Description** 3 – Enveloped acceleration signal 2 – Raw acceleration signal 1 – Enveloped velocity signal Only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output. 0 – Raw velocity signal Only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.
3-0	Selects which input channel should be used to calculate the frequency band **Value** / **Description** 15 - 4 – Invalid 3 – Channel 4 2 – Channel 3 1 – Channel 2 0 – Channel 1

Table 612: FrequencyBand01Config - FrequencyBand32Config

FrequencyBandConfigRead

Name:
FrequencyBand01ConfigRead to FrequencyBand32ConfigRead

Registers for reading the configuration of individual frequency bands.

Data type	Value
UINT	0 to 65535

FrequencyBandDmgFreq60rpm

Name:
FrequencyBand01DmgFreq60rpm to FrequencyBand32DmgFreq60rpm

Standardized damage frequency at 60 rpm if the frequency band is configured as speed-dependent.

This is multiplied with the configured velocity data point in the module to calculate the frequency band.

The standardized damage frequency must be specified in 1/100.

Data type	Value
UINT	1 bis 65,535

FrequencyBandDmgFreq60rpmRead

Name:
FrequencyBand01DmgFreq60rpmRead to FrequencyBand32DmgFreq60rpmRead

Register to read the standardized damage frequency at 60 rpm for the individual frequency bands.

The standardized damage frequency is specified in 1/100.

Data type	Value
UINT	1 bis 65,535

FrequencyBandTolerance

Name:
FrequencyBand01Tolerance to FrequencyBand32Tolerance

If the frequency band is configured as speed-dependent, then this data point can be used to specify the frequency band's width.

The FrequencyBandTolerance is subtracted once from the damage frequency calculated from the ActSpeed and FrequencyBandDmgFreq60rpm to get the frequency band's lower frequency and added once to get the higher frequency.

The tolerance must be specified in 1/100 Hz. Valid values are 1 to 65535.

Data type	Value
UINT	1 bis 65,535

FrequencyBandToleranceRead

Name:
FrequencyBand01ToleranceRead to FrequencyBand32ToleranceRead

Registers for reading the tolerance of individual frequency bands.

The tolerance is specified in 1/100 Hz.

Data type	Value
UINT	1 to 65,535

FrequencyBandLowerFrequency

Name:
FrequencyBand01LowerFrequency to FrequencyBand32LowerFrequency

Minimum frequency for calculating the frequency band if it is not speed-dependent.

The minimum frequency must be specified in 1/4 Hz.

Data type	Value
UINT	1 to 40,000

FrequencyBandLowerFrequencyRead

Name:
FrequencyBand01LowerFrequencyRead to FrequencyBand32LowerFrequencyRead

Registers for reading the minimum frequency of individual frequency bands.

The minimum frequency is specified in 1/4 Hz.

Data type	Value
UINT	1 to 40,000

FrequencyBandUpperFrequency

Name:
FrequencyBand01UpperFrequency to FrequencyBand32UpperFrequency

Maximum frequency for calculating the frequency band if it is not speed-dependent.

The maximum frequency must be specified in 1/4 Hz.

Data type	Value
UINT	1 to 40,000

FrequencyBandUpperFrequencyRead

Name:
FrequencyBand01UpperFrequencyRead to FrequencyBand32UpperFrequencyRead

Registers for reading the maximum frequency of individual frequency bands.

The maximum frequency is specified in 1/4 Hz.

Data type	Value
UINT	1 to 40,000

4.26.4.5.6.3 AutogainDelay01

This register can be used to configure the autogain delay for all four channels.

To ensure that even smaller signals can be calculated precisely, the autogain can be increased in steps. This happens if there has been no overflow in the number of measurement cycles configured in this register and all conditions for the next step were always met. If an overflow does occur, then autogain is reduced immediately by one step.

The unit for delaying autogain is specified in measurement cycles (300 ms). Only values from 1 - 200 are valid.

4.26.4.5.6.4 AutogainDelay01Read

Register for reading the current "AutogainDelay01" configuration.

4.26.4.5.6.5 Control01

General control register for the X20CM4810

Bit	Description
15-2	Reserved = 0
1	MinMaxUpdate01, asynchronous min. and max. values refreshed at each edge
0	RequestBufferLock01 or RequestDataLock01 (0 = Don't lock data, 1 = Lock data)

Table 613: Control01

RequestBufferLock01 or RequestDataLock01:

Function model 0 - Standard and Function model 1 - Fast master:
RequestBufferLock01 can be used to lock all buffers and parameters on the X20CM4810 module. When the bit is set to 1, all buffers (raw data and FFT) are locked starting at the beginning of the next measurement. Before a buffer can be uploaded, all data on the X20CM4810 must be locked.
The characteristic values associated with the locked buffers are transferred in the FlatStream characteristic values as soon as BufferLockValid01 = 1.

Information:

Since the measurement is universal, the parameters associated with the buffers are only transferred once.

Function model 2 - Slow master and Function model 254 - Bus controller:
RequestDataLock01 can be used to lock all parameters on the X20CM4810 module. When the bit is set to 1, then a consistent version of all measurement values is retained until the next measurement. Once all data on the module has been locked, all the calculated characteristic values can be read asynchronously from the module.
Data on the X20CM4810 is only locked once the BufferLockValid01 or DataLockValid01 bit has been set in the status register ("Status01").
Once the data has been uploaded, the RequestBufferLock01 or RequestDataLock01 bit can be reset to 0. Once BufferLockValid01 or DataLockValid01 in the status register ("Status01") has returned to 0, the data one the module is no longer locked.
The module doesn't permit another freeze until the channel's buffer has been filled with the maximum buffer length. The buffer length depends on "MaxFrequencyRaw01" and "MaxFrequencyEnvelope01".

MinMaxUpdate01

An edge on MinMaxUpdate01 updates all asynchronous minimum and maximum values. A new cycle then starts internally to generate the minimum and maximum values that are again copied to the acyclic registers on the next edge. Once an edge has been reached, the current minimum and maximum values can be read asynchronously in the next X2X cycle. The "MinMaxCounter01" register specifies how many measurement cycles were analyzed with minimum and maximum mapping. The minimum/maximum values themselves are only valid if the counter has a value other than 0.

4.26.4.5.6.6 DataConsistentWithLockedBuffers01

If the data buffers on the module are locked to prevent uploading, this bit is used to indicate the time at which all characteristic values and frequency bands are consistent with the locked buffers on the module.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.7 DataToggleBit01

This bit changes its value whenever new characteristic values are loaded from the module and updated (approximately every 300 ms).

It is only available in Function model 0 - Standard.

4.26.4.5.6.8 HighFrequencyConfig01

Register for defining the envelope signal high-pass and the high-frequency characteristic value ("PeakHighFrequency" and "RmsHighFrequency") for the entire module.

Bit	Description
15-4	Reserved = 0
3-0	High-pass configuration for the entire module **Value** / **Description** 15 - 3: Invalid 2: 500 Hz 1: 1000 Hz 0: 2000 Hz

Table 614: HighFrequencyConfig01

4.26.4.5.6.9 HighFrequencyConfig01Read

Register for reading the high-pass configuration for the envelope and high-frequency characteristic value ("PeakHighFrequency" and "RmsHighFrequency") of the module.

4.26.4.5.6.10 MaxFrequencyEnvelope01

This register defines the maximum channel frequency. Reducing the maximum frequency allows the frequency resolution in the spectrum to be increased.

Bit	Description
15-12	Maximum frequency for channel 4. For possible values, see channel 1.
11-8	Maximum frequency for channel 3. For possible values, see channel 1.
7-4	Maximum frequency for channel 2. For possible values, see channel 1.
3-0	Maximum frequency for channel 1 **Value** / **Description** 15 - 4: Invalid 3: 200 Hz 2: 500 Hz 1: 1000 Hz 0: 2000 Hz

Table 615: MaxFrequencyEnvelope01

Maximum frequency	Sample frequency	Duration of measurement	Frequency resolution in the frequency spectrum
2000 Hz	5156 Hz	1.5888 s	0.6294 Hz
1000 Hz	2578 Hz	3.1775 s	0.3147 Hz
500 Hz	1289 Hz	6.3550 s	0.1574 Hz
200 Hz	516 Hz	15.8875 s	0.0629 Hz

Table 616: Overview of the maximum frequency of the envelope signal

Important information for configuring the maximum frequency

- The frequency domain must be larger than the damage frequency. Otherwise, it must be kept as small as possible in order to obtain a good resolution.
- When using broad values (e.g. PeakRaw), only the largest peak value is returned during a measurement. Using a longer measurement time at a lower frequency can lead to the measured value being overlooked in some applications.
- The maximum frequency influences the size of the sample frequency and can be configured using the "Analog input" function.

4.26.4.5.6.11 MaxFrequencyEnvelope01Read

This register is used to read the configured maximum frequency for the individual channels' envelope signal.

4.26.4.5.6.12 MaxFrequencyRaw01

This register defines the maximum channel frequency. Reducing the maximum frequency allows the frequency resolution in the spectrum to be increased.

Bit	Description
15-12	Maximum frequency for channel 4. For possible values, see channel 1.
11-8	Maximum frequency for channel 3. For possible values, see channel 1.
7-4	Maximum frequency for channel 2. For possible values, see channel 1.
3-0	Maximum frequency for channel 1

Value	Description
15 - 6	Invalid
5	200 Hz
4	500 Hz
3	1000 Hz
2	2000 Hz
1	5000 Hz
0	10000 Hz

Table 617: MaxFrequencyRaw01

Maximum frequency	Sample frequency	Duration of measurement	Frequency resolution in the frequency spectrum
10000 Hz	25781 Hz	0.3178 s	3.1471 Hz
5000 Hz	12891 Hz	0.6355 s	1.5736 Hz
2000 Hz	5156 Hz	1.5888 s	0.6294 Hz
1000 Hz	2578 Hz	3.1775 s	0.3147 Hz
500 Hz	1289 Hz	6.3550 s	0.1574 Hz
200 Hz	516 Hz	15.8875 s	0.0629 Hz

Table 618: Overview of the maximum frequency of the raw signal

Important information for configuring the maximum frequency

- The frequency domain must be larger than the damage frequency. Otherwise, it must be kept as small as possible in order to obtain a good resolution.
- When using broad values (e.g. PeakRaw), only the largest peak value is returned during a measurement. Using a longer measurement time at a lower frequency can lead to the measured value being overlooked in some applications.
- The maximum frequency influences the size of the sample frequency and can be configured using the "Analog input" function.

4.26.4.5.6.13 MaxFrequencyRaw01Read

This register is used to read the configured maximum frequency for the raw signal of individual channels.

4.26.4.5.6.14 MinFrequencyEnvelope01

This register is used to configure the lowest frequency of the envelope signal still awaiting evaluation for the individual channels.

This configuration only needs to be set for channels whose EnableVelocityCalculation bit has been set (configured in the "SensorConfig01" register). Otherwise, the following minimum values based on the maximum frequency ("MaxFrequencyEnvelope") are used:

Maximum frequency	Frequency resolution in the frequency spectrum	Minimum frequency
2000 Hz	0.6294 Hz	1.888 Hz
1000 Hz	0.3147 Hz	0.944 Hz
500 Hz	0.1574 Hz	0.472 Hz
200 Hz	0.0629 Hz	0.188 Hz

Table 619: Minimum MinFrequencyEnvelope based on MaxFrequencyEnvelope

If the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) is set for the respective channel, then the following configuration applies:

Bit	Description
15-12	Minimum frequency for channel 4. For possible values, see channel 1.
11-8	Minimum frequency for channel 3. For possible values, see channel 1.
7-4	Minimum frequency for channel 2. For possible values, see channel 1.
3-0	Minimum frequency for channel 1 **Value** / **Description** 15 - 5: Invalid 4: 0.5 Hz 3: 1 Hz 2: 2 Hz 1: 5 Hz 0: 10 Hz

Table 620: MinFrequencyEnvelope01

Information:

If a channel's frequency is set lower than the minimum frequency, then the channel will be limited to this lower frequency.

4.26.4.5.6.15 MinFrequencyEnvelope01Read

This register is used to read the lowest frequency of the envelope signal still awaiting evaluation for the individual channels.

Bit	Description
15-12	Minimum frequency for channel 4. For possible values, see channel 1.
11-8	Minimum frequency for channel 3. For possible values, see channel 1.
7-4	Minimum frequency for channel 2. For possible values, see channel 1.
3-0	Minimum frequency for channel 1 **Value** / **Description** 15: Limited to minimum frequency 14 - 5: Invalid 4: 0.5 Hz 3: 1 Hz 2: 2 Hz 1: 5 Hz 0: 10 Hz

Table 621: MinFrequencyEnvelope01

4.26.4.5.6.16 MinFrequencyRaw01

This register is used to configure the lowest frequency of the raw signal still awaiting evaluation for the individual channels.

This configuration only needs to be set for channels whose EnableVelocityCalculation bit has been set (configured in the "SensorConfig01" register). Otherwise the following minimum values, based on the maximum frequency, ("MaxFrequencyRaw") are used:

Maximum frequency	Frequency resolution in the frequency spectrum	Minimum frequency
10000 Hz	3.1471 Hz	9.441 Hz
5000 Hz	1.5736 Hz	4.720 Hz
2000 Hz	0.6294 Hz	1.888 Hz
1000 Hz	0.3147 Hz	0.944 Hz
500 Hz	0.1574 Hz	0.472 Hz
200 Hz	0.0629 Hz	0.188 Hz

Table 622: Minimum MinFrequencyRaw based on MaxFrequencyRaw

If the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) is set for the respective channel, then the following configuration applies:

Bit	Description
15-12	Minimum frequency for Channel 4. For possible values, see channel 1.
11-8	Minimum frequency for Channel 3. For possible values, see channel 1.
7-4	Minimum frequency for Channel 2. For possible values, see channel 1.
3-0	Minimum frequency for channel 1 **Value** – **Description** 15 - 5 – Invalid 4 – 0.5 Hz 3 – 1 Hz 2 – 2 Hz 1 – 5 Hz 0 – 10 Hz

Table 623: MinFrequencyRaw01

Information:

If a channel's frequency is set lower than the minimum frequency, then the channel will be limited to this lower frequency.

4.26.4.5.6.17 MinFrequencyRaw01Read

This register is used to read the lowest frequency of the raw signal still awaiting evaluation for the individual channels.

Bit	Description
15-12	Minimum frequency for Channel 4. For possible values, see channel 1.
11-8	Minimum frequency for Channel 3. For possible values, see channel 1.
7-4	Minimum frequency for Channel 2. For possible values, see channel 1.
3-0	Minimum frequency for channel 1 **Value** – **Description** 15 – Limited to minimum frequency 14 - 5 – Invalid 4 – 0.5 Hz 3 – 1 Hz 2 – 2 Hz 1 – 5 Hz 0 – 10 Hz

Table 624: MinFrequencyRaw01Read

4.26.4.5.6.18 OverflowAnalogInput01-04

Indicates whether a signal is pending on the input that is greater than the configured "AnalogInputScale01".

Information:

This is always based on a 100 mV/g sensor.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.19 OverflowCharacteristicValues01-04

This register contains an overflow indicator bit for each characteristic value of the respective channel (1 = Overflow).

Bit	Description
15	Reserved (always 0)
14	RmsRaw overflow
13	Iso10816 overflow
12	Vdi3832KtRaw overflow
11	KurtosisRaw overflow
10	SkewnessRaw overflow
9	CrestFactorRaw overflow
8	PeakRaw overflow
7	RmsVelRaw overflow
6	RmsAccRaw overflow
5	RmsVelEnvelope overflow
4	RmsAccEnvelope overflow
3	Vdi3832KtHighFrequency overflow
2	CrestFactorHighFrequency overflow
1	RmsHighFrequency overflow
0	PeakHighFrequency overflow

Table 625: OverflowCharacteristicsValues01-04

This register is only available in Function model 0 - Standard.

4.26.4.5.6.20 OverflowFrequencyBands01

This register contains an overflow indicator bit for each frequency band (1 = overflow).

Bit	Description
31	FrequencyBand32 overflow
...	...
0	FrequencyBand01 overflow

Table 626: OverflowFrequencyBands01

This register is only available in Function model 0 - Standard.

4.26.4.5.6.21 PeakHighFrequencyRef01-04

Reference (correct state) of the high frequency signal's peak value for calculating the Vdi3832 K(t) of the high frequency signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.22 PeakHighFrequencyRefCalculated01-04

Reference (correct state) of the high frequency signal's peak value that was used to calculate the Vdi3832 K(t) of the peak value.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.23 PeakRawRef01-04

Reference (correct state) of the raw signal's peak value used to calculate the Vdi3832 K(t) of the raw signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.24 PeakRawRefCalculated01-04

Reference (correct state) of the raw signal's peak value that was used to calculate the Vdi3832 K(t) of the raw signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.25 RmsHighFrequencyRef01-04

Reference (correct state) of the high frequency signal's root mean square used to calculate the Vdi3832 K(t) of the high frequency signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.26 RmsHighFrequencyRefCalculated01-04

Reference (correct state) of the high frequency signal's root mean square that was used to calculating the Vdi3832 K(t) of the high frequency signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.27 RmsRawRef01-04

Reference (correct state) of the raw signal's root mean square for calculating the Vdi3832 K(t) of the raw signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.28 RmsRawRefCalculated01-04

Reference (correct state) of the raw signal's root mean square that was used to calculate the Vdi3832 K(t) of the raw signal.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.29 SensitivitySensor01-04

The X20CM4810 always calculates the characteristic values based on a 100 mV/g sensor on the input. Other sensors can be used by specifying the sensor resolution in mV/g for each channel on these data points. All cyclical characteristic values are then automatically scaled to the correct sensor resolution by Automation Runtime. If this parameter is changed, then the next measurement indicated by "DataToggleBit01" is invalid.

This register is only available in Function model 0 - Standard.

4.26.4.5.6.30 SensorConfig01

This register can be used to enable or disable the IEPE sensor supply for individual channels.

Bit	Description
15	1 = Function model 1 - Fast master 0 = Function model 2 - Slow master and Function model 254 - Bus controller
14	Buffer length (0 = 8192 bytes, 1 = 65535 bytes)
13-12	Reserved = 0
11	EnableVelocityCalculation for channel 4
10	EnableVelocityCalculation for channel 3
9	EnableVelocityCalculation for channel 2
8	EnableVelocityCalculation for channel 1
7-4	Reserved = 0
3	IEPE supply for channel 4 (0 = Off, 1 = On)
2	IEPE supply for channel 3 (0 = Off, 1 = On)
1	IEPE supply for channel 2 (0 = Off, 1 = On)
0	IEPE supply for channel 1 (0 = Off, 1 = On)

Table 627: SensorConfig01

EnableVelocityCalculation

This bit can be used to enable the calculation of all characteristic values calculated on the velocity spectrum (1 = Calculation enabled).
If this calculation is not enabled, 0 is output for all characteristic values calculated on the velocity spectrum.
To maximize the precision of the characteristic values based on the acceleration spectrum, it is recommended to only enable this bit if the velocity signals are absolutely required.

4.26.4.5.6.31 SensorConfig01Read

Register for reading the current "SensorConfig01" configuration.

4.26.4.5.6.32 Status01

General status register for the X20CM4810:

Bit	Description
15-13	Reserved
12	AnalogInputToggleBit04 toggles with each new calculation and each new input value from AnalogInput04.
11	AnalogInputToggleBit03 toggles with each new calculation and each new input value from AnalogInput03.
10	AnalogInputToggleBit02 toggles with each new calculation and each new input value from AnalogInput02.
9	AnalogInputToggleBit01 toggles with each new calculation and each new input value from AnalogInput01.
8	Overflow04 indicates an overflow of one or more characteristic values calculated on channel 4 (1 = Overflow).
7	Overflow03 indicates an overflow of one or more characteristic values calculated on channel 3 (1 = Overflow).
6	Overflow02 indicates an overflow of one or more characteristic values calculated on channel 2 (1 = Overflow).
5	Overflow01 indicates an overflow of one or more characteristic values calculated on channel 1 (1 = Overflow).
4	BufferLockValid01 and DataLockValid01 confirm RequestBufferLock01 and RequestDataLock01 (1 = Data locked, consistent and valid).
3	BrokenWire04 indicates an open line on channel 4 (1 = Open line).
2	BrokenWire03 indicates an open line on channel 3 (1 = Open line).
1	BrokenWire02 indicates an open line on channel 2 (1 = Open line).
0	BrokenWire01 indicates an open line on channel 1 (1 = Open line).

Table 628: Status01

4.26.4.5.7 Module registers - Characteristic values (acyclic)

The following applies to all characteristic value module registers:

- These registers are only available in Function model 2 - Slow master and Function model 254 - Bus controller.
- All calculated characteristic values can be locked using RequestDataLock01, which allows all registers to be read in a consistent manner.

4.26.4.5.7.1 CrestFactorRaw01-04

Asynchronous register for reading the characteristic value "CrestFactorRaw" of the respective channel.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	1

4.26.4.5.7.2 FrequencyBand01-32

Asynchronous register to read the respective frequency band. See section 4.26.4.2.9 "Frequency bands" on page 2601.

If the frequency band parameter is set to a velocity signal, then this value is only calculated if the EnableVelocity-Calculation bit (configured in the "SensorConfig01" register) for the respective channel is set; otherwise, 0 is output.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 g or 0.001 mm/s depending on the configuration	16777215
24-bit unsigned	1/65536 g or 1/65536 mm/s depending on the configuration	16777215

Parameter after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg or mm/s depending on the configuration

4.26.4.5.7.3 Iso10816_01-04

Asynchronous register for reading the characteristic value "ISO10816" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 mm/s	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mm/s

4.26.4.5.7.4 KurtosisRaw01-04

Asynchronous register for reading the characteristic value "KurtosisRaw" of the respective channel.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Format	Resolution and unit	Value on overflow
24-bit signed	0.001	8388607

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	1

4.26.4.5.7.5 PeakHighFrequency01-04

Asynchronous register for reading the characteristic value "PeakHighFrequency" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	1/65536 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.6 PeakRaw01-04

Asynchronous register for reading the characteristic value "PeakRaw" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	1/65536 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.7 RmsAccEnvelope01-04

Asynchronous register for reading the characteristic value "RmsAccEnvelope" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.8 RmsAccRaw01-04

Asynchronous register for reading the characteristic value "RmsAccRaw" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.9 RmsHighFrequency01-04

Asynchronous register for reading the characteristic value "RmsHighFrequency" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	1/65536 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.10 RmsRaw01-04

Asynchronous register for reading the characteristic value "RmsRaw" of the respective channel.

Format	Resolution and unit	Value on overflow
24-bit unsigned	1/65536 g	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mg

4.26.4.5.7.11 RmsVelEnvelope01-04

Asynchronous register for reading the characteristic value "RmsVelEnvelope" of the respective channel.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 mm/s	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mm/s

4.26.4.5.7.12 RmsVelRaw01-04

Asynchronous register for reading the characteristic value "RmsVelRaw" of the respective channel.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

Format	Resolution and unit	Value on overflow
24-bit unsigned	0.001 mm/s	16777215

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	mm/s

4.26.4.5.7.13 SkewnessRaw01-04

Asynchronous register for reading the characteristic value "SkewnessRaw" of the respective channel.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

Format	Resolution and unit	Value on overflow
24-bit signed	0.001	8388607

Characteristic value after preparation by Automation Runtime in Function model 0 - Standard

Format	Unit
REAL	1

4.26.4.5.8 Module registers - Minimum and maximum values

The characteristic values of the X20CM4810 are recalculated every 300 ms. To prevent values from being lost, it is necessary to collect this data quickly enough. If this is not possible, the characteristic values on the module can be locked using the RequestDataLock01 data point and then read asynchronously in Function model 2 - Slow master and Function model 254 - Bus controller. However, this method results in measurements being lost.

To prevent measurements from being lost, a special function has been implemented in the X20CM4810 that records the minimum and maximum values of all characteristic values calculated in the module. When an edge of the MinMaxUpdate01 data point occurs, a new measurement can be started whereby the minimum and maximum values are reinitialized. The current data is copied to the asynchronous register at the same time.

The number of collected measurements can then be read using the asynchronous data point "MinMaxCounter01". The respective values are read using the asynchronous minimum and maximum data points.

Example

For *Iso10816*, these are the *Iso10816Min01-04* and *Iso10816Max01-04 registers*.

Information:

- **If data is locked with RequestDataLock01, no further measurement values are collected. This only affects Function model 2 - Slow master and Function model 254 - Bus controller since the characteristic values are not locked in the standard function model.**
- **If a characteristic value overflow or open line occurs, no new values are collected.**
- **The minimum and maximum data points are each initialized using the maximum and minimum of the respective data type (see 4.26.4.2.11 "Characteristic value format" on page 2602). If there is no valid value on the characteristic value for the overall measurement, then the initial value is retained (e.g. on overflow, open line or locked data).**
- **If the data on the module is locked (DataLockValid01 = 1), then no new values are added when determining the minimum. The measurement cycles are still counted, however.**

Registers are only updated at an edge from "MinMaxUpdate01" and are only valid if "MinMaxCounter01" is not equal to 0. The asynchronous register "MinMaxCounter01" specifies the collected measurement cycles for the minimum and maximum.

4.26.4.5.8.1 CrestFactorRawMax01-04

Asynchronous maximum value of the "CrestFactorRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.2 CrestFactorRawMin01-04

Asynchronous minimum value of the "CrestFactorRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.3 FrequencyBandMax01-32

Asynchronous maximum value of the respective frequency band in thousandths of a mm/s or g depending on the configuration. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 and 4.26.4.2.9 "Frequency bands" on page 2601 for additional information.

If the frequency band parameter is set to a velocity signal, then this value is only calculated if the EnableVelocity-Calculation bit (configured in the "SensorConfig01" register) for the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.4 FrequencyBandMin01-32

Asynchronous minimum value of the respective frequency band in thousandths of a mm/s or g depending on the configuration. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 and 4.26.4.2.9 "Frequency bands" on page 2601 for additional information.

If the frequency band parameter is set to a velocity signal, then this value is only calculated if the EnableVelocity-Calculation bit (configured in the "SensorConfig01" register) for the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.5 Iso10816Max01-04

Asynchronous maximum value of the "ISO10816" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.6 Iso10816Min01-04

Asynchronous minimum value of the "ISO10816" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.7 KurtosisRawMax01-04

Asynchronous maximum value of the "KurtosisRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.8 KurtosisRawMin01-04

Asynchronous minimum value of the "KurtosisRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.9 MinMaxCounter01

This asynchronous register specifies how many measurements were collected the last time the minimum and maximum were determined. It is only updated when an edge occurs for MinMaxUpdate01. If the MinMaxUpdate01 bit is not toggled after 65535 measurements, then the counter is limited to 65535. Determination of the minimum and maximum continues, however. All asynchronous minimum and maximum values are only valid if "MinMax-Counter01" is not equal to 0.

4.26.4.5.8.10 PeakHighFrequencyMax01-04

Asynchronous maximum value of the "PeakHighFrequency" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.11 PeakHighFrequencyMin01-04

Asynchronous minimum value of the "PeakHighFrequency" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.12 PeakRawMax01-04

Asynchronous maximum value of the "PeakRaw" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.13 PeakRawMin01-04

Asynchronous minimum value of the "PeakRaw" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.14 RmsAccEnvelopeMax01-04

Asynchronous maximum value of the "RmsAccEnvelope" characteristic value of the respective channel in thousandths of a g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.15 RmsAccEnvelopeMin01-04

Asynchronous minimum value of the "RmsAccEnvelope" characteristic value of the respective channel in thousandths of a g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.16 RmsAccRawMax01-04

Asynchronous maximum value of the "RmsAccRaw" characteristic value of the respective channel in thousandths of a g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.17 RmsAccRawMin01-04

Asynchronous minimum value of the "RmsAccRaw" characteristic value of the respective channel in thousandths of a g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.18 RmsHighFrequencyMax01-04

Asynchronous maximum value of the "RmsHighFrequency" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.19 RmsHighFrequencyMin01-04

Asynchronous minimum value of the "RmsHighFrequency" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.20 RmsRawMax01-04

Asynchronous maximum value of the "RmsRaw" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.21 RmsRawMin01-04

Asynchronous minimum value of the "RmsRaw" characteristic value of the respective channel in 1/65536 g. See also 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.22 RmsVelEnvelopeMax01-04

Asynchronous maximum value of the "RmsVelEnvelope" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.23 RmsVelEnvelopeMin01-04

Asynchronous minimum value of the "RmsVelEnvelope" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.24 RmsVelRawMin01-04

Asynchronous minimum value of the "RmsVelRaw" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.25 RmsVelRawMax01-04

Asynchronous maximum value of the "RmsVelRaw" characteristic value of the respective channel in thousandths of a mm/s. See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

This value is only calculated if the EnableVelocityCalculation bit (configured in the "SensorConfig01" register) of the respective channel is set; otherwise, 0 is output.

4.26.4.5.8.26 SkewnessRawMax01-04

Asynchronous maximum value of the "SkewnessRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.8.27 SkewnessRawMin01-04

Asynchronous minimum value of the "SkewnessRaw" characteristic value of the respective channel in thousandths.

Since division by the RMS value takes place in the module ("RmsRaw"), there may be an overflow if the RMS value is very small. To prevent this, the module has an internal lower limit of 1 mg for the RMS value.

See also section 4.26.4.5.8 "Module registers - Minimum and maximum values" on page 2705 for additional information.

4.26.4.5.9 Maximum cycle time

The maximum cycle time defines how far the cycle time of the X2X Link can be increased without causing a communication error or impaired functionality.

Maximum cycle time	
Function model 0 - Standard	10 ms
Function model 1 - Fast master	10 ms
Function model 2 - Slow master	-
Function model 254 - Bus controller	-

Table 629: X20CM4810 - Maximum cycle time

4.26.4.5.10 Minimum cycle time

The minimum cycle time defines how far the cycle time of the X2X Link can be reduced without causing a communication error or impaired functionality. It is important to note that very fast cycles leave less idle time for monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Function model 0 - Standard	400 µs

Table 630: X20CM4810 - Minimum cycle time

4.26.4.6 FlatStream

4.26.4.6.1 FlatStream communication

4.26.4.6.1.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transfer adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

4.26.4.6.1.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.26.4.6.1.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

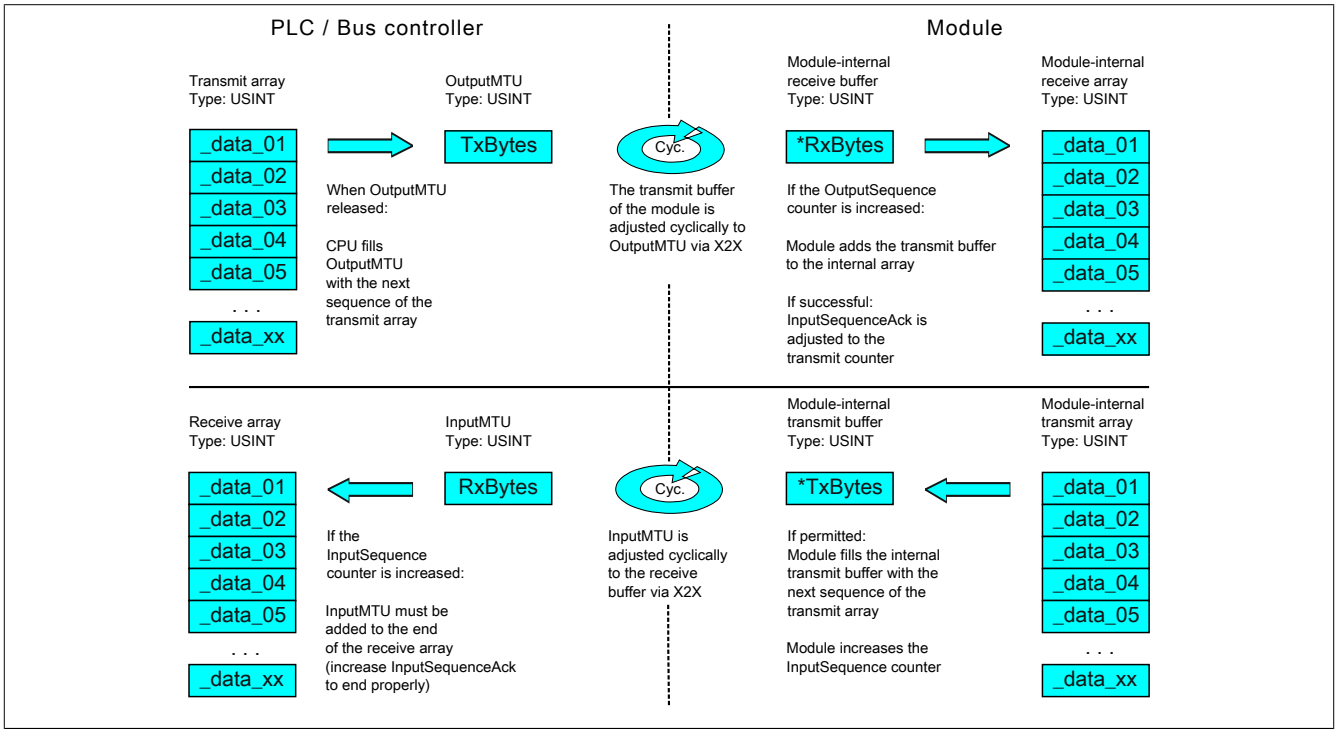

Figure 482: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.26.4.6.1.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

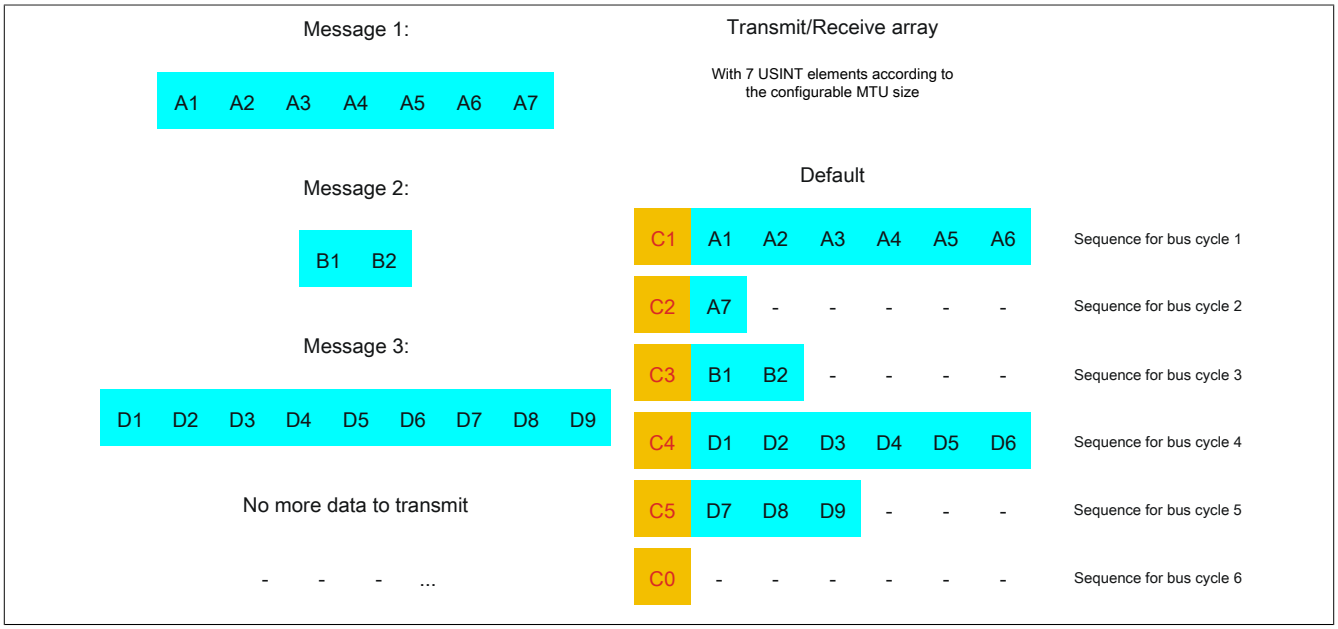

Figure 483: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			C1 (control byte 1)			C2 (control byte 2)		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 631: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			C4 (control byte 4)			C5 (control byte 5)		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 632: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

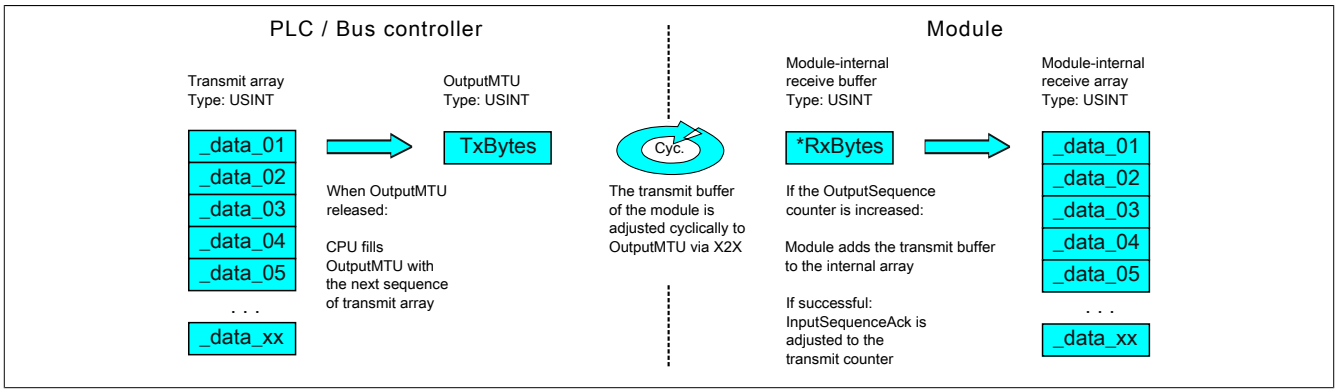

Figure 484: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

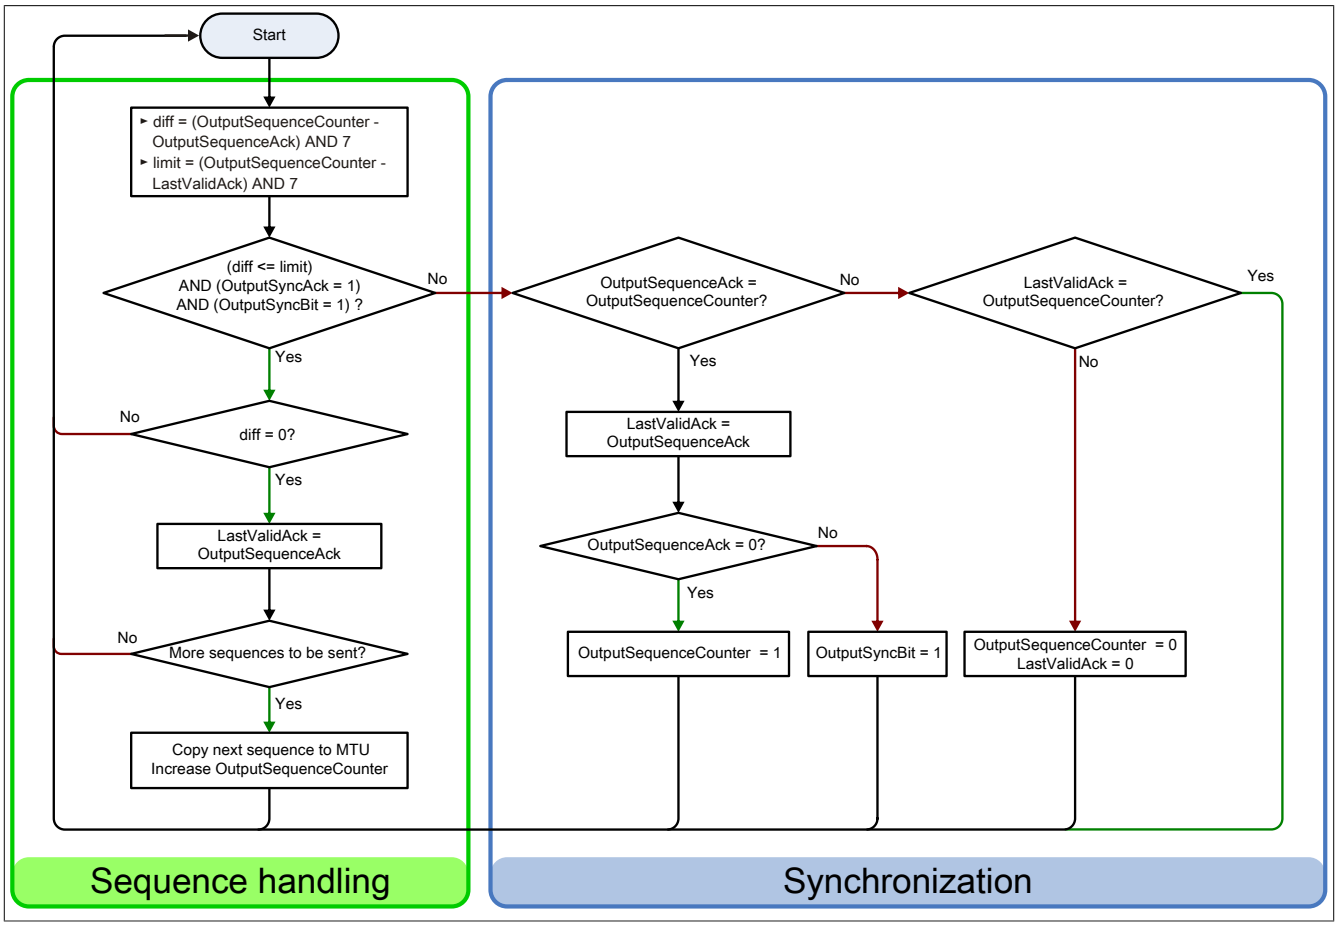

Figure 485: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

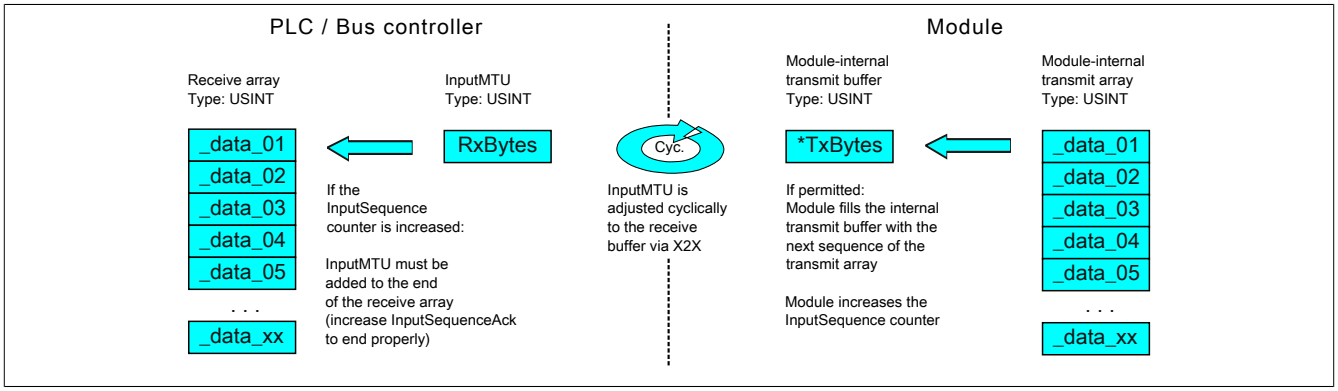

Figure 486: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

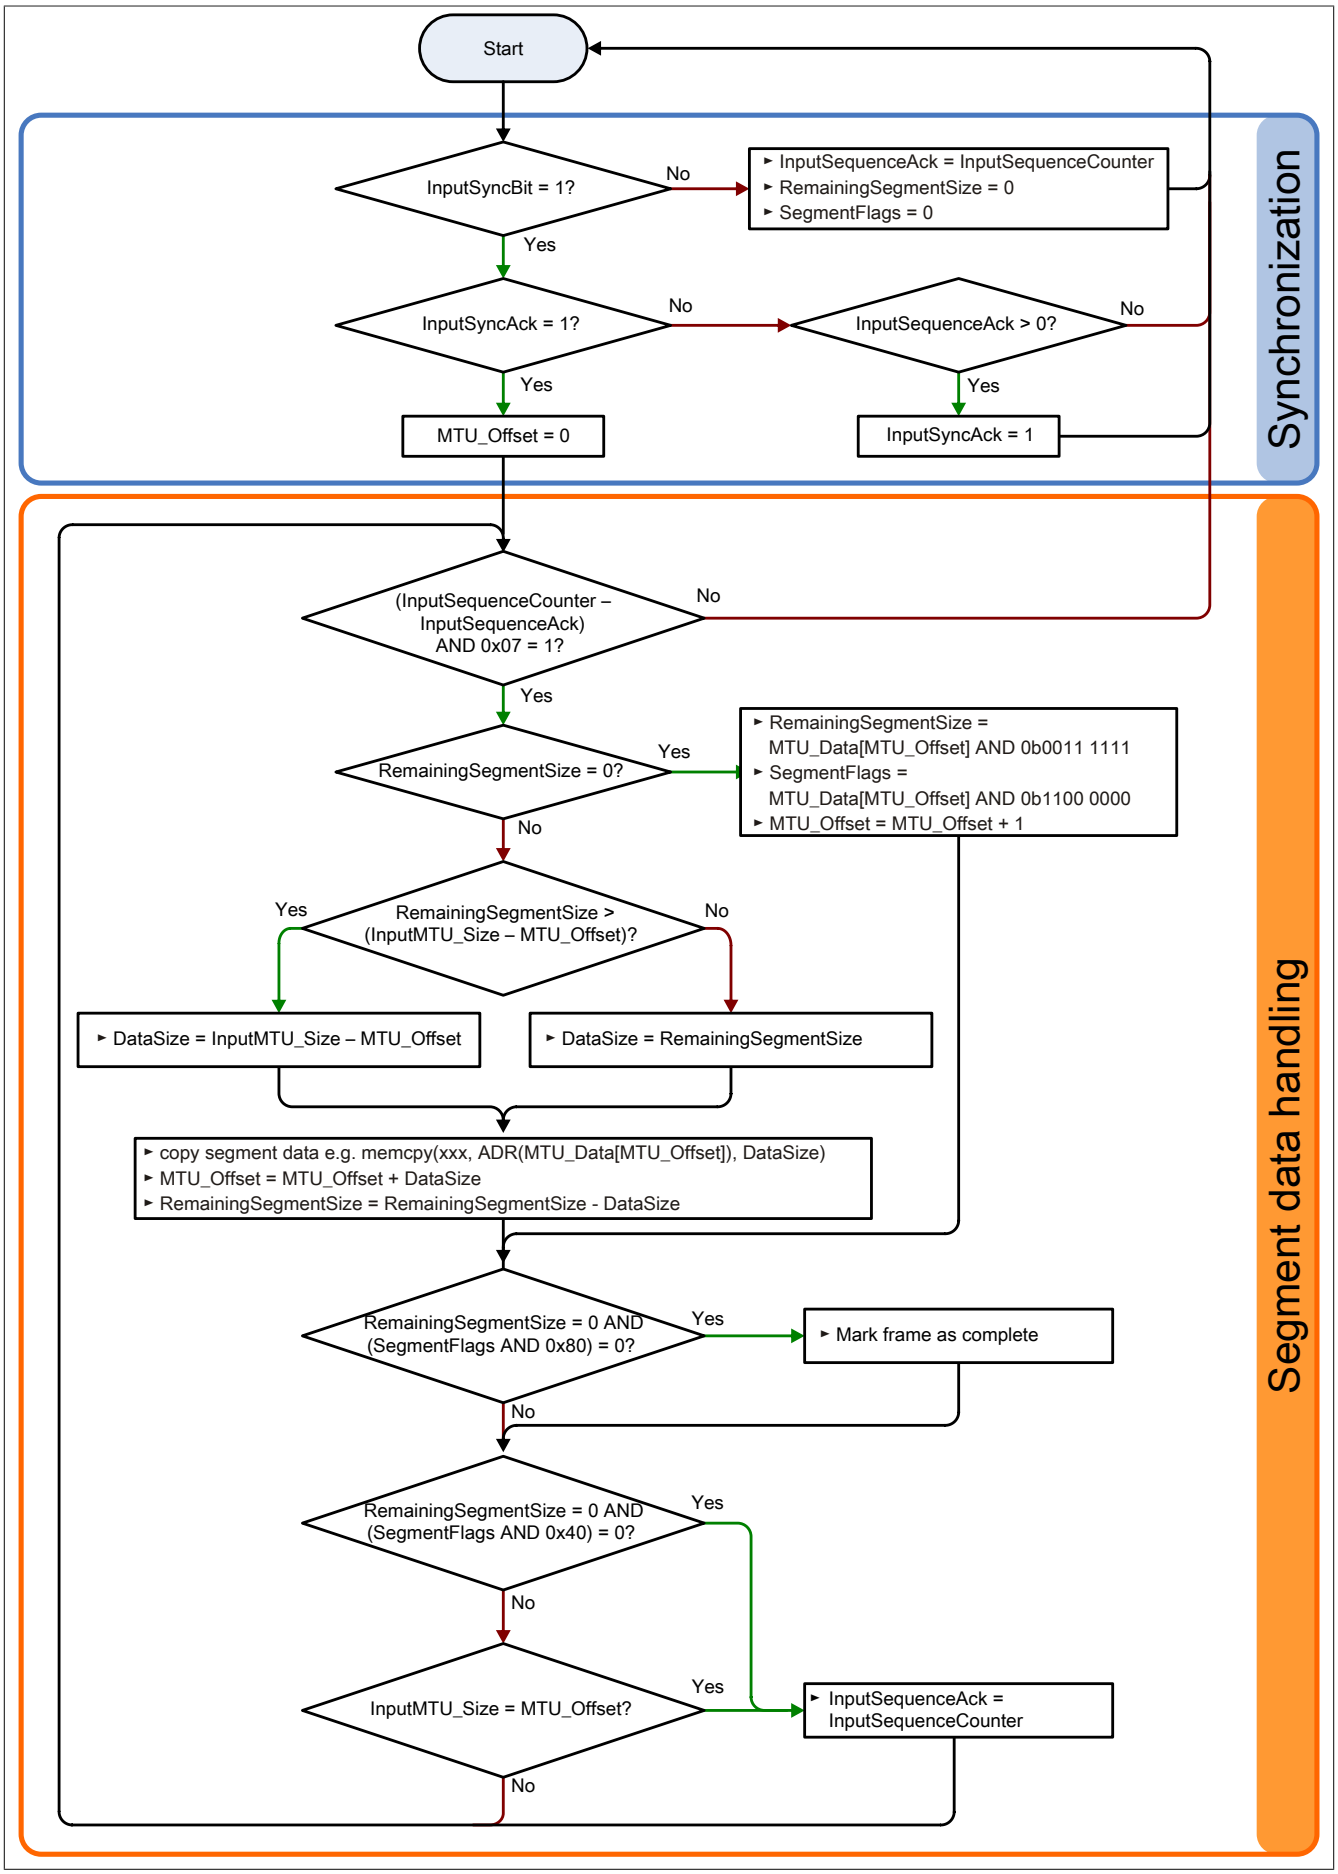

Figure 487: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode register

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name		Information
0	MultiSegmentMTU	0	Not permitted (default; can't be configured)
1	Large segments	0	Not permitted (default; can't be configured)
2-7	Reserved		

Default:
By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

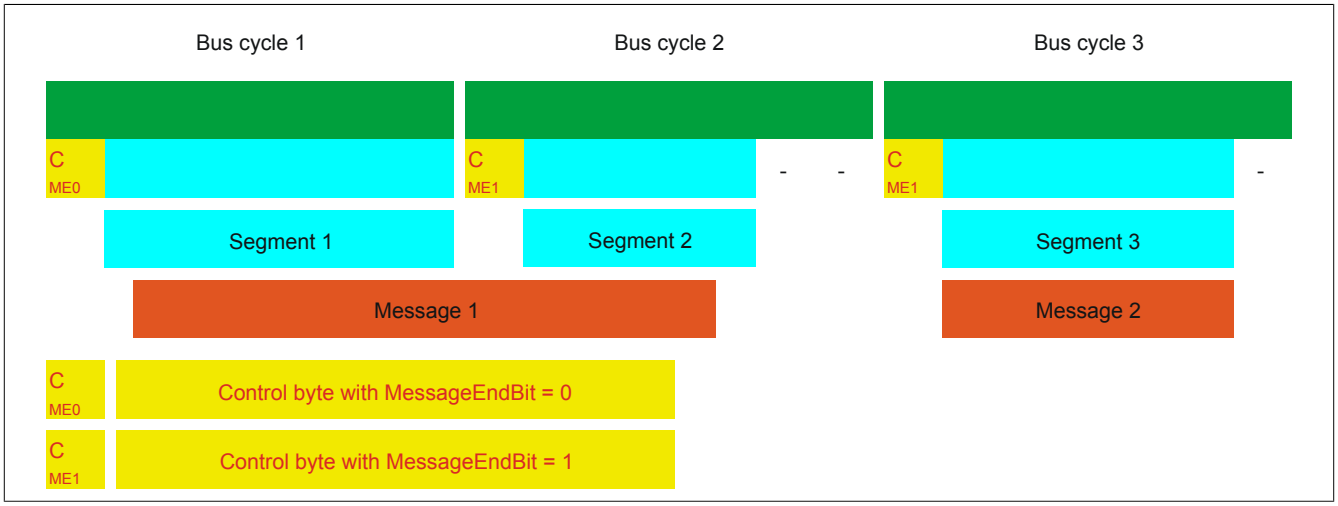

Figure 488: Message arrangement in the MTU (default)

4.26.4.6.1.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

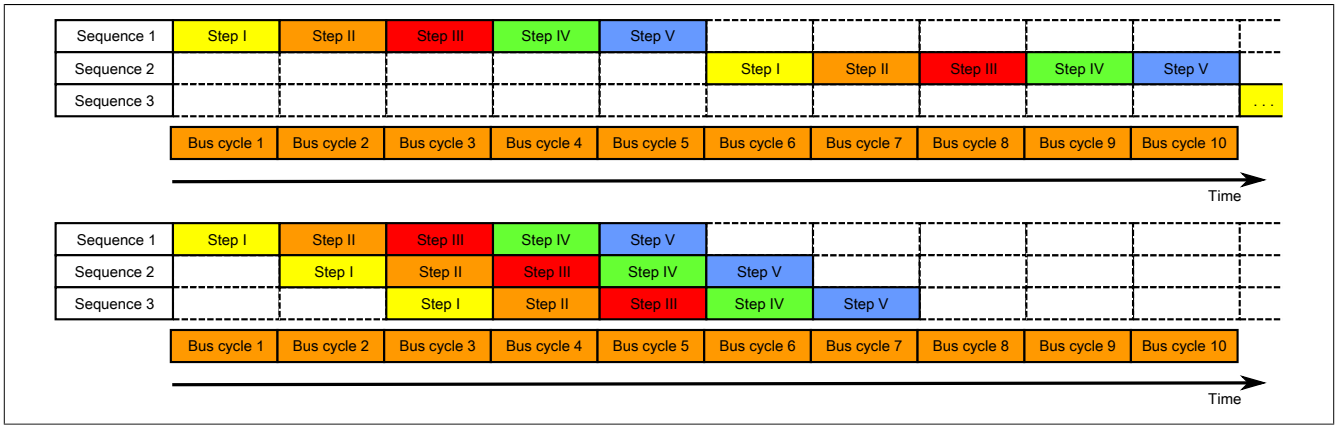

Figure 489: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration (defined by module)

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Forward:
With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	Default: 7

ForwardDelay:
The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Values [µs]
UINT	0...65535 Default: 0

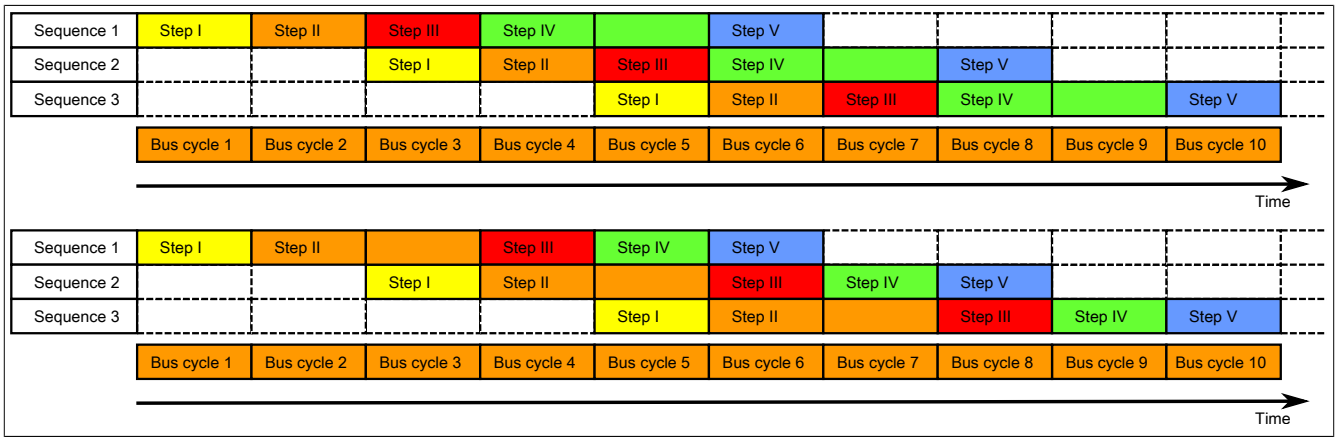

Figure 490: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting:

Cyclic status query: *- The Module monitors the OutputSequenceCounter.*
0. Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1. Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2. Transmitting: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module responds since OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array.* *- The module is acknowledged and the currently received value of the OutputSequenceCounter is transferred to OutputSequenceAck.* *- The module requests the status cyclically again.*
3. Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving:

0. Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck.* *- The module checks if InputMTU is enabled.* *→ Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array.*
Action: *- The module transmits the current part of the transmit array to the receive buffer.* *- The module increases the InputSequenceCounter.* *- The module waits for a new bus cycle.* *- The module repeats the action if the InputMTU is enabled.*
1 Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck.* *→ A sequence is only considered to have been transmitted successfully if it has been acknowledged via InputSequenceAck .*

Details/Background:

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > ## Information:
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

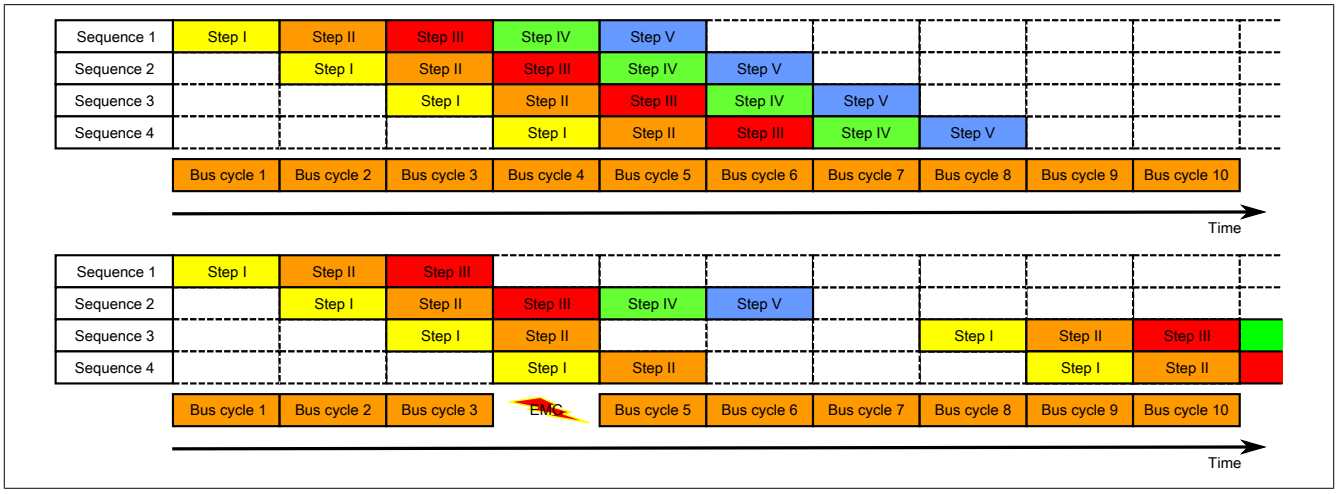

Figure 491: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

The Forward function on the X20CM4810

The ForwardDelay for BufferFlatstream can be asynchronously configured in Function model 0 - Standard and Function model 1 - Fast master in the I/O configuration of the X20CM4810 module (BufferForwardDelay01). When using the "Fast master" function model, the ForwardDelay can also be asynchronously configured for the ParameterFlatStream in the I/O configuration (ParamterForwardDelay01).

Forwarding for the parameter FlatStream and buffer FlatStream can be asynchronously adjusted (Forward01 and BufferForward01 parameters). However, it should only be adjusted after the ForwardDelay has been configured for the respective FlatStream.

When using a SG4 CPU, the ForwardDelay cannot be manually configured for the ParameterFlatStream. From version J3.09 and J4.01 of Automation Runtime, it is automatically configured and in earlier versions, it is ForwardDelay 0.

4.26.4.6.2 Transferring characteristic values via FlatStream

4.26.4.6.2.1 General information

For information about FlatStream functionality, see section 4.3.7.10.8 "FlatStream communication" on page 223.

Transferring characteristic values via FlatStream is only available on the module in Function model 0 - Standard and Function model 2 - Slow master.

Every 300 ms, the characteristic values calculated by the module are transferred automatically via the characteristic value FlatStream, but only if the previous transfer is already complete. For this reason a maximum X2X Link cycle time of 10 ms is recommended to prevent measurement data from being lost. It is also important to note that the module refreshes the data points of the characteristic value FlatStream every X2X Link cycle. Once the transmission is complete, the characteristic values from the stream need to be "reassembled" on the PLC.

Automation Runtime handles FlatStream communication when transferring characteristic values in the "Standard" function model. The user is automatically provided with all characteristic values, already properly scaled. Only the task cycle needs to be checked to make sure it is correct. As a result, the data points for the characteristic value FlatStream are not shown in the Function model 0 - Standard I/O mapping.

4.26.4.6.2.2 Registers for the characteristic value FlatStream

The following registers are needed to transfer characteristic values:

ParameterInputSequence01
ParameterRxByte01-13
ParameterOutputSequence01

This results in an InputMTU of 13 bytes and an OutputMTU of 0 bytes for the characteristic value FlatStream.

4.26.4.6.2.3 Structure of the characteristic value FlatStream

Each characteristic value transferred from the module via FlatStream has a length of 3 bytes with the high byte first. For the exact format, see section 4.26.4.2.11 "Characteristic value format" on page 2602. The stream has a total length of 240 bytes. First, all characteristic values from channel 1 are transferred, then those from channels 2, 3 and 4. The 32 frequency bands then follow next.

The RmsVelRaw and RmsVelEnvelope characteristic values and the frequency bands are only transferred if they are set to a velocity signal and the EnableVelocityCalculation bit for the respective channel is set. Otherwise, 0 is output. EnableVelocityCalculation is configured in the "SensorConfig01" register.

Byte offset in the stream				Characteristic value
Channel 1	Channel 2	Channel 3	Channel 4	
Channel parameters				
0	36	72	108	"RmsAccRaw"
3	39	75	111	"RmsVelRaw"
6	42	78	114	"RmsAccEnvelope"
9	45	81	117	RmsVelEnvelope
12	48	84	120	"PeakHighFrequency"
15	51	87	123	"RmsHighFrequency"

4.26.4.6.3 Uploading buffers via FlatStream

4.26.4.6.3.1 General information

For information about FlatStream functionality, see section 4.3.7.10.8 "FlatStream communication" on page 223.

Uploading buffers via FlatStream is only available on the module in Function model 0 - Standard and Function model 1 - Fast master.

When requested (buffer FlatStream in Tx direction), the module's raw data buffers (raw signal and FFT) can be transferred via the buffer FlatStream (Rx direction). However, this is only possible if the buffers are first locked on the module with the settings RequestBufferLock01 = 1 and BufferLockValid01 = 1. It is important to note that the module refreshes the data points of the buffer FlatStream every X2X Link cycle. Once the transmission is complete, the buffer from the stream needs to be "reassembled" on the PLC.

4.26.4.6.3.2 Registers for the buffer FlatStream

The following registers are needed to upload buffers:

BufferInputSequence01
BufferRxByte01-05
BufferOutputSequence01
BufferTxByte01-04

This results in an InputMTU of 5 bytes and an OutputMTU of 4 bytes for the buffer FlatStream.

4.26.4.6.3.3 Buffer upload procedure

Before a buffer can be uploaded from the X20CM4810 module, it must first be locked on the module. This can be done by setting RequestBufferLock01 = 1. The upload can only begin once the buffers have been locked by setting BufferLockValid01 = 1. If an FFT buffer is being uploaded, it is important to check the asynchronous parameters CorrFFTRaw01-04 and CorrEnvelope01-04.

If a velocity buffer is being uploaded, it only contains values if the EnableVelocityCalculation bit is set for the respective channel; otherwise, 0 is output. The EnableVelocityCalculation bit can be configured in the "SensorConfig01" register.

A buffer first needs to be requested from the module via the buffer FlatStream (Tx direction). This means:

- BufferTxByte01: Value 0x83 (frame end and 3 byes are valid)
- BufferTxByte02: The request buffer from the module
- BufferTxByte03: High byte of the number of the values to be read (per 4-byte value)
- BufferTxByte04: Low byte of the number of the values to be read (per 4-byte value)

The sequence is subsequently increased by 1. Once the module has confirmed the sequence, it is important to set the number of valid bytes to 0 in BufferTxByte since the module would otherwise interpret this as a new request. The module can temporarily store up to 2 consecutive requests.

As soon as the module receives the request, it begins streaming the requested number of values from the specified buffer via the buffer FlatStream (Rx direction). Values are always transferred in 16.16 fixed data point format (1/65536) with the high byte first. A scaling factor is transferred first. All other values are then multiplied by this factor. With time signal buffers, the first value according to the scaling factor is always the oldest. With FFT buffers, the first value according to the scaling factor is always 0 Hz. FFT buffers are only valid from the configured MinFrequency to the configured MaxFrequency of the respective signal (raw or envelope) and the respective channel.

For the time and frequency intervals of individual values, see the "MinFrequencyRaw01" or "MinFrequencyEnvelope01" register.

RequestBufferLock01 must be set to 1 throughout the entire uploading process. Once the requested buffers have been uploaded from the module, the lock can be reset. In the module, the buffers are then once again filled with new values. After some time has passed, they can be locked and uploaded again (see register "Control01").

Buffer number (Dec)				Buffer	Max. values, 4 bytes each
Channel 1	Channel 2	Channel 3	Channel 4		
9	11	13	15	Raw signal (filtered to "MaxFrequencyRaw01")	8193[1)]
25	27	29	31	Envelope signal (filtered to "MinFrequencyEnvelope01")	8193
66	70	74	78	FFT amplitude spectrum raw velocity signal (filtered to "MaxFrequencyRaw01")	4097
67	71	75	79	FFT amplitude spectrum raw acceleration signal (filtered to "MaxFrequencyRaw01")	4097
82	86	90	94	FFT amplitude spectrum envelope velocity signal (filtered to "MinFrequencyEnvelope01")	4097
83	87	91	95	FFT amplitude spectrum envelope acceleration signal (filtered to "MinFrequencyEnvelope01")	4097

1) The first value in the buffer is the scaling factor.

In special applications it may be necessary to upload larger buffers.

In the SensorConfig01 register, a buffer length of 8192 or 65535 bytes can be configured using bit 14. This makes it possible to read the raw signal and acceleration signal (buffer number 9, 11, 13, 15, 25, 27, 29 and 31) using 65535 values, including the scaling factor, from the module. However, the FFT buffers also include 4097 values including a scaling factor and refer to the previous 8192 of the 65535 values of the raw or envelop signal.

After locking the buffer for the upload (RequestBufferLock01) until the next locking, it is necessary to wait until the longest buffer is filled again. If the buffer tries to lock again before this time elapses, it is prevented by the module until after the buffer is filled.

4.26.4.7 X20CM4810 on the fieldbus

4.26.4.7.1 Bus coupler with FieldbusDESIGNER support

Only Function model 1 - Fast master and Function model 2 - Slow master are available for this.

The X20CM4810 module is configured using FieldbusDESIGNER in Automation Studio. Implementation must be handled on the master.

4.26.4.7.2 Bus coupler without FieldbusDESIGNER support

Only Function model 2 - Slow master is available for this. Configuration and implementation must be handled on the master.

4.26.4.7.3 B&R SG4 CPU with an interface module

This combination offers the following advantages:

- Modular condition monitoring solution possible
- All characteristic values prepared by Automation Runtime (no extra work required for implementation)
- Communication with the master via the interface card

4.26.4.7.4 CANIO bus coupler

Only Function model 254 - Bus controller is available for this. Configuration and implementation must be handled on the master.

4.26.5 X20CM6209

4.26.5.1 General information

This module is a diode array module with six diodes. It is usually used to capture the status of a key. The diodes can also be used as freewheeling diodes or decoupling diodes.

The diode array module has no connection to X2X Link. It behaves like a dummy module.

- 6 potential-free diodes
- 24 VDC
- 1 A current load for each diode

4.26.6.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green		Input state of the corresponding digital input
	1 - 2	Orange		Output status of the corresponding digital output
	1	Green	Off	Open line or sensor is disconnected
			Blinking	Input signal overflow or underflow
			On	Analog/digital converter running, value OK
	1	Orange	Off	Value = 0
			On	Value ≠ 0

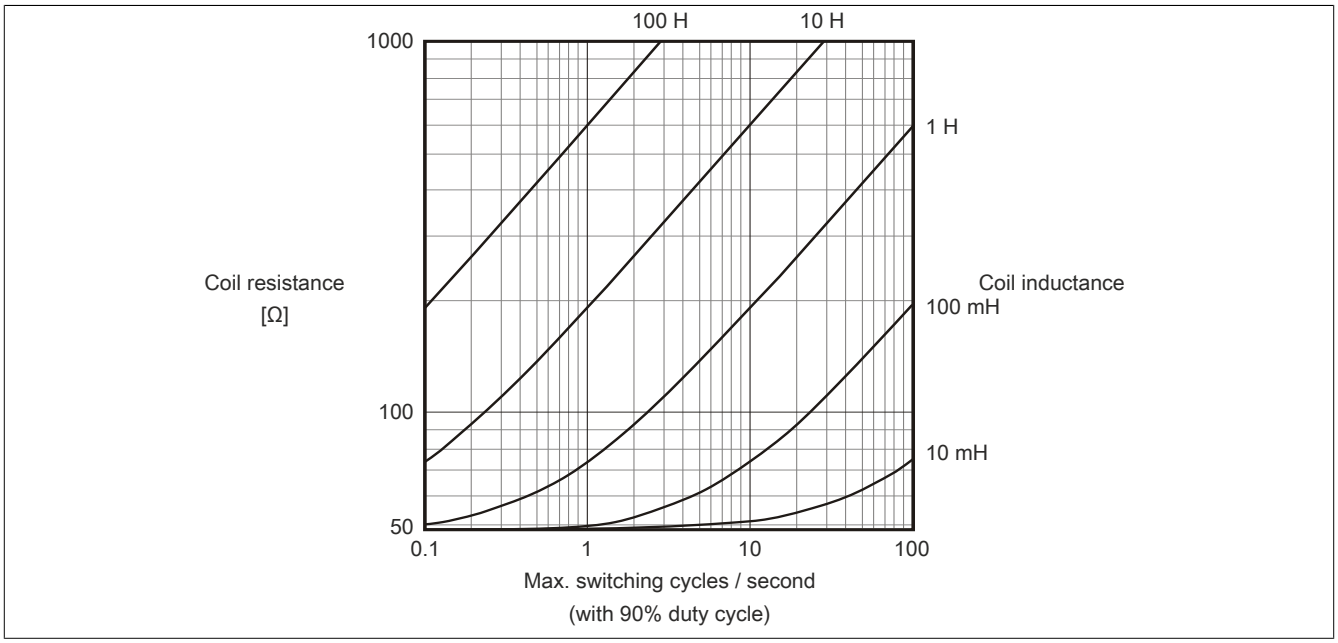
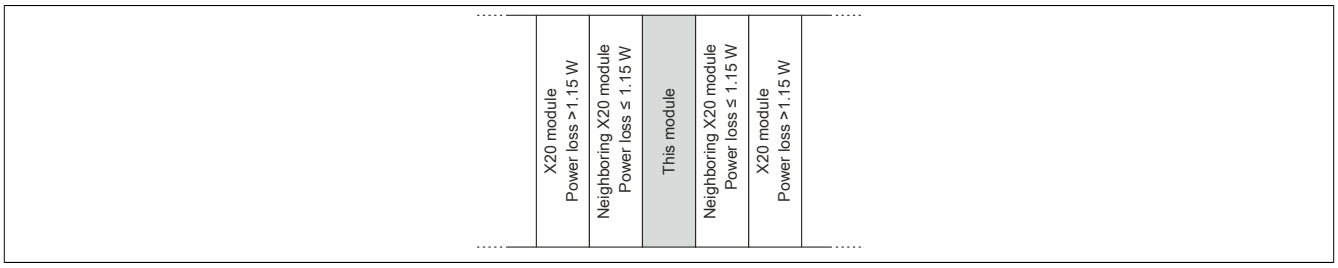
4.26.6.9 Switching inductive loads



4.26.6.10 Derating

There is no derating when operated below 55°C.

When operated at temperatures above 55°C, the power consumption of the modules to the left and right of this module must not exceed 1.15 W



4.26.6.11 Register description

4.26.6.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.6.11.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

4.26.6.11.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.26.6.11.4 Digital inputs

Unfiltered

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

Filtered

The filtered status is collected with a fixed offset to the network cycle and transferred in the same cycle. Filtering takes place asynchronously to the network in multiples of 200 µs with a network-related jitter of up to 50 µs.

4.26.6.11.4.1 Digital inputs and status of the digital outputs

Name:
DigitalInput01 to DigitalInput04
StatusDigitalOutput01 to StatusDigitalOutput02

This register is used to indicate the input state of the digital inputs and the status of the digital outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input state - Digital input 1
4	StatusDigitalOutput01	0	Digital output channel 1: No error
		1	Digital output channel 1: Short circuit or overload
5	StatusDigitalOutput02	0	Digital output channel 2: No error
		1	Digital output channel 2: Short circuit or overload
6 - 7	Reserved	-	

4.26.6.11.4.2 Digital input filter

Register name:
ConfigOutput01

This register can be used to specify the filter value for all digital inputs.

The filter value can be configured in steps of 100 µs. It makes sense to enter values in steps of 2, however, since the input signals are sampled every 200 µs.

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.26.6.11.4.3 Event or gate counter

Event counter operation

The rising (positive) edges are registered on the counter input.

The counter status is collected with a fixed offset to the network cycle and transferred in the same cycle.

Gate measurement

The time of rising to falling edges for the gate input is registered using an internal frequency. The result is checked for overflow (0xFFFF) and corrected with the adjustable prescaler.

The recovery time between measurements must be >100 µs.

The measurement result is transferred with the falling edge to the result memory.

Event or gate counter

Name:
Counter01 to Counter02

Counter01 is intended for event counter operation.

Event counter operation or gate measurement can be selected for Counter02:

Data type	Value
USINT	Counter value

Counter configuration

Name:
ConfigOutput02

This register can be used to configure and reset the individual counters.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Counter02 (counter frequency, only with gate measurement)	0	48 MHz
		1	3 MHz
		2	187.5 kHz
		3	24 MHz
		4	12 MHz
		5	6 MHz
		6	1.5 MHz
		7	750 kHz
		8	375 kHz
4	ResetCounter01	0	No influence on the counter
		1	Clear counter (at positive edge)
5	ResetCounter02	0	No influence on the counter
		1	Clear counter (at positive edge)
6 - 7	Counter02 (operating mode)	0	Event counter measurement
		1	Gate measurement

This register also includes configuration data in addition to the cyclic data. If the register is used cyclically and in the init script, then the preset configuration only remains available when operated directly on the CPU. On the bus controller, the configuration is always overwritten with 0.

However, starting with upgrade version 1.0.2.1, the cyclic bit can be hidden in order to prevent the configuration from being overwritten.

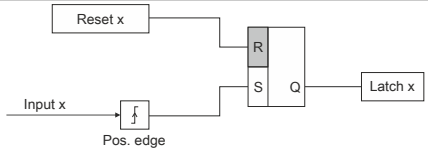
Information:

If the counter should be cleared, this must be done using a non-cyclic write command. When doing so, the configuration bit must be transferred together with the reset counter bit!

4.26.6.11.4.4 Rising edge input latch

Using this function, the rising edges of the input signal can be latched with a resolution of 200 µs. With the "Acknowledge - input latch" function, the input latch is either reset or prevented from latching.

It works in the same way as a dominant reset RS flip-flop.



R	S	Q	Status
0	0	x	Do not change
0	1	1	Set
1	0	0	Reset
1	1	0	Reset

Input state of digital latch inputs 1 - 4

Name:
DigitalInputLatch01 to DigitalInputLatch04

This register is used to indicate input state of digital inputs 1 to 4 after expiration of the input filter time.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInputLatch01	0 or 1	Input state of digital input 1 after expiration of the delay time
...		...	
3	DigitalInputLatch04	0 or 1	Input state of digital input 4 after expiration of the delay time
4 - 7	Reserved	-	

Acknowledge digital inputs

Name:
DigitalInput01LatchQuitt to DigitalInput04LatchQuitt

This register is used to reset the input latches channel by channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01LatchQuitt	0	No influence on the latch status
		1	Resets the latch status
...		...	
3	DigitalInput04LatchQuitt	0	No influence on the latch status
		1	Resets the latch status
4 - 7	Reserved	-	

4.26.6.11.5 Digital outputs

The output status is transferred to the output channels with a fixed offset (<60 µs) in relation to the network cycle (SyncOut).

4.26.6.11.5.1 Switching state of digital outputs 1 to 2

Name:
DigitalOutput01 to DigitalOutput02

This register is used to store the switching state of digital outputs 1 to 2.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalOutput01	0	Digital output 01 reset
		1	Digital output 01 set
1	DigitalOutput02	0	Digital output 02 reset
		1	Digital output 02 set

4.26.6.11.5.2 Digital inputs and status of the digital outputs

Name:
DigitalInput01 to DigitalInput04
StatusDigitalOutput01 to StatusDigitalOutput02

This register is used to indicate the input state of the digital inputs and the status of the digital outputs.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	DigitalInput01	0 or 1	Input state - Digital input 1
...		...	
3	DigitalInput04	0 or 1	Input state - Digital input 1
4	StatusDigitalOutput01	0	Digital output channel 1: No error
		1	Digital output channel 1: Short circuit or overload
5	StatusDigitalOutput02	0	Digital output channel 2: No error
		1	Digital output channel 2: Short circuit or overload
6 - 7	Reserved	-	

4.26.6.11.6 Analog inputs

The input state is collected with a fixed offset to the network cycle and transferred in the same cycle.

4.26.6.11.6.1 Analog input register

Name:
AnalogInput01

This register is used to indicate the analog input value depending on the configured operating mode.

Data type	Value	Input signal:
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA
	0 to 32767	Current signal 4 mA to 20 mA

4.26.6.11.6.2 Input filter

This module is equipped with a configurable input filter. The minimum cycle time must be >400 µs. Filtering is disabled for shorter cycle times.

If the input filter is active, then the channels are scanned in 1 ms cycles. Conversion is performed acyclically to the X2X cycle.

Information:

The filter sampling time is fixed at 1 ms and is acyclic to the X2X cycle.

Input ramp limitation

Input ramp limitation can only take place when a filter is used; the input ramp is limited before filtering takes place.

The amount the input value changes is checked to make sure that specified limits are not exceeded. If the values are exceeded, the adjusted input value is equal to the old value ± the limit value.

Configurable limit values:

Value	Limit value
0	The input value is used without limitation.
1	0x3FFF = 16383
2	0x1FFF = 8191
3	0x0FFF = 4095
4	0x07FF = 2047
5	0x03FF = 1023
6	0x01FF = 511
7	0x00FF = 255

Input ramp limitation is well suited for suppressing disturbances (spikes). The following examples show the function of the input ramp limitation based on an input jump and a disturbance.

Example 1

The input value jumps from 8,000 to 17,000. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

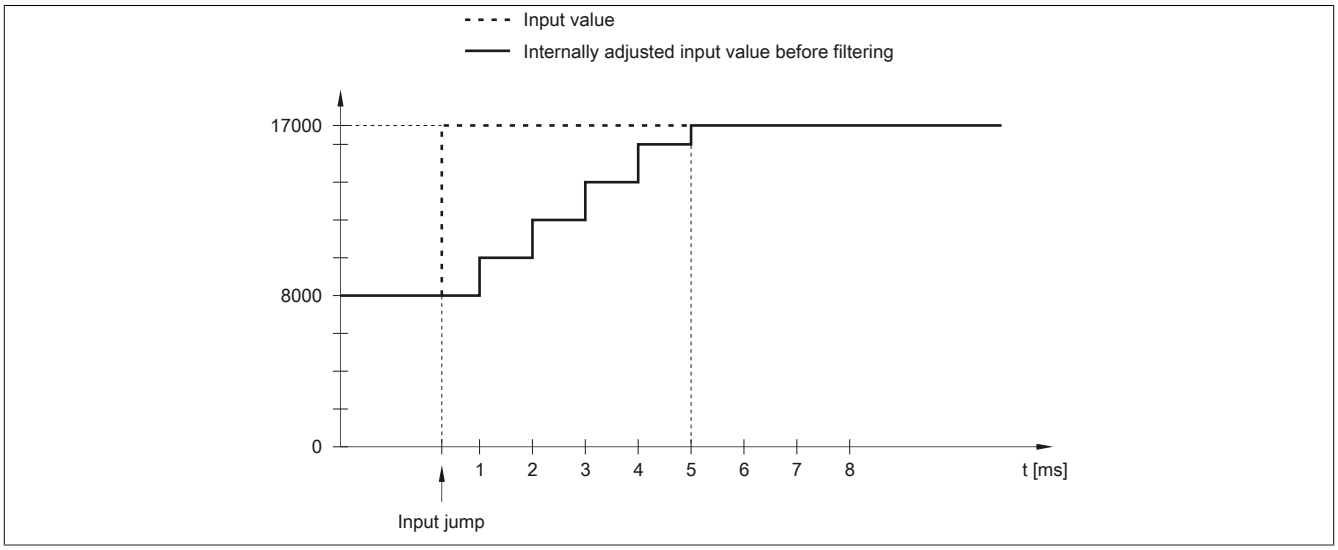


Figure 495: Adjusted input value for input jump

Example 2

A disturbance interferes with the input value. The diagram shows the adjusted input value with the following settings:

Input ramp limitation = 4 = 0x07FF = 2047

Filter level = 2

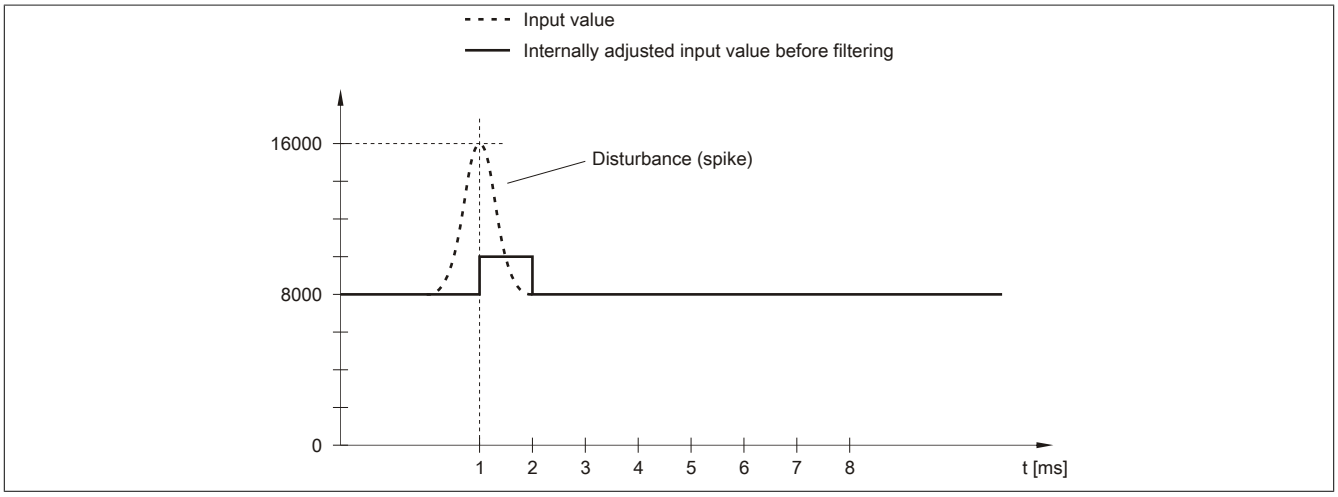

Figure 496: Adjusted input value for disturbance

Filter level

A filter can be defined to prevent large input jumps. This filter is used to bring the input value closer to the actual analog value over a period of several milliseconds.
Filtering takes place after input ramp limitation.

Formula for calculating the input value:

$$Value_{new} = Value_{old} - \frac{Value_{old}}{Filter\ level} + \frac{Input\ value}{Filter\ level}$$

Adjustable filter levels:

Value	Filter level
0	Filter switched off
1	Filter level 2
2	Filter level 4
3	Filter level 8
4	Filter level 16
5	Filter level 32
6	Filter level 64
7	Filter level 128

The following examples show how filtering works in the event of an input jump or disturbance.

Example 1

The input value jumps from 8,000 to 16,000. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

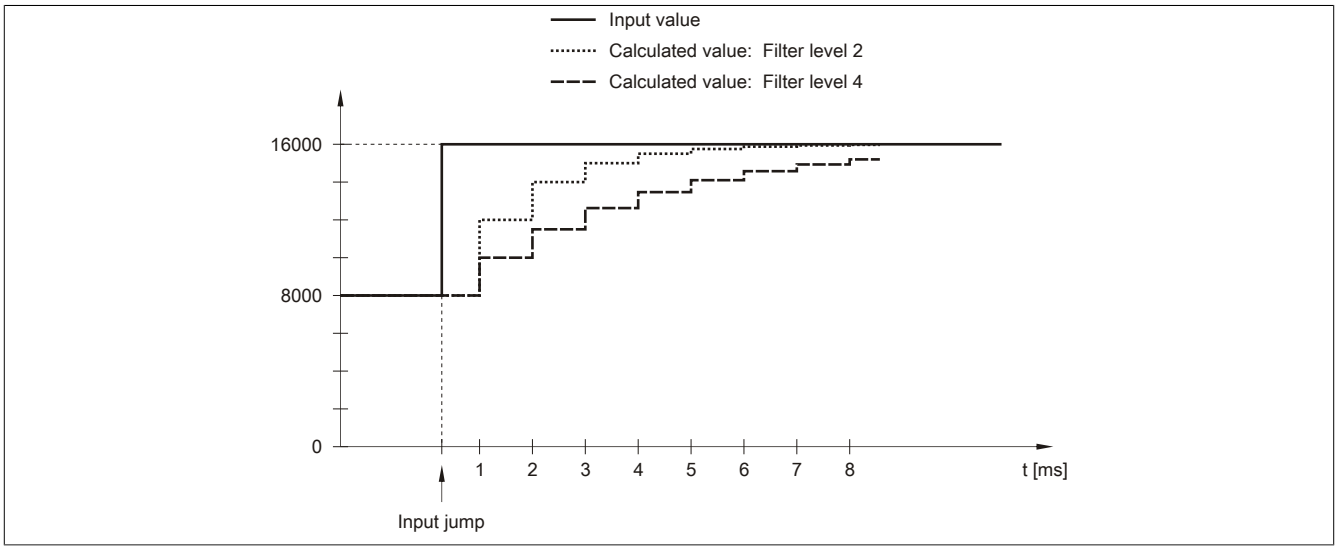

Figure 497: Calculated value during input jump

Example 2

A disturbance interferes with the input value. The diagram shows the calculated value with the following settings:

Input ramp limitation = 0

Filter level = 2 or 4

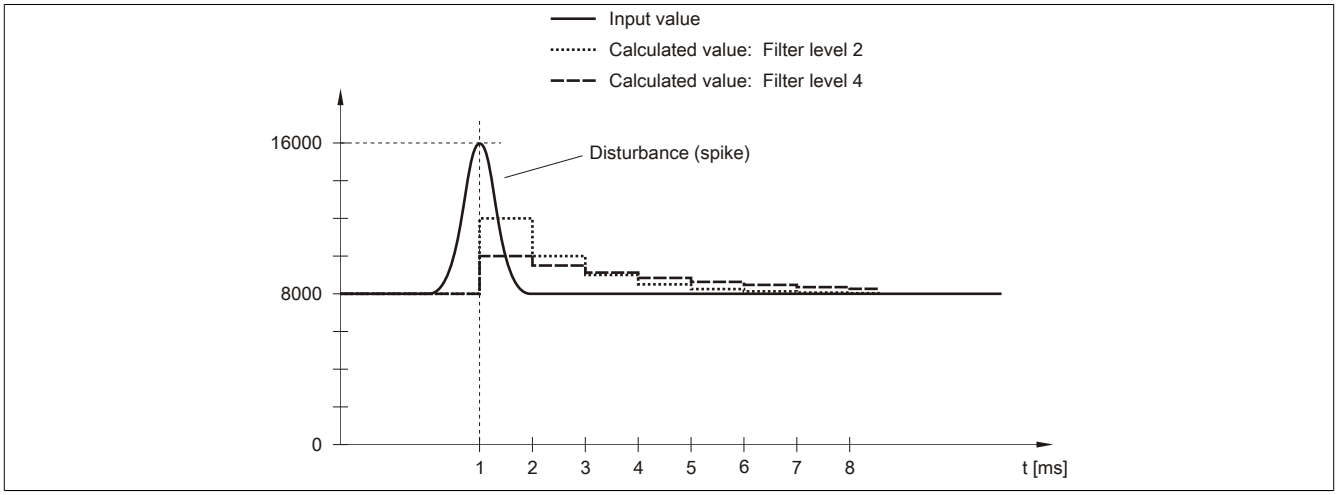

Figure 498: Calculated value during disturbance

4.26.6.11.6.3 Configuring the input filter

Name:
ConfigOutput03

This register is used to define the filter level and input ramp limitation of the input filter.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Defines the filter level	000	Filter switched off
		001	Filter level 2
		010	Filter level 4
		011	Filter level 8
		100	Filter level 16
		101	Filter level 32
		110	Filter level 64
		111	Filter level 128
3	Reserved	0	
4 - 6	Defines the input ramp limitation	000	The input value is used without limitation
		001	Limit value = 0x3FFF (16383)
		010	Limit value = 0x1FFF (8191)
		011	Limit value = 0x0FFF (4095)
		100	Limit value = 0x07FF (2047)
		101	Limit value = 0x03FF (1023)
		110	Limit value = 0x01FF (511)
		111	Limit value = 0x00FF (255)
7	Reserved	0	

4.26.6.11.6.4 Lower limit for the analog value

Name:
ConfigOutput05

This register can be used to configure the lower limit for analog values. If the analog value goes below the limit value, it is frozen at this value and the corresponding error status bit is set.

Information:

- **The default value of -32768 corresponds to the minimum default value of -10 VDC.**
- **For current measurements, this value should be set to 0.**
- **When configured as 4 to 20 mA, this value can be set to -8192 (corresponds to 0 mA) in order to display values <4 mA.**

Data type	Value
INT	-32768 to 32767

4.26.6.11.6.5 Upper limit for the analog value

Name:
ConfigOutput06

This register can be used to configure the upper limit for analog values. If the analog value goes above the limit value, it is frozen at this value and the corresponding error status bit is set.

Information:

- **The default value of 32767 corresponds to the maximum default value of 20 mA or +10 VDC.**

Data type	Value
INT	-32768 to 32767

4.26.6.11.6.6 Status of the analog input

Name:
StatusInput01

This register is used to monitor the analog input on the module. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line[1)]
2 - 7	Reserved	0	

1) Open-circuit detection does not occur during current signal measurement.

4.26.6.11.7 Analog output

The channel can be configured for either current or voltage signals. The type of signal is also determined by the connection terminals used.

4.26.6.11.7.1 Analog output register

Name:
AnalogOutput01

This register is used to output the analog output value appears depending on the operating mode that is set.

Data type	Value	Information
INT	-32768 to 32767	Voltage signal -10 to 10 VDC
	0 to 32767	Current signal 0 to 20 mA

4.26.6.11.8 Configuration of the analog inputs and outputs

Name:
ConfigOutput04

This register can be used to define the type and range of signal measurement.

Each channel is capable of handling either current or voltage signals. The type of signal is determined by the connection terminals used. Since current and voltage require different adjustment values, it is also necessary to configure the desired type of output signal.

Input signal:

- ±10 V voltage signal (default)
- 0 to 20 mA current signal
- 4 to 20 mA current signal

Output signal:

- ±10 V voltage signal
- 0 to 20 mA current signal

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Analog input	00	Voltage signal -10 VDC to +10 VDC
		01	Current signal 0 mA to 20 mA
		11	Current signal 4 mA to 20 mA
2 - 3	Reserved	0	
4	Analog output	0	Voltage signal -10 VDC to +10 VDC
		1	Current signal 0 mA to 20 mA
5 - 7	Reserved	0	

4.26.6.11.9 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without filtering	100 µs
With filtering	150 µs

4.26.6.11.10 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Digital without filtering	150 µs
Digital with filtering	200 µs
Analog without filtering	400 µs
Analog with filtering	1000 µs

4.26.7 X20CM8323

4.26.7.1 General information

The module has digital outputs for switching electromechanical loads (e.g. valves, relays) and additional functions.

- 8 digital outputs
- Current trace
- Switching time detection
- Pulse width modulation

4.26.7.2 Order data

Model number	Short description	Figure
	Other functions	
X20CM8323	X20 PWM module, 8 digital outputs for switching electromechanical loads, 0.6 A continuous current, 2 A peak current, current monitoring, switching time detection	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous

Table 642: X20CM8323 - Order data

4.26.7.3 Technical data

Product ID	X20CM8323
Short description	
I/O module	8 digital outputs for switching electromechanical loads, current monitoring, switching time detection, pulse width modulation
General information	
B&R ID code	0x1D43
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Outputs	Yes, using status LED and software (output error status)
Power consumption	
Bus	0.01 W
Internal I/O	1 W (Rev. ≥ G0), 1.5 W (Rev. < G0)
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Channel - I/O supply	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Digital outputs	
Nominal voltage	24 VDC
Nominal output current	0.6 A
Total nominal current	4.8 A
Connection type	1-wire connections
Output circuit	Sink
Output protection	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
Pulse width modulation	
Period duration	1 ms (1 kHz) or 20 µs (50 kHz)
Pulse duration	0 to 100 %
Resolution for pulse duration	1%
Starting current	Max. 2 A for max. 25.5 ms

Table 643: X20CM8323 - Technical data

Product ID	X20CM8323
Braking voltage when switching off inductive loads	39 VDC
Reverse polarity protection	No (must be protected externally)
Output voltage	
Minimum	18 VDC
Nominal	24 VDC
Maximum	42 VDC
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	0 to 60°C (Rev. ≥ G0); 0 to 55°C (Rev. < G0) [2]
Vertical installation	0 to 50°C [3]
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately Order 1x X20BM11 bus module separately
Spacing	12.5$^{+0.2}$ mm

Table 643: X20CM8323 - Technical data

1) Ta min.: 0°C
Ta max.: See environmental conditions
2) Rev. G0 and higher: Up to a maximum of 6 channels only are permitted to be switched on simultaneously over 55°C.
3) Rev. G0 and higher: Up to a maximum of 6 channels only are permitted to be switched on simultaneously over 45°C.

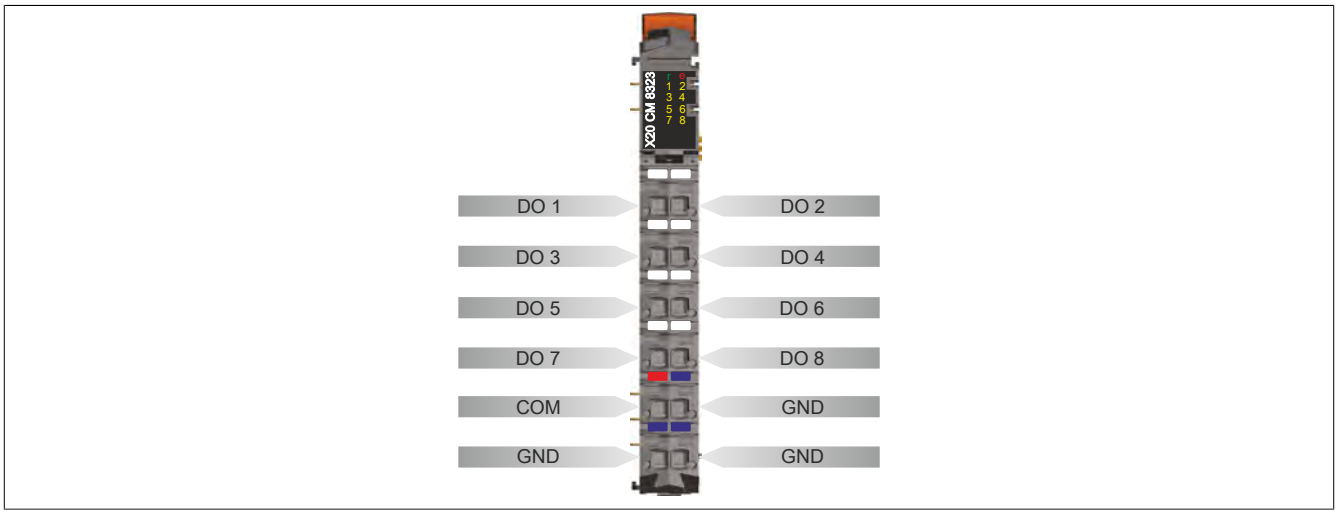
4.26.7.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

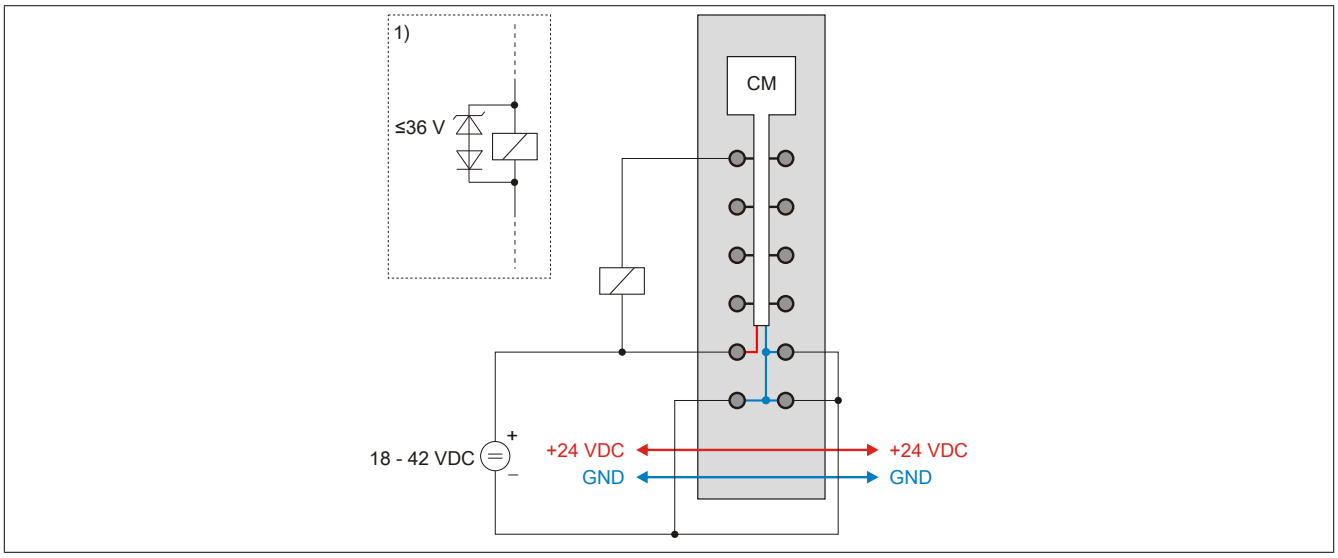
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	Warning/Error on an I/O channel. Level monitoring for digital outputs has been triggered.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 8	Orange	On/Off	Status of the digital outputs
			Blinking	Short-circuit / overcurrent cutoff **Information:** **The output is not automatically activated after an overcurrent cutoff. It must be switched on again.**

1) Depending on the configuration, a firmware update can take up to several minutes.

4.26.7.5 Pinout

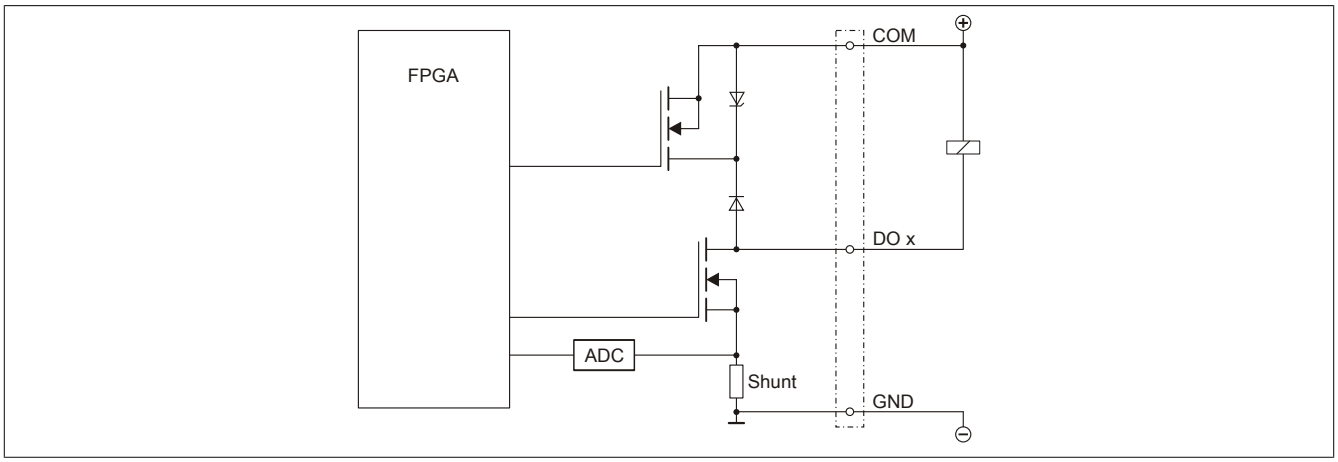


4.26.7.6 Connection example



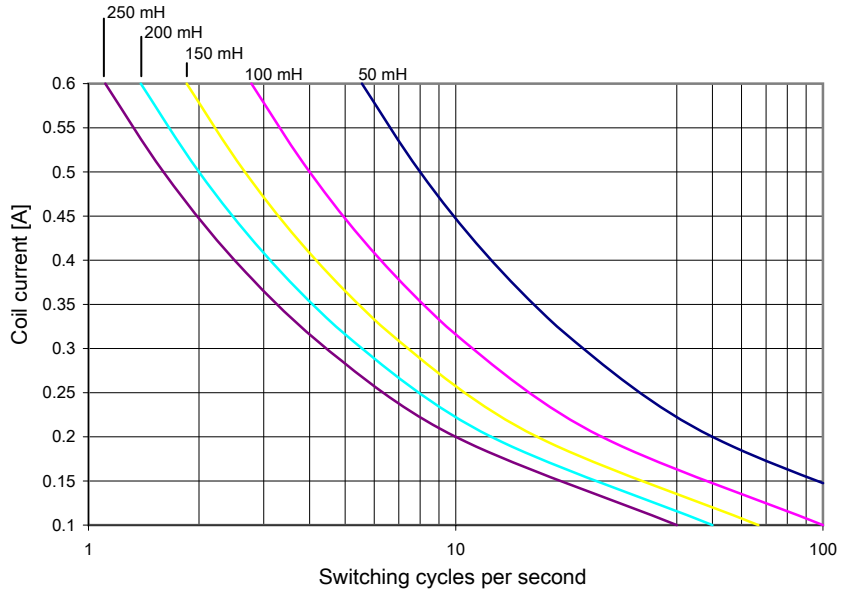
1) If larger inductances or more current are used; the "transil-diode combination" must be placed externally on the relay/valve.

4.26.7.7 Output circuit diagram

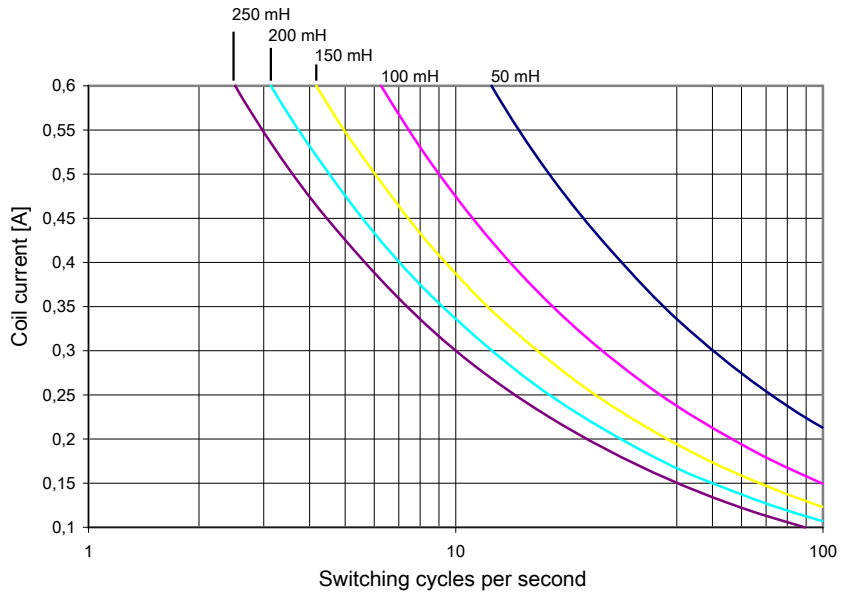


4.26.7.8 Switching inductive loads

Before revision G0



From revision G0



In principle, the inductance that is connected is limited by the maximum power dissipation of the module.

If larger inductances or more current are used, the the "transil-diode combination" must be placed externally on the relay/valve (see 4.26.7.6 "Connection example").

Information:

The inductance of a relay/valve depends greatly on the core material being used. Therefore, an inductance must be used that corresponds to the diagram at 1Hz. This information can be found in the data sheet of the connected inductance (relay/valve).

4.26.7.9 Register description

4.26.7.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.7.9.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

4.26.7.9.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.26.7.9.5 Configuration registers

4.26.7.9.5.1 Excitation time

Name:
ConfigOutput02

The excitation time is configured in this register.
The output is switched fully on for the time set in this register after the module is switched on. After the excitation time expires, the module goes into PWM mode.

Data type	Value	Information
USINT	0 to 255	In steps of 100 µs or 1000 µs

4.26.7.9.5.2 PWM ratio

Name:
ConfigOutput03

The PWM ratio between switch-off time and period duration is set in this register (in percent).

Data type	Value	Information
USINT	0	Permanently switched off
	1 to 99	Ratio = switch-off time / period duration (1 to 99%)
	100	Permanently switched off

4.26.7.9.5.3 Module configuration

Name:
ConfigOutput04

This register is used to configure the module's general parameters.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	PWM frequency	0	1 kHz
		1	50 kHz
1	Reserved		
2	Excitation time base	0	100 µs
		1	1000 µs
3	Reserved		
4	Switching point search	0	Low-point method
		1	Curvature method
5 - 7	Reserved		

4.26.7.9.5.4 Current and time differential

Name:
ConfigOutput05 to ConfigOutput20

The switching point search is configured with the parameters dI and dt in these non-cyclic registers.

- dI - Current differential in LSB
- dt - Time differential in 100 µs steps

For a sample configuration, see 4.26.7.9.7 "Configuring dI and dt"

Data type	Value
USINT	0 to 255

Registers	Description	
ConfigOutput05	**dI**	Channel 1
ConfigOutput06	d**t**	
...		...
ConfigOutput19	**dI**	Channel 8
ConfigOutput20	d**t**	

4.26.7.9.5.5 Disables the high-speed cutoff

Name:
ConfigOutput21

This register can be used to enable or disable the high-speed cutoff for individual channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	High-speed cutoff	0	Enabled for Channel 1
		1	Disabled for Channel 1
...		...	
7	High-speed cutoff	0	Enabled for Channel 8
		1	Disabled for Channel 8

4.26.7.9.5.6 Configuration of the time base

Name:
TimeBase

This register can be used to configure the interval between current measurement points.
The interval between measurement points is normally one quarter of the defined X2X Link cycle. When using a CAN controller this value is not available. The time base for the 1/4 measurement cycle must therefore be set separately in Function model 254 - Bus controller.

Data type	Value	Information
UINT	400 to 10000	Measurement point interval in µs for 1/4 measurement cycle

4.26.7.9.6 Communication registers

4.26.7.9.6.1 Uploading the current curves (function models 0 and 1)

A current curve with 200 values is recorded for each channel. The interval between measurement points is equal to a quarter of the defined X2X Link cycle.

The following registers are used to read the current curve recorded by the module:

- AnalogInput01
- AnalogInput02 to Analog09

Set the channel number and line index

Name:
AnalogInput01

If this register contains a valid value (i.e. index is in the valid range) then registers AnalogInput02 to AnalogInput09 provide a block of 8 current values for Channel X.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Channel number	0	Channel 1
		...	
		7	Channel 8
3 - 7	Index	0 to 24	Line index

The index specifies which part of the current curve is represented by the block of 8 values:

Value X of the current curve	Index	Register
1	0	AnalogInput02
2		AnalogInput03
...		...
8		AnalogInput09
9	1	AnalogInput02
...	:	...
193	24	AnalogInput02
...		...
200		AnalogInput09

Table 644: Relationship between index, channel and AnalogInput02 - AnalogInput09

Examples

The 200th value of the curve contains the switching point of the connected valve/relay found by the module.

- Value 200 = 78: The 78th measurement point corresponds to the switching point of the valve/relay.
- Value 200 = 255: No switching point was found.

Analog input values

Name:
AnalogInput02 to AnalogInput09

A current curve with 200 values is recorded for each channel. These registers provide a block of 8 current values from Channel X.
The following register is required for configuration:

- The AnalogInput01 register defines the channel used and the block index.
- The interval between measurement points is equal to a quarter of the defined X2X Link cycle.

Data type	Value
USINT	0 to 255

Programming example in ANSI C for uploading the curves:

```
#include <bur/plctypes.h>
#define ILEN 200

typedef struct {
      USINT                         data[ILEN];
}     curve_typ;
typedef struct {
      BOOL                          ok;
      UDINT                         serial;
      UINT                          id, hw, fwver;
      BOOL                          out[8];
      UINT                          delay;
      USINT                         i_addr;
      USINT                         i_ch1_in, i_ch2_in, i_ch3_in, i_ch4_in;
      USINT                         i_ch5_in, i_ch6_in, i_ch7_in, i_ch8_in;
      curve_typ                     curves[8];
      USINT                         switched;
}     cm8323_typ;
_LOCAL cm8323_typ                   cm;
_LOCAL USINT                        ventilNummer, adrPtr;

void _INIT up() {}

void _CYCLIC cycle() {
      ventilNummer = cm.i_addr & 0x07;
      adrPtr = cm.i_addr >> 3;

      if(cm.i_addr != 200 && ventilNummer <= 7) {
            cm.curves[ventilNummer].data[adrPtr * 8 + 0] = cm.i_ch1_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 1] = cm.i_ch2_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 2] = cm.i_ch3_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 3] = cm.i_ch4_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 4] = cm.i_ch5_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 5] = cm.i_ch6_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 6] = cm.i_ch7_in;
            cm.curves[ventilNummer].data[adrPtr * 8 + 7] = cm.i_ch8_in;
      }
}
```

I/O mapping of following data points for curve evaluation:

Data point	Variable
AnalogInput01	cm.i_addr
AnalogInput02	cm.i_ch1_in
AnalogInput03	cm.i_ch2_in
AnalogInput04	cm.i_ch3_in
AnalogInput05	cm.i_ch4_in
AnalogInput06	cm.i_ch5_in
AnalogInput07	cm.i_ch6_in
AnalogInput08	cm.i_ch7_in
AnalogInput09	cm.i_ch8_in

4.26.7.9.6.2 Uploading the current curves with CAN I/O

A current curve with 200 values is recorded for each channel. The interval between measurement points is equal to the value set in the 4.26.7.9.5.6 "TimeBase" register.

The following registers are needed in order to read the current curve recorded by the module in the Function model 254 - Bus controller:

- BlockID_Set
- BlockID_Act
- LineID_Set
- LineID_Act
- AnalogInput01 to AnalogInput04

Summary of set registers

Name:
AddressSet

This register is a summary of the LineID_Set and BlockID_Set registers.

Data type	Bit	Information
UINT	0 - 7	LineID_Set
	8 - 15	BlockID_Set

Summary of read registers

Name:
IndexAct

This register is a summary of the LineID_Act and BlockID_Act.

Data type	Bit	Information
UINT	0 - 7	LineID_Act
	8 - 15	BlockID_Act

Sets the channel number

Name:
BlockID_Set

The channel for the data stream can be selected in this register. The value of this register can be read using BlockID_Act.

Data type	Value	Information
USINT	0	Channel 1
	...	...
	7	Channel 8

Reads the channel number

Name:
BlockID_Act

Reads the BlockID_Set register. This register allows you to determine which channel is providing the current values in registers AnalogInput01 to AnalogInput04. If the selected channel or line does not exist, then this register returns the value 255.

Data type	Value	Information
USINT	0 to 7	Channel or line currently being used
	255	Invalid selection

Setting the line index

Name:
LineID_Set

The line index for the data stream can be selected in this register. The value of this register can be read using LineID_Act.

Data type	Value	Information
USINT	0 to 49	Line index currently used

Reading the line index

Name:
LineID_Act

Reads the LineID_Set register. This register allows you to determine which line is providing the current values in registers AnalogInput01 to AnalogInput04. If the selected channel or line does not exist, then this register returns the value 255.

If the channel number and index are in the valid range, then registers AnalogInput01 to AnalogInput04 provide a block of 4 current values for Channel X.
The index specifies which part of the current curve is represented by the block of 4 values:

Data type	Value	Information	
USINT	**Value X of the current curve**	**Index**	**Register**
	1	0	AnalogInput01
	...		...
	4		AnalogInput04
	5	1	AnalogInput01
	...		...
	197	49	AnalogInput01
	...		...
	200		AnalogInput04
	255	Invalid selection	

Analog input values - CAN I/O

Name:
AnalogInput01 to AnalogInput04

A current curve with 200 values is recorded for each channel. These registers provide a block of 4 current values from Channel X.
The following registers are required for configuration:

- The BlockID_Set register defines the channel used.
- The LineID_Set register defines the block index within the channel.
- The interval between measurement points is equal to the value set in the TimeBase register.

Data type	Value
USINT	0 to 255

4.26.7.9.6.3 Digital outputs

Name:
DigitalOutput
DigitalOutput01 to DigitalOutput08

Registers "DigitalOutput01" to "DigitalOutput08" set the output value of Channels 1 to 8.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalOutput01	0 or 1	Output value of digital output 01
...		...	
7	DigitalOutput08	0 or 1	Output value of digital output 08

4.26.7.9.6.4 Status of the outputs

Name:
StatusInput01

This register indicates whether a switching point has been found for a channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Switching point	0	Channel 1 was not switched or no switching point was found
		1	Switching point found for Channel 1
...		...	
7	Switching point	0	Channel 8 was not switched or no switching point was found
		1	Switching point found for Channel 8

4.26.7.9.6.5 Module status

Name:
StatusInput02

The current module status is indicated in this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Reserved	0	
3	Overload cutoff	0	No overcurrent
		1	Overcurrent cutoff activated
4 - 7	Reserved	0	

4.26.7.9.6.6 Switching delay of channels

Name:
StatusOutput01

2 bits of this register are used to set the switching delay for each channel. Values of the switching delay are specified in quarter-steps of the X2X Link cycle.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Switching delay of channel 1	00	No delay
		01	1/4 of the X2X Link cycle
		10	2/4 of the X2X Link cycle
		11	3/4 of the X2X Link cycle
2 - 3	Switching delay of channel 2	x	For possible values, see channel 1.
...		...	
14 - 15	Switching delay of channel 8	x	For possible values, see channel 1.

4.26.7.9.6.7 Reads actual values of the current

Name:
Current01 to Current08

These registers are used to read the actual value of the current from channels 1 to 8. These values have no units and are used only as characteristic values. A more precise, compensated current measurement is not possible using this module.

Relationship between register name and channel number:

Register name	Channel number
Current01	Actual value of the current of Channel 1
...	...
Current08	Actual value of the current of Channel 8

If an output is switched off, the corresponding register returns the value 0. After the output is switched on, valid current measurements are not available on the module until after two X2X Link cycles. The measurements in the registers are delayed by two cycles to account for this.

When the output is switched on, the corresponding bit in the StatusCurrent register can be used to check whether the register contains valid measurements. The first measured value is provided with the rising edge of this bit.

Data type	Value	Information
USINT	0	Output is switched off
	1 to 255	Current value

4.26.7.9.6.8 Checking for measured values

Name:
StatusCurrent
StatusCurrent01 to StatusCurrent08

These registers can be used to check whether registers Current01 bis Current08 contain valid measured values.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusCurrent01	0	Output switched off
		1	Current value of Channel 01 is valid
...		...	
7	StatusCurrent08	0	Output switched off
		1	Current value of Channel 08 is valid

4.26.7.9.7 Configuring dI and dt

4.26.7.9.7.1 Procedure - Searching for switching points

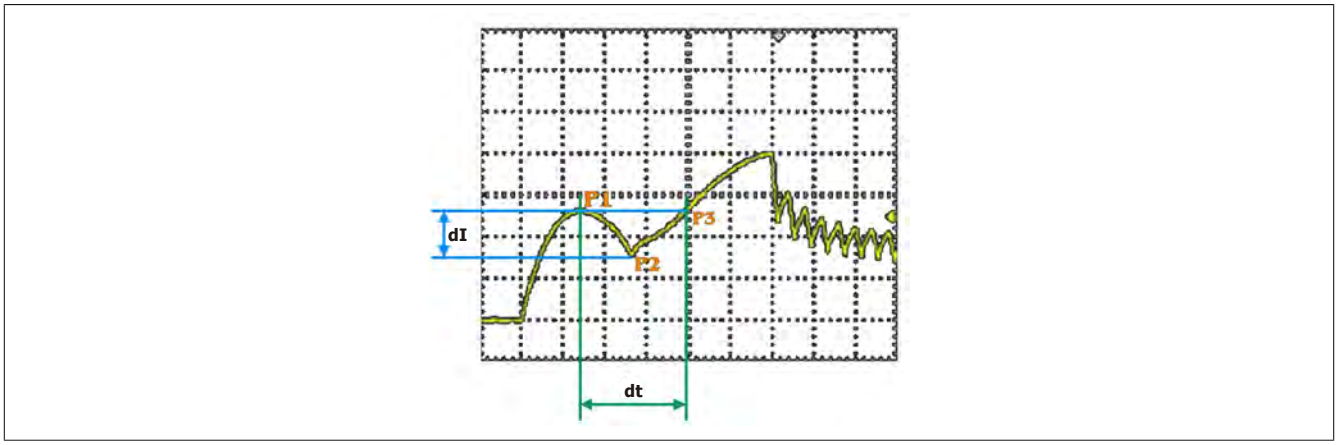

Figure 499: Searching for switching points

The current in the inductance gradually rises when the valve is switched on. The valve starts to move mechanically at a certain point. This process becomes noticeable due to a current dip that occurs as a result of the braking voltage (anti-EMF) (point P1).

When this mechanical process is complete, the current returns to its original curve and continues to rise (point P2).

Point P3 and point P1 have the same current value, but different times.

A valid low-point, which simultaneously corresponds to the switching point, must meet the following criteria:

- Point 2 must be lower than P1 by dI
- The time between P1 and P3 must be longer than dt

4.26.7.9.7.2 Configuration example for dI and dt with trace data from Automation Studio

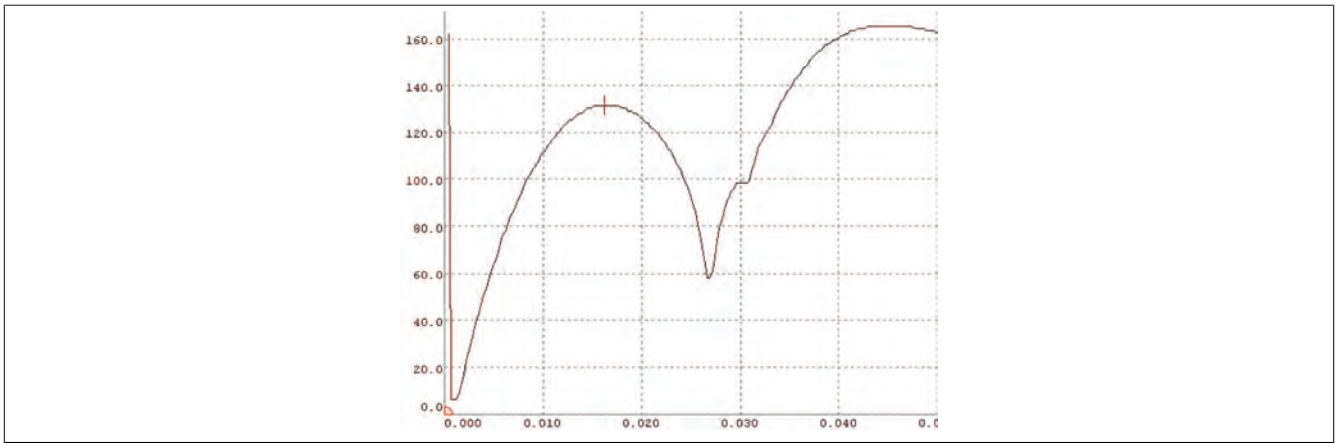

Figure 500: Search for the switching point with trace data from Automation Studio

The difference between the "current high-point" (P1 = 131) and the subsequent low-point (P2 = 58) is calculated (P1 - P2 = 73). The module compares this difference to the configured parameter dI.

If the difference measured by the module is larger than the configured dI value, then the first condition for a switching point search is met:

- In the module, the parameter dI should therefore be set to at least 72.

The next criteria is the time between P1 and P3. This must be larger than the value set for the parameter dt.

According to the trace data, this is 4.43 ms:

- In the module, the parameter dt should therefore be set to 43 (4430 µs / 100 µs).

With that, the second condition is met and a valid switching point can be detected.

It is recommended to avoid setting values all the way to the limits, since valves and relays change mechanically over time, which can lead to faulty readings (unless you wish to detect every minor deviation from the reference curve).

4.26.7.9.7.3 Modified switching point search (curvature method)

The method described (searching for and detecting switching points by locating low-points in the current trace) may not provide the desired level of reliability for certain types of valves and under certain conditions (e.g. pneumatic pressure).

For this reason, an alternative method of switchover detection is provided. This method is based on an evaluation of the curvature of the current curve. In the module configuration, the user can select which method to use for switchover detection (see 4.26.7.9.5.3 "Module configuration").

The modified switching point search calculates the first derivative (slope) and then the second derivative (curvature) for every point in the current curve. At the switching point this second derivative has a local maximum, which is found by the module. More specifically, in order to improve the signal/noise ratio, a summation window is moved over the second derivative and the maximum of this summation is searched for.

This is not only valid when the current trace itself has a more or less low minimum in the switching point, but also in cases where the current increase only levels-out in the area of the switching point, but never becomes negative. Therefore, it can be said that the curvature method should generally be more sensitive.

Like the switching point search with the low-point method, valid switching points are configured using the parameters dI and dt. The meaning of these parameters is different here, however.

- dI - minimum curvature sum
- dt - width of the summation window in 1/4 X2X Link cycles

Meaningful values for this parameter can no longer be obtained simply by reading / measuring the current trace. That is why the module provides, in addition to the switching point (200th value of the current curve), also the following measurement and calculation values that can be used for the configuration:

Value X of the current curve	Description
1	1. Value of the current curve
:	:
197	Peak position of the first valid or highest invalid curvature peak
198	Height of the peak sum of the first valid or highest invalid peak
199	Width of the first valid or highest invalid peak (**Important:** not standardized to 100 µs)
200	255 at invalid peak, otherwise peak position in the current trace

When a valid maximum curvature has been found (Value 198 ≥ dI) then Values 197 to 199 represent the position (= Value 200), height and width of the first maximum that meets the criteria. Any higher and/or wider maximum that occurs later will not be found!

If no maximum curvature reaches the necessary height, then Values 197 through 200 represent the highest invalid maximum.

Determining the parameters dI and dt

dI << Value 198	Set dI much lower than 198
dt ≈ Value 199	dt should be set approximately the same as Value 199 **Note**: Maximum value for dt = 16

A certain amount of jitter in Value 198 must be assumed due to the high sensitivity of the modified switching point search. It is therefore recommended to monitor Value 198 over several switching cycles before setting dI with a safety clearance from the lowest monitored value.

As you can see in the examples below, the switching point peak is a number of times higher than any other peak in the summation curves.

The switching point peak is also still the first peak that occurs in the positive range. Therefore, it should not be a problem to set dI far enough from the minimum of the Value198 and far above the highest peak that arises from the noise (or valve chatter).

Example 1:

Configuration example of the modified switching point detection for a valve with a distinctive switching point.

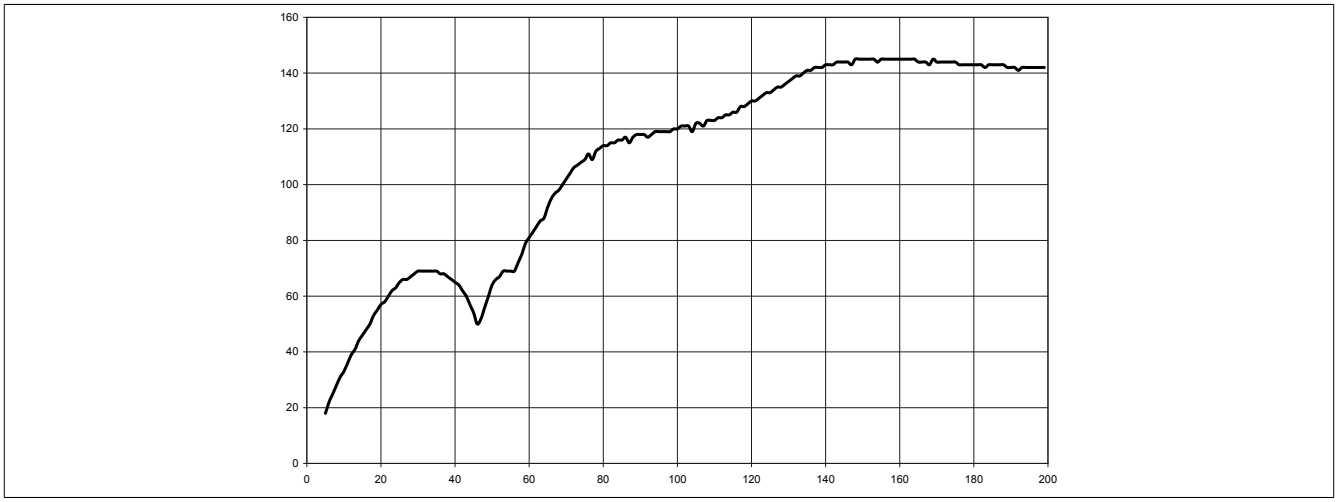

Figure 501: Example 1 - Valve current

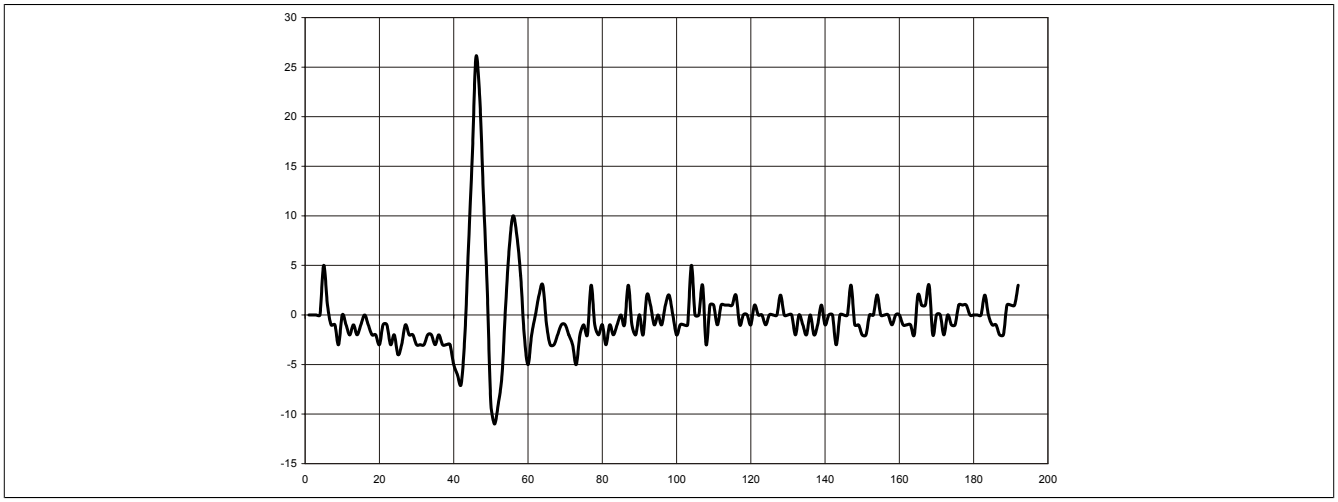

Figure 502: Example 1 - Calculated curvature (2nd derivative) of the current curve

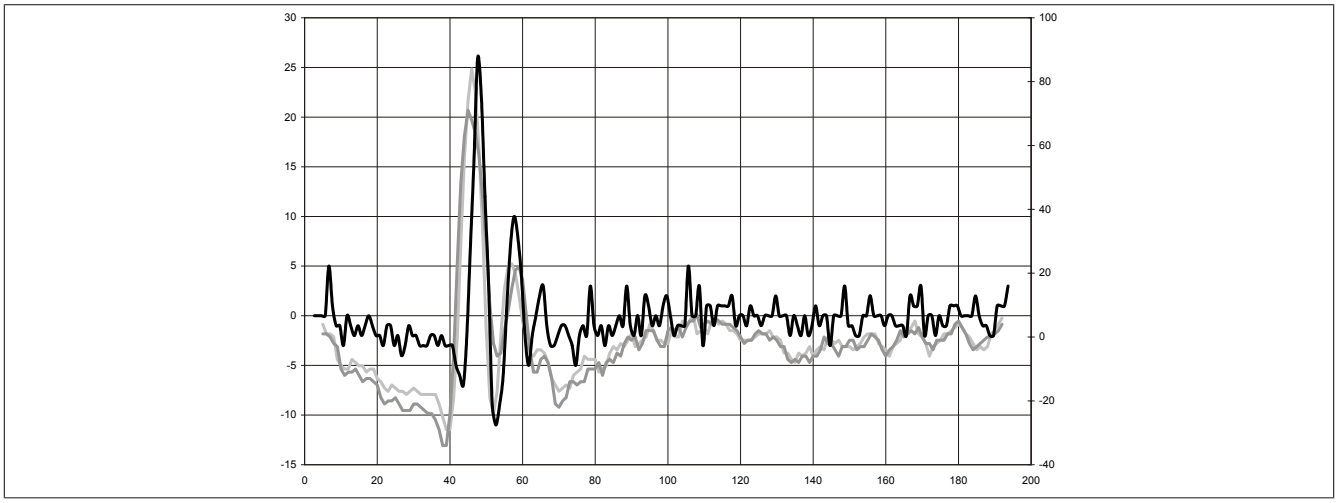

Figure 503: Example 1 - Calculated curvature (2nd derivative) of the current curve including overlapping sum with 3 different window widths

Example 2:

Configuration example of the modified switching point detection for a valve with a faintly distinctive switching point.

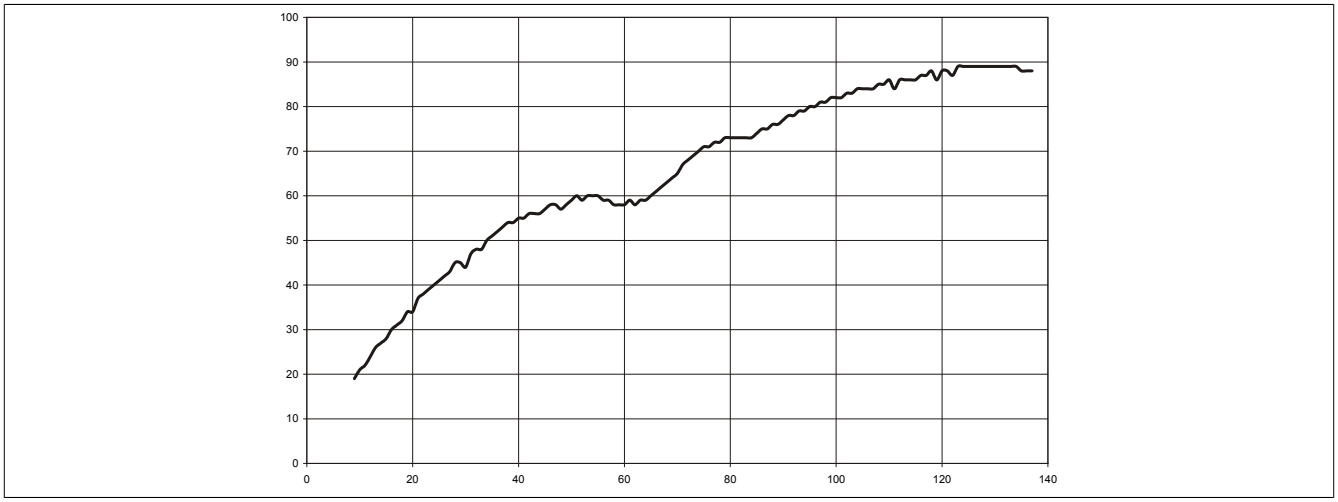

Figure 504: Example 2 - Valve current

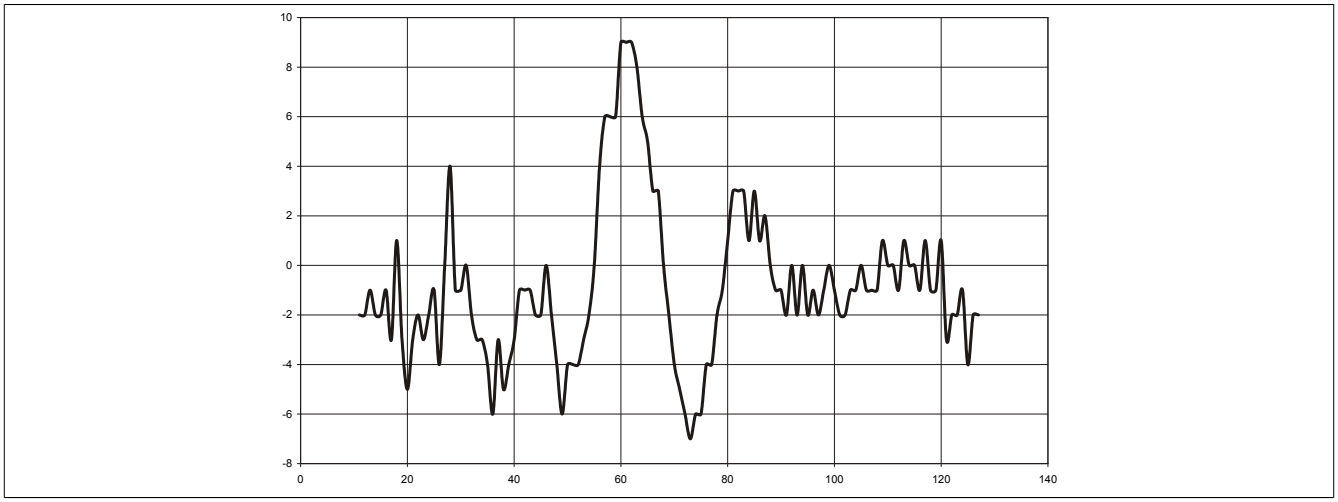

Figure 505: Example 2 - Calculated curvature (2nd derivative) of the current curve

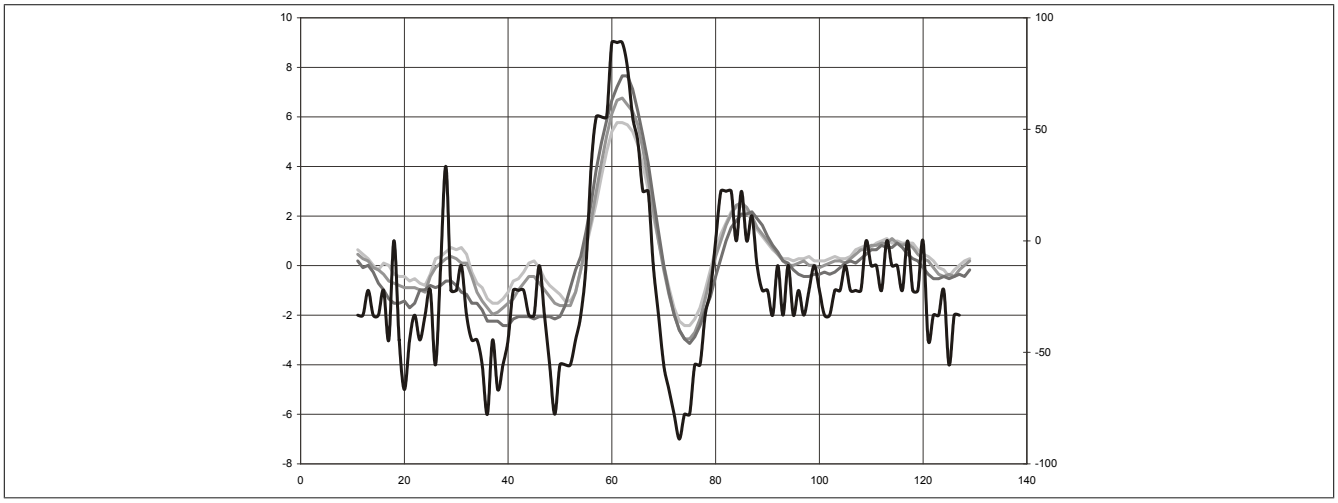

Figure 506: Example 2 - Calculated curvature (2nd derivative) of the current curve including overlapping sum with 3 different window widths

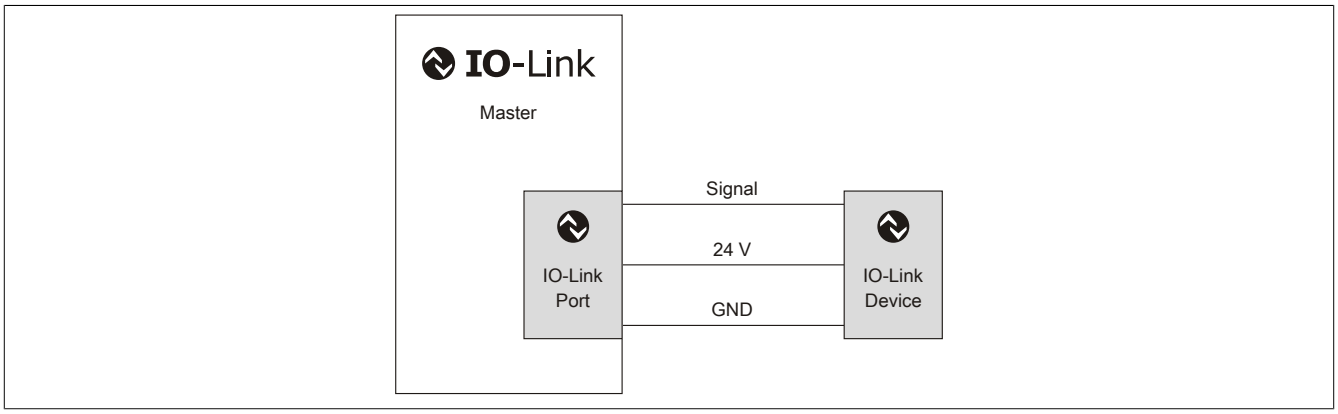
4.26.8 X20DS4387

4.26.8.1 General information

IO-Link is a standardized communication system for connecting intelligent sensors and actuators in an automation system. The standardization includes electrical connection data as well as a digital communication protocol, which is used by the sensors and actuators in the automation system for data exchange.

An IO-Link system consists of an IO-Link master and one or more IO-Link devices, i.e. sensors and actuators. The IO-Link master makes the interface available for higher level control and controls communication with the connected IO-Link devices.

An IO-Link device is an intelligent sensor or actuator. With regard to IO-Link, "intelligent" means that a device possesses a series number or parameter data (sensitivity, switching delays or characteristic curves), which can be written to or read via the IO-Link protocol.



Process optimization

The use of intelligent sensors and actuators contributes to process optimization. Process optimization means that downtimes should be kept as short as possible. These consist mainly of standstills due to errors and setup times.

Integrated communication down to the IO-Link devices offers many advantages in error diagnostics. Errors are detected much faster than before. If a sensor or actuator must be replaced, lengthy configuration work is no longer necessary after the change thanks to a potentiometer, or a configuration tool and laptop. After changing the sensor/actuator, the parameters are automatically transferred to the sensor.

This parameter download is not only beneficial when errors occur. It can also be used for changing parameters when a load change is performed. This shortens setup times, making product changes and small batches more economical.

Integration of IO-Link in X20 System

IO-Link is integrated in the X20 system using this digital module. All 4 channels are IO-Link interfaces, but can also be used as standard inputs or outputs. The specified 3-wire connections can be ideally implemented thanks to the X20 connector system with 12 terminal points per module. All specified transfer rates are also supported.

POWERLINK integration

IO-Link doesn't stop at the I/O module. It must be integrated in the higher-level bus system to fully utilize the benefits. When using POWERLINK, access is made possible via device description files in XML format.

- 4 IO-Link interfaces per module
- Each interface can be configured as a standard input or output
- Seamless integration in POWERLINK
- Supports all transfer rates

4.26.8.2 Order data

Model number	Short description	Figure

4.26.8.3 Technical data

Product ID	X20DS4387
Short description	
I/O module	IO-Link master with 4 IO-Link interfaces
General information	
B&R ID code	0xA38E
Status indicators	IO-Link, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
IO-Link operating state	Yes, using status LED and software
C/Q status	Yes, using status LED and software
Cable specification	
Cable type	3-pin standard sensor cable
Cable length	Max. 20 m
Line capacitance	Max. 3 nF
Loop resistance	Max. 6 Ω
Power consumption	
Bus	0.01 W
Internal I/O	1.6 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Bus - IO-Link	Yes
IO-Link - IO-Link	No
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Sensor/Actuator supply	
Voltage	I/O supply minus voltage drop for short circuit protection
Voltage drop for short circuit protection at 0.3 A	Max. 1 VDC
Power consumption	Max. 9 W per interface
Short circuit protection	Yes
IO-Link in master mode	
Transfer rates	
COM1	4.8 kbaud
COM2	38.4 kbaud
COM3	230.4 kbaud
Limits for COM3	
Max. connection capacity	47 nF (cable + device)
Max. load	100 Ω / 0.3 A
Data format	1 start bit, 8 data bits, 1 parity bit (even), 1 stop bit
Bus level	24 VDC (active), 0 VDC (resting voltage)
IO-Link device supply	24 VDC / max. 0.3 A per interface (protected)
IO-Link in master mode or in SIO mode "digital output"	
Design	Bipolar, positive and negative switching
Diagnostics	Output monitoring with 100 ns delay and internal semiconductor protection with 100 µs delay

Table 646: X20DS4387 - Technical data

Product ID	X20DS4387
Peak short circuit current	<1.5 A
Residual voltage	<1.5 VDC at nominal current 0.2 A
Switching voltage	I/O supply minus voltage drop for short circuit protection and semiconductor switch
Voltage drop on semiconductor switch	Max. 1.5 VDC at 0.2 A
Switching frequency	Typ. 25 kHz 300 kHz in IO-Link master mode
Switching delay	
0 -> 1	<10 µs
1 -> 0	<10 µs
Switching on after overload or short circuit cutoff	Approx. 10 ms (depends on the module temperature)
Braking voltage when switching off inductive loads	Typ. 52 VDC
Isolation voltage between IO-Link and bus	500 V_{eff}
IO-Link in SIO mode "digital output"	
Nominal voltage	24 VDC
Nominal output current	0.2 A
Total nominal current	0.4 A
Output circuit	Sink or source
Output protection	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
Actuator supply	24 VDC / max. 0.3 A per interface (protected)
IO-Link in SIO mode "digital input"	
Nominal voltage	24 VDC
Input filter	
Hardware	100 ns
Software	-
Input circuit	Sink
Sensor supply	24 VDC / max. 0.3 A per interface (protected)
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Typ. 5 mA
Input resistance	Typ. 4.8 kΩ
Switching threshold	
Low	<8 VDC
High	>13 VDC
Isolation voltage between IO-Link and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	0 to 55°C
Vertical installation	0 to 45°C
Derating	-
Storage	-25 to 70°C
Transport	-25 to 70°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately, Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Ta max.: See environmental conditions

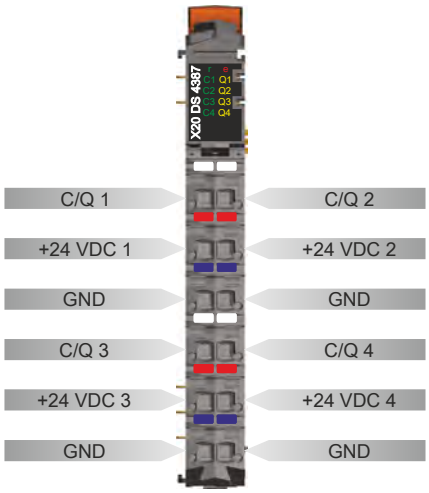
4.26.8.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

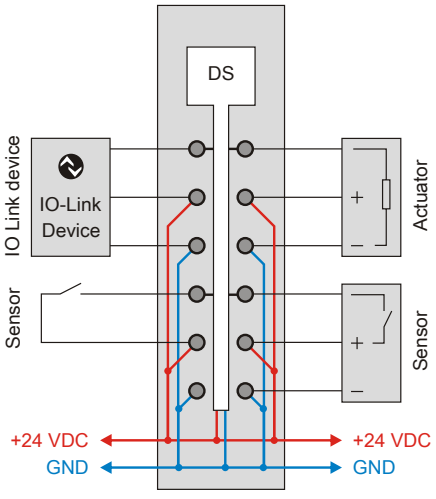
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Single flash	Warning / error for an IO-Link interface
	1 - 4	Green/Red	Off	Interface in SIO mode
			Green	Interface in IO-Link mode
			Red	Output overloaded (short circuit, temperature)
	1 - 4	Orange		Input/output status of the corresponding IO-Link interface

1) Depending on the configuration, a firmware update can take up to several minutes.

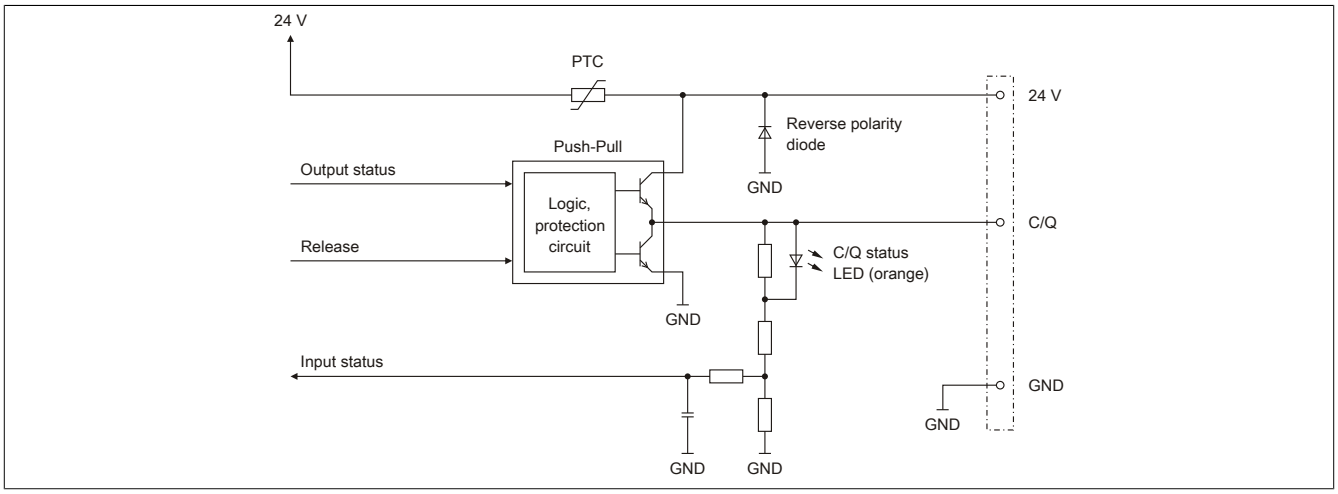
4.26.8.5 Pinout



4.26.8.6 Connection example



4.26.8.7 Output circuit diagram



4.26.8.8 Register description

4.26.8.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.8.8.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Interface operation						
321 + (N-1) * 256	Control0N (index N = 1 to 4)	USINT				●

1) The offset specifies the position of the register within the CAN object.

4.26.8.8.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.26.8.8.4 Limitations

The I/O module offers extensive function and configuration options. Many of these options require cycle data. The amount of cycle data required depends on the following parameters:

- Number of interfaces in use
- Use of events
- Runtime configuration in the cycle data

Take note that the amount of cycle data available for each I/O module used in the system is limited:

Sum of the input data:	29 bytes
Sum of the output data:	30 bytes

Runtime configuration and events

Each I/O module requires the following amounts of cycle data for runtime configuration and events, if enabled:

Activated function	Input	Output
Runtime configuration in the cycle data	6	10
Events	4	1

Interface data

The following amounts of cyclic data are required for each interface being used:

Functionality	Operating state							
	OPERATE		DIGINPUT		DIGOUTPUT		INACTIVE	
	Input	Output	Input	Output	Input	Output	Input	Output
Payload	0 to 27[1)]	0 to 30[1)]	1	-	-	1	-	-
Status information	2	-	2	-	2	-	-	-

1) User configurable

4.26.8.8.5 Interface operation

4.26.8.8.5.1 Communication mode

Name:
Control01 to Control04

Writing to this register defines the desired state of the IO-Link device. This register can be used to define if the IO-Link device should be operated in "normal" communication mode (OPERATE), as a digital input (DIGINPUT) or as a digital output (DIGOUTPUT).

Switching to SIO mode can make sense for IO-Link devices that only transfer digital information anyway (e.g. light curtains) but after the basic configuration should be faster than is possible in "normal" communication mode. A parameter configuration for the object directory can also be made in SIO mode.

To deactivate an interface, INACTIV should be used.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Communication mode	0	INACTIV
		1	DIGINPUT
		2	DIGOUTPUT
		10	OPERATE
4 - 7	Reserved	-	

4.26.8.8.5.2 Operating state

Name:
StatusEvents01 to StatusEvents04

The actual status of communication between the module and the IO-Link device is indicated in this register. Additionally, the number of events read by the IO-Link device are also counted in this register.

Data type	Value
USINT[1)]	See bit structure.
UINT	

1) In the bus controller or standard function model, of communication mode = INACTIV

Bit structure:

Bit	Description	Value	Information
0 - 3	Status of the IO-Link device	x	See table below
4 - 7 or 15	Event counter from the respective IO-Link device	x	

Status of the IO-Link device

Value	ID	Description
0	INACTIVE	Interface is active: No communication and signal output or input. This state is not changed automatically.
1	DIGINPUT	SIO input mode: The interface acts like a digital input
2	DIGOUTPUT	SIO output mode: The interface acts like a digital output
4	ESTABLISHCOMM	Establishing connection to IO-Link device. This state remains as long as a device is not found.
5	INITMASTER	Consecutive states experienced during booting and configuration of an IO-Link device.
6	INITDEVICE	
7	INITOPERATE	
8	PREOPERATE	
9	READYTOOPERATE	Waiting for valid data from the IO-Link device. This state can follow the OPERATE state if the device reports during operation that it cannot send any more valid data.
10	OPERATE	Communication with the IO-Link device via serial protocol. Valid data is exchanged.
11	COMSTOP	The IO-Link interface is reinitialized. The ESTABLISHCOMM state follows this state.
12	FALLBACK	For switching to SIO mode
13	STARTUP	IO-Link device restart
14	SIO	Switching to SIO mode

States with a gray background are applied continuously, all others are intermediate states. An exception is the state ESTABLISHCOMM (4): This state is applied continuously if there is no device connected.

Dynamic values from the IO-Link device make up the input data for an IO-Link interface if one of the states DIGINPUT, DIGOUTPUT or OPERATE has been reached. These states can also be exited when errors occur. The device is restarted if a fatal error occurs, which means the state reverts back to ESTABLISHCOMM. Another possibility is that there is no new data being read from the device in the OPERATE state. In this case, the state changes to READYTOOPERATE and waits for new data.

During the first boot procedure, the module sends the value 0 for the inputs of an IO-Link interface. If the states DIGINPUT, DIGOUTPUT or OPERATE are exited, then the inputs are frozen at the most recently read value until valid data is able to be read from the device again.

4.26.8.8.5.3 Length of the I/O cycle

Name:
CycleLength01 to CycleLength04

The value in this register specifies how many X2X cycles are required on the respective interface for a the IO-Link process data to be completely updated.

The module automatically selects the best possible IO-Link cycle time per interface for the connected IO-Link device. This is always a multiple of the X2X cycle time. The cycle times of the 4 IO-Link interfaces are independent of one another.

Data type	Value
UINT	0 to 65535

4.26.8.8.5.4 Reading

Name:
DeviceID01 to DeviceID04

This register contains the IO-Link device ID assigned by the manufacturer. The device ID can be read for every IO-Link interface.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.8.8.5.5 Function ID

Name:
FunctionID01 to FunctionID04

This register contains the IO-Link function ID assigned by the manufacturer. The function ID can be read for every IO-Link interface.

Data type	Value
UINT	0 to 65535

4.26.8.8.5.6 IO-Link vendor ID

Name:
VendorID01 to VendorID04

This register contains the IO-Link vendor ID. The ID can be read for every IO-Link interface.

Data type	Value
UINT	0 to 65535

4.26.8.8.5.7 Cyclic input data

Name:
DataIn01_01 to DataIn01_27 (bus controller function model: up to xx01_04)
...
DataIn04_01 to DataIn04_27 (bus controller function model: up to xx04_04)

This register contains the cyclic input data for the respective interface.

Data type	Value
USINT	0 to 255

4.26.8.8.5.8 Cyclic output data

Name:
DataOut01_01 to DataOut01_30 (bus controller function model: up to xx01_04)
...
DataOut04_01 to DataOut04_30 (bus controller function model: up to xx04_04)

This register contains the cyclic output data for the respective interface.

Data type	Value
USINT	0 to 255

4.26.8.8.6 SIO mode

The IO-Link interface can be used like a digital input or output in SIO mode. To activate the SIO mode, the operating state must be set in the 4.26.8.8.5.1 "Control0x" register to DIGINPUT or DIGOUTPUT. Runtime configuration is not possible during operation in SIO mode, however the boot configuration can be used.

4.26.8.8.6.1 Digital input filter

Name:
ChInputFilter01 to ChInputFilter04

When used as a digital input, a filter time can be configured in this register. Valid values for the filter time are 0 and 2 to 250. A value of 0 will deactivate the filter. Other values specify the filter time as a multiple of 0.1 ms. The default value is 10 (= 1 ms).

Data type	Value	Filter
USINT	0	No software filter
	2	0.2 ms
	...	...
	250	25 ms - Higher values are limited to this value

4.26.8.8.6.2 Digital inputs

Name:
DigitalInput01 to DigitalInput04

These registers display the input states of the digital inputs individually for each channel.

Data type	Value
USINT	See bit structure.

Bit	Name	Value	Information
0	DigitalInput0x	0 or 1	Input state - Digital input x
1 - 7	Reserved	-	

4.26.8.8.6.3 Digital outputs

Name:
DigitalOutput01 to DigitalOutput04

These registers display the output states of the digital outputs individually for each channel.

Data type	Value
USINT	See bit structure.

Bit	Name	Value	Information
0	DigitalOutput0x	0	Digital output x reset
		1	Digital output x set
1 - 7	Reserved	-	

4.26.8.8.7 Parameter

IO-Link devices can provide user parameters. There are two ways to access these parameters:

- Boot configuration
- Runtime configuration

4.26.8.8.7.1 Boot configuration

The values specified by the user are transferred during the boot procedure (or when the IO-Link device is connected).

Up to 32 parameter values can be specified for each IO-Link interface. 1, 2, and 4 byte parameters are supported.

The boot configuration can be used in the operating states OPERATE, DIGINPUT and DIGOUTPUT.

The following specifications are necessary for parameters that should be set during the boot procedure:

Name	Range of values	Description
Index	0 to 65535	Parameter index according to device manufacturer's specifications
Subindex	0 to 255	Parameter sub index according to device manufacturer's specifications
Length	1, 2, 4	Length of data in bytes
Data	0 to 4,294,967,295	Data to be written. Only low-order bytes are used for 1 or 2 byte parameters.

4.26.8.8.7.2 Runtime configuration

The runtime configuration can also be made after the IO-Link device has booted up. Parameters can be read or written.

The runtime configuration can take place in the cyclic data or through acyclic communication (function blocks AsIOAccRd and AsIOAccWr).

Runtime configuration is available for interfaces in the OPERATE state.

The following specifications are necessary for accessing parameters:

Name	Range of values	Description
Interface	0, 1, 2, 3	Addressed interface of the module
Sequence number	0 to 15	A change to this value indicates a new task. The sequence number is set identically to the value of the request in the response message.
Index	0 to 65535	Parameter index according to device manufacturer's specifications.
Subindex	0 to 255	Parameter sub index according to device manufacturer's specifications.
Length	0 to 228 (229)	Length of data in bytes. Up to 228 bytes are supported for write access and 229 bytes for read access. The length does not have to be specified when requesting a read access (the device reports the length of the read data).
Data		IO-Link supports up to 228 (229) bytes of data each time a parameter is accessed. The length is limited to 1, 2 or 4 bytes in the cyclic data with boot configuration and runtime configuration. The full data range can be used with acyclic runtime configuration (AsIOAcc Library).
Read/write	0, 1	For the request to the IO-Link device. 0 → read 1 → write
Errors	0, 1	Defined in the response from the IO-Link device. 0 → No error occurred 1 → Error When an error occurs, the first two bytes of data are contained in the error code (the reported length is 2).
Sequence number	0 to 15	

Access to an IO-Link device's parameters occurs via a request and subsequent response from the device.

A new request is detected due to a changed sequence number. Therefore, the sequence number must be the last data item that is written.

The response contains the sequence number of the request.

The length is not relevant for a read request. It is automatically determined by the IO-Link device and reported in the response message.

If an error occurs (e.g. due to accessing an index or sub index that does not exist), this is signaled by a set error bit in the response. The error response always has a length of 2. These 2 bytes contain the manufacturer-specific error code.

4.26.8.8.8 Object directory access

Writing to the corresponding registers 4.26.8.8.8.4 "ParameterCmdOut" and 4.26.8.8.8.2 "ParameterCtrlOut" defines and sends an order for reading or writing an IO-Link object.

Procedure for sending an order

- Define register 4.26.8.8.8.4 "ParameterCmdOut" by entering the length, index and subindex
- During write access, write the required parameter data that is to be stored in the object directory to registers 4.26.8.8.8.6 "ParameterDataOut_0" to ParameterDataOut_57.
- Define register 4.26.8.8.8.2 "ParameterCtrlOut" by entering the interface number, read/write ID and the incremental sequence number. Additionally, an error bit can be configured during read access.

The module detects when the sequence number changes and accepts the order. Communication with the IO-Link device takes place.

When evaluating read/write access, the following is available from the register 4.26.8.8.8.1 "ParameterCtrlIn":

- Access sequence number
- Access interface number
- Type of access
- Payload length for read access to values smaller than 15 bytes
- Read access error bit

When evaluating read/write access, the following is available from the register 4.26.8.8.8.3 "ParameterCmdIn":

- Payload length for read access
- Access index and subindex

When evaluating read access, the following is available from the register 4.26.8.8.8.5 "ParameterDataIn_0" to ParameterDataIn_57:

- Values read/written

During write access, the sequence number in register 4.26.8.8.8.1 "ParameterCtrlIn" is only set to the written value when processing the order has been completed and the parameter data has been read from the object directory for the IO-Link device and entered in the registers 4.26.8.8.8.5 "ParameterDataIn_0" to ParameterDataIn_57.

A response provided by increasing the sequence number must be guaranteed (a timeout may be necessary for this purpose). That means, if the written sequence number from register 4.26.8.8.8.2 "ParameterCtrlOut" is accepted by register 4.26.8.8.8.1 "ParameterCtrlIn", then the application can safely assume that access has taken place.

Limit values for write/read access

- Index: 0 to 65535
- Subindex: 0 to 255
- Data length: 1 to 228 bytes for write access
- Data length: 1 to 229 bytes for read access

The resulting changes are written once to the IO-Link device without being temporarily saved on the module. That means, after disconnecting the IO-Link device, the values from the ODW registers are written back to the IO-Link device (see register 4.26.8.8.8.7 "ODW_Data_0" to ODW_Data_127).

4.26.8.8.8.1 Response to read/write access

Name:
ParameterCtrlIn

This register contains the response for dynamic read/write access of the object directory.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Sequence number	x	
4 - 7	Interface number	00	Interface 1
		01	Interface 2
		10	Interface 3
		11	Interface 4
8 - 11	Nutzdatenlänge	0000 to 1111	Number of bytes
12 - 13	Reserved	-	
14	Read / write	0	Read access
		1	Write access
15	Errors	0	No error
		1	Errors

Payload data length

The payload data length of the parameter access is copied by the module from the register 4.26.8.8.8.3 "ParameterCmdIn" (bit 24 to 27). Because this is a 4-bit value, the specification of the payload length is possible for a value with a maximum of 15 bytes. In the event that parameter sets larger than 15 bytes are accessed, the information about the number of bytes read during the parameter access must be taken from "ParameterCmdIn".

4.26.8.8.8.2 Configuration of dynamic read/write access

Name:
ParameterCtrlOut

This register is used to configure dynamic read/write access of the object directory.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Sequence number	x	
4 - 7	Interface number	00	Interface 1
		01	Interface 2
		10	Interface 3
		11	Interface 4
8 - 13	Reserved	-	
14	Read / write	0	Read access
		1	Write access
15	Error response (only defined for read access, this bit should be set to "0" for write access)	0	Inactive
		1	Active

4.26.8.8.8.3 Feedback from I/O object information

Name:
ParameterCmdIn

This register returns the number of bytes read during a read access.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 15	Object index being used	x	
16 - 23	Object subindex being used	x	
24 - 31	Number of bytes read	x	

4.26.8.8.8.4 Configuration of the I/O object information

Name:
ParameterCmdOut

This register is used to configure dynamic read/write access of the object directory.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 15	Object index	0 to 65535	
16 - 23	Object subindex	0 to 255	
24 - 31	Payload length in bytes	0 to 255	

4.26.8.8.8.5 Runtime parameter data read

Name:
ParameterDataIn_0 to ParameterDataIn_57

The corresponding parameter data is written to this register during read access of the object directory for the IO-Link device.

The length specified in register "ParameterCmdOut" determines how many 4-byte registers are read from the object directory for the IO-Link device and how many in the last byte are still valid.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.8.8.8.6 Runtime parameter data written

Name:
ParameterDataOut_0 to ParameterDataOut_57

The parameter data from this register is written during write access of the object directory for the IO-Link device.

The length specified in register 4.26.8.8.8.4 "ParameterCmdOut" determines how many 4-byte registers are written to the object directory for the IO-Link device and how many in the last byte are still valid.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.8.8.8.7 Boot parameter data

Name:
ODW_Data_0 to ODW_Data_127

This register contains parameter data for configuration of the IO-Link device.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.8.8.8 Boot I/O object information

Name:
ODW_Target_0 to ODW_Target_127

A write procedure on this register will transfer the parameter information from the corresponding ODW_Data register to the IO-Link device.

Example:

If the ODW_Target_0 register is written to, the parameter data from ODW_Data_0 is applied by the module and transferred to the object dictionary of the IO-Link device.

Unlike short-term access, the values are also stored in RAM on the module in order to be able to reload these parameters in the object directory for the IO-Link device when restarting the IO-Link device.

Information:

"ODW_Data" must be defined before "ODW_Target".

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 15	Object index	x	
16 - 23	Subindex	x	
24 - 27	Interface number	00	Interface 1
		01	Interface 2
		10	Interface 3
		11	Interface 4
28 - 30	Length in bytes	x	

4.26.8.8.9 Errors and warnings

Name:
ErrorsWarnings01 to ErrorsWarnings04

The counter is increased by one if the IO-Link device reports an error or warning.

An error is a fatal event if it causes an IO-Link device to lose its intended functionality. An error causes the IO-Link device to leave the OPERATE state (see section 4.26.8.8.5.2 "Operating state" on page 2784) and re-initialize.

The cause of a warning could be one-time communication disturbances. Warnings are events that deviate from normal operating behavior but do not necessarily result in loss of functionality. Several consecutively occurring warnings can result in an error.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Warning counter	x	Counts the errors that do not immediately lead to ending the communication with the IO-Link device
4-7	Error counter	x	Counts the errors that causes the IO-Link device to change from status "10 = cyclic data exchange" and be reinitialized

4.26.8.8.10 Event handling

If an event occurs on an IO-Link device, then the device retrieves it and stores the data in the following registers:

Register	Description
4.26.8.8.10.3 "EventPortSeq"	IO-Link device interface that triggered the event.
	Sequence number, incremented with each event
4.26.8.8.10.2 "Event description"	Event description: Instance, type and mode
4.26.8.8.10.1 "Event code"	Event code

The sequence number for the event counter is incremented by 1 with each event in order to notify the application. After the application has read the event data, the module has to use the 4.26.8.8.10.4 "EventQuit" register to signal that the values were retrieved from registers "EventQualifier" and "EventCode" and then the module can read the next event from IO-Link device. The value in register "EventPortSeq" is considered a correct acknowledgment value.

Events are available for interfaces in the OPERATE state. An event inhibit can also be set in Automation Studio. This is specified as a number of X2X Link cycles for an event before it can be overwritten by the next event. Events that occur during the inhibit time are cached on the module.

4.26.8.8.10.1 Event code

Name:
EventCode

This register is used to indicate the manufacturer-specific code for the IO-Link device.
In addition to manufacturer-specific codes, there are also the event codes specified for IO-Link in case the IO-Link device does not provide an EventCode.

Data type	Value	Information
UINT	0 to 65535	Event code
	0x34 / 0xFFF0	Invalid event from the IO-Link device
	0x54 / 0xFF80	IO-Link device message
	0x74 / 0xFF80	IO-Link device error
	0x74 / 0x6320	Parameter error
	0x70 / 0xFF10	Communication error

4.26.8.8.10.2 Event description

Name:
EventQualifier

IO-Link devices can generate events (including manufacturer-specific events). Information about the instance, type and mode of the event can be read from this register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Instance layer generated by the event	000	Unknown
		001	Hardware
		010	Data exchange layer for the IO-Link device
		011	Application layer for the IO-Link device
		100	Application
		101 to 111	Reserved
3	Reserved	-	
4 - 5	Type of event	00	Reserved
		01	Information
		10	Warning
		11	Errors
6 - 7	Mode of the event	00	Reserved
		01	One-time event
		10	Pending event is gone
		11	Pending event

4.26.8.8.10.3 Event interface

Name:
EventPortSeq

IO-Link devices can generate events (including manufacturer-specific events). Information about the interface that caused the event can be read from this register. By reading the sequence number, the application can determine if a new event has occurred. For this topic, see also 4.26.8.8.10 "Event handling".

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Interface	0	Interface 1
		1	Interface 2
		2	Interface 3
		3	Interface 4
		4 - 7	Reserved
4 - 7	Event counter	0 to 15	Sequence number is incremented with each new event that occurs

4.26.8.8.10.4 Acknowledge events

Name:
EventQuit

Register for acknowledging events so that the module can retrieve the next event. The event that has been read must be acknowledged with the value from register 4.26.8.8.10.3 "EventPortSeq".

Data type	Value
USINT	0 to 255

4.26.8.8.11 IO-Link cycle time

The I/O module automatically selects the best possible IO-Link cycle time per interface for the connected IO-Link device. This is always a multiple of the X2X cycle time. The cycle times of the 4 IO-Link interfaces are independent of one another. The module can read back which cycle time was selected for an IO-Link interface.

The minimum cycle time is 2.3 ms.

4.26.9 X20DS438A

4.26.9.1 General information

The module is an IO-Link master that can be used to connect intelligent sensors and actuators to the X20 system in accordance with the IO-Link standard. The module can operate up to 4 IO-Link devices. All IO-Link channels can be used as standard digital inputs or outputs.

- 4 IO-Link devices
- 4 digital channels, can be configured as input or output
- 24 VDC and GND for sensor/actuator supply

4.26.9.2 Order data

Model number	Short description	Figure
	Other functions	
X20DS438A	X20 digital signal module, 4x I/O-Link master V1.1, can also be configured as 4x digital input or output channels, 3-wire connections	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	

Table 647: X20DS438A - Order data

4.26.9.3 Technical data

Product ID	X20DS438A
Short description	
I/O module	IO-Link master with 4 IO-Link interfaces
General information	
B&R ID code	0xCAC0
Status indicators	IO-Link, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
IO-Link operating state	Yes, using status LED and software
C/Q status	Yes, using status LED and software
Cable specification	
Cable type	3-pin standard sensor cable, unshielded
Cable length	Max. 20 m
Line capacitance	Max. 3 nF
Loop resistance	Max. 6 Ω
Power consumption	
Bus	0.01 W
Internal I/O	0.71 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Bus - IO-Link	Yes
IO-Link - IO-Link	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
GOST-R	Yes
Sensor/Actuator supply	
Voltage	I/O supply minus voltage drop for short circuit protection
Voltage drop for short circuit protection at 0.5 A	Max. 0.3 V
Power consumption	Max. 12 W per IO-Link interface
Short circuit protection	Yes
Overload protection	
Turn-off delay	Configurable using software
Turn-off duration	Configurable using software
IO-Link in master mode	
Transfer rates	
COM1	4.8 kbaud
COM2	38.4 kbaud
COM3	230.4 kbaud
Limits for COM3	
Max. connection capacity	22 nF (cable + IO-Link device)
Max. load	96 Ω / 250 mA
Data format	1 start bit, 8 data bits, 1 parity bit (even), 1 stop bit
Bus level	24 VDC (active), 0 VDC (resting voltage)
IO-Link in master mode or in SIO mode "digital output"	
Design	Bipolar, positive and negative switching
Peak short circuit current	<1.3 A
Residual voltage	<0.7 VDC at nominal current 0.25 A
Switching voltage	I/O supply minus voltage drop for short circuit protection and semiconductor switch
Voltage drop on semiconductor switch	Max. 0.5 VDC at 0.25 A
Switching frequency	Typ. 25 kHz 300 kHz in IO-Link master mode
Switching delay	
0 -> 1	<10 µs
1 -> 0	<10 µs
Switching on after overload or short circuit cutoff	Configurable with software
Isolation voltage between IO-Link and bus	500 V_{eff}
IO-Link in SIO mode "digital output"	
Nominal voltage	24 VDC
Nominal output current	0.25 A
Total nominal current	Max. 1 A
Output circuit	Sink or source
Switching frequency (resistive load)	Max. 500 Hz
Output protection [2)]	Thermal cutoff if overcurrent or short circuit occurs, integrated protection for switching inductances
IO-Link in SIO mode "digital input"	
Nominal voltage	24 VDC
Input filter	
Hardware	300 ns
Software	-
Input circuit	Sink

Table 648: X20DS438A - Technical data

Product ID	X20DS438A
Input voltage	24 VDC -15 % / +20 %
Input current at 24 VDC	Typ. 4 mA
Input resistance	Typ. 6 kΩ
Switching threshold	
Low	<5 VDC
High	>15 VDC
Isolation voltage between IO-Link and bus	500 V_{eff}
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C
Derating	-
Storage	-40 to 85°C
Transport	-40 to 85°C
Relative humidity	
Operation	5 to 95%, non-condensing
Storage	5 to 95%, non-condensing
Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 terminal block separately, Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 648: X20DS438A - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) Interrupting current during overload: Between 0.3 A and 0.8 A.

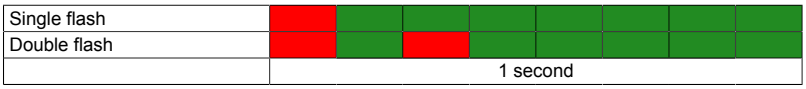
4.26.9.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

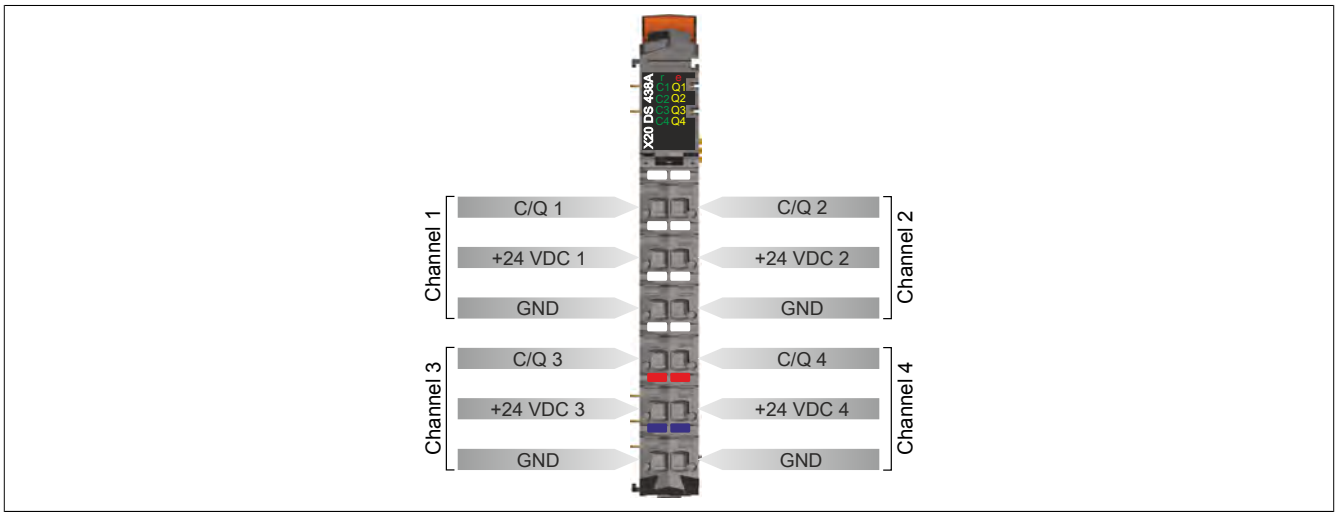
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			Double flash	BOOT mode (during firmware update)[1]
			On	OPERATE mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Double flash	One of the following errors has curred:
	C1 - C4	Red	On	Overload on the supply or on the channel's C/Q line
		Green/Red	Off	Interface in SIO mode
			Single flash	Channel in OPERATE mode, no IO-Link communication
			Double flash	Channel in OPERATE mode, error on inspection level
		Green	On	Channel in OPERATE mode, IO-Link communication active
	Q1 - Q4	Orange		Input/output state of corresponding IO-Link interface

1) Depending on the configuration, a firmware update can take up to several minutes.

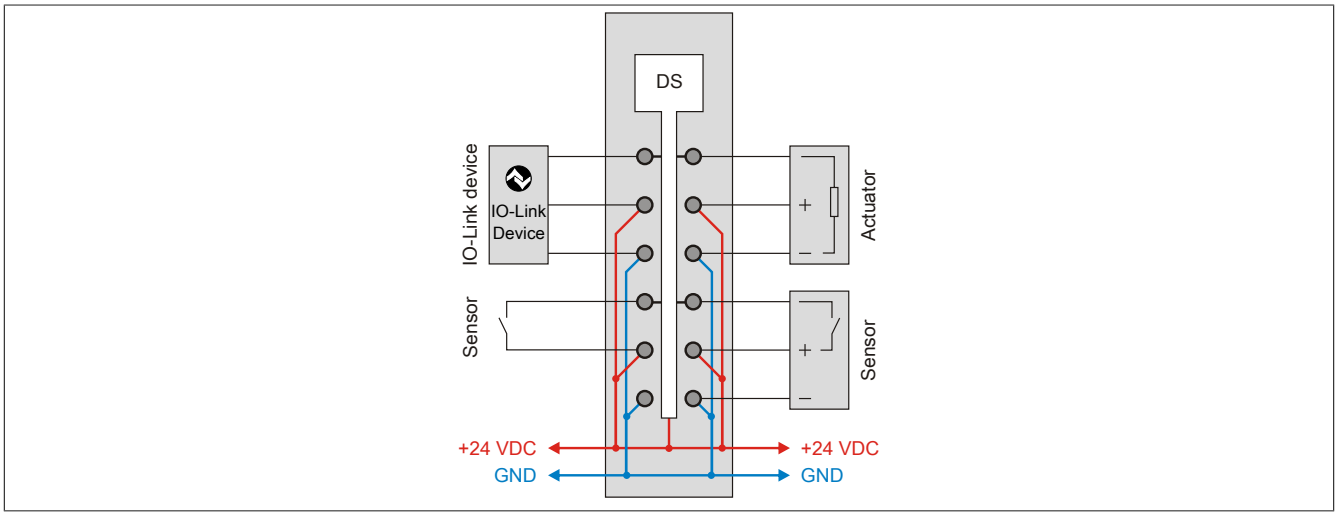
Blink times of LEDs C1 through C4 for single and double flash.



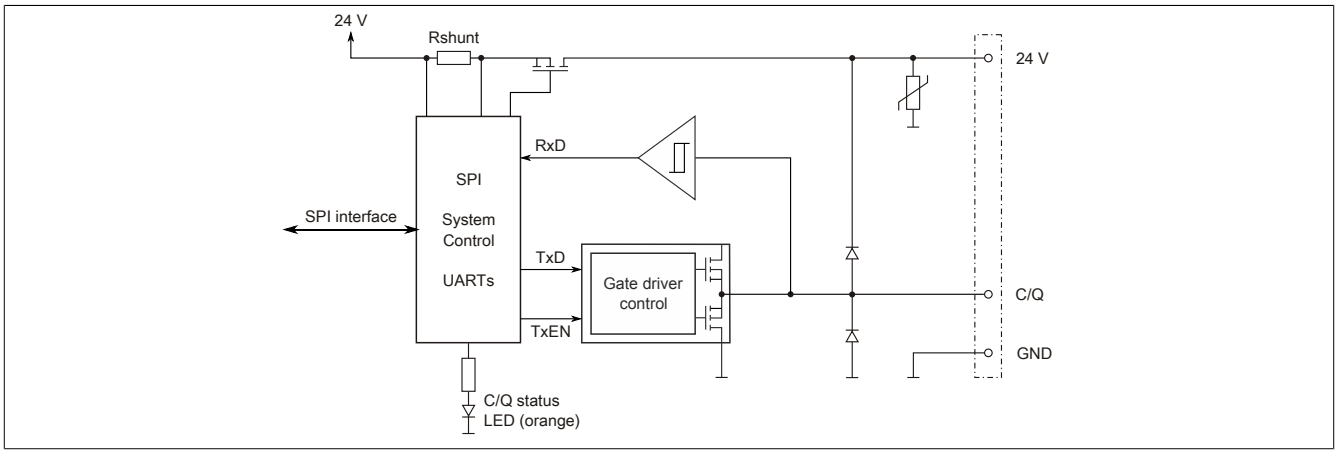
4.26.9.5 Pinout



4.26.9.6 Connection example



4.26.9.7 Input/output circuit diagram



4.26.9.8 SG3 support

This module does not support SG3 target systems.

4.26.9.9 Register description

4.26.9.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.9.9.2 Function model 0 - Standard

1) The offset specifies the position of the register within the CAN object.

4.26.9.9.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.26.9.9.4 General module properties

The module has the option of supplying power to IO-Link devices.
To prevent damage to hardware, each channel is monitored individually and equipped with its own overload protection. In this way, an overload in the power supply on one channel does not affect the other channels.

4.26.9.9.4.1 Configuring overload protection for the IO-Link supply

Name:
CfO_SupplyConfig

This register can be used to define how the module supply behaves for all channels when an overload occurs. The following rules apply:

- The overload duration (bits 6-7) corresponds to the time that the supply remains switched on after an overload is detected. The supply is only cut off if the overcurrent occurs for the entire time configured.
- The switch-off duration (bits 4-5) corresponds to the time that the supply remains switched off after a overload-related cutoff until it is switched back on.
  For this reason, an overload that occurs over a longer period can cause the module supply to cyclically switch on/off.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Reserved	-	
4 - 5	Switch-off duration after overload	00	5 ms
		01	20 ms
		10	50 ms
		11	Forbidden
6 - 7	Overload duration until error detection	00	1 ms
		01	4 ms
		10	10 ms
		11	Forbidden

4.26.9.9.4.2 OperatingMode

Name:
CfO_OperatingMode01 to CfO_OperatingMode04

This register is the same as the first bytes of the ChannelMode register in the IO-Link configuration.
It can be used to switch a channel's mode at runtime. The rest of the settings for the ChannelMode register are unchanged and continue to be used in the selected mode.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel mode	00	Mode: Inactive
		01	Mode: SIO output The channel's C/Q connector is configured as a digital output.
		10	Mode: SIO input The channel's C/Q connector is configured as a digital input.
		11	Mode: Operate The channel's C/Q connector is configured for IO-Link data transfer.
2 - 7	Reserved	-	

4.26.9.9.5 IO-Link - configuration

In order to establish communication between the module and IO-Link device, the ChannelMode register must be configured at least. Additional registers allow the data stream to be adjusted and the connected devices to be checked. This way, the IO-Link communication can be better adjusted to the user's requirements.

4.26.9.9.5.1 ChannelMode

Name:
CfO_ChannelMode01 to CfO_ChannelMode04

The user has the option of setting all channel-specific settings via this register.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel mode	00	Mode: Inactive
		01	Mode: SIO output The channel's C/Q connector is configured as a digital output.
		10	Mode: SIO input The channel's C/Q connector is configured as a digital input.
		11	Mode: Operate The channel's C/Q connector is configured for IO-Link data transfer.
2 - 7	Reserved	-	
8 - 9	Threshold value for overcurrent on the channel[1)] (OverCurrentThreshold in Automation Studio configuration)	00	250 mA
		01	125 mA
		10	75 mA
		11	50 mA
10 - 11	Reserved	-	
12 - 13	Switch-off duration after overload[1)] (OverloadOffTime in Automation Studio configuration)	00	20 ms
		01	12 ms
		10	6.4 ms
		11	32 ms
14 - 15	Reserved	-	
16 - 17	Synchronization mode	00	Free-wheeling (asynchronous)
		01	Synchronous (manual)
		10	Synchronous (automatic)
		11	Forbidden
18 - 19	Reserved	-	
20 - 23	Inspection level	0	Tests disabled
		1	Testing VendorID and DeviceID
24 - 25	IO-Link timestamp	00	No timestamp
		01	Input timestamp
		10	Output timestamp
		11	Input and output timestamps
26	Format of the IO-Link output timestamp[2)]	0	32-bit (DINT)
		1	16-bit (INT)
27 - 32	Reserved	-	

1) This is overload protection for the C/Q connector of the IO-Link channel (IO-Link data line or SIO output) as opposed to overload protection of the IO-Link supply.
2) This bit informs the module of the format used for the IoLinkTimestampOut output timestamp. In Automation Studio, this setting is made implicitly in the I/O configuration together with the selection of the data type for the IO-Link timestamp.

4.26.9.9.5.2 IdentificationVendorID

Name:
CfO_IdentificationVendorId01 to CfO_IdentificationVendorId04

If the Vendor ID is to be verified during startup, then the expected value must be specified in this register. The verification can be enabled by setting the inspection level in the ChannelMode register.

Information:

If the expected ID does not match the actual ID of the connected IO-Link device, communication will not be started for this channel.

Data type	Value
UINT	0 to 65535

4.26.9.9.5.3 IdentificationDeviceID

Name:
CfO_IdentificationDeviceId01 to CfO_IdentificationDeviceId04

If the device ID should be verified during startup, then the expected ID of the IO-Link device must be specified in this register. The verification can be enabled by setting the inspection level in the ChannelMode register.

Information:

If the expected ID does not match the actual ID of the connected IO-Link device, communication will not be started for this channel.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.9.9.5.4 PDI_TypeInfo

Name: CfO_PDI_TypeInfo01 to CfO_PDI_TypeInfo04

To transfer process data from the IO-Link device to the CPU (application), the information is first read from the module and saved temporarily. Typically, four bytes are reserved for each piece for registered information (see 4.26.9.9.9 "IO-Link process data").

This register can be used to configure how the incoming IO-Link process data stream (IO-Link frame) is divided up. According to this configuration, the IO-Link process data is made available to the application via the corresponding InputData registers. The input data registers are assigned to individual data points with the corresponding data type in the I/O mapping.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 to 3	IO-Link information 1	0000	Array[4] of Bytes
		0001	USINT
		0010	SINT
		0011	UINT
		0100	INT
		0101	UDINT
		0110	DINT
		0111	REAL
		1000 - 1111	Reserved
4 - 7	IO-Link information 2		Possible values are identical with IO-Link information 1
8 - 11	IO-Link information 3		
12 - 15	IO-Link information 4		
16 - 19	IO-Link information 5		
20 - 23	IO-Link information 6		
24 - 27	IO-Link information 7		
28 - 31	IO-Link information 8		

Information:

With setting 0 (Array[4] of Bytes), the bytes are copied from the IO-Link data stream unchanged. In all other modes, the byte order is changed (from big endian to little endian).

4.26.9.9.5.5 PDO_TypeInfo

Name: CfO_PDO_TypeInfo01 to CfO_PDO_TypeInfo04

To transfer process data to an IO-Link device, this register can be used to configure which data types of the individual OutputData registers are used to put together the outgoing IO-Link process data stream (IO-Link frame, see 4.26.9.9.9 "IO-Link process data"). According to this configuration, OutputData registers are assigned to data points with the corresponding data types in Automation Studio (I/O mapping).

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 to 3	IO-Link information 1	0000	Array[4] of Bytes
		0001	USINT
		0010	SINT
		0011	UINT
		0100	INT
		0101	UDINT
		0110	DINT
		0111	REAL
		1000 - 1111	Reserved
4 - 7	IO-Link information 2		Possible values are identical with IO-Link information 1
8 - 11	IO-Link information 3		
12 - 15	IO-Link information 4		
16 - 19	IO-Link information 5		
20 - 23	IO-Link information 6		
24 - 27	IO-Link information 7		
28 - 31	IO-Link information 8		

Information:

With setting 0 (Array[4] of Bytes), the bytes are copied from the IO-Link data stream unchanged. In all other modes, the byte order is changed (from big endian to little endian).

4.26.9.9.5.6 Timing of IO-Link communication

At runtime, the module needs to manage data sets from 2 different communication standards. For efficient X2X Link communication, it is important to make sure that the cycle time of all X2X modules is the same as the bus cycle time.

Cycle times specified in IO-Link

The IO-Link specification defines the timing cycle for polling an IO-Link device. This cycle is called the IO-Link cycle. Valid IO-Link cycle times range from 0.4 ms to 132.8 ms. There are three ranges:

Area	Increment	Calculation	Valid cycle times
0.4 to 6.3 ms	0.1 ms	Cycle time = 0.1 ms * n + 0.4 ms	0.4, 0.5, 0.6 to 6.2, 6.3 ms
6.4 to 32.6 ms	0.4 ms	Cycle time = 0.4 ms * n + 6.4 ms	6.4, 6.8, 7.2 to 32.2, 32.6 ms
32.0 to 132.8 ms	1.6 ms	Cycle time = 1.6 ms * n + 32.0 ms	32.0, 33.6, 35.2 to 131.2, 132.8 ms

Module timer

An internal module timer that applies globally to all channels serves as the bases for synchronizing the individual channels. Using this defined time basis, X2X and IO-Link communication can be synchronized with each other. The period duration for the module timer can be defined in µs. To make communication as efficient and deterministic as possible, the module timer is configured in automatic mode to match the X2X Link cycle time by default. If necessary, the start of the module timer can be offset using the TimerOffset.

The module timer's cycle is synchronized automatically with the X2X cycle. Depending of the ratio between the X2X and module timer cycle time, there may be different ratios between the cycles.

Examples

1 to 1	(X2X cycle 1000, cycle timer 1000)	→ Always exactly one timer cycle per X2X cycle
2 to 1	(X2X cycle 2000, cycle timer 1000)	→ Always exactly two timer cycles per X2X cycle
1 to 2	(X2X cycle 1000, cycle timer 2000)	→ Always exactly one timer cycle per 2 X2X cycles
3 to 5	(X2X cycle 1500, cycle timer 2500)	→ Always exactly 3 timer cycles per 5 X2X cycles

Synchronous operation

Unlike to free-running operation, synchronous mode and the synchronization cycle time in this operating mode can be configured individually for each channel.

The SYNCHRONIZED operating mode optimizes the interaction between X2X and IO-Link communication. The module's resources were designed for this mode, so this configuration should be used for the module's channels.

- In the mode SYNCHRONIZED (automatic), the module calculates the necessary timing parameters itself. An IO-Link cycle is set that complies with the IO-Link specification. The selected IO-Link cycle time corresponds to the lowest possible multiple of the module timer cycle time that meets the following conditions:
  - Valid IO-Link cycle time
  - Greater than or equal to the minimum cycle time on the device
- In the mode SYNCHRONIZED (manual), the user can configure the module's timing manually. Both the synchronization cycle time and the IO-Link cycle can be defined manually by setting a factor.

Synchronization cycle time

Synchronization cycle time = Timer cycle time * CfO_ReqCycleMultiple0x

The synchronization ensures that synchronization cycles run parallel with the same synchronization cycle time and are not offset by timer cycles.

IO-Link cycle time

IO-Link cycle time = Synchronization cycle time / CfO_ReqCycleDivisor0x

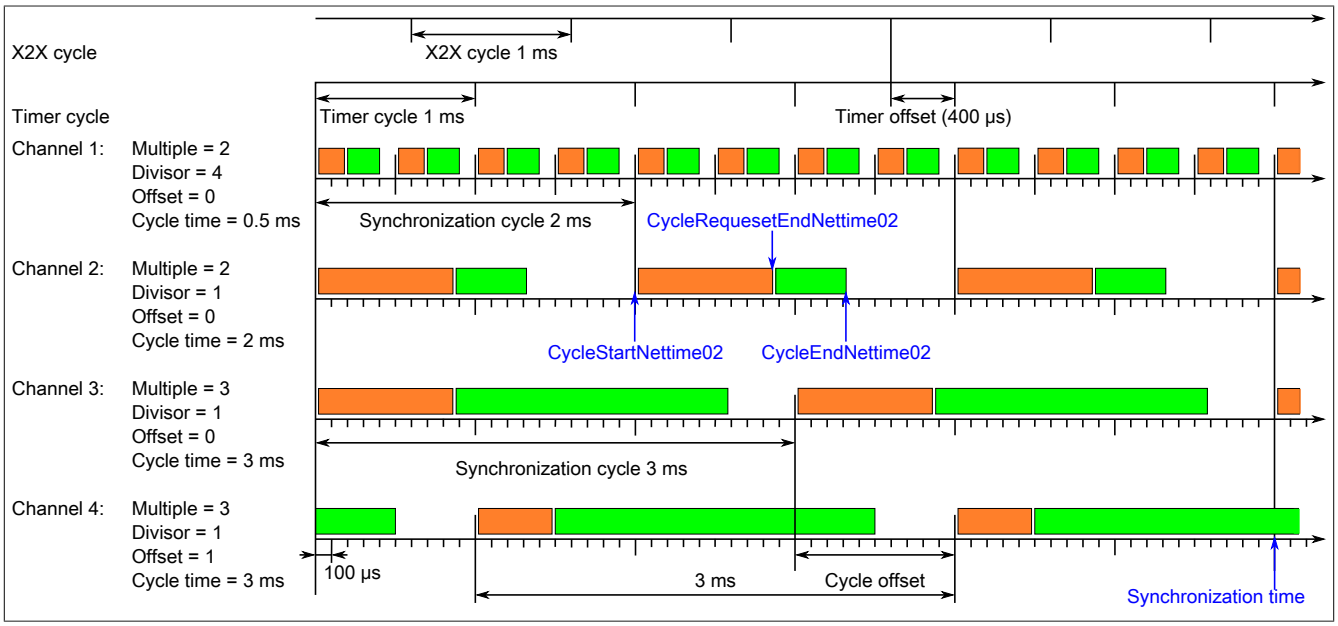
The IO-Link cycle is set individually for each channel. If necessary, the IO-Link cycle of a channel can be offset using a channel-specific offset. This allows channels to be adjusted so that their queries end at the same time, for example.
With very short cycle times (<1 ms) it is possible that the data cannot be processed fast enough. When this happens, the subsequent cycles are delayed, which is indicated by the status bit for synchronization being reset.

Information:

If the IO-Link cycle is configured to be less than the device's minimum cycle time, then a cycle that meets the following conditions is selected automatically:

- **Multiple of the module timer cycle**
- **Valid IO-Link cycle time**
- **Greater than or equal to the minimum cycle time on the device**

Example of a configuration



The module timer in this example

- The duration of the module timer period was not defined explicitly. In this case, it corresponds to the X2X Link cycle time.
- An offset of 400 µs was applied to the module timer; i.e. the module timer cycle begins 400 µs after the X2X Link cycle.

IO-Link communication in this example

- The parameters Multiple and Divisor produce a channel-specific cycle time for IO-Link communication.
- Channels 1 and 2 have a shared synchronization cycle of 2 ms.
  Channels 3 and 4 have a shared synchronization cycle of 3 ms, which is shifted due to the offset.
- Channels start their query together at the beginning of a shared synchronization cycle.
- The IO-Link cycle of the fourth channel was delayed with an offset of 1 ms.
- All channels have a shared synchronization cycle of 6 ms.

Free-running (asynchronous) mode

If the IO-Link and X2X cycle times cannot be synchronized, then the IO-Link cycle time can be defined explicitly. IO-Link communication then runs independently of the module timer and X2X cycle. Except for CycleEndNettime, no other net time data points can be used. The cycle times of free-running IO-Link channels are defined directly via the corresponding registers. However, deviations may occur if the module's resources are exhausted.

TimerCycle

Name:
CfO_TimerCycle

This register can be used to configure synchronous IO-Link communication. If the module timer is not meant to be operated with the same cycle, then it is possible to define the period length of the module timer in µs using this register. This allows channels to be synchronized with one another even if using a very unusual X2X cycle time.

Data type	Value
UDINT	0 to 4,294,967,295

TimerOffset

Name:
CfO_TimerOffset

This register can be used to configure synchronous IO-Link communication. If the module timer should run with a timing offset to X2X Link, this register can be used to define how many microseconds in front of or behind the module timer should be shifted.

Data type	Value
INT	-32768 to 32767

ReqCycleMultiple

Name:
CfO_ReqCycleMultiple01 to CfO_ReqCycleMultiple04

This register can be used to manually configure the synchronization cycle time. This cycle time can be used together with the ReqCycleDivisor register to define the IO-Link cycle time. See Synchronous operation for an example.

Information:

If this register is not defined for an IO-Link channel or predefined with zero, the values of the CycleMultiple and CycleDivisor registers are calculated automatically when the module is started.

Data type	Value
UINT	0 to 65535

ReqCycleDivisor

Name:
CfO_ReqCycleDivisor01 to CfO_ReqCycleDivisor04

This register can be used together with ReqCycleMultiple to define the IO-Link cycle time. See Synchronous operation for an example.

Information:

If this register is not defined for an IO-Link channel or predefined with zero, the values of the CycleMultiple and CycleDivisor registers are calculated automatically when the module is started.

Data type	Value
UINT	0 to 65535

ReqCycleOffset

Name:
CfO_ReqCycleOffset01 to CfO_ReqCycleOffset04

This register can be used to offset the IO-Link cycle of a channel with the synchronization cycle.
This offset may be sensible if all channels are running with the same cycle time. In this case, all channels are finished at the same time, which could result in the module not being able to process all data in time. Offsets can be used to prevent these sorts of bottlenecks so that data traffic can be divided up more evenly.

Data type	Value	Information
UINT	0 to 65535	Configured in timer cycles

ReqCycleTime

Name:
CfO_ReqCycleTime01 to CfO_ReqCycleTime04

This register is used with free-running (asynchronous) IO-Link communication. It contains the explicitly defined cycle time for the IO-Link query in µs.

Information:

- **In free-running mode, no net time data points are permitted to be used except for CycleEnd-Nettime.**
- **If the cycle time predefined for IO-Link communication falls below the device's minimum cycle time, the IO-Link data is queried using the device's minimum cycle time.**
- **For efficient IO-Link communication, the configured query time should correspond to the specified IO-Link cycle times. If a value is unsuitable, the next suitable cycle time is used automatically.**

Data type	Value	Information
UINT	0 to 65535	In 100 µs steps

4.26.9.9.6 IO-Link - General

The following registers are used for general communication. They are mainly used for repair status and runtime control.

4.26.9.9.6.1 Digital SIO outputs

Name:
DigitalOutput01 to DigitalOutput04
DisablePowerSupply01 to DisablePowerSupply04

If a channel is being operated in SIO mode (SIO output), this register can be used to control the SIO output of the IO-Link channel. It is also possible switch on/off the supply for each IO-Link channel individually.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalOutput01	0	Reset digital SIO output 01
		1	Set digital SIO output 01
...		...	
3	DigitalOutput04	0	Reset digital SIO output 04
		1	Set digital SIO output 04
4	DisablePowerSupply01	0	Switch on supply for IO-Link channel 01
		1	Switch off supply for IO-Link channel 01
...		...	
7	DisablePowerSupply04	0	Switch on supply for IO-Link channel 04
		1	Switch off supply for IO-Link channel 04

4.26.9.9.6.2 Digital SIO inputs

Name:
DigitalInput01 to DigitalInput04

If a channel is being operated in SIO mode (SOI input), this register can be used to read the input status of the channel.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	DigitalInput01	0	Reset digital SIO input 01
		1	Set digital SIO input 01
...		...	
3	DigitalInput04	0	Reset digital SIO input 04
		1	Set digital SIO input 04
4 - 7	Reserved	-	

4.26.9.9.6.3 Sync (status byte)

Name:
Synchronized01 to Synchronized04
CycleEnd01 to CycleEnd04

The module uses this status register to report whether error-free communication with the device was possible during the last module cycle.

- The CycleEnd bits indicate whether the last data transmitted to the IO-Link device has been processed. The CycleEnd bits are reset after each X2X cycle.
- The synchronized bits indicate that the channel is synchronized without errors.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Synchronized01	0	Synchronization for channel 1 not OK
		1	Synchronization for channel 1 OK
...		...	
3	Synchronized04	0	Synchronization for channel 4 not OK
		1	Synchronization for channel 1 OK
4	CycleEnd01	0	I/O cycle end: No new IO-Link data
		1	I/O cycle end: New data transmitted and received
...		...	
7	CycleEnd04	0	I/O cycle end: No new IO-Link data
		1	I/O cycle end: New data transmitted and received

4.26.9.9.6.4 Overload (status byte)

Name:
Overload01 to Overload04

This status register is used by the module to report whether an overload in the form of overcurrent or overtemperature occurred in the channel supply.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Overload01	0	Channel 1: No overload
		1	Channel 1: Overload
...		...	
3	Overload04	0	Channel 4: No overload
		1	Channel 4: Overload
4 - 7	Reserved	-	

4.26.9.9.6.5 ChannelStatus

Name:
ChannelStatus01 to ChannelStatus04

This register is used to show the current status of the IO-Link channel.

Data type	Value	Information	Status
USINT	0	Channel inactive	Disabled
	1	Use as digital SIO output	SIO mode
	2	Use as digital SIO input	
	3	Startup of IO-Link device, PREOPERATIONAL mode	Communication is running but no process data is exchanged. However, acyclic access is also possible.
	4	Operation, OPERATE mode	Communication is running
	5	Operation, parameter server data OK	
	6	Parameter server: Upload active	Communication is running and process data is being returned.
	7	Parameter server: Download active	
	8	Parameter server: Deleting active	
	9	IODD parameters are written	
	10 to 19	Reserved	
	21	General error in the parameter server. For example: • Parameter server not supported • Error accessing an object that is managed by the parameter server • Internal error	Communication is running. However, an error has occurred on the parameter server. Parameter server errors can be acknowledged via the DsControl register.
	22	Parameter server locked by IO-Link device	
	23	Parameter server empty: Tried to load data to the IO-Link device even though no data is saved in EEPROM	
	24	New serial number recognized: The user must decide via the DsControl register what has to be done (Upload – Download – Restore default values)	
	25	Parameter server not compatible (new DeviceID or new VendorID recognized): The data in EEPROM is not suitable for the connected IO-Link device. The user must decide via the DsControl register whether an upload should be carried out.	
	26	Upload request received. The user must decide via the DsControl register what must be done (Upload – Download – Restore default values).	
	27	The parameter checksum of the IO-Link device has changed: The user must decide via the DsControl register what must be done (Upload – Download – Restore default values).	
	28	Error when sending the SAVE command	
	29	Reserved	
	30	Process data invalid	Communication is running. However, process data was marked as invalid by the device.
	31 - 39	Reserved	
	40	No connection	No communication
	41	Reserved	
	42	The DeviceID and VendorID of the connected IO-Link device do not match the predefined IDs.	Communication is running but no process data is exchanged. However, acyclic access is also possible.
	43	Reserved	
	44	Timestamp error The IO-Link device does not support IO-Link timestamps.	
	45	Error starting up the device	No communication
	46 to 255	Reserved	

4.26.9.9.6.6 FrameCount

Name:
FrameCount01 to FrameCount04

Received IO-Link frames are counted in this register. Unlike the sync bits, the FrameCount register ensures that all frames are actually recognized. This is the case even if X2X cycles are lost or if the IO-Link cycle is faster than the X2X cycle.

Data type	Value
SINT	-128 to 127

4.26.9.9.6.7 CycleStartNettime

Name:
CycleStartNettime01 to CycleStartNettime04

This register can be used to read out the value of the net time at the start of the last IO-Link cycle.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.26.9.9.6.8 CycleEndNettime

Name:
CycleEndNettime01 to CycleEndNettime04

This register can be used to read out the value of the net time at the end of the last IO-Link cycle.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.26.9.9.7 IO-Link data storage

The parameter server

If supported by the IO-Link device, the IO-Link parameter server can be used to read the application-specific device configuration from the IO-Link master, for example. The parameter server of the module is generally activated and can be used with the help of a controller register.

Which data storage parameters are transferred depends on the connected IO-Link device. The read information is stored in EEPROM on the DS module and can be fed back automatically after replacing the device, for example.

The module is capable of processing the data storage upload request (event code 0xFF91) of the IO-Link specification. The request is usually triggered if parameters on the device are changed. In this case, depending on the configuration, an upload of data storage data can be started (standard).

Automatic management of data storage parameters

Automatic management has been designed according to IO-Link specification. Since the IO-Link standard exhibits a degree of tolerance here, it is possible that some IO-Link devices may have to be handled differently. This can be configured using the 4.26.9.9.7.3 "CfO_DS_Config" register.

An upload/download is performed under the following conditions:

- DsControl0x = 1
- When the device is being started up or if a data storage upload requirement has been received.

Offline configuration

With offline configuration, the configuration data set up for the device in Automation Studio is stored in the project. This data is then used to configure the CPU automatically when the project is downloaded or data is generated for the memory card. In contrast to the parameter server, where values are read from an existing device, the values in this case are defined explicitly in the application. The values are automatically configured only one time after the download. This procedure only occurs again if a new parameter file is received from Automation Studio, the device is replaced or if the download is started manually by the library.

This function works independently of the parameter server. If the parameter server is still enabled, however, it can be started as needed after the offline configuration to store the corresponding data. In the event of a replaced device, the data can be loaded to the device from the parameter server.

4.26.9.9.7.1 DsControl

Name:
DsControl01 to DsControl04

This register can be used to control the parameter server manually. Each action is carried out exactly once when the corresponding value is set. If the same action should be executed multiple times, then this register must be set to the value 0 beforehand.

Data type	Value	Information
USINT	0	No action
	1	Operating mode of the parameter server: Automatic upload and download
	2	Upload if data storage parameters are available on the device
	3	Download if data storage parameters are available in the CPU's memory and the device can process them
	4	Acknowledge error status from parameter server (see 4.26.9.9.6.5 "ChannelStatus": error messages 21 to 28)
	5	Delete data storage parameters on the CPU's memory
	6	Start dummy upload. Starts an upload without saving the data. This can be used to acknowledge an upload request.
	7 to 255	Reserved

4.26.9.9.7.2 DsProgress

Name:
DsProgress01 to DsProgress04

The module uses this register to report the progress of the upload or download from the parameter server. The values from 0 to 100 can be used for implementing a progress display.

Data type	Value
USINT	0 to 100

4.26.9.9.7.3 CfO_DS_Config

Name:
CfO_DS_Config01 to CfO_DS_Config04

This register can be used to set the behavior of the parameter server module (when operating the parameter server manually). By doing this, a corresponding reaction is assigned to every trigger event.

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Event	Value	Reaction
0 - 3	The device ID of the connected device no longer matches the device ID saved together with the parameters.	000	No response
		001	Cancel
		010	User-defined reaction. See 4.26.9.9.6.5 "ChannelStatus": Status message 25
		011	Upload (default value)
4 - 7	The device transmitted an upload request.	000	No response
		001	Cancel
		010	User-defined reaction. See 4.26.9.9.6.5 "ChannelStatus": Status message 26
		011	Upload (default value)
8 - 11	A new parameter checksum was detected when starting the device.	000	No response
		001	Cancel
		010	User-defined reaction. See ChannelStatus: Status message 27
		011	Upload
		100	Download (default value)
12 - 15	The serial number of the connected device no longer matches the serial number saved together with the parameters.	000	No response
		001	Cancel
		010	User-defined reaction. See ChannelStatus: Status message 24
		011	Upload
		100	Download (default value)
16 - 23	Reserved	-	
24 - 26	Specifies the order that individual events are checked	000	DeviceID, serial number, upload request, parameter checksum (default value)
		001	DeviceID, serial number, parameter checksum, upload request
		010	DeviceID, upload request, parameter checksum, serial number
		011	DeviceID, upload request, serial number, parameter checksum
		100	DeviceID, parameter checksum, upload request, serial number
		101	DeviceID, parameter checksum, serial number, upload request
27 - 31	Reserved	-	

4.26.9.9.7.4 CfO_DS_SaveCtrl

Name:
CfO_DS_SaveCtrl01 to CfO_DS_SaveCtrl04

This register is used together with 4.26.9.9.7.5 "CfO_DS_SaveData".

Some IO-Link devices must be instructed to save transferred data storage parameters in remanent memory after a download. In order for these parameters to be applied to remanent memory on these devices, the recorded index and subindex in these registers must be sent together with the save command (e.g. value 163 on index 2, subindex 0).

Data type	Value
UDINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 15	Index	0 to 255	Device-specific index for save command
16 - 24	Subindex	0 to 255	Device-specific subindex for save command
24 - 26	Data length	0	Save command disabled
		1 to 4	The data length of the save command estimated by the device in bytes
27 - 31	Reserved		

4.26.9.9.7.5 CfO_DS_SaveData

Name:
CfO_DS_SaveData01 to CfO_DS_SaveData04

This register is used together with 4.26.9.9.7.4 "CfO_DS_SaveCtrl" and contains the value written to the index configured in the CfO_DS_SaveCtrl register.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.9.9.8 IO-Link timestamp

The IO-Link timestamp register allows the relation of IO-Link timestamps to the net time of a controller, and vice versa.

This makes it possible to relate the times of value changes of the IO-Link device exactly to the net time of the controller, and vice versa. Events can be captured or triggered with a higher timing resolution than would be possible with the IO-Link cycle. This allows a highly precise timed response from the controller to signals from the sensor, and vice versa. The resolution depends on the devices being used.

Examples

- For an input device, the timestamp is saved directly by the device when a certain event occurs (e.g. photo-electric sensor triggered) and then transferred via IO-Link. The IO-Link master converts this IO-Link-specific timestamp to a net time timestamp that can be used across the system.
- In the output direction, a converted timestamp is transferred to the device via IO-Link. The output device responds at the corresponding instant and executes the intended event (e.g. closes a switch).

Information:

- **The timestamp function is device-specific and not supported by every IO-Link device.**
- **This function cannot be used if the channel is being operated in free-running mode (asynchronous).**

4.26.9.9.8.1 IoLinkTimestampIn

Name:
IoLinkTimestampIn01 to IoLinkTimestampIn04

This register indicates the net time instant at which the application event occurred.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.26.9.9.8.2 IoLinkTimestampInStatusSeq

Name:
IoLinkTimestampInStatusSeq01 to IoLinkTimestampInStatusSeq04

This register indicates information about the timestamp input.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Sequence number	0 to 15	The sequence number is increased by 1 each time a valid timestamp is received. If the sequence number is increased by more than 1, it means that the event was lost.
4	Event 1 triggered by application	x	Signal state when timestamp occurs
5	Event 2 triggered by application	x	Signal state when timestamp occurs **Example:** Signal state when timestamp occurs – Photoelectric sensor triggered → This bit = 0 – Photoelectric sensor not triggered → This bit = 1
6	Reserved	-	
7	Timestamp error	0	No error
		1	An error occurred on the IO-Link device. Possible causes: • More timestamps were generated than could be transferred. • The value of the IO-Link timestamp exceeded the permitted range of values. In both cases, it may help to reduce the IO-Link cycle time.

4.26.9.9.8.3 IoLinkTimestampOut

Name:
IoLinkTimestampOut01 to IoLinkTimestampOut04

The user can write the net time for the output timestamp to this register.
The net time is automatically converted to an IO-Link timestamp. The event is triggered at the defined net time. The IoLinkTimestampOutStatus register is used for acknowledgment.

Information:

The net time must be at least three IO-Link cycles in the future; otherwise, a warning is set in IoLinkTimestampOutStatus.

This register's data type must match the format configured in register 4.26.9.9.5.1 "ChannelMode", bit 26.

Data type	Value
INT	-32,768 to 32,767
DINT	-2,147,483,648 to 2,147,483,647

4.26.9.9.8.4 IoLinkTimestampOutCtrlSeq

Name:
IoLinkTimestampOutCtrlSeq01 to IoLinkTimestampOutCtrlSeq04

This register is used to control how the timestamp is applied.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Sequence number	0 to 15	Output timestamp and application event bits applied when the sequence number is increased by 1
4	Application event 1	x	Output state at the timestamp
5	Application event 2	x	Output state at the timestamp
6	Acknowledge warning	0	Do not acknowledge
		1	Acknowledge warning
7	Acknowledging errors	0	Do not acknowledge
		1	Acknowledging errors

4.26.9.9.8.5 IoLinkTimestampOutStatus

Name:
IoLinkTimestampOutStatus01 to IoLinkTimestampOutStatus04

This register is used to show the status of the timestamp output.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Acknowledgment of sequence number	0 to 15	When an output timestamp has been successfully applied, then the sequence number from IoLinkTimestampOutCtrlSeq is acknowledged here.
4 - 5	Reserved	-	
6	Warning	0	No warning
		1	A timestamp was not at least 3 cycles in the future, so output may be delayed.
7	Errors	0	No error
		1	More timestamps were transferred to the module than could be output.

4.26.9.9.9 IO-Link process data

The input or output data stream of IO-Link process data can be broken down into any structure. The structure is configured as follows:

- The firmware provides 8 32-bit registers for each channel to allow the mapping of maximum 32 bytes of IO-Link process data.
- The I/O configuration sets the type with which the register should be registered. So that the length is correct, the PDI_TypeInfo register (for input data) or PDO_TypeInfo register (for output data) is used to configure how many bytes of the IO-Link data stream should be copied to the register, or vice versa.

Limitations:

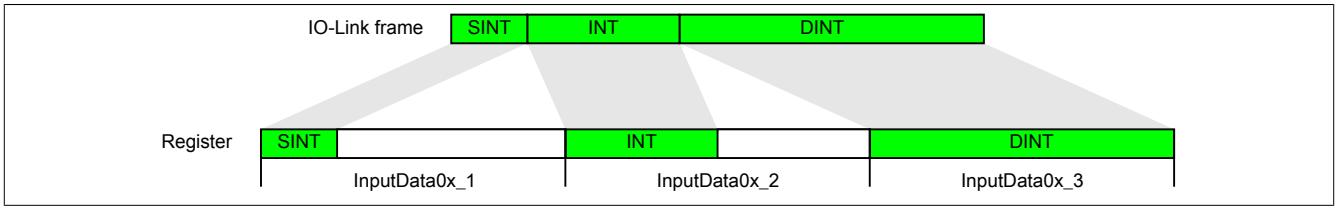
8 registers with 32 bits are available per channel. This makes it possible to register any 8 data points in this way. If this is not sufficient, it is also possible to use a byte array. The user then has to make sure that the bytes are divided up into the necessary data types.

Information:

With a bit array, it is important that the byte arrangement is correct within the register. The module DOES NOT make any necessary conversions from big-endian to little-endian or reverse.

Example

Dividing up elements from an IO-Link data stream into multiple 32-bit registers:



4.26.9.9.9.1 OutputData

Name:
OutputData01_1 to OutputData04_8

Output data from the IO-Link device in IO-Link communication mode. A byte array is also a possible alternative. The user then has to make sure that the bytes are divided up into the necessary data types.
The PDO_TypeInfo register can be used to configure how many bytes should be applied to the IO-Link frame from the output registers.

Data type	Value
USINT	0 to 255
SINT	-128 to 127
UINT	0 to 65535
INT	-32,768 to 32,767
UDINT	0 to 4,294,967,295
DINT	-2,147,483,648 to 2,147,483,647
REAL	-3.4E38 – 3.4E38

4.26.9.9.9.2 InputData

Name:
InputData01_1 to InputData04_8

Input data from the IO-Link device in IO-Link communication mode. A byte array is also a possible alternative. The user then has to make sure that the bytes are divided up into the necessary data types.

Data type	Value
USINT	0 to 255
SINT	-128 to 127
UINT	0 to 65535
INT	-32,768 to 32,767
UDINT	0 to 4,294,967,295
DINT	-2,147,483,648 to 2,147,483,647
REAL	-3.4E38 – 3.4E38

4.26.9.9.10 IO-Link information data

The IO-Link information data is used to read device-specific values as well as to check the IO-Link configuration. It is only possible to read the following registers.

4.26.9.9.10.1 VendorId

Name:
VendorId01 to VendorId04

This register contains the unique vendor ID of the IO-Link device.

Data type	Value
UINT	0 to 65535

4.26.9.9.10.2 DeviceId

Name:
DeviceId01 to DeviceId04

This register contains the unique ID of the IO-Link device.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.9.9.10.3 FunctionId

Name:
FunctionId01 to FunctionId04

This register contains the device's function class provided by the vendor.

Data type	Value
UINT	0 to 65535

4.26.9.9.10.4 CycleTime

Name:
CycleTime01 to CycleTime04

Some IO-Link devices cannot handle high-speed cycles and require a higher cycle time. This register can be used to read back the channel's IO-Link cycle time currently being used. The time used for communication is always a multiple of 100 µs, e.g. 50 for 5 ms cycle time.

Data type	Value	Information
UINT	0 to 65535	Specified in 100 µs steps

4.26.9.9.10.5 CycleMultible

Name: CycleMultible01 to CycleMultible04

This register can be used to read back the multiplicator currently being used for the channel's IO-Link cycles.

Data type	Value
UINT	0 to 65535

4.26.9.9.10.6 CycleDivisor

Name:
CycleDivisor01 to CycleDivisor04

This register can be used to read back the divisor currently being used for the channel's IO-Link cycles.

Data type	Value
UINT	0 to 65535

4.26.9.9.10.7 MinCycleTime

Name:
MinCycleTime01 to MinCycleTime04

This register can be used to read back the minimum IO-Link cycle time. The minimum IO-Link cycle time depends on the IO-Link device and is read from the module after establishing communication with the IO-Link device.

Data type	Value
UINT	0 to 65535

4.26.9.9.10.8 PDI_Size

Name:
PDI_Size01 to PDI_Size04

This register can be used to read back the size of the input process data defined by the device. This value is read when starting up the IO-Link device.

Data type	Value
USINT	0 to 255

4.26.9.9.10.9 PDO_Size

Name:
PDO_Size01 to PDO_Size04

This register can be used to read back the size of the output process data defined by the device. This value is read when starting up the IO-Link device.

Data type	Value
USINT	0 to 255

4.26.9.9.10.10 Baud rate

Name:
Baudrate01 to Baudrate04

This register can be used to read back the baud rate defined by the IO-Link device. This value is read when starting up the IO-Link device.

Data type	Value	Information
USINT	1	COM1 = 4.8 kbit/s
	2	COM2 = 38.4 kbit/s
	3	COM3 = 230.4 kbit/s

4.26.9.9.10.11 IoLinkVersionID

Name:
IoLinkVersionID01 to IoLinkVersionID04

This register can be used to read back the IO-Link version.

Data type	Value	Information
USINT	16 (= 0x10)	V1.0
	17 (= 0x11)	V1.1

4.26.9.9.11 Event interface

IO-Link devices are able to send events that can be retrieved using cyclic data points. The events are written to a FIFO buffer that has space for up to 16 elements. If events are not retrieved or more than 16 events take place, then the oldest event is automatically discarded.

Sequence for reading an event

- A new event was triggered by the device. This is indicated by an increase in EventPortSeq.
- Event data can be read using the EventQualifier and EventCode registers.
- The event must be acknowledged. To do so, the sequence number from EventPortSeq must be copied to the sequence number from EventQuit.
- The next event is specified only after the event is acknowledged.

4.26.9.9.11.1 EventPortSeq

Name:
EventPortSeq

As soon as a new event is generated by an IO-Link device, the sequence number is increased in this register. The affected channel number is also displayed.

Data type	Value
USINT	0 to 255

Bit structure:

Bit	Description	Value	Information
0 - 3	Sequence number	0 to 15	
4 - 5	IO-Link channel number	00	IF1 (channel 1)
		01	IF2 (channel 2)
		10	IF3 (channel 3)
		11	IF4 (channel 4)
6 - 7	Reserved	0	

4.26.9.9.11.2 EventQualifier

Name:
EventQualifier

This register contains additional information about the event.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 2	Instance layer generated by the event	000	Unknown
		001	Hardware
		010	Data exchange layer of the IO-Link device
		011	Application layer of the IO-Link device
		100	Application
3	Cause of the event	0	Device
		1	Master
4 - 5	Type of event	00	Reserved
		01	Information
		10	Warning
		11	Errors
6 - 7	Mode of the event	00	Reserved
		01	One-time event
		10	Event no longer reported (e.g. voltage OK again)
		11	Event reported (e.g. voltage too low)

4.26.9.9.11.3 EventCode

Name:
EventCode

The event code of the event being transferred is indicated in this register. The event codes may be vendor-specific event codes or event codes defined in the IO-Link specification.

Data type	Value
UINT	0 to 65535

4.26.9.9.11.4 EventsLeft

Name:
EventsLeft

This register indicates the number of as yet unprocessed events in the FIFO buffer.

Data type	Value
USINT	0 to 16

4.26.9.9.11.5 EventQuit

Name:
EventQuit

This register can be used to acknowledge errors. This is done by copying the sequence number of the event to be acknowledged to this register.

Data type	Value
USINT	0 to 15

4.26.9.9.11.6 EventQuitReadBack

Name:
EventQuitReadBack

This register contains the sequence number of the most recently acknowledged event.

Data type	Value
USINT	0 to 15

4.26.9.9.12 Command interface

The command interface offers the option of accessing the object dictionary of the IO-Link device using the index and subindex. Access is also possible using the AsIOLink library or FlatStream.

Information:

With this interface, up to the first 4 bytes of an object can be read or written.

Procedure for write operation:

- Set the object to be written using ParameterIndexOut and ParameterSubIndexOut.
- Write the data to be written to ParameterDataOut.
- Set read/write, IF and the sequence number increased by 1 in the ParameterCtrlOut register.
- Wait until the sequence acknowledgment in ParameterCtrlIn is the same as the sequence number.

Procedure for read operation:

- Set the object to be read using ParameterIndexOut and ParameterSubIndexOut.
- Delete bit 7 in the ParameterCtrlOut parameter, set the channel number and increase the sequence number.
- Wait until the sequence acknowledgment in ParameterCtrlIn is the same as the sequence number.
- Read the error status from ParameterCtrlIn. An error is indicated by a set error bit.
- Read the data from ParameterCtrlIn.

For error-related behavior, see 4.26.9.9.15 "Error codes".

4.26.9.9.12.1 ParameterIndexOut

Name:
ParameterIndexOut

This register defines the index of the object in the object dictionary that should be accessed.

Data type	Value
UINT	0 to 65535

4.26.9.9.12.2 ParameterSubIndexOut

Name:
ParameterSubIndexOut

This register defines the subindex of the object in the object dictionary that should be accessed.

Data type	Value
USINT	0 to 255

4.26.9.9.12.3 ParameterCtrlOut

Name:
ParameterCtrlOut

This register defines the type of access to be used.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Sequence number	0 to 3	
2 - 3	IO-Link channel number	0	IF1 (channel 1)
		1	IF2 (channel 2)
		2	IF3 (channel 3)
		3	IF4 (channel 4)
4 - 6	Data length	0 to 4	
7	Read or write	0	Read
		1	Write

4.26.9.9.12.4 ParameterDataOut

Name:
ParameterDataOut_0

This register contains the data that should be written.

Data type	Value
UDINT	0 to 4,294,967,295

4.26.9.9.12.5 ParameterCtrlIn

Name:
ParameterCtrlIn

This register monitors the status of the access.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Sequence confirmation	0 to 3	
2 - 3	IO-Link channel number	0	IF1 (channel 1)
		1	IF2 (channel 2)
		2	IF3 (channel 3)
		3	IF4 (channel 4)
4 - 6	Data length	0 to 4	
7	Error bit	0	No error
		1	Error, the error code is indicated in ParameterDataIn.

4.26.9.9.12.6 ParameterDataIn

Name:
ParameterDataIn_0

After a successful read operation, this register contains the input data. In the event of an error, it contains the error codes.

Data type	Value
UDINT	0 to 4,294,967,295

Error display

- If the error code does not equal 8 (e.g. error reported by device), then the LSB receives the error code.
- If an error is reported by the device, then the error specified by the IO-Link device is also indicated.

UDINT			
MSB			**LSB**
Reserved	IO-Link error code	Additional IO-Link error code	8

4.26.9.9.13 FlatStream communication

4.26.9.9.13.1 Introduction

B&R offers an additional communication method for some modules. "FlatStream" was designed for X2X and POWERLINK networks and allows data transmission to be adapted to individual demands. Although this method is not 100% real-time capable, it still allows data transmission to be handled more efficiently than with standard cyclic polling.

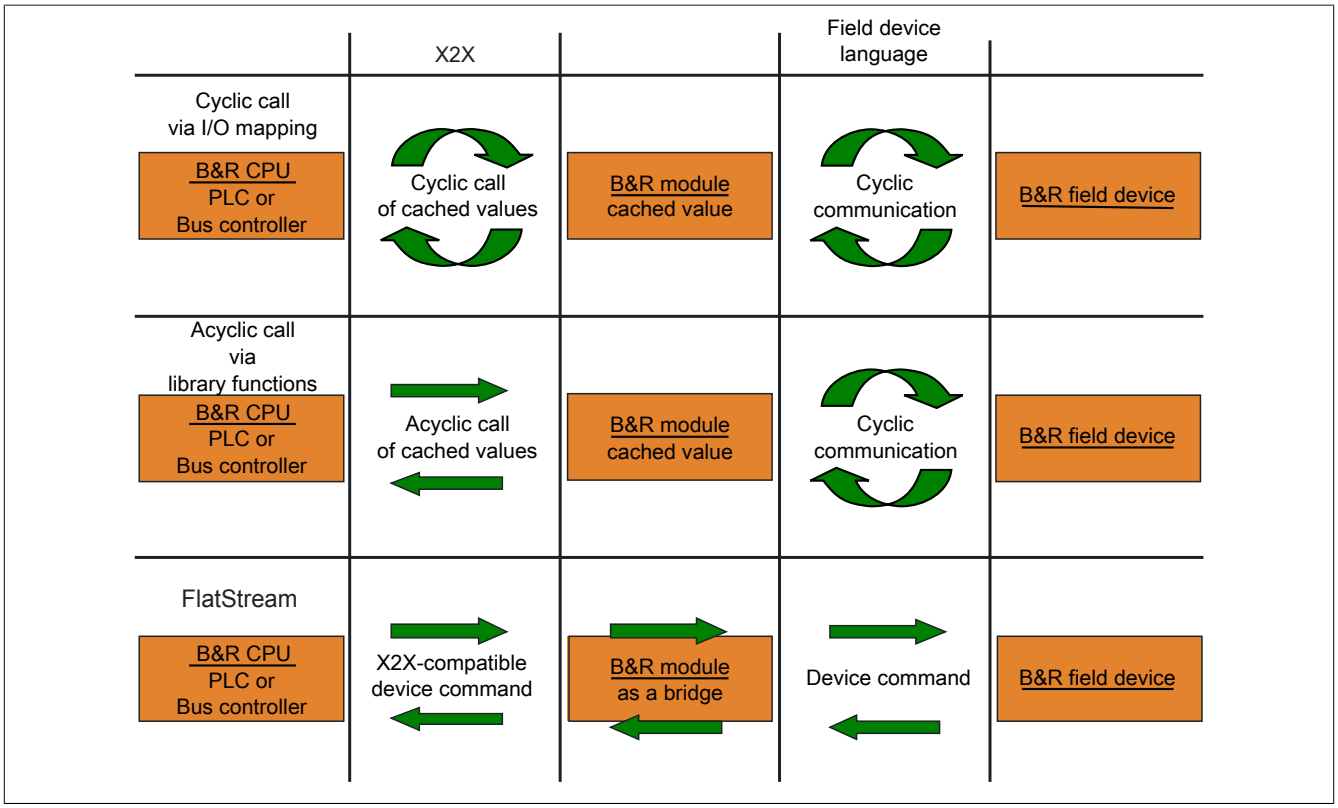


Figure 507: Three types of communication

FlatStream extends cyclic and acyclic data queries. With FlatStream communication, the module acts as a bridge. It is used to pass CPU queries directly on to the field device.

4.26.9.9.13.2 Message, segment, sequence, MTU

The physical properties of the bus system limit the amount of data that can be transmitted during one bus cycle. With FlatStream communication, all messages are viewed as part of a continuous data stream. Long data streams must be broken down into several fragments that are sent one after the other. To understand how the receiver puts these fragments back together to get the original information, it is important to understand the difference between a message, a segment, a sequence and an MTU.

Message

A message refers to information exchanged between two partner stations. The length of a message is not restricted by the FlatStream communication method. Nevertheless, module-specific limitations must be considered.

Segment (logical division of a message):

A segment has a finite size and can be understood as a section of a message. The number of segments per message is arbitrary. So that the recipient can correctly reassemble the transmitted segments, each segment is preceded by a byte with additional information. This control byte contains information such as the length of a segment and whether the approaching segment completes the message. This makes it possible for the receiving station to interpret the incoming data stream correctly.

Sequence (how a segment needs to be arranged physically):

The maximum size of a sequence corresponds to the number of enabled Rx or Tx bytes (later: "MTU"). The transmitting station splits the transmit array into valid sequences. These sequences are then written successively to the MTU and transmitted to the receiving station where they are put back together again. The receiver stores the incoming sequences in a receive array, obtaining an image of the data stream in the process.
With FlatStream communication, the number of sequences sent are counted. Successfully transmitted sequences must be acknowledged by the receiving station to ensure the integrity of the transmission.

MTU (Maximum Transmission Unit) – Physical transport:

MTU refers to the enabled USINT registers used with FlatStream. These registers can accept at least one sequence and pass it on to the receiving station. A separate MTU is defined for each direction of communication. The OutputMTU defines the number of FlatStream Tx bytes, and the InputMTU specifies the number of FlatStream Rx bytes. The MTUs are transported cyclically via the X2X Link, increasing the load with each additional enabled USINT register.

Features

FlatStream messages are not transmitted cyclically or in 100% real time. Many bus cycles may be needed to transmit a particular message. Although the Rx and Tx registers are exchanged between the transmitter and the receiver cyclically, they are only processed further if explicitly accepted by the "InputSequence" or "OutputSequence" register.

Behavior in the event of an error (brief summary)

The protocol for X2X and POWERLINK networks specifies that the last valid values should be retained when disturbances occur. With conventional communication (cyclic/acyclic data queries), this type of error can generally be ignored.
In order for communication to also take place without errors using FlatStream, all of the sequences issued by the receiver must be acknowledged. If Forward functionality is not used, then subsequent communication is delayed for the length of the disturbance.
If Forward functionality is being used, the receiving station receives a transmission counter that is incremented twice. The receiver stops, i.e. it no longer returns any acknowledgments. The transmitting station uses the SequenceAck to determine that the transmission was faulty and that all affected sequences will have to be repeated.

4.26.9.9.13.3 The FlatStream principle

Prerequisites and requirements

Before FlatStream can be used, the respective communication direction must be synchronized, i.e. both communication partners cyclically query the sequence counter on the opposite station. This checks to see if there is new data that should be accepted.

Communication

If a communication partner wants to transmit a message to its opposite station, it should first create a transmit array that corresponds to FlatStream conventions. This allows the FlatStream data to be organized very efficiently without having to block other important resources.

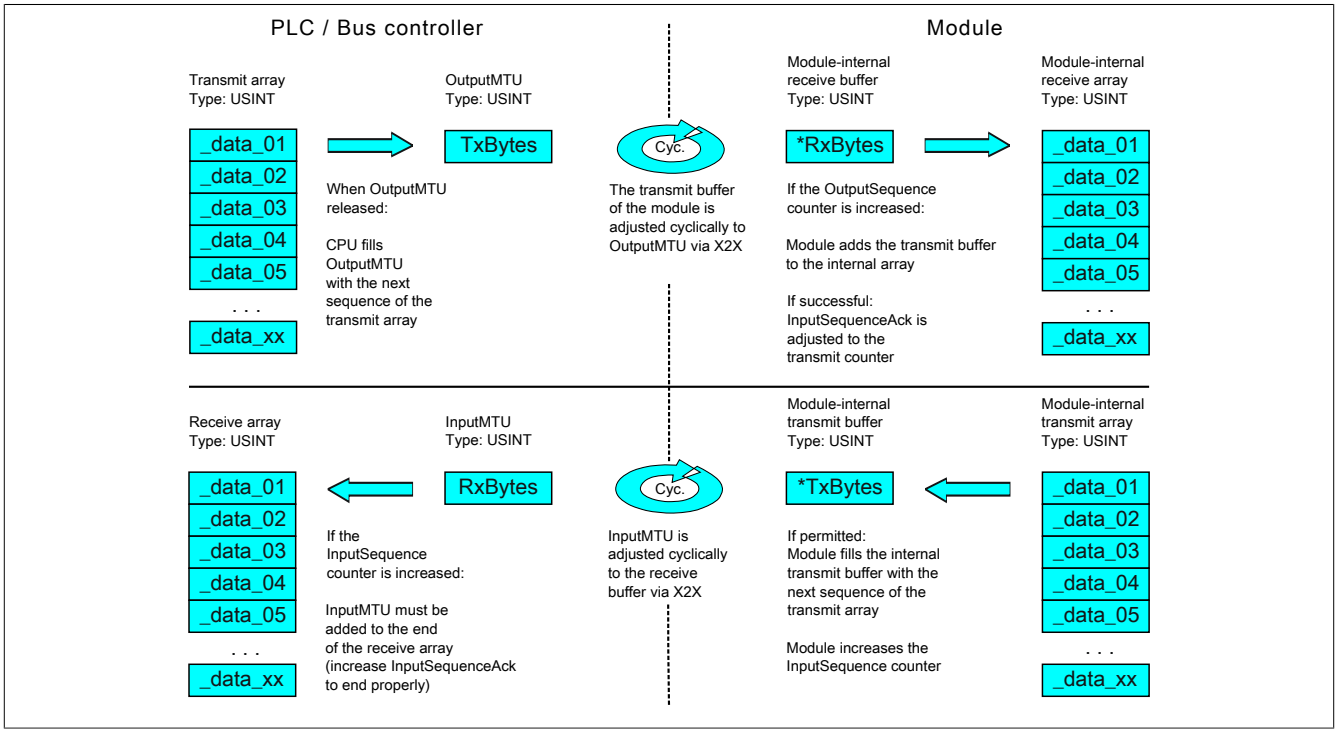

Figure 508: FlatStream communication

Procedure

The first thing that happens is that the message is broken into valid segments of up to 63 bytes, and the corresponding control bytes are created. The data is formed into a data stream made up of one control bytes per associated segment. This data stream can be written to the transmit array. The maximum size of each array element matches that of the enabled MTU so that one element corresponds to one sequence.
When the array has been completely created, the transmitter checks whether the MTU is allowed to be refilled. Then it copies the first element of the array or the first sequence to the Tx byte registers. The MTU is transported to the receiver station via X2X Link and stored in the corresponding Rx byte registers. To signal that the data should be accepted by the receiver, the transmitter increases its SequenceCounter.
If the communication direction is synchronized, the opposite station detects the incremented SequenceCounter. The current sequence is appended to the receive array and acknowledged by SequenceAck. This acknowledgment signals to the transmitter that the MTU can now be refilled.

If the transmission is successful, the data in the receive array will correspond 100% to the data in the transmit array. During the transmission, the receiving station must detect and evaluate the incoming control bytes. A separate receive array should be created for each message. This allows the receiver to immediately begin further processing of messages once they have been completely transmitted.

4.26.9.9.13.4 Registers for FlatStream mode

Five registers are available for configuring FlatStream. The default configuration can be used to transmit small amounts of data relatively easily.

Information:

The CPU communicates directly with the field device via the "OutputSequence" and "InputSequence" as well as the enabled Tx and Rx bytes. For this reason, the user needs to have sufficient knowledge of the communication protocol being used on the field device.

FlatStream configuration

To use FlatStream, the program sequence must first be expanded. The cycle time of the FlatStream routines must be set to a multiple of the bus cycle. Other program routines should be implemented in Cyclic #1 to ensure data consistency.

At the absolute minimum, the "InputMTU" and "OutputMTU" registers need to be configured. All other registers are filled in with default values at the beginning and can be used immediately. These registers are used for additional options, e.g. to transmit data in a more compact way or to increase the efficiency of the general procedure.

The Forward registers extend the functionality of the FlatStream protocol. This functionality is useful for substantially increasing the FlatStream data rate, but it also requires quite a bit of extra work when creating the program sequence.

Number of enabled Tx and Rx bytes

Name:
OutputMTU
InputMTU

These registers define the number of enabled Tx or Rx bytes, i.e. the maximum size of a sequence. The user must consider that the more bytes made available also means a higher load on the bus system.

Information:

In the rest of this documentation, the names "OutputMTU" and "InputMTU" do not refer to the registers explained here. Instead, they are used as synonyms for the currently enabled Tx or Rx bytes.

Data type	Value
USINT	See the module-specific register overview (theoretically: 3 to 27)

FlatStream operation

When using FlatStream, the communication direction is enormously important. For sending data to a module ("output" direction), the Tx bytes are used. For receiving data from a module ("input" direction), the Rx bytes are used. The "OutputSequence" and "InputSequence" registers are used to control and ensure that communication is taking place properly, i.e. the transmitter issues the directive that the data should be accepted and the receiver acknowledges that a sequence has been transmitted successfully.

Transporting the payload data and the control bytes

Name:
TxByte1 to TxByteN
RxByte1 to RxByteN

(The value the number N is different depending on the bus controller model used.)

The Tx and Rx bytes are cyclic registers used to transport the payload data and the necessary control bytes. The number of active Tx and Rx bytes is taken from the configuration of the "OutputMTU" and "InputMTU" registers, respectively.
In the user program, only the Tx and Rx bytes from the CPU can be used. The corresponding counterparts are located in the module and are not accessible to the user. For this reason, names were chosen from the CPU point of view.

- "T" - "Transmit" →CPU *transmits* data to the module.
- "R" - "Receive" →CPU *receives* data from the module.

Data type	Value
USINT	0 to 65,535

Control bytes

In addition to the payload data, the Tx and Rx bytes also transmit the necessary control bytes. These control bytes contain additional information about the data stream so that the receiver can reconstruct the original message from the transmitted segments.

Bit structure of a control byte

Bit	Name	Value	Information
0 - 5	SegmentLength	0 - 63	Size of the subsequent segment in bytes (default: Max. MTU size - 1)
6	nextCBPos	0	Next control byte at the beginning of the next MTU
		1	Next control byte directly after the end of the current segment
7	MessageEndBit	0	Message continues after the subsequent segment
		1	Message ended by the subsequent segment

SegmentLength

The segment length lets the receiver know the length of the coming segment. If the configured segment length is insufficient for a message, then the information must be distributed over several segments. In these cases, the actual end of the message is detected using bit 7 of the control byte.

Information:

The control byte is not included in the calculation to determine the segment length. The segment length is only derived from the bytes of payload data.

nextCBPos

This bit indicates the position where the next control byte is to be expected. This information is especially important when using the "MultiSegmentMTU" option.
When using FlatStream communication with multi-segment MTUs, the next control byte is no longer expected in the first Rx byte of the subsequent MTU, but directly after the current segment.

MessageEndBit

The "MessageEndBit" is set if the subsequent segment completes a message. The message has then been completely transmitted and is ready for further processing.

Information:

In the output direction, this bit must also be set if one individual segment is enough to hold the entire message. The module will only process a message internally if this identifier is detected.
The size of the message being transmitted can be calculated by adding all of the message's segment lengths together.

FlatStream formula for calculating message length:

Message [bytes] = SegmentLengths (all CBs without ME) + SegmentLength (of the first CB with ME)	CB	Control byte
	ME	MessageEndBit

Communication status of the CPU

Name:
OutputSequence

The "OutputSequence" register contains information about the communication status of the CPU. It is written by the CPU and read by the module.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	OutputSequenceCounter	0 - 7	Counter for the sequences issued in the output direction
3	OutputSyncBit	0	Output direction disabled
		1	Output direction enabled
4 - 6	InputSequenceAck	0 - 7	Mirrors the InputSequenceCounter value
7	InputSyncAck	0	Input direction not ready (disabled)
		1	Input direction ready (enabled)

OutputSequenceCounter

The OutputSequenceCounter is a continuous counter of sequences that have been issued by the CPU. The CPU uses the OutputSequenceCounter to direct the module to accept a sequence (the output direction must be synchronized when this happens).

OutputSyncBit

The CPU uses the OutputSyncBit to attempt to synchronize the output channel.

InputSequenceAck

InputSequenceAck is used for acknowledgment. The value of the InputSequenceCounter is mirrored if the CPU has received a sequence successfully.

InputSyncAck

The InputSyncAck bit acknowledges the synchronization of the input channel for the module. This indicates that the CPU is ready to receive data.

Communication status of the module

Name:
InputSequence

The "InputSequence" register contains information about the communication status of the module. It is written by the module and should only be read by the CPU.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	InputSequenceCounter	0 - 7	Counter for sequences issued in the input direction
3	InputSyncBit	0	Not ready (disabled)
		1	Ready (enabled)
4 - 6	OutputSequenceAck	0 - 7	Mirrors the OutputSequenceCounter value
7	OutputSyncAck	0	Not ready (disabled)
		1	Ready (enabled)

InputSequenceCounter

The InputSequenceCounter is a continuous counter of sequences that have been issued by the module. The module uses the InputSequenceCounter to direct the CPU to accept a sequence (the input direction must be synchronized when this happens).

InputSyncBit

The module uses the InputSyncBit to attempt to synchronize the input channel.

OutputSequenceAck

OutputSequenceAck is used for acknowledgment. The value of the OutputSequenceCounter is mirrored if the module has received a sequence successfully.

OutputSyncAck

The OutputSyncAck bit acknowledges the synchronization of the output channel for the CPU. This indicates that the module is ready to receive data.

Relationship between OutputSequence and InputSequence

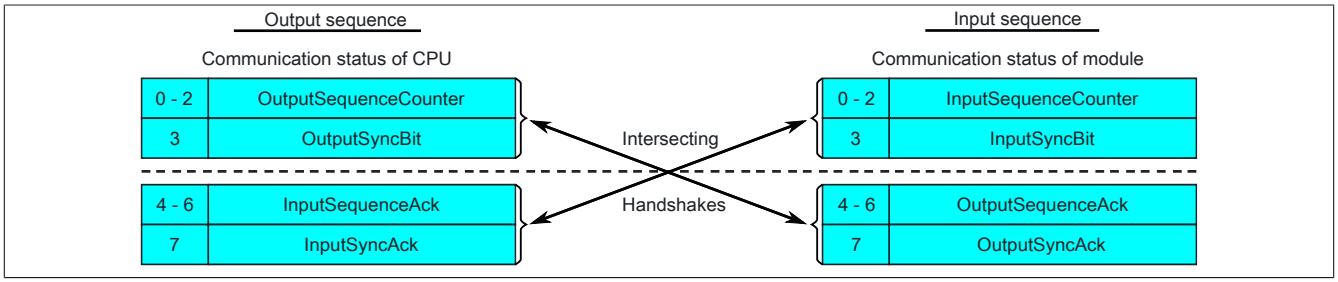

Figure 509: Relationship between OutputSequence and InputSequence

The "OutputSequence" and "InputSequence" registers are logically composed of two half-bytes. The low part signals to the opposite station whether a channel should be opened or if data should be accepted. The high part is to acknowledge that the requested action was carried out.

SyncBit and SyncAck

If SyncBit and SyncAck are set in one communication direction, then the channel is considered "synchronized", i.e. it is possible to send messages in this direction. The status bit of the opposite station must be checked cyclically. If SyncAck has been reset, then the SyncBit must be adjusted on that station. Before new data can be transmitted, the channel needs to be resynchronized.

SequenceCounter and SequenceAck

The communication partners cyclically check whether the low nibble on the opposite station changes. When one of the communication partners finishes writing a new sequence to the MTU, it increments its SequenceCounter. The current sequence is then transmitted to the receiver, which acknowledges its receipt with SequenceAck. In this way, a "handshake" is initiated.

Information:

If communication is interrupted, segments from the unfinished message are discarded. All messages that were transmitted completely are processed.

Synchronization

During synchronization, a communication channel is opened. It is important to make sure that a module is present and that the current value of the SequenceCounter is stored on the station receiving the message.
FlatStream can handle full-duplex communication. This means that both channels / communication directions can be handled separately. They have to be synchronized independently so that simplex communication can theoretically be carried out as well.

Synchronization in the output direction (CPU as the transmitter):

The corresponding synchronization bits (OutputSyncBit and OutputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the CPU to the module.

Algorithm

1) The CPU must write 000 to the OutputSequenceCounter and reset the OutputSyncBit. The CPU must cyclically query the high nibble of the "InputSequence" register (checks for 000 in OutputSequenceAck and 0 in OutputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
2) If the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 0 in InputSyncAck).
The module doesn't accept the current contents of the InputMTU since the channel is not yet synchronized. *The module matches OutputSequenceAck and OutputSyncAck to the values of OutputSequenceCounter and OutputSyncBit.*
3) When the CPU registers the expected values in OutputSequenceAck and OutputSyncAck, it is allowed to increment the OutputSequenceCounter. The CPU continues cyclically querying the high nibble of the "OutputSequence" register (checks for 001 in OutputSequenceAck and 1 in InputSyncAck). **Note:** Theoretically, data can be transmitted from this point forward. However, it is still recommended to wait until the output direction is completely synchronized before transmitting data.
The module sets OutputSyncAck.
The output direction is synchronized, and the CPU can transmit data to the module.

Synchronization in the input direction (CPU as the receiver):

The corresponding synchronization bits (InputSyncBit and InputSyncAck) are reset. Because of this, FlatStream cannot be used at this point in time to send messages from the module to the CPU.

Algorithm

The module writes 000 to InputSequenceCounter and resets InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 000 in InputSequenceAck and 0 in InputSyncAck.*
1) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it increments the InputSequenceCounter. *The module monitors the high nibble of the "OutputSequence" registers and expects 001 in InputSequenceAck and 0 in InputSyncAck.*
2) The CPU is not allowed to accept the current contents of the InputMTU since the channel is not yet synchronized. The CPU has to match InputSequenceAck and InputSyncAck to the values of InputSequenceCounter and InputSyncBit.
If the module registers the expected values in InputSequenceAck and InputSyncAck, it sets the InputSyncBit. *The module monitors the high nibble of the "OutputSequence" register and expects 1 in InputSyncAck.*
3) The CPU is allowed to set InputSyncAck. **Note:** Theoretically, data can already be transmitted in this cycle. If the InputSyncBit is set and InputSequenceCounter has been increased by 1, the values in the enabled Rx bytes have to be accepted and acknowledged (see also "Communication in the input direction").
The input direction is synchronized, and the module can transmit data to the CPU.

Transmitting and receiving

If a channel is synchronized, then the opposite station is ready to receive messages from the transmitter. Before the transmitter can send data, it needs to first create a transmit array in order to meet FlatStream requirements.

The transmitting station must also generate a control byte for each segment created. This control byte contains information about how the subsequent part of the data being transmitted should be processed. The position of the next control byte in the data stream can vary. For this reason, it must be clearly defined at all times when a new control byte is being transmitted. The first control byte is always in the first byte of the first sequence. All subsequent positions are determined recursively.

FlatStream formula for calculating the position of the next control byte:

Position (of the next control byte) = Current position + 1 + Segment length

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The rest of the configuration corresponds to the default settings.

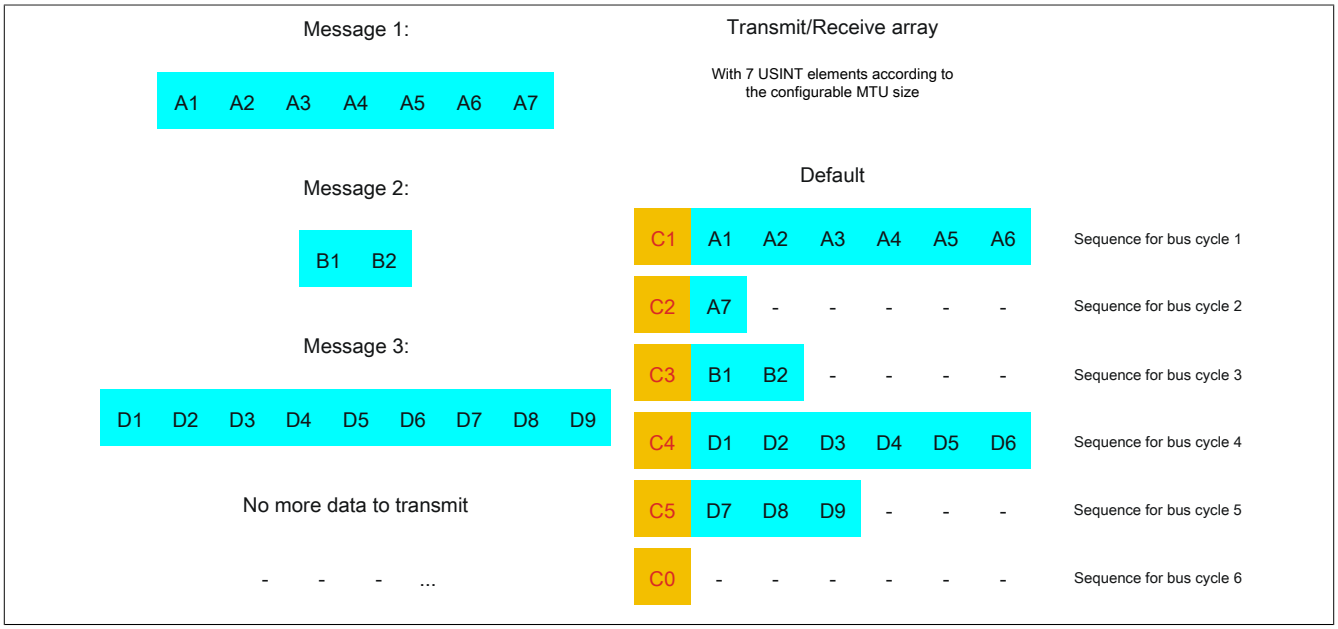

Figure 510: Transmit/Receive array (default)

First, the messages must be split into segments. In the default configuration, it is important to ensure that each sequence can hold an entire segment, including the associated control byte. The sequence is limited to the size of the enable MTU. In other words, a segment must be at least 1 byte smaller than the MTU.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 1 data byte
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data
  - ⇨ Second segment = Control byte + 3 data bytes
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C0 (control byte 0)			**C1 (control byte 1)**			**C2 (control byte 2)**		
- SegmentLength (0)	=	0	- SegmentLength (6)	=	6	- SegmentLength (1)	=	1
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (0)	=	0	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	0	Control byte	Σ	6	Control byte	Σ	129

Table 649: FlatStream determination of the control bytes for the default configuration example (part 1)

C3 (control byte 3)			**C4 (control byte 4)**			**C5 (control byte 5)**		
- SegmentLength (2)	=	2	- SegmentLength (6)	=	6	- SegmentLength (3)	=	3
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	130	Control byte	Σ	6	Control byte	Σ	131

Table 650: FlatStream determination of the control bytes for the default configuration example (part 2)

Transmitting data to a module (output)

When transmitting data, the transmit array must be generated in the application program. Sequences are then transmitted one by one using FlatStream and received by the module.

Information:

Although all B&R modules with FlatStream communication always support the most compact transmissions in the output direction, it is recommended to use the same design for the transfer arrays in both communication directions.

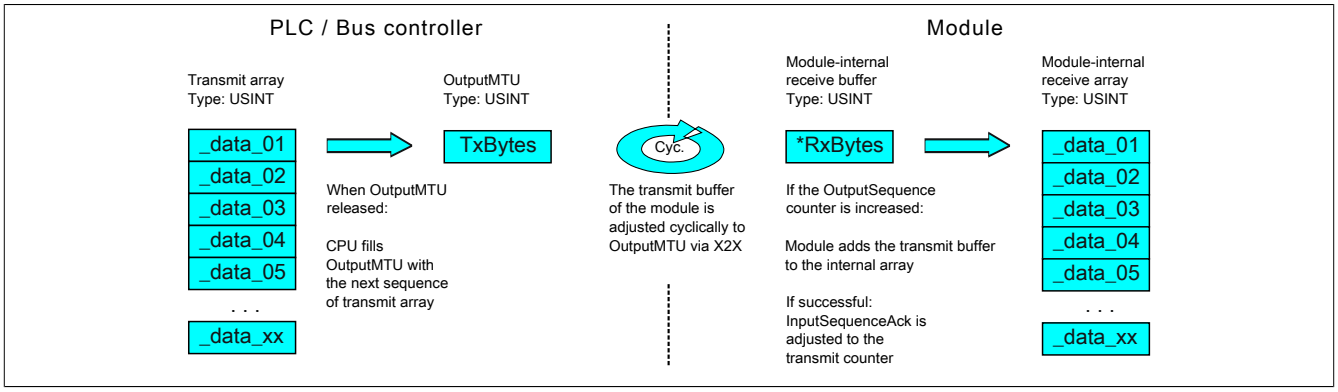

Figure 511: FlatStream communication (output)

The length of the message is initially smaller than the OutputMTU. In this case, one sequence would be sufficient to transmit the entire message and the necessary control byte.

Algorithm

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > InputSequenceAck: MTU is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU transfers the current element of the transmit array to the OutputMTU. → The OutputMTU is transferred cyclically to the module's transmit buffer but not processed further. - The CPU must increase the OutputSequenceCounter.
Response: *- The module accepts the bytes from the internal receive buffer and adds them to the internal receive array* *- The module sends acknowledgment, writes the value of OutputSequenceCounter to OutputSequenceAck*
3) Completion: - The CPU must monitor OutputSequenceAck. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the length of the *Completion* phase is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost. (The relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually.) - Subsequent sequences can only be transmitted in the next bus cycle after the completion check has been carried out successfully.

Message larger than the OutputMTU

The transmit array, which needs to be created in the program sequence, consists of several elements. The user has to arrange the control and data bytes correctly and transfer the array elements one after the other. The transfer algorithm remains the same and is repeated starting at the point *Cyclic checks*.

General flow chart

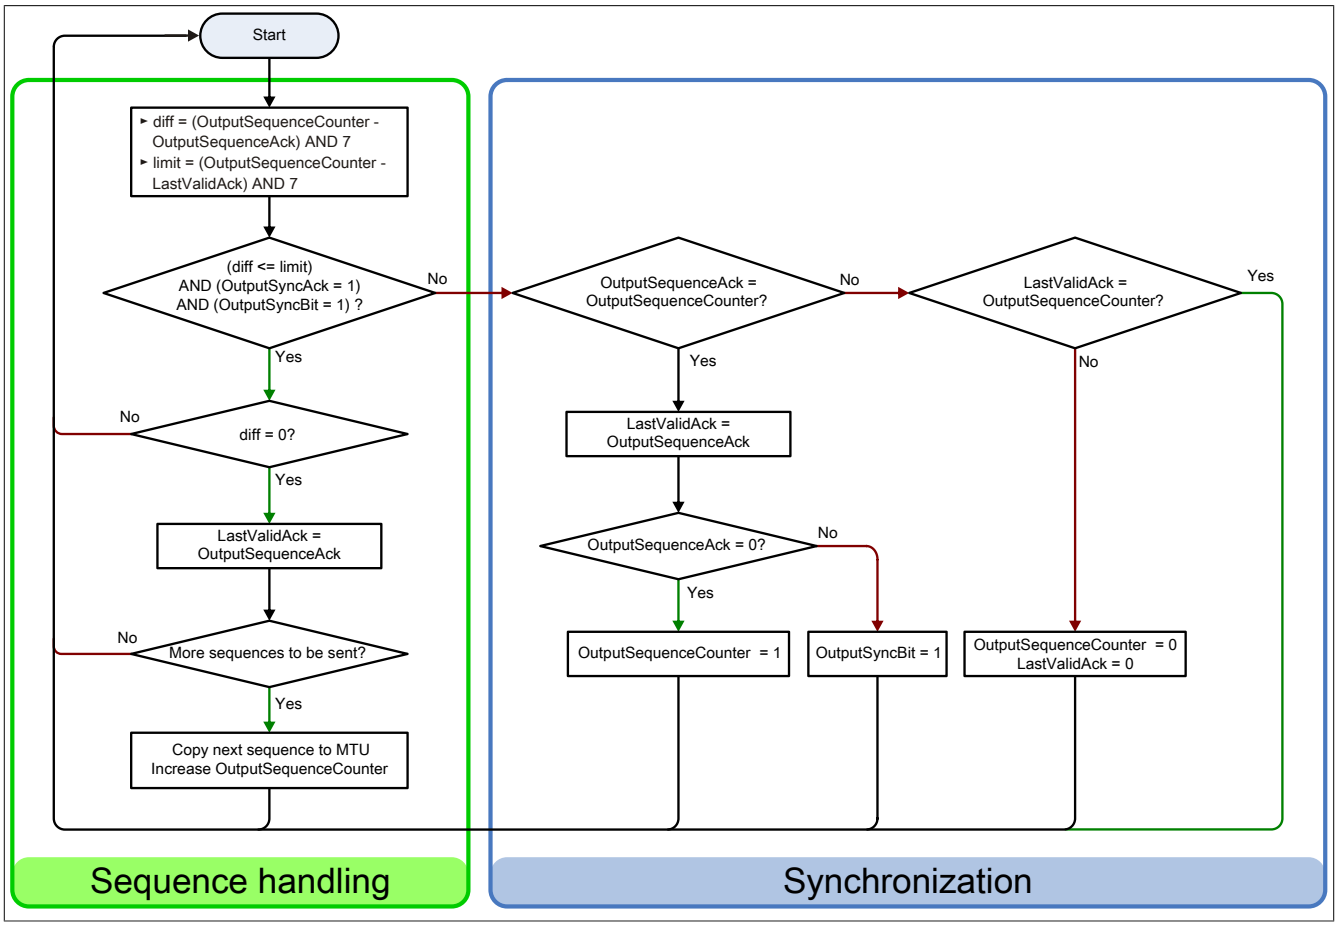

Figure 512: Flow chart for the output direction

Receiving data from a module (input)

When receiving data, the transmit array is generated by the module, transferred via FlatStream and must then be reproduced in the receive array. The structure of the incoming data stream can be configured with the mode register. The algorithm for receiving the data does not change in this regard.

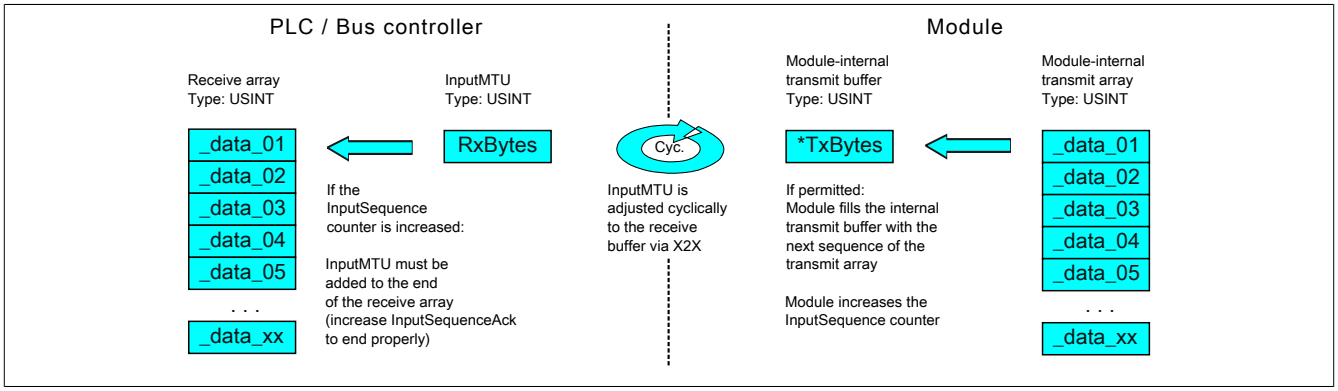

Figure 513: FlatStream communication (input)

Algorithm

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputSequenceAck*
Preparation: *- The module forms the segments, creates the control bytes and transmit array*
Action: *- The module transfers the current element of the internal transmit array to the internal transmit buffer* *- The module increases InputSequenceCounter*
1) Receiving (as soon as InputSequenceCounter is increased): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.* *- Subsequent sequences may only be sent in the next bus cycle after the completion check has been carried out successfully.*

General flow chart

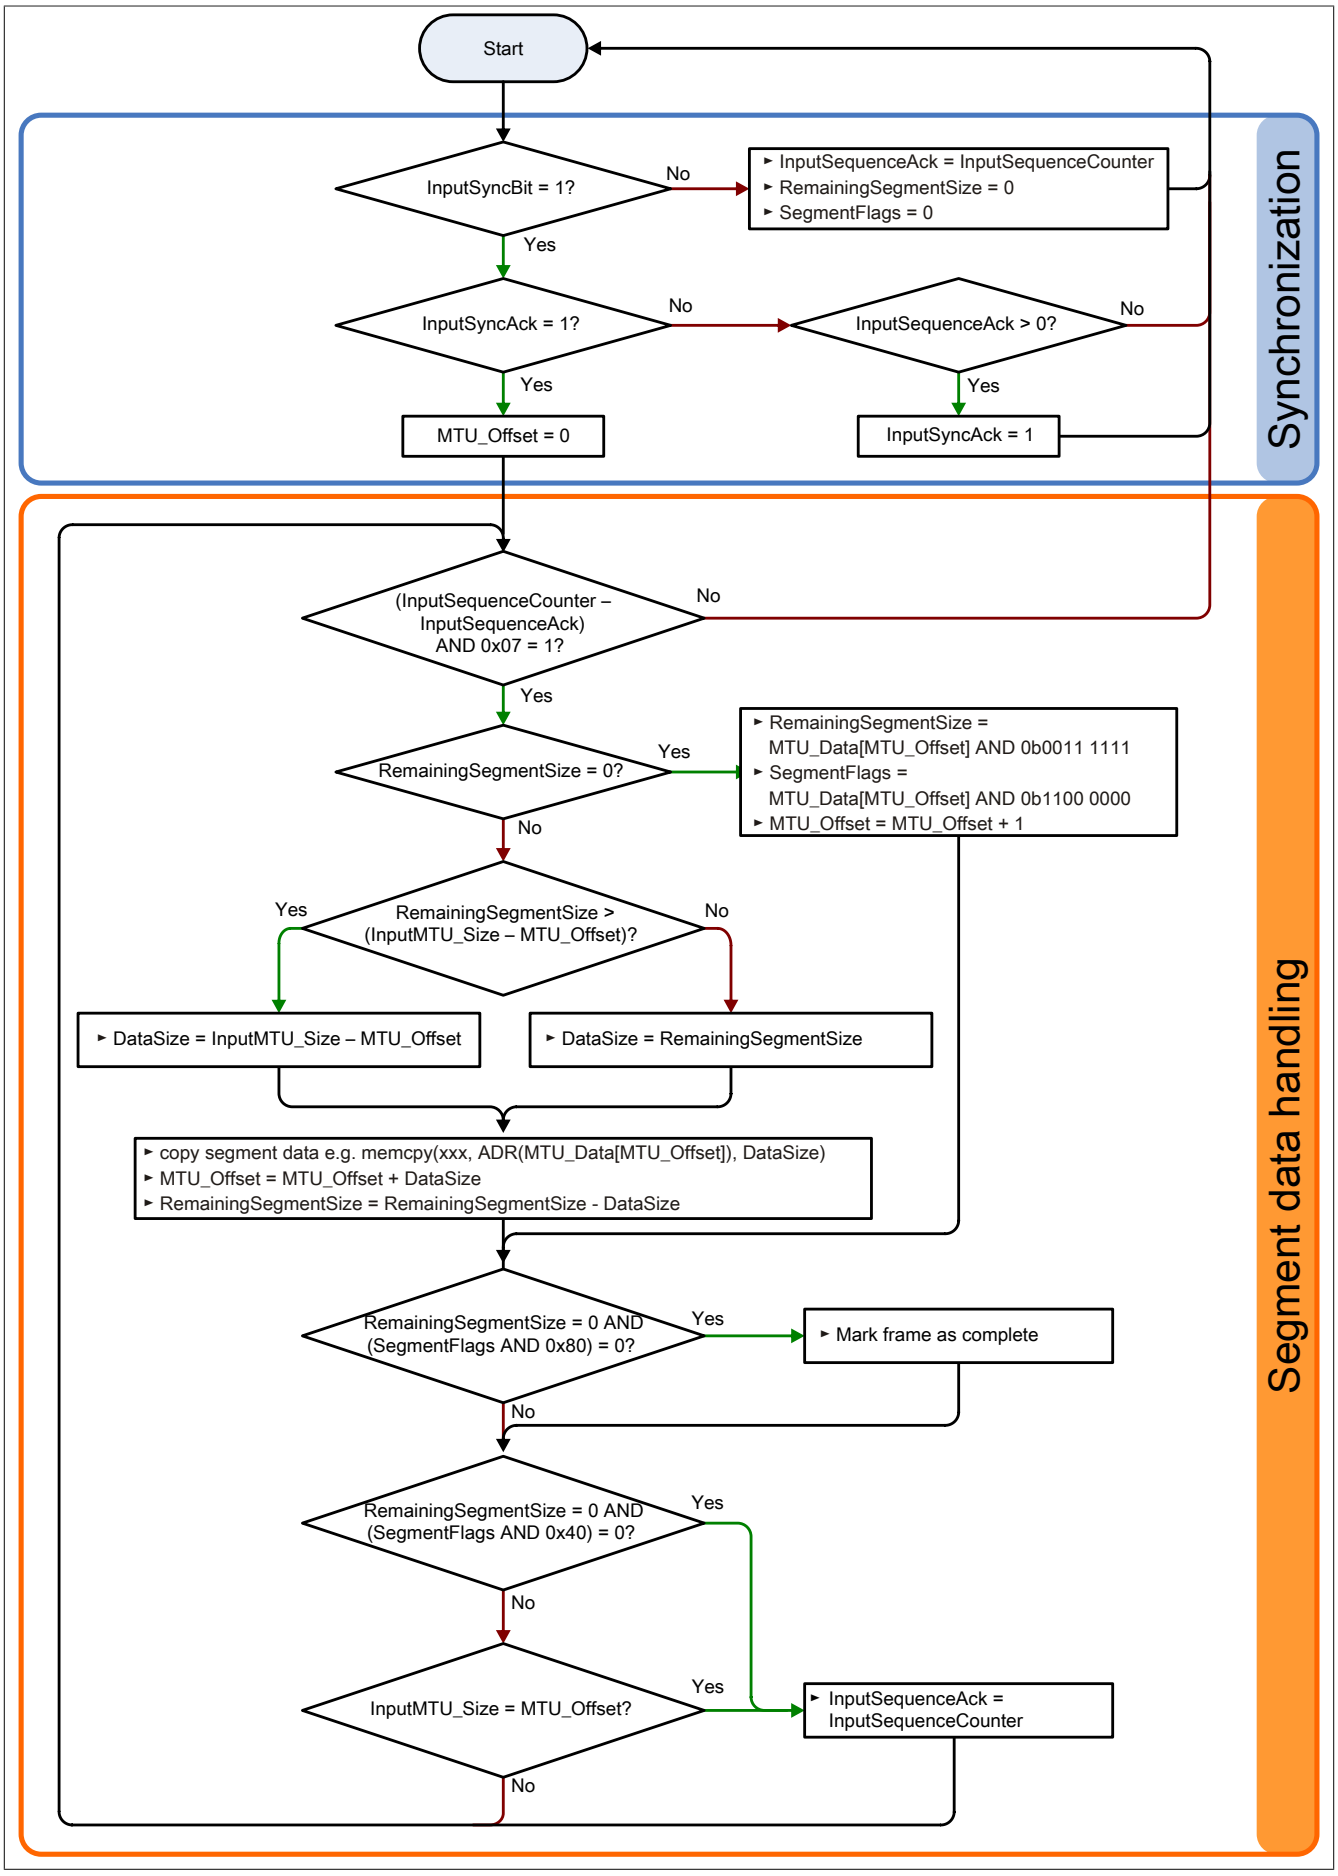

Figure 514: Flow chart for the input direction

Details

It is recommended to store transmitted messages in separate receive arrays.

After a set MessageEndBit is transmitted, the subsequent segment should be added to the receive array. The message is then complete and can be passed on internally for further processing. A new/separate array should be created for the next message.

Information:

When transmitting with MultiSegmentMTUs, it is possible for several small messages to be part of one sequence. In the program, it's important to make sure that a sufficient number of receive arrays can be managed. The entire sequence must be accepted before it is possible to change the Acknowledge register.

If a SequenceCounter is incremented by more than one value, then an error has occurred.

Note: This situation is very unlikely when operating without "Forward" functionality.

In this case, the receiver stops. All additional incoming sequences are ignored until the transmission with the correct SequenceCounter is retried. This response prevents the transmitter from receiving any more acknowledgments for transmitted sequences. The transmitter can identify the last successfully transmitted sequence from the opposite station's SequenceAck and continue the transmission from this point.

Acknowledgments must be checked for validity.

If the receiver has successfully accepted a sequence, it must be acknowledged. The receiver takes on the SequenceCounter value sent along with the transmission and matches the SequenceAck to it. The transmitter reads the SequenceAck and registers the successful transmission. If the transmitter acknowledges a sequence that has not yet been dispatched, then the transmission needs to be interrupted and the channel resynchronized. The synchronization bits are reset and the current/incomplete message is discarded. It needs to be sent again once the channel has been resynchronized.

FlatStream mode

Name:
FlatstreamMode

In the input direction, the transmit array is generated automatically. This register offers two options to the user that allow an incoming data stream to have a more compact arrangement. Once enabled, the program code for evaluation must be adapted accordingly.

Information:

All B&R modules that offer FlatStream mode support the options "Large segments" and "MultiSegmentMTUs" in the output direction. Compact transmission only needs to be explicitly allowed in the input direction.

Bit structure:

Bit	Name	Value	Information
0	MultiSegmentMTU	0	Not allowed (default)
		1	Allowed
1	Large segments	0	Not allowed (default)
		1	Allowed
2 - 7	Reserved		

Standard

By default, both options relating to compact transmission in the input direction are disabled.

1. The module only forms segments that are at least one byte smaller than the enabled MTU. Each sequence begins with a control byte so that the data stream is clearly structured and relatively easy to evaluate.
2. Since a FlatStream message can be of any length, the last segment of the message frequently doesn't fill up all of the MTU's space. By default, the remaining bytes during this type of transfer cycle are not used.

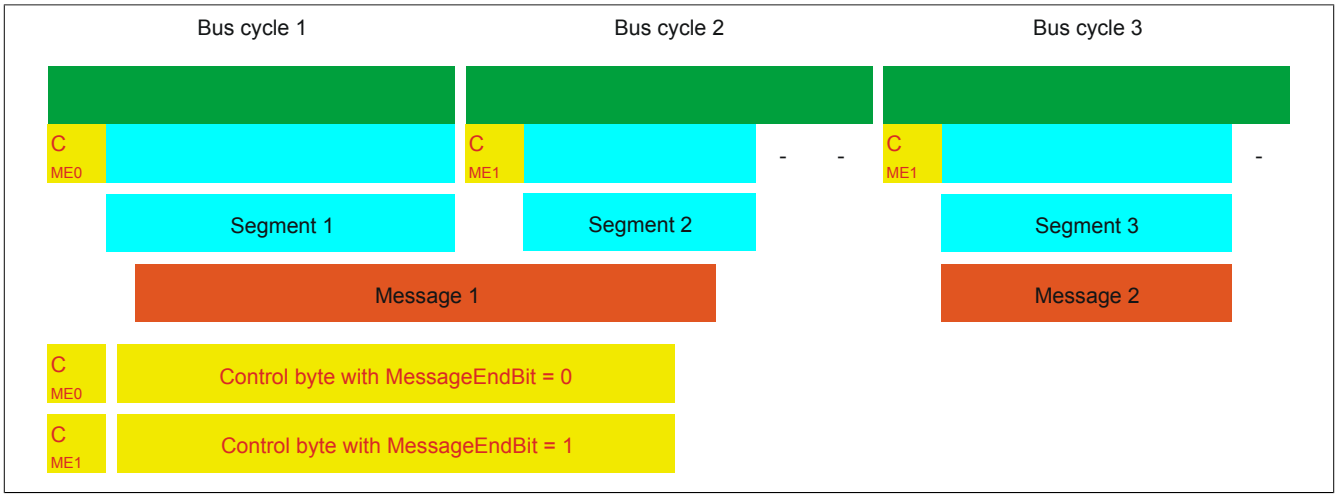

Figure 515: Message arrangement in the MTU (default)

MultiSegmentMTUs allowed

With this option, the InputMTU is completely filled (if enough data is pending). The previously unfilled Rx bytes transmit the next control bytes and their segments. This allows the enabled Rx bytes to be used more efficiently.

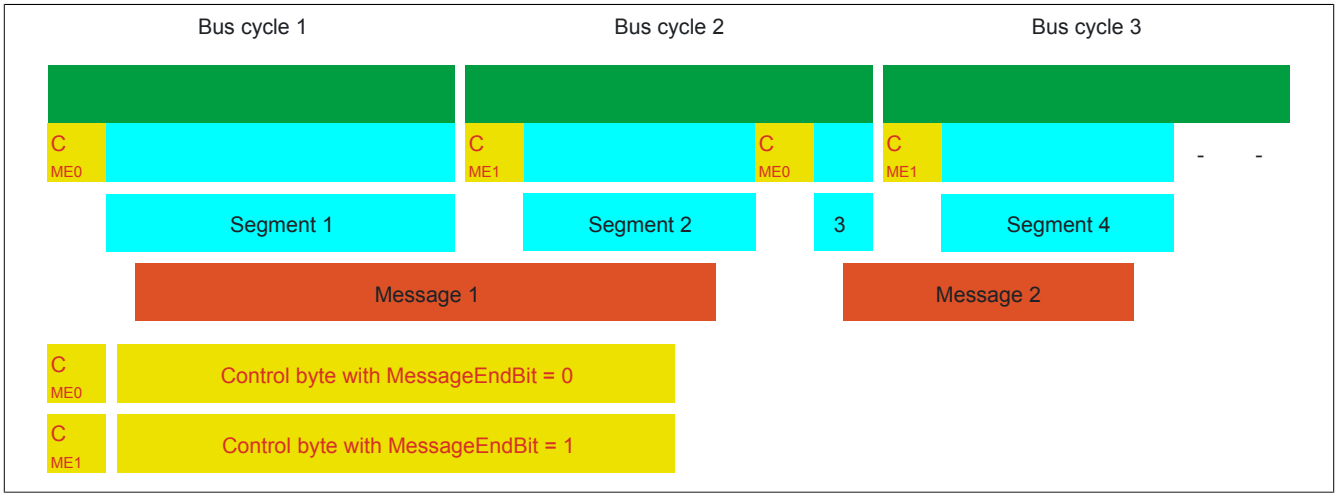

Figure 516: Arrangement of messages in the MTU (MultiSegmentMTUs)

Large segments allowed:

When transmitting very long messages or when enabling only very few Rx bytes, then a great many segments must be created by default. The bus system is more stressed than necessary since an additional control byte needs to be created and transmitted for each segment. With the "Large segments" option, the segment length is limited to 63 bytes independently of the InputMTU. One segment can stretch across several sequences, i.e. it is possible for "pure" sequences to occur without a control byte.

Information:

It is still possible to split up a message into several segments, however. If this option is used and messages with more than 63 bytes occur, for example, then messages can still be split up among several segments.

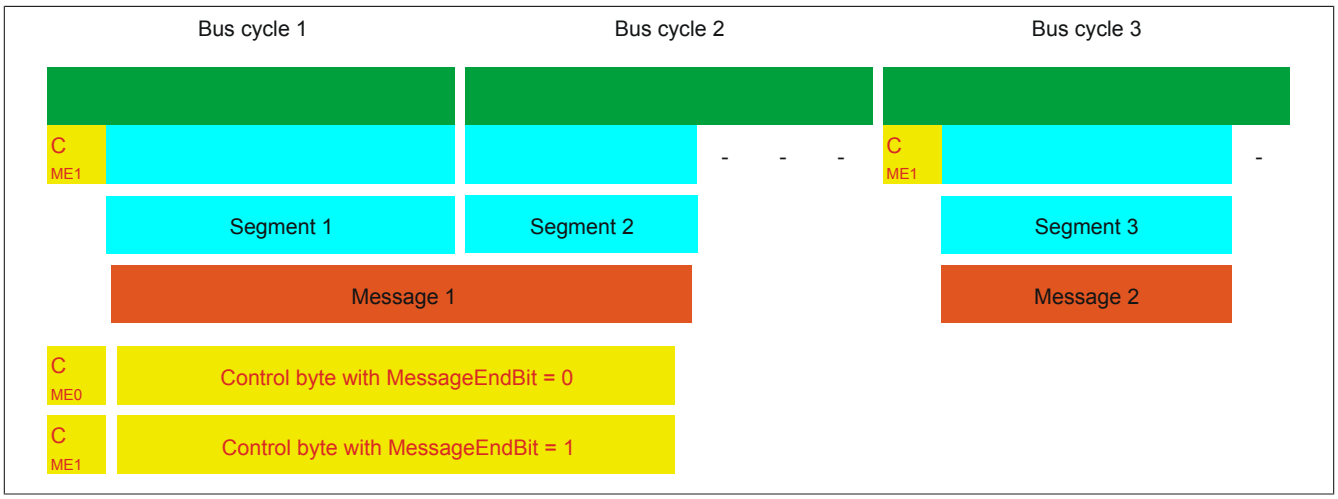

Figure 517: Arrangement of messages in the MTU (large segments)

Using both options

It is also possible to use both options at the same time.

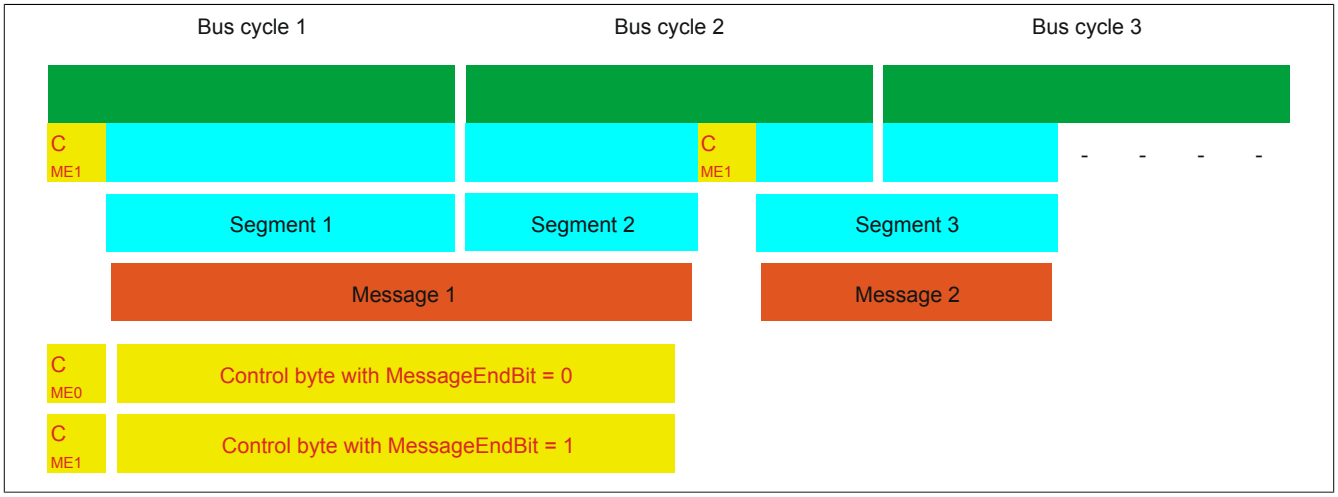

Figure 518: Arrangement of messages in the MTU (large segments and MultiSegmentMTUs)

Adjusting the FlatStream

If the way messages are structured is changed, then the way data in the transmit/receive array is arranged is also different. The following changes apply to the example given earlier.

MultiSegmentMTU

If MultiSegmentMTUs are allowed, then "open positions" in an MTU can be used. These "open positions" occur if the last segment in a message does not fully use the entire MTU. MultiSegmentMTUs allow these bits to be used to transmit the subsequent control bytes and segments. In the program sequence, the "nextCBPos" bit in the control byte is set so that the receiver can correctly identify the next control byte.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of MultiSegmentMTUs.

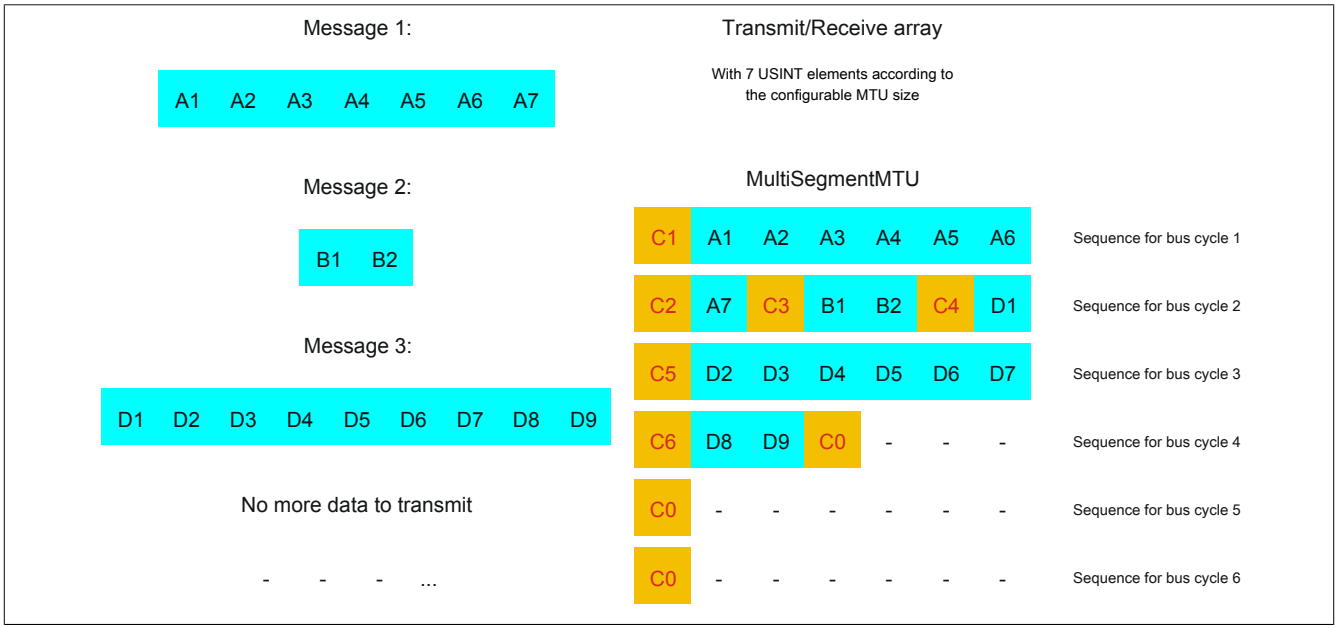

Figure 519: Transmit/receive array (MultiSegmentMTUs)

First, the messages must be split into segments. As in the default configuration, it is important for each sequence to begin with a control byte. The free bits in the MTU at the end of a message are filled with data from the following message, however. With this option, the "nextCBPos" bit is always set if payload data is sent after the control byte.

MTU = 7 bytes → Max. segment length = 6 bytes

- Message 1 (7 bytes)
  - ⇨ First segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Second segment = Control byte + 1 byte of data (MTU still has 5 open bytes)
- Message 2 (2 bytes)
  - ⇨ First segment = Control byte + 2 bytes of data (MTU still has 2 open bytes)
- Message 3 (9 bytes)
  - ⇨ First segment = Control byte + 1 byte of data (MTU full)
  - ⇨ Second segment = Control byte + 6 bytes of data (MTU full)
  - ⇨ Third segment = Control byte + 2 bytes of data (MTU still has 4 open bytes)
- No more messages
  - ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (6)	=	6	- SegmentLength (1)	=	1	- SegmentLength (2)	=	2
- nextCBPos (1)	=	64	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	70	Control byte	Σ	193	Control byte	Σ	194

Table 651: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 1)

Warning!

The second sequence must have been completely processed before it can be acknowledged with SequenceAck. In this example, there are three different segments within the second sequence, i.e. the program must include enough receive arrays to handle this situation.

C4 (control byte 4)			C5 (control byte 5)			C6 (control byte 6)		
- SegmentLength (1)	=	1	- SegmentLength (6)	=	6	- SegmentLength (2)	=	2
- nextCBPos (6)	=	6	- nextCBPos (1)	=	64	- nextCBPos (1)	=	64
- MessageEndBit (0)	=	0	- MessageEndBit (1)	=	0	- MessageEndBit (1)	=	128
Control byte	Σ	7	Control byte	Σ	70	Control byte	Σ	194

Table 652: FlatStream determination of the control bytes for the MultiSegmentMTU example (part 2)

Large segments

Segments are limited to a maximum of 63 bytes. This means they can be larger than the active MTU. These large segments are divided among several sequences when transmitted. It is possible for sequences to be completely filled with payload data and not have a control byte.

Information:

It is still possible to subdivide a message into several segments so that the size of a data packet does not also have to be limited to 63 bytes.

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows the transmission of large segments.

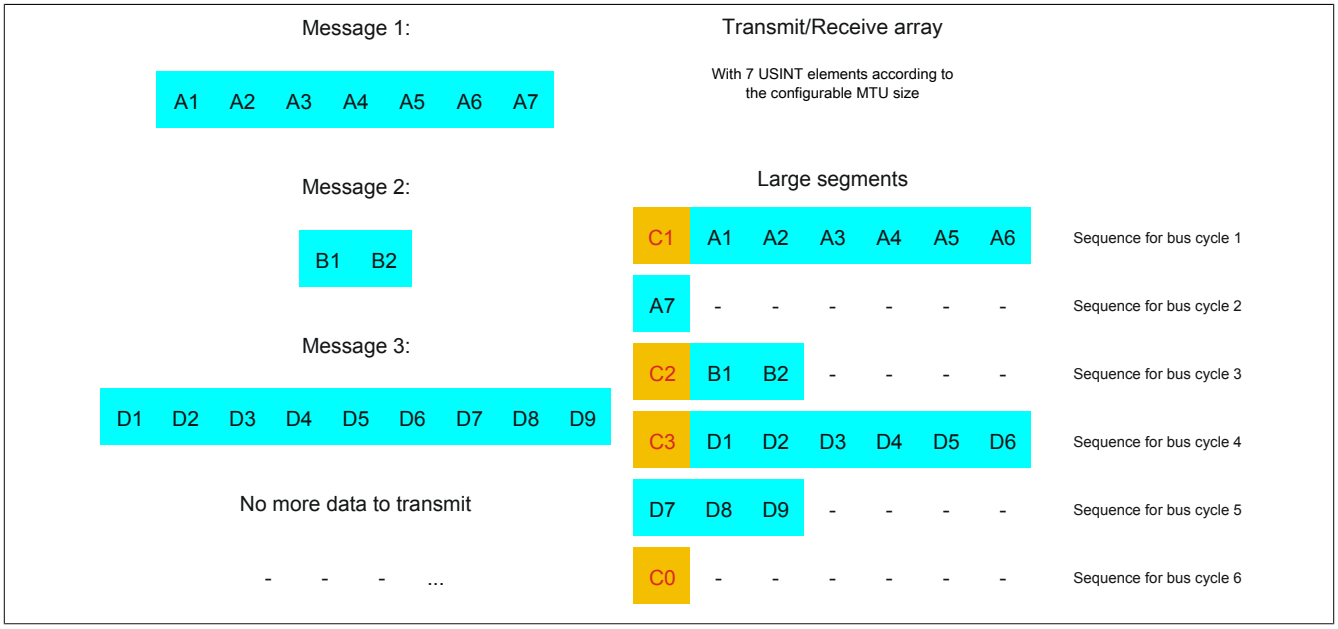

Figure 520: Transmit/receive array (large segments)

First, the messages must be split into segments. The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 653: FlatStream determination of the control bytes for the large segment example

Large segments and MultiSegmentMTU

Example

Three autonomous messages (7 bytes, 2 bytes and 9 bytes) are being transmitted using an MTU with a width of 7 bytes. The configuration allows transmission of large segments as well as MultiSegmentMTUs.

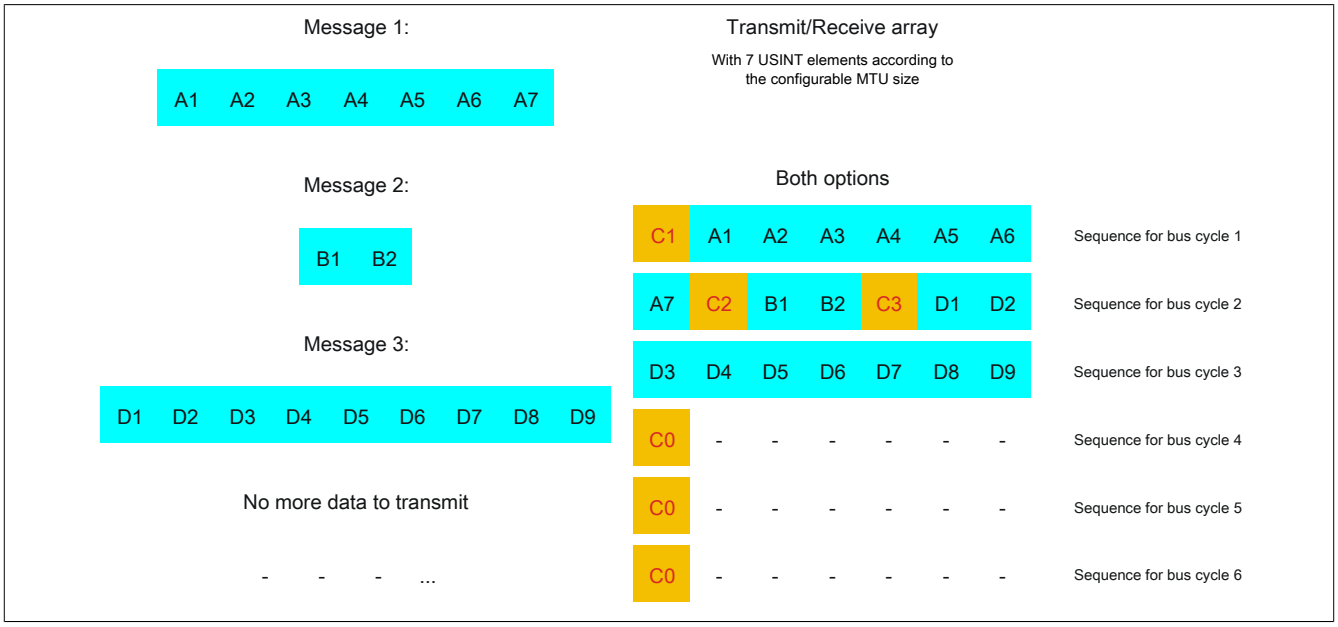

Figure 521: Transmit/receive array (large segments and MultiSegmentMTUs)

First, the messages must be split into segments. If the last segment of a message does not completely fill the MTU, it can be used for other data in the data stream. The "nextCBPos" bit must always be set if the control byte belongs to a segment with payload data.
The ability to form large segments means that messages are split up less frequently, which results in fewer control bytes generated. Control bytes are generated in the same way as with the "Large segments" option.

Large segments allowed → Max. segment length = 63 bytes

- Message 1 (7 bytes)

  ⇨ First segment = Control byte + 7 bytes of data

- Message 2 (2 bytes)

  ⇨ First segment = Control byte + 2 bytes of data

- Message 3 (9 bytes)

  ⇨ First segment = Control byte + 9 bytes of data

- No more messages

  ⇨ C0 control byte

A unique control byte must be generated for each segment. In addition, the C0 control byte is generated to keep communication on standby.

C1 (control byte 1)			C2 (control byte 2)			C3 (control byte 3)		
- SegmentLength (7)	=	7	- SegmentLength (2)	=	2	- SegmentLength (9)	=	9
- nextCBPos (0)	=	0	- nextCBPos (0)	=	0	- nextCBPos (0)	=	0
- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128	- MessageEndBit (1)	=	128
Control byte	Σ	135	Control byte	Σ	130	Control byte	Σ	137

Table 654: FlatStream determination of the control bytes for the large segment and MultiSegmentMTU example

4.26.9.9.13.5 Example of Forward functionality on X2X Link

Forward functionality is a method that can be used to substantially increase the FlatStream data rate. The basic principle is also used in other technical areas such as "pipelining" for microprocessors.

Operating principle

X2X Link communication cycles through five different steps to transmit a FlatStream sequence. At least five bus cycles are therefore required to successfully transfer the sequence.

	Step I	Step II	Step III	Step IV	Step V
Actions	Transfer sequence from transmit array, increase Sequence-Counter	Cyclic matching of MTU and module buffer	Append sequence to receive array Adjust SequenceAck	Cyclic matching of MTU and module buffer	Check SequenceAck
Resource	Transmitter (task to transmit)	Bus system (direction 1)	Recipient (task to receive)	Bus system (direction 2)	Transmitter (task for Ack checking)

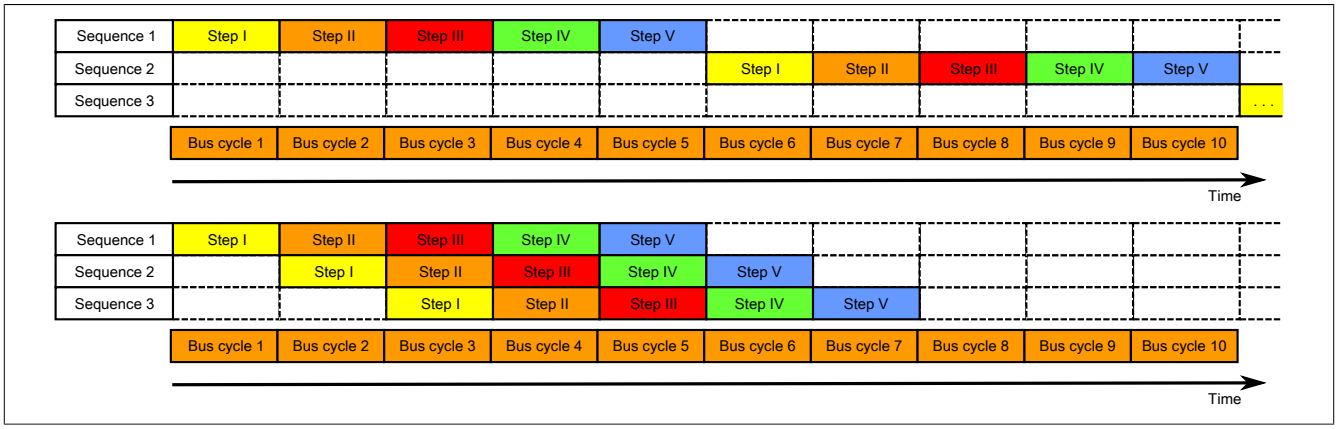

Figure 522: Comparison of transmission without/with Forward

Each of the five steps (tasks) requires different resources. If Forward functionality is not used, the sequences are executed one after the other. Each resource is then only active if it is needed for the current sub-action.
With Forward, a resource that has executed its task can already be used for the next message. The condition for enabling the MTU is changed to allow for this. Sequences are then passed to the MTU according to the timing. The transmitting station no longer waits for an acknowledgment from SequenceAck, which means that the available bandwidth can be used much more efficiently.
In the most ideal situation, all resources are working during each bus cycle. The receiver still has to acknowledge every sequence received. Only when SequenceAck has been changed and checked by the transmitter is the sequence considered as having been transmitted successfully.

Configuration

The Forward function only has to be enabled for the input direction. Two additional configuration registers are available for doing so. FlatStream modules have been optimized in such a way that they support this function. In the output direction, the Forward function can be used as soon as the size of the OutputMTU is specified.

Number of unconfirmed sequences

Name:
Forward

With the "Forward" register, the user specifies how many unacknowledged sequences the module is allowed to transmit.

Recommendation:
X2X Link: Max. 5
POWERLINK: Max. 7

Data type	Value
USINT	1 to 7 Default: 1

Delay time

Name:
ForwardDelay

The "ForwardDelay" register is used to specify the delay time in µs. This is the amount of time the module has to wait after sending a sequence until it is allowed to write new data to the MTU in the following bus cycle. The program routine for receiving sequences from a module can therefore be run in a task class whose cycle time is slower than the bus cycle.

Data type	Value
UINT	0 to 65,535 [µs] Default: 0

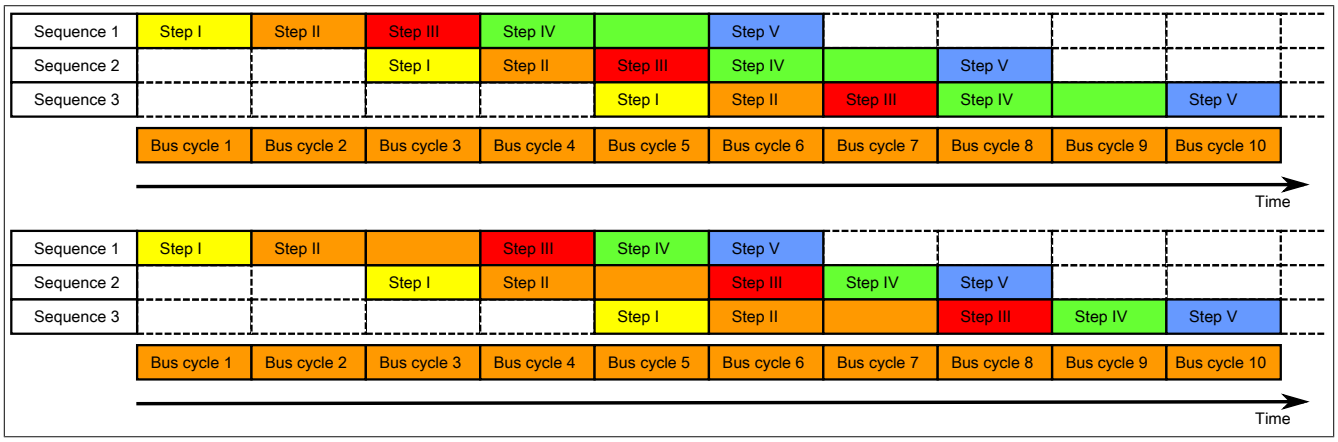

Figure 523: Effect of ForwardDelay when using FlatStream communication with the Forward function

In the program, it is important to make sure that the CPU is processing all of the incoming InputSequences and InputMTUs. The ForwardDelay value causes delayed acknowledgment in the output direction and delayed reception in the input direction. In this way, the CPU has more time to process the incoming InputSequence or InputMTU.

Transmitting and receiving with Forward

The basic algorithm for transmitting and receiving data remains the same. With the Forward function, up to seven unacknowledged sequences can be transmitted. Sequences can be transmitted without having to wait for the previous message to be acknowledged. Since the delay between writing and response is eliminated, a considerable amount of additional data can be transferred in the same time window.

Algorithm for transmitting

Cyclic status query: *- Module monitors OutputSequenceCounter*
0) Cyclic checks: - The CPU must check OutputSyncAck. → If OutputSyncAck = 0: Reset the OutputSyncBit and resynchronize the channel. - The CPU must check whether OutputMTU is enabled. → If OutputSequenceCounter > OutputSequenceAck + 7, then it is not enabled because the last sequence has not yet been acknowledged.
1) Preparation (create transmit array): - The CPU must split up the message into valid segments and create the necessary control bytes. - The CPU must add the segments and control bytes to the transmit array.
2) Transmit: - The CPU must transfer the current part of the transmit array to the OutputMTU. - The CPU must increase the OutputSequenceCounter for the sequence to be accepted by the module. - The CPU can then *transmit* in the next bus cycle if the MTU has been enabled.
The module respondssince OutputSequenceCounter > OutputSequenceAck: *- The module accepts data from the internal receive buffer and appends it to the end of the internal receive array* *- Module acknowledged; current received value of OutputSequenceCounter transferred to OutputSequenceAck* *- The module polls the status once more*
3) Completion (acknowledgment): - The CPU must check OutputSequenceAck cyclically. → A sequence is only considered to have been transmitted successfully if it has been acknowledged via OutputSequenceAck. In order to detect potential transmission errors in the last sequence as well, it is important to make sure that the algorithm is run through long enough. **Note:** To monitor communication times exactly, the task cycles that have passed since the last increase of the OutputSequenceCounter should be counted. In this way, the number of previous bus cycles necessary for the transmission can be measured. If the monitoring counter exceeds a predefined threshold, then the sequence can be considered lost (the relationship of bus to task cycle can be influenced by the user so that the threshold value needs to be determined individually).

Algorithm for receiving

0) Cyclic status query: - The CPU must monitor the InputSequenceCounter.
Cyclic checks: *- The module checks InputSyncAck* *- The module checks InputMTU for enabling* *→Enabling criteria: InputSequenceCounter > InputSequenceAck + Forward*
Preparation: *- The module forms the control bytes / segments and creates the transmit array*
Action: *- The module transfers the current part of the transmit array to the receive buffer* *- The module increases the InputSequenceCounter* *- The module waits on a new bus cycle after the ForwardDelay time has passed* *- The module repeats the action if InputMTU is enabled*
1) Receiving (InputSequenceCounter > InputSequenceAck): - The CPU must accept data from the InputMTU and append it to the end of the receive array. - The CPU must match InputSequenceAck to the InputSequenceCounter of the sequence currently being processed.
Completion: *- The module monitors InputSequenceAck* *→ A sequence is only considered to have been transferred successfully if it has been acknowledged via InputSequenceAck.*

Details/Background

1. Illegal SequenceCounter size (counter offset)
   Error situation: MTU not enabled
   If the difference between SequenceCounter and SequenceAck is larger than allowed during transmission, then a transmission error has occurred. In this case, all unacknowledged sequences must be repeated with the old SequenceCounter value.
2. Checking an acknowledgment
   After an acknowledgment has been received, a check must verify whether the acknowledged sequence has been transmitted and had not yet been unacknowledged. If a sequence has been acknowledged more than once, then a fatal error has occurred. The channel must be closed and resynchronized (same behavior as when not using Forward).

   > **Information:**
   >
   > **In exceptional cases, the module can increment OutputSequenceAck by more than 1 when using Forward.**
   > **This is not an error. The CPU is permitted to consider all sequences up to the one being acknowledged as having been transmitted successfully.**

3. Transmit and receive arrays
   The Forward function has no effect on the structure of the transmit and receive arrays. They are created and must be evaluated in the same way.

Errors when using Forward

In industrial environments, it is often the case that many different devices from various manufacturers are being used side by side. The electrical and/or electromagnetic properties of these technical devices can sometimes cause them to interfere with one another. These kinds of situations can be reproduced and protected against in laboratory conditions only to a certain point.

Precautions have been taken for X2X Link transmissions if this type of interference occurs. For example, if an invalid checksum occurs, the I/O system will ignore the data from this bus cycle and the receiver receives the last valid data once more. With conventional (cyclic) data points, this error can often be ignored. In the following cycle, the same data point is again retrieved, adjusted and transmitted.

Using Forward functionality with FlatStream communication makes this situation more complex. The receiver receives the old data again in this situation as well, i.e. the previous values for SequenceAck/SequenceCounter and the old MTU.

Loss of acknowledgment (SequenceAck)

If a SequenceAck value is lost, then the MTU was already transmitted properly. For this reason, the receiver is permitted to continue processing with the next sequence. The SequenceAck is aligned with the associated SequenceCounter and sent back to the transmitter. Checking the incoming acknowledgments shows that all sequences up to the last one acknowledged have been transmitted successfully (see sequences 1 and 2 in the image).

Loss of transmission (SequenceCounter, MTU):

If a bus cycle drops out and the SequenceCounter value and/or filled MTU are lost, then no data reaches the receiver. At this point, the transmission routine is not yet affected by the error. The time-controlled MTU is released again and can be rewritten to.
The receiver receives SequenceCounter values that have been incremented several times. For the receive array to be put together correctly, the receiver is only allowed to process transmissions whose SequenceCounter has been increased by one. The incoming sequences must be ignored, i.e. the receiver stops and no longer transmits back any acknowledgments.
If the maximum number of unacknowledged sequences has been sent and no acknowledgments are returned, the transmitter must repeat the affected SequenceCounter and associated MTUs (see sequence 3 and 4 in the image).

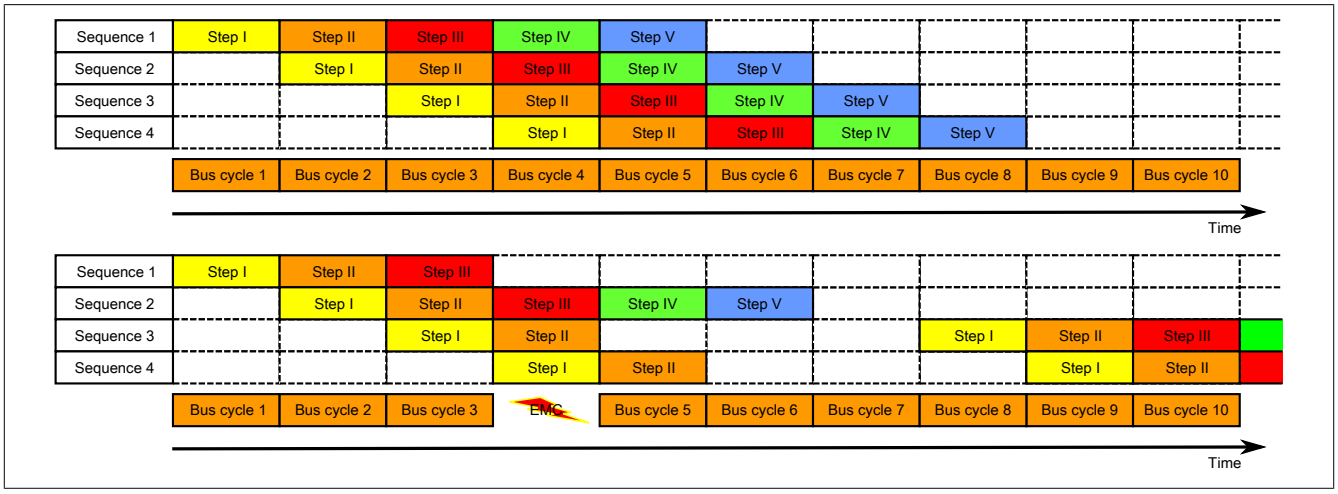

Figure 524: Effect of a lost bus cycle

Loss of acknowledgment

In sequence 1, the acknowledgment is lost due to disturbance. Sequences 1 and 2 are therefore acknowledged in Step V of sequence 2.

Loss of transmission

In sequence 3, the entire transmission is lost due to disturbance. The receiver stops and no longer sends back any acknowledgments.
The transmitting station continues transmitting until it has issued the maximum permitted number of unacknowledged transmissions.
Five bus cycles later at the earliest (depending on the configuration), it begins resending the unsuccessfully sent transmissions.

4.26.9.9.14 Using IO-Link with FlatStream

With this module, the user has the option of communicating with the connected IO-Link device via FlatStream.

Communication takes place separately with respect to timing, i.e. output data is transferred completely from the CPU to the module and checked. Only then does the module initiate the actual communication with the IO-Link device.

The module acts the same way in the input direction. Messages from the IO-Link device must have been received completely by the X2X module before the FlatStream message is generated and transmitted to the CPU.

4.26.9.9.14.1 General handling of FlatStream

Input/Output sequence	Rx/Tx bytes	
(unchanged)	Control byte (unchanged)	Payload data for FlatStream (IO-Link information)

The user has a choice when using FlatStream.

- Using FlatStream as described in the "FlatStream communication" section
- Using the "AsFltGen" library to manage input/output sequence and FlatStream control bytes automatically

In both cases, a module-specific array with FlatStream payload data must be created in the application.

4.26.9.9.14.2 IO-Link information for the FlatStream

To be able to use IO-Link communication via FlatStream, you must define an individual array in the application.

The following must be defined for the query in the direction CPU → Module → IO-Link device:

- Module's channel number
- Frame number for the query
- Type of query
- The corresponding IO-Link data must then be attached depending on the query.

The response consists of the following parts:

- The frame number, access type and type of query are repeated.
- The module generates the error bit and manages the confirmation bit.
- The successfully received IO-Link information or corresponding error code is then appended.

Module-specific FlatStream array for IO-Link communication

Bytes	Name	Value	Description
1	Channel number	1 to 4	
2	Frame number	0 to 255	This number is repeated in the module's response. This allows the later response from the module to be distinctly attributed to the request.
3	See Byte 3	x	
...	IO-Link data or error code		Depends on byte 3

Byte 3

Bit	Description	Value	Information
0 - 2	Type of query	0	Access to object dictionary
		1	Access to inputs' process data
		2	Access to outputs' process data
		3	Read individual event
		4	Read multiple events
		5	Enable event forwarding
		6	Disable event forwarding
		7	Announcement of automatically forwarded event
3 - 4	Reserved	-	
5	Confirm	0	Message without query
		1	Response to query[1)]
6	Status bit (for response frame)	0	No error
		1	Error
7	Access types	0	Read
		1	Write

1) This confirmation bit is additionally set with the response to a query. The response for confirming a query frequently contains additional data that must be processed.

4.26.9.9.14.3 IO-Link data

Depending on the type of query, different IO-Link data results that must be appended to the FlatStream array.

Access to object dictionary

Request

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	High index number	0 to 255	Index of the desired IO-Link parameter
5	Low index number	0 to 255	
6	Subindex number	0 to 255	Subindex of the IO-Link parameter
7 to ...	Data	0 to 255	Optional, for write operation

Response

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4 to ...	Data / Error code	0 to 255	Omitted if data has been written successfully

Accessing process data

Request

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Data	0 to 255	Optional, for write operation

Response

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Data / Error code	0 to 255	Omitted if data has been written successfully

Accessing event data

Request

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		

Response

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Event counter - Current	Bit 0 to 3	Number of attached events
	Event counter - Pending	Bit 4 to 7	Number of pending events
5	Event 0 – Event qualifier	0 to 255	See EventQualifier.
6	Event 0 – High event data	0 to 255	
7	Event 0 – Low event data	0 to 255	
8 - 10	Event 1		
x to (x + 2)	Event n[1)]		

1) Applies only if multiple events were queried with byte 3 (bits 0 to 2 = 4). Only 1 event comes with byte 3 (bits 0 to 2 = 3).

or

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Error code	0 to 255	

Enable/Disable event forwarding

Request

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		

Response

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		

or

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Error code	0 to 255	

Announcement of forwarded event

After enabling event forwarding, events no longer have to be queried cyclically. The module generates the event as soon as the corresponding event occurs.

Message

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Event counter - Current	Bit 0 to 3	Number of attached events
	Event counter - Pending	Bit 4 to 7	Number of pending events
5	Event 0 – Event qualifier	0 to 255	See EventQualifier.
6	Event 0 – High event data	0 to 255	
7	Event 0 – Low event data	0 to 255	
8 - 10	Event 1		
x to (x + 2)	Event n[1)]		

1) Applies only if multiple events were queried with byte 3 (bits 0 to 2 = 4). Only 1 event comes with byte 3 (bits 0 to 2 = 3).

or

Bytes	Name	Value	Description
1 to 3	Module-specific FlatStream array for IO-Link communication		
4	Error code	0 to 255	

4.26.9.9.15 Error codes

Queries can be made via registers or FlatStream. If a query fails, the error bit is set and an error code generated. In addition to general error codes, vendor-specific error codes can also occur. Information about these can be found in the operating instructions for the corresponding IO-Link device.

Error indicators in the registers

- The error bit is set in ParameterCtrIn, whereas the length of the error code is indicated in the data length parameter.
- ParameterDataIn contains the error code.

Error indicators in FlatStream

If the error bit is set, the FlatStream bytes are put together as follows:

- Bytes 1 to 3: Module-specific FlatStream array
- Byte 4: Error code; if 8 (error reported by device), bytes 5 and 6 will include additional information.
- Bytes 5 and 6: Error code from IO-Link device
- ...

Error codes

Code	Function
1	No device on this channel
2	IO-Link disabled
3	Communication error with device
4	Query buffer full
5	Event queue empty
6	Query not supported
7	Object access failed
8	Object access, error reported by device
9	Incorrect channel number
10	Write operation not possible
11	No input data available
12	Frame too short
13	One or more events discarded
14	Device has no input data
15	Device has no output data

4.26.9.9.16 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time	
Without IO-Link (all channels in SIO-Modus)	≥200 µs
With IO-Link	≥400 µs

4.26.9.9.17 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
Without IO-Link (all channels in SIO-Modus)	≥200 µs
With IO-Link	≥400 µs (depends on the minimum IO-Link cycle time of the IO-Link device)

4.26.10 X20PD0011

4.26.10.1 General information

The potential distributor module provides 12x ground (from the internal I/O supply) on the terminal connections and opens up additional wiring possibilities for actuators and sensors. The module is equipped with a replaceable microfuse between the GND potential on the terminal block and the X20 system I/O supply. The function of the fuse is monitored.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed

Information:

The wired load must be supplied with 24 VDC!

4.26.11.7 Register description

4.26.11.7.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.11.7.2 Function model 1 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	1	Module status	USINT	•			
		StatusFuse	Bit 0				

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

4.26.11.7.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	USINT	•			
		StatusFuse	Bit 0				

1) The offset specifies the position of the register within the CAN object.

4.26.11.7.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.26.11.7.4 Module status

Name:
Module status
StatusFuse

This register can be used to read the status of the installed fuse.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusFuse	0	Fuse OK
		1	Fuse not OK
1 - 7	Reserved	-	

4.26.11.7.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.26.11.7.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.26.12 X20PD0016

4.26.12.1 General information

The potential distributor module provides 5x 24 VDC and 5x ground connections (from an external supply) at the terminals. There is no connection to the internal I/O supply, so this module only serves to distribute an external supply for the load and electronics supply. The externally fed 24 VDC supply is provided on the terminal connections through a replaceable microfuse. The 24 VDC feed and the functionality of the fuse are monitored.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed
- Distribution of the load and electronics supply
- Isolation from the internal I/O supply

4.26.12.2 Order data

Model number	Short description	Figure

4.26.12.3 Technical data

Product ID	X20PD0016
Short description	
Potential distributor module	5x 24 VDC on the terminal connections, 5x ground on the terminal connections
General information	
B&R ID code	0x2680
Status indicators	Operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Fuse monitoring	Yes, using status LED and software
Power consumption [1]	
Bus	0.12 W
Internal I/O	-
External I/O	1.15 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Certification	
CE	Yes
cULus	Yes
cCSAus HazLoc Class 1 Division 2	Yes
ATEX Zone 2 [2]	Yes
KC	Yes
GL	Yes
GOST-R	Yes
Input supply	
Nominal input voltage	24 VDC -15% / +20% external, external ground
Fuse	Integrated 6.3 A, slow-blow, can be replaced
Reverse polarity protection	No
Output supply	
Rated output voltage	24 VDC, ground
Permitted contact load	10 A
Behavior if a short circuit occurs	
On the 24 VDC supply	Integrated fuse
On the GND connection	No protection available
Operating conditions	
Mounting orientation	
Horizontal	Yes
Vertical	Yes
Installation at elevations above sea level	
0 to 2000 m	No limitations
>2000 m	Reduction of ambient temperature by 0.5°C per 100 m
EN 60529 protection	IP20
Environmental conditions	
Temperature	
Operation	
Horizontal installation	-25 to 60°C
Vertical installation	-25 to 50°C

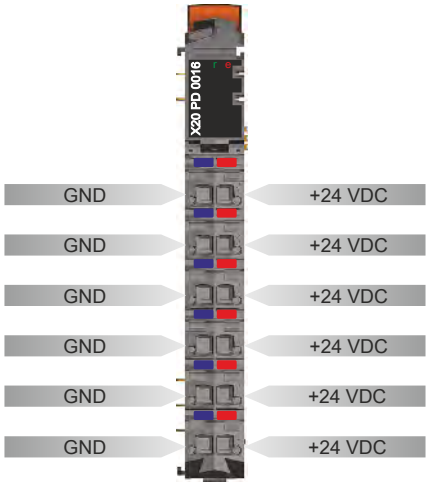
4.26.12.4 LED status indicators

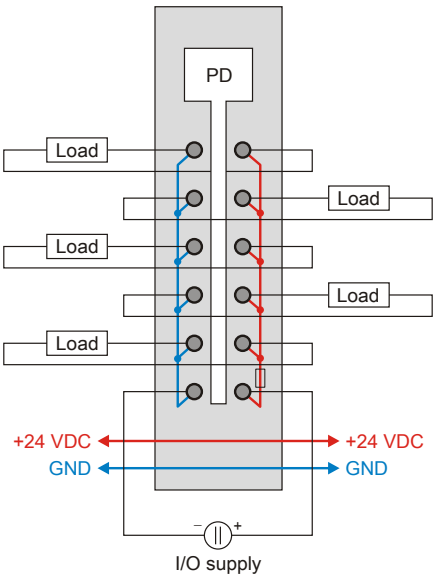
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Fuse defective or missing
			Double flash	Supply voltage too low
	e + r	Red on / Green single flash		Invalid firmware

4.26.12.5 Pinout



4.26.12.6 Connection example



4.26.12.7 Register description

4.26.12.7.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.12.7.2 Function model 1 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	1	Module status	USINT	•			
		StatusFuse	Bit 0				
		StatusPowerSupply	Bit 1				
2	2	Counter01	USINT	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

4.26.12.7.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	USINT	•			
		StatusFuse	Bit 0				
		StatusPowerSupply	Bit 1				
2	2	Counter01	USINT	•			

1) The offset specifies the position of the register within the CAN object.

4.26.12.7.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.26.12.7.4 Module status

Name:
Module status
StatusFuse
StatusPowerSupply

This register can be used to read the status of the power supply.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusFuse	0	Fuse OK
		1	Fuse not OK
	StatusPowerSupply	0	Level of fed voltage OK
		1	Level of fed voltage not OK
2 - 7	Reserved	-	

4.26.12.7.5 Counter for the voltage dips

Name:
Counter01

This register is used to count how often the voltage dips on the PD module.

Data type	Value
USINT	0 to 255

4.26.12.7.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.26.12.7.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.26.13 X20(c)PD2113

4.26.13.1 General information

The potential distributor module with feed can provide 6x 24 VDC and 6x ground connections from the internal I/O supply on the terminals. This module can also be used instead of a special feed module for the internal I/O supply. The internal 24 VDC supply is connected to the terminal connections through a replaceable microfuse for protection. The 24 VDC feed and the functionality of the fuse are monitored.

Information:

Since the 6x 24 VDC terminals are interconnected and the fuse is located between the terminals and the internal I/O supply, the terminal potentials are not protected against short circuits from an external feed. If using an external feed, the respective 24 VDC terminals must be protected with an external fuse. In this case a X20BM01 bus module should be used.

- Integrated exchangeable microfuse
- Monitoring of the fuse
- Potential for routing as needed
- Can be used as feed module for the I/O supply

4.26.13.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.26.13.8 Register description

4.26.13.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.26.13.8.2 Function model 1 - Standard

Register	Fixed offset	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	1	Module status	USINT	•			
		StatusFuse	Bit 0				
		StatusPowerSupply	Bit 1				
2	2	Counter01	USINT	•			

Fixed modules require their data points to be in a specific order in the X2X frame. Cyclic access occurs according to a predefined offset, not based on the register address.

Non-cyclic access continues to be based on the register numbers.

4.26.13.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	USINT	•			
		StatusFuse	Bit 0				
		StatusPowerSupply	Bit 1				
2	2	Counter01	USINT	•			

1) The offset specifies the position of the register within the CAN object.

4.26.13.8.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.26.13.8.4 Module status

Name:
Module status
StatusFuse
StatusPowerSupply

This register can be used to read the status of the power supply.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	StatusFuse	0	Fuse OK
		1	Fuse not OK
	StatusPowerSupply	0	Level of fed voltage OK
		1	Level of fed voltage not OK
2 - 7	Reserved	-	

4.26.13.8.5 Counter for the voltage dips

Name:
Counter01

This register is used to count how often the voltage dips on the PD module.

Data type	Value
USINT	0 to 255

4.26.13.8.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.26.13.8.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
100 µs

4.26.14 X20PS4951

4.26.14.1 General information

In order to connect potentiometers, modules must first be supplied with the appropriate voltage. The potentiometer supply module can be used to supply four potentiometers with ±10 V. The data is evaluated using standard analog input modules.

- Open circuit and short circuit detection
- Simple implementation of potentiometer inputs
- 4x supply

4.26.14.2 Order data

				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Supply status	USINT	•			
		ShortCircuit01	Bit 0				
		...	...				
		ShortCircuit01	Bit 3				
		OpenLine01	Bit 4				
		...	...				
		OpenLine04	Bit 7				

1) The offset specifies the position of the register within the CAN object.

4.26.14.8.3.1 CAN I/O bus controller

The module occupies 1 digital logical slot on CAN-I/O.

4.26.14.8.4 Supply status

Name:
OpenLine01 to OpenLine04
ShortCircuit01 to ShortCircuit04

This register can be used to display the status of the respective channels.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	ShortCircuit01	0	No short circuit
		1	Short circuit on channel 1
...		...	
3	ShortCircuit04	0	No short circuit
		1	Short circuit on channel 4
4	OpenLine01	0	No open line
		1	Open line on channel 1
...		...	
7	OpenLine04	0	No open line
		1	Open line on channel 4

4.26.14.8.5 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.26.14.8.6 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.27 Power supply modules

The internal I/Os and the X2X Link are fed by the supply modules.

4.27.1 Brief information

Product ID	Short description	on page
X20PS2100	X20 power supply module, for internal I/O supply	2884
X20PS2110	X20 supply module, for internal I/O supply, integrated microfuse	2889

X20cPS2100	X20 power supply module, coated, for internal I/O supply	2884
X20cPS2110	X20 power supply module, coated, for internal I/O supply, integrated microfuse	2889
X20cPS3300	X20 power supply module, coated, for X2X Link and internal I/O supply	2900

4.27.2 X20(c)PS2100

4.27.2.1 General information

The supply module is used for the internal I/O supply.

- 24 VDC supply module for internal I/O supply

4.27.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

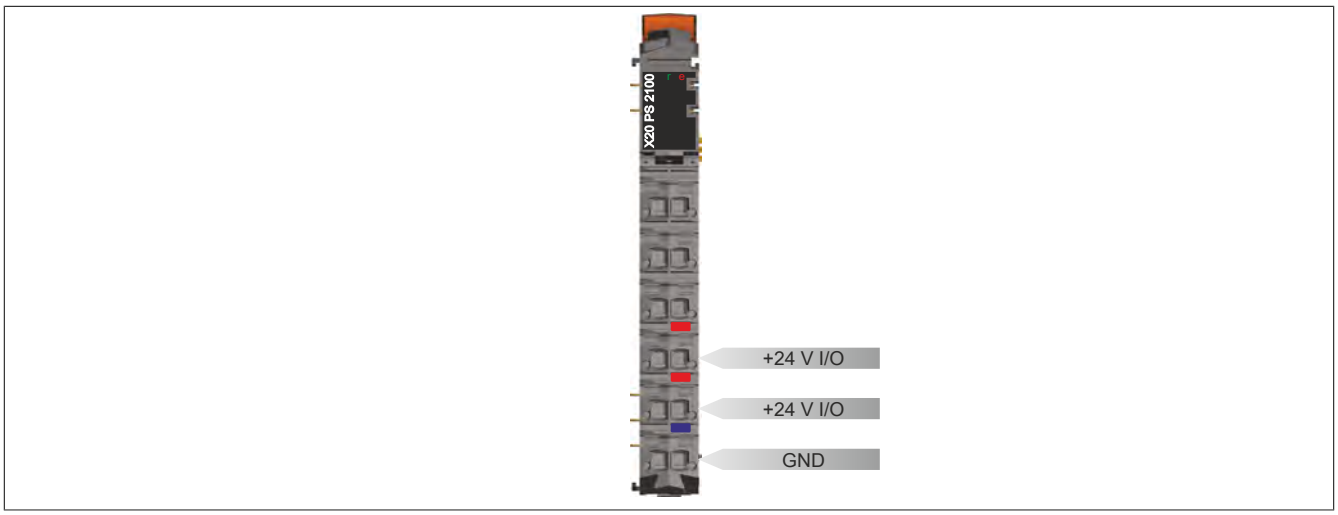
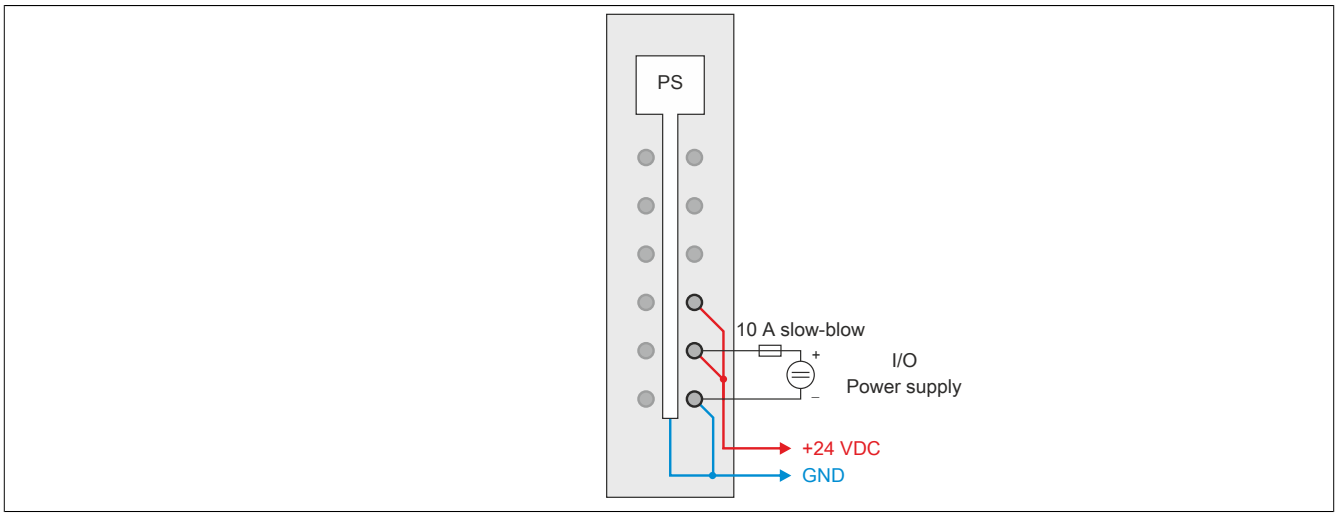
			Double flash	LED indicates one of the following states: • I/O supply too low • X2X link voltage too low
	e + r	Red on / Green single flash		Invalid firmware

4.27.2.6 Pinout



4.27.2.7 Connection example



4.27.2.8 Shutting the potential group down safely

In safety-related applications, it must be guaranteed that the potential group is safely shutdown in order to achieve category 4 shutdown in accordance with ISO 13849. An X20PS2100 (rev.F0 or higher) or X20PS2110 (rev.C0 or higher) supply module must be used to do this.

Important notes on "Safe shutdown" are listed in the X20 system user's manual, section"Mechanical and electrical configuration", section "Safe shutdown". The user's manual is available in the Downloads section of the B&R website (www.br-automation.com).

4.27.2.9 Register description

4.27.2.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.27.2.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
4	SupplyVoltage	USINT	•			

4.27.2.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.27.2.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.27.2.9.4 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Bus supply warning - Undervoltage (<4.7V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.27.2.9.5 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.2.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.27.2.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.27.3 X20(c)PS2110

4.27.3.1 General information

The supply module is used for the internal I/O supply. The module has an integrated replaceable fuse for the I/O supply.

- 24 VDC supply module for internal I/O supply
- Fuse for I/O supply integrated in module

4.27.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.27.3.3 Order data

Model number	Short description	Figure
	Power supplies	
X20PS2110	X20 supply module, for internal I/O supply, integrated microfuse

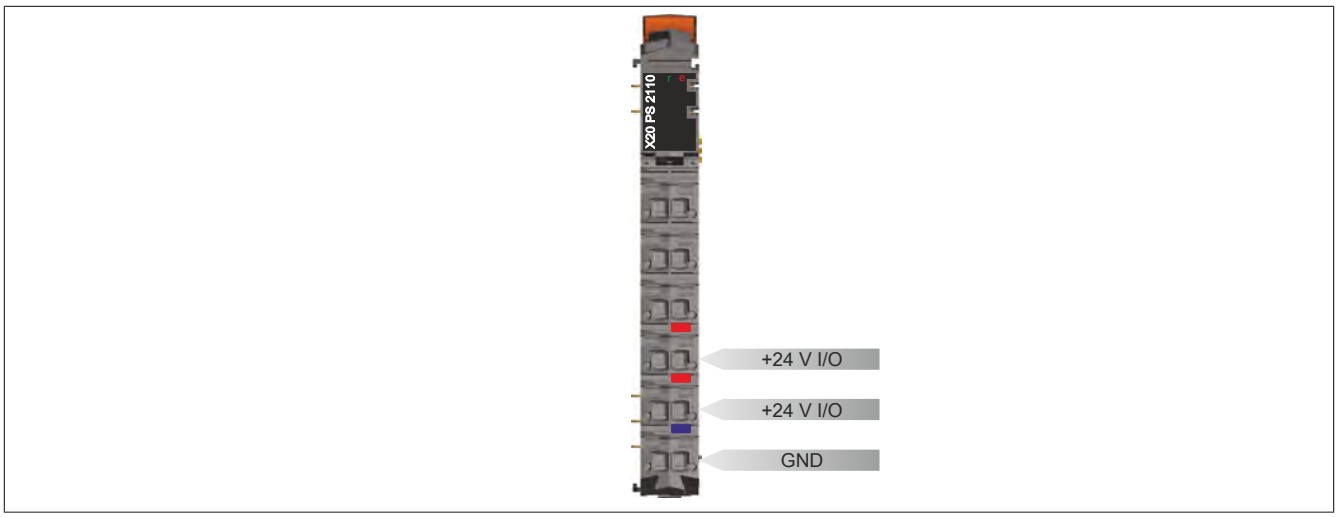
2) Ta min.: 0°C
Ta max.: See environmental conditions

4.27.3.5 LED status indicators

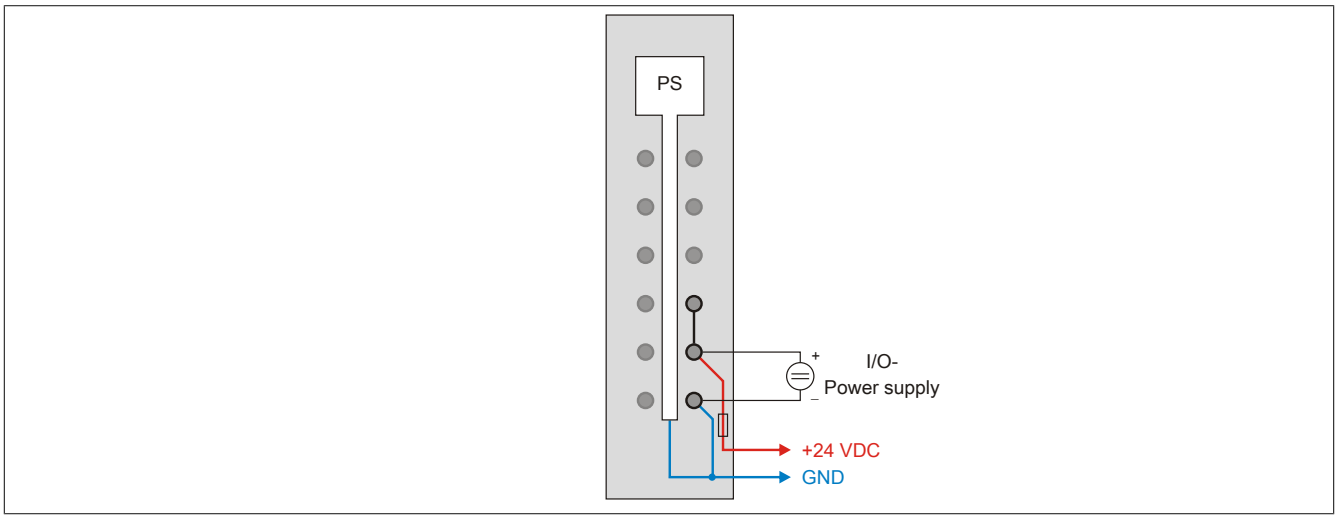
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • I/O supply too low • X2X Link voltage too low
	e + r	Red on / Green single flash		Invalid firmware

4.27.3.6 Pinout



4.27.3.7 Connection example



4.27.3.8 Shutting the potential group down safely

In safety-related applications, it must be guaranteed that the potential group is safely shutdown in order to achieve category 4 shutdown in accordance with ISO 13849. An X20PS2100 (rev.F0 or higher) or X20PS2110 (rev.C0 or higher) supply module must be used to do this.

Important notes on "Safe shutdown" are listed in the X20 system user's manual, section"Mechanical and electrical configuration", section "Safe shutdown". The user's manual is available in the Downloads section of the B&R website (www.br-automation.com).

4.27.3.9 Register description

4.27.3.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.27.3.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 1				
	StatusInput03	Bit 2				
4	SupplyVoltage	USINT	•			

4.27.3.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 1				
		StatusInput03	Bit 2				
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.27.3.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.27.3.9.4 Module status

Name:
Module status

The following module supply voltages are monitored in this register:

Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.
Fuse status:	Applies for hardware revision C0 and later. When using modules C0, a defective fuse is not detected.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Bus supply warning - Undervoltage (<4.7V)
1	StatusInput02	0	Fuse OK or hardware revision <C0
		1	Fuse defective
2	StatusInput03	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.27.3.9.5 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.3.9.6 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.27.3.9.7 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.27.4 X20(c)PS3300

4.27.4.1 General information

The supply module is equipped with a feed for the X2X Link as well as the internal I/O supply.

- Feed for X2X Link and internal I/O supply
- Electrical isolation of feed and X2X Link supply
- Redundancy of X2X Link supply possible by operating multiple supply modules simultaneously

4.27.4.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

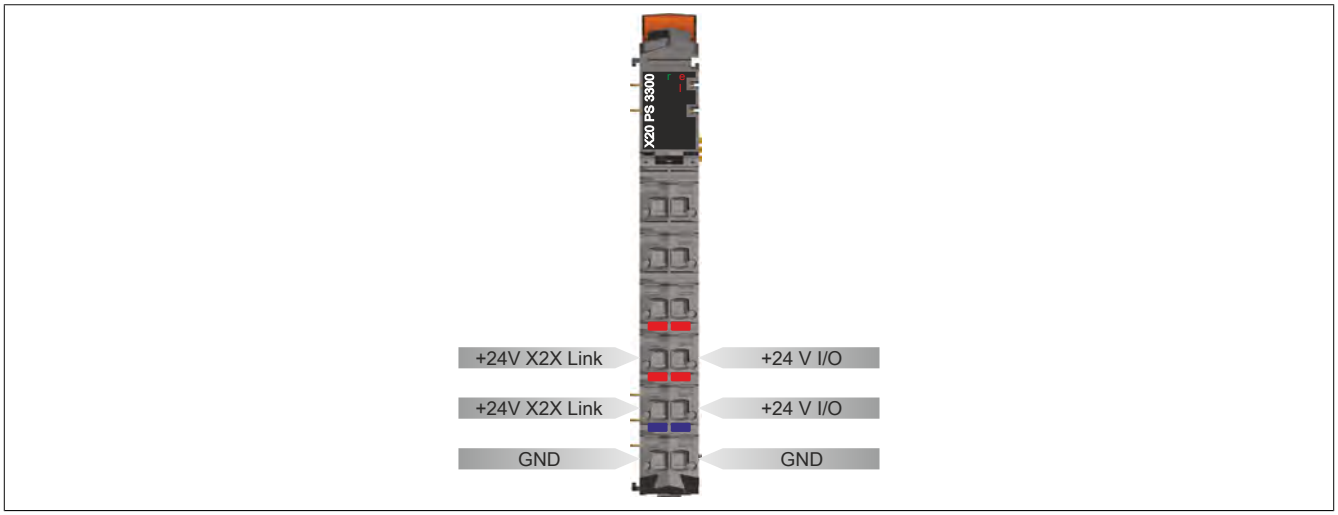
2) Ta min.: 0°C
   Ta max.: See environmental conditions
3) In parallel operation, only 75% of the rated power can be assumed. It is important to make sure that all power supplies operated in parallel are switched on and off at the same time.

4.27.4.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

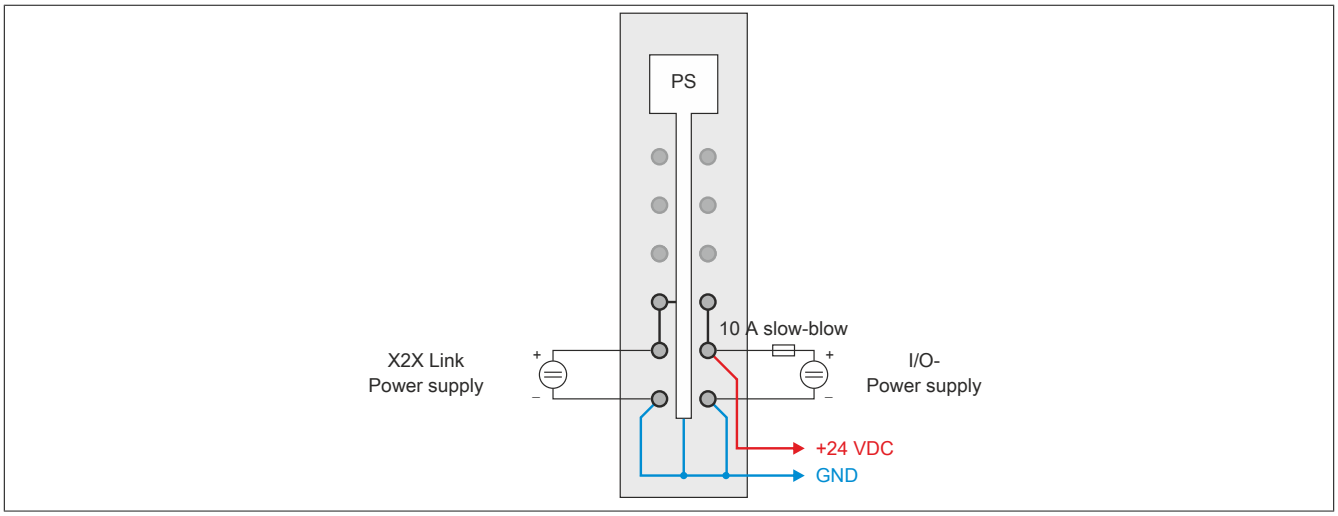
Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			Double flash	LED indicates one of the following states: • The X2X Link supply for the power supply is overloaded • I/O supply too low • Input voltage for X2X Link supply too low
	e + r	Red on / Green single flash		Invalid firmware
	l	Red	Off	The X2X Link supply is within the valid limits
			On	The X2X Link supply for the power supply is overloaded

4.27.4.6 Pinout

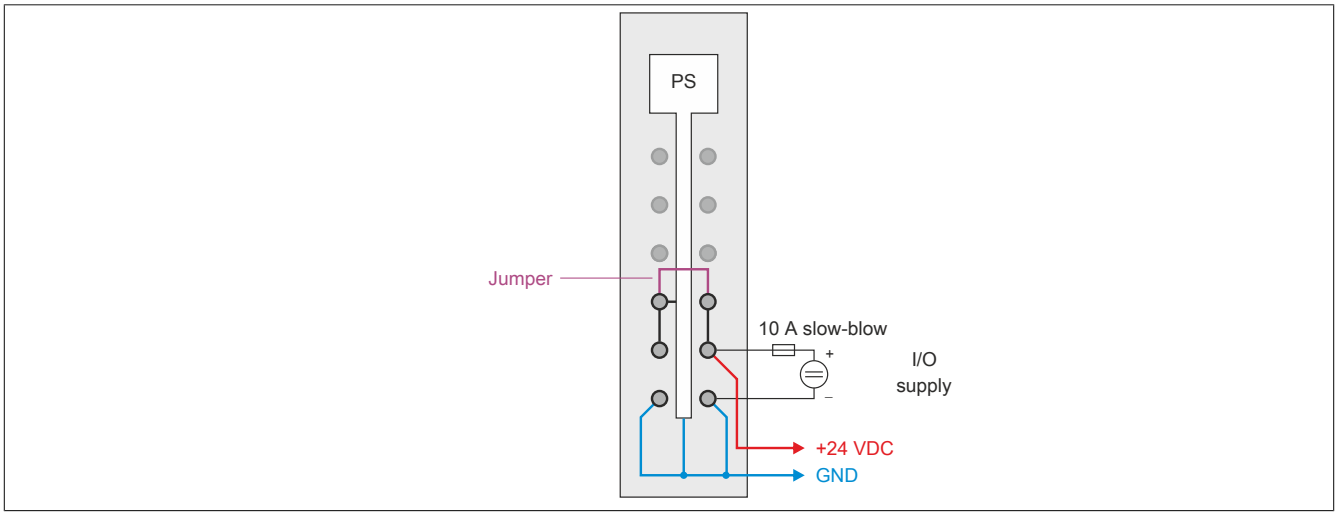


4.27.4.7 Connection examples

With 2 separate supplies

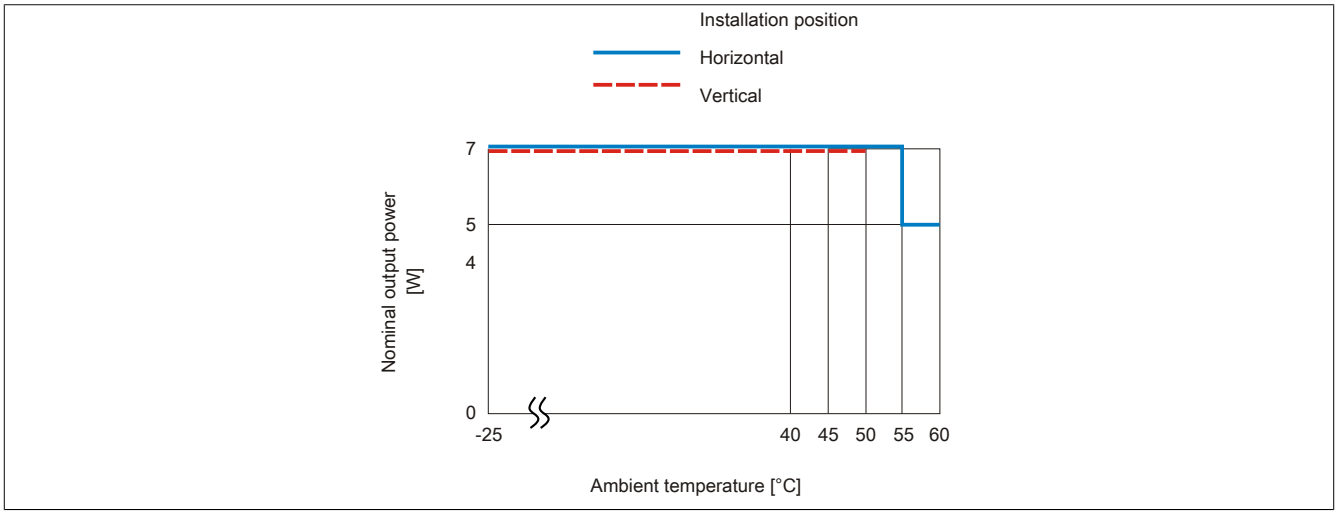


With a supply and jumper



4.27.4.8 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.27.4.9 Register description

4.27.4.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.27.4.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.27.4.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
2	2	SupplyCurrent	UINT	•			
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.27.4.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.27.4.9.4 Module status

Name:
Module status

The following voltage and current states of the module are monitored in this register:

Bus supply current:	A bus supply current of >2.3A is displayed as a warning.
Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Warning - overcurrent (>2.3 A) or undervoltage (<4.7 V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.27.4.9.5 Bus supply current

Name:
SupplyCurrent

This register displays the bus supply current measured at a resolution of 0.1 A.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.4.9.6 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.4.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.27.4.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.27.5 X20(c)PS3310

4.27.5.1 General information

The supply module is equipped with a feed for the X2X Link as well as the internal I/O supply. The module has an integrated replaceable fuse for the I/O supply.

- Feed for X2X Link and internal I/O supply
- Electrical isolation of feed and X2X Link supply
- Redundancy of X2X Link supply possible by operating multiple supply modules simultaneously
- Fuse for I/O supply integrated in module

4.27.5.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

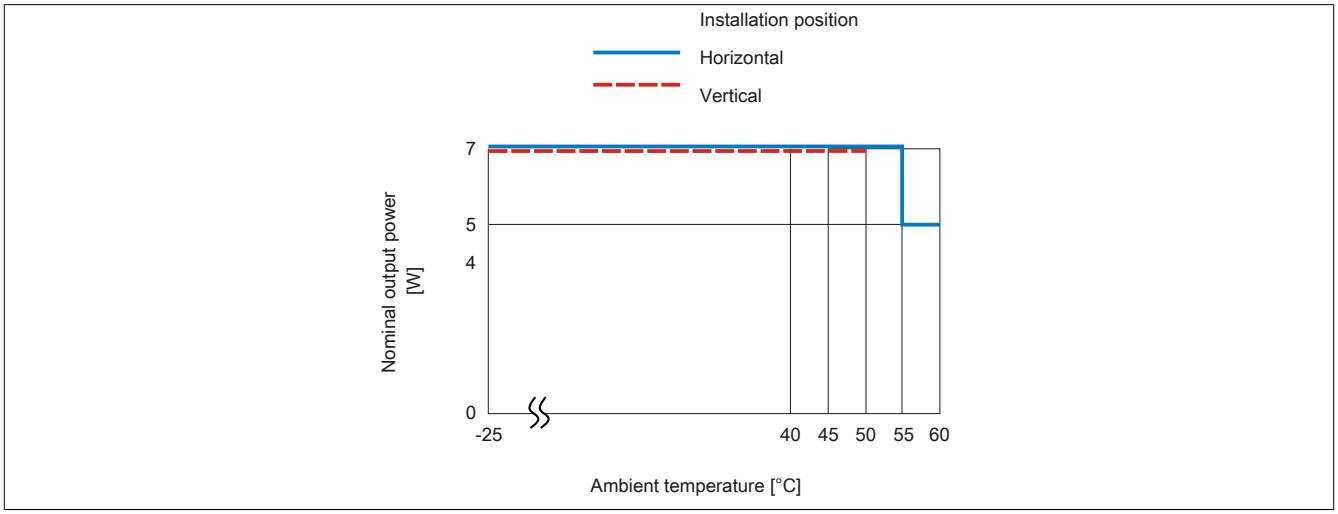
4.27.5.8 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.27.5.9 Register description

4.27.5.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.27.5.9.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	Module status	USINT	•			
	StatusInput01	Bit 0				
	StatusInput02	Bit 2				
2	SupplyCurrent	USINT	•			
4	SupplyVoltage	USINT	•			

4.27.5.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Non-cyclic	Cyclic	Non-cyclic
0	0	Module status	UINT	•			
		StatusInput01	Bit 0				
		StatusInput02	Bit 2				
2	2	SupplyCurrent	UINT	•			
4	4	SupplyVoltage	UINT	•			

1) The offset specifies the position of the register within the CAN object.

4.27.5.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.27.5.9.4 Module status

Name:
Module status

The following voltage and current states of the module are monitored in this register:

Bus supply current:	A bus supply current of >2.3A is displayed as a warning.
Bus supply voltage:	A bus supply voltage of <4.7V is displayed as a warning.
24 VDC I/O supply voltage:	An I/O supply voltage of <20.4 V is displayed as a warning.

Function model	Data type	Value
0 - Standard	USINT	See bit structure.
254 - Bus controller	UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	StatusInput01	0	No error
		1	Warning - overcurrent (>2.3 A) or undervoltage (<4.7 V)
1	Reserved	0	
2	StatusInput02	0	I/O supply above the warning level of 20.4 V
		1	I/O supply below the warning level of 20.4 V
3 - x	Reserved	0	

4.27.5.9.5 Bus supply current

Name:
SupplyCurrent

This register displays the bus supply current measured at a resolution of 0.1 A.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.5.9.6 Bus supply voltage

Name:
SupplyVoltage

This register displays the bus supply voltage measured at a resolution of 0.1 V.

Function model	Data type
0 - Standard	USINT
254 - Bus controller	UINT

4.27.5.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.27.5.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
2 ms

4.28 Redundancy system

Redundant network cabling is often essential to safe operation, especially in processing plants. The potential for danger, especially to the lines that run through the plant, can be disproportionately high in relation to the need to keep communication active in all operating situations. Redundant cabling and separate cable routing are effective ways to help reduce this risk.

POWERLINK cable redundancy is based on the principle of doubling the communication lines as well as providing continuous and simultaneous monitoring. A mechanism feeds data simultaneously into two cable lines. The same mechanisms are used to receive this data from the redundant network.

The following modules can be used to set up a POWERLINK network with cable redundancy:

- X20IF2181-2 interface module
- X20HB8884 compact link selector
- X20BC8084 bus controller

4.28.1 Brief information

Product ID	Short description	on page
X20HB8884	X20 compact link selector, 2x RJ45, order bus base, power supply module and terminal block separately.	2908
X20cHB8884	X20 compact link selector, coated, 2x RJ45, order bus base, power supply module and terminal block separately.	2908

4.28.2 X20(c)HB8884

4.28.2.1 General information

POWERLINK is a standard protocol for Fast Ethernet with hard real-time properties. The Ethernet POWERLINK Standardization Group (EPSG) ensures that the standard remains open and is continually developed. www.ethernet-powerlink.org

Systems with redundant cabling can be implemented easily using POWERLINK. Unlike ring redundancy, cable redundancy does not require cable looping, which can sometimes be problematic. This allows the creation of all types of tree structures. When using a device with the link selector function, data is always transferred via the highest quality network lines. The link selector function is integrated in the module compact link selector. This makes it easy to connect any POWERLINK device to a redundant POWERLINK network.

- Connecting POWERLINK devices to the POWERLINK cable redundancy system
- Integrated compact link selector function

4.28.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Spacing [2]		
X20BB81	62.5 $^{+.02}$ mm	
X20BB82	87.5 $^{+0.2}$ mm	

Table 674: X20HB8884, X20cHB8884 - Technical data

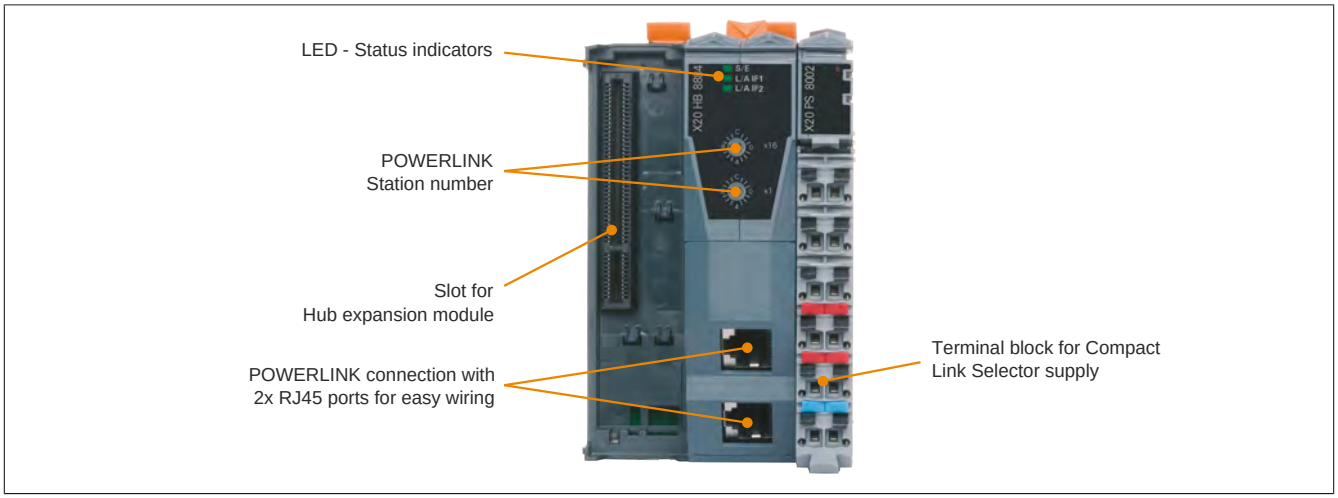
1) Ta min.: 0°C
Ta max.: See environmental conditions
2) Spacing is based on the width of the X20BB81 or X20BB82 bus base. One X20HB2880 hub expansion module or two X20HB2885 hub expansion modules and an X20PS8002 supply module are also always required for the compact link selector.

4.28.2.5 LED status indicators

Figure	LED	Color	Status	Description
	S/E[1]	Green	On	An active POWERLINK network was detected on both networks.
		Red	Single flash	Network 2 is active. Disturbances detected on network 1 or there is no POWERLINK network active. **The LED blinks red several times immediately after startup. This is not an error.**
			Double flash	Network 1 is active. Disturbances detected on network 2 or there is no POWERLINK network active. Note: The LED blinks red several times immediately after startup. This is not an error.
			On	Failure of both networks.
	L/A IFx	Green	Blinking	A link to the peer station has been established. The LED blinks when Ethernet activity is taking place on the bus.
			On	A link to the remote station has been established.

1) The Status/Error LED is a green/red dual LED.

4.28.2.6 Operating and connection elements

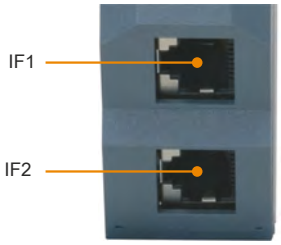


4.28.2.7 POWERLINK node numbers

The number switches have no function during operation. They are only used for product testing.

4.28.2.8 Ethernet interface

Information about cabling X20 modules with an Ethernet interface can be found in the module's download section on the B&R website (www.br-automation.com).



Interface	Pinout		
	Pin	Ethernet	
 1 Shielded RJ45	1	RXD	Receive data
	2	RXD\	Receive data\
	3	TXD	Transmit data
	4	Termination	
	5	Termination	
	6	TXD\	Transmit data\
	7	Termination	
	8	Termination	

4.28.2.9 POWERLINK cable redundancy system

It is often indispensable to have redundant network cabling, especially in systems that handle technical processes. The potential for danger, especially to the lines that run through the system, is disproportionately high in relation to the need to keep communication active in all operating situations. This risk is effectively reduced with double cabling that is routed separately.

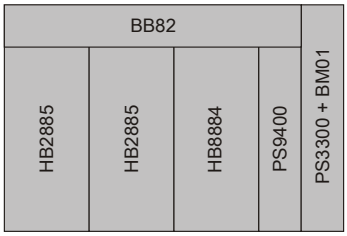
The POWERLINK cable redundancy system is based on the principle of doubling the transfer routing as well as providing continual and simultaneous monitoring. That means data is simultaneously fed into two cable lines using a corresponding mechanism. The same mechanisms are used to receive these telegrams from the redundant network.

Details about the structure of a redundancy system can be found in the "Redundancy for control systems" user's manual. The user's manual is available in the Downloads section of the B&R website www.br-automation.com.

4.28.2.10 Redundant supply voltage

When operating the X20HB8884 with two X20HB2885 hub modules, a redundant supply voltage for the system can be easily implemented using two X20 supply modules.

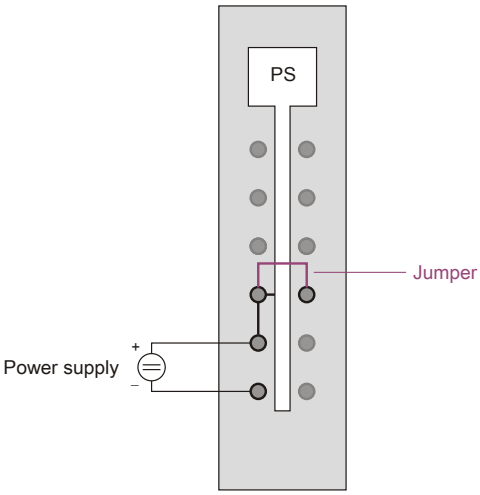
Hardware configuration



Connection example for supply modules

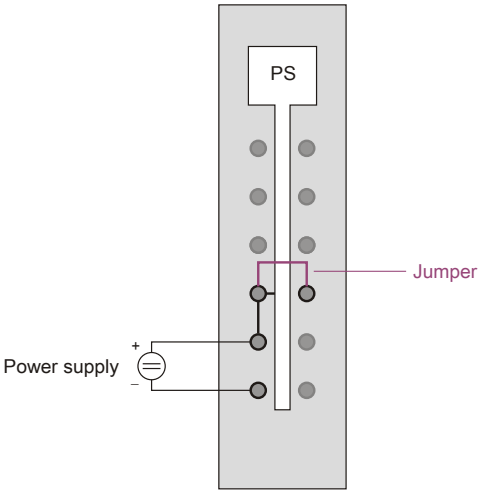
X20PS9400

On the X20PS9400, only the supply for the X20HB8884 is connected. For correct operation of the Error LED, a jumper is required.



X20PS3300

The supply module X20PS3300 is operated with a X20BM01 bus module. Only the supply for the X20HB8884 is connected. For correct operation of the Error LED, a jumper is required.



4.29 System modules for the X20 hub system

The X20 hub system has a modular structure. In addition to the basis modules, the following system modules are also required,

- Bus base
- Hub expansion module(s)
- Power supply module for standalone hub

4.29.1 Brief information

Product ID	Short description	on page
X20HB1881	X20 hub expansion module, integrated 1-port hub, for fiber optic cable	2914
X20HB2880	X20 hub expansion module, integrated 2-port hub, 2x RJ45	2917
X20HB2881	X20 hub expansion module, integrated 2-port hub, for fiber optic cable	2920
X20HB28G0	X20 EtherCAT junction module, integrated 2-port EtherCAT junction, 2x RJ45	2923
X20PS8002	X20 power supply module for standalone hub and compact link selector	2926
X20cHB1881	X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable	2914
X20cHB2880	X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45	2917
X20cHB2881	X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable	2920
X20cPS8002	X20 power supply module, coated, for standalone hub and compact link selector	2926

4.29.2 X20(c)HB1881

4.29.2.1 General information

The POWERLINK bus controllers X20BC8083, X20BC8084 (revision D0 or higher) and the stand-alone hub X20HB8880 are equipped with a modular hub expansion. An additional 1 or 2 slots are available, depending on the bus base used. The X20HB1881 hub expansion module can be operated in these slots. Note that the hardware revision of the X20BC8083 and the X20HB8880 must be ≥F0.

The hub expansion module is a 1x hub. The Ethernet connection is made using 62.5/125 µm or 50/125 µm fiber optic multimode cable with a duplex LC connection. The module and network status is indicated using LEDs.

- Hub expansion module
- 1x hub 100 BASE-FX
- Hot-swap-capable

4.29.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.29.4.8 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 µm or 50/125 µm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

4.29.5 X20HB28G0

4.29.5.1 General information

The X20BC80G3 expandable EtherCAT bus controller and the X20HB88G0 stand-alone EtherCAT junction base module are equipped with an additional slot. The X20HB28G0 EtherCAT junction module is operated in this slot.

The X20HB28G0 module is equipped with a 2x EtherCAT junction. The status of the module and network are indicated by LEDs.

- EtherCAT junction module
- 2x EtherCAT junction

4.29.6 X20(c)PS8002

4.29.6.1 General information

The supply module is used to supply X20 stand-alone devices. These include e.g. the X20HB8884 POWERLINK compact link selector and the X20HB8880 stand alone hub.

- Supply for X20 stand-alone devices
- No electrical isolation between the I/O supply and the device power supply

4.29.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

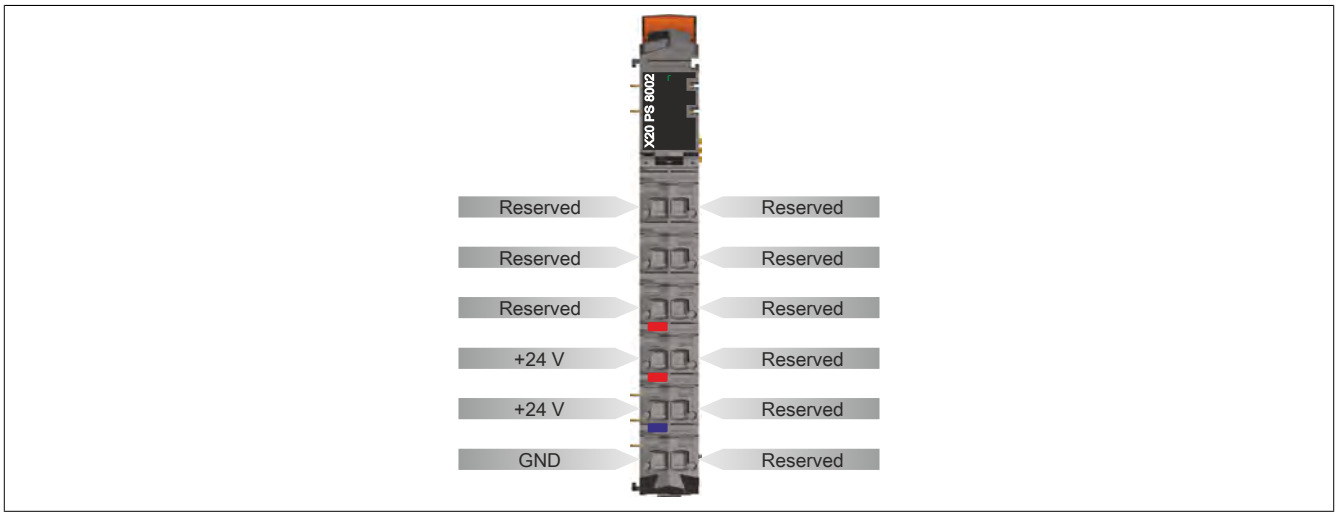
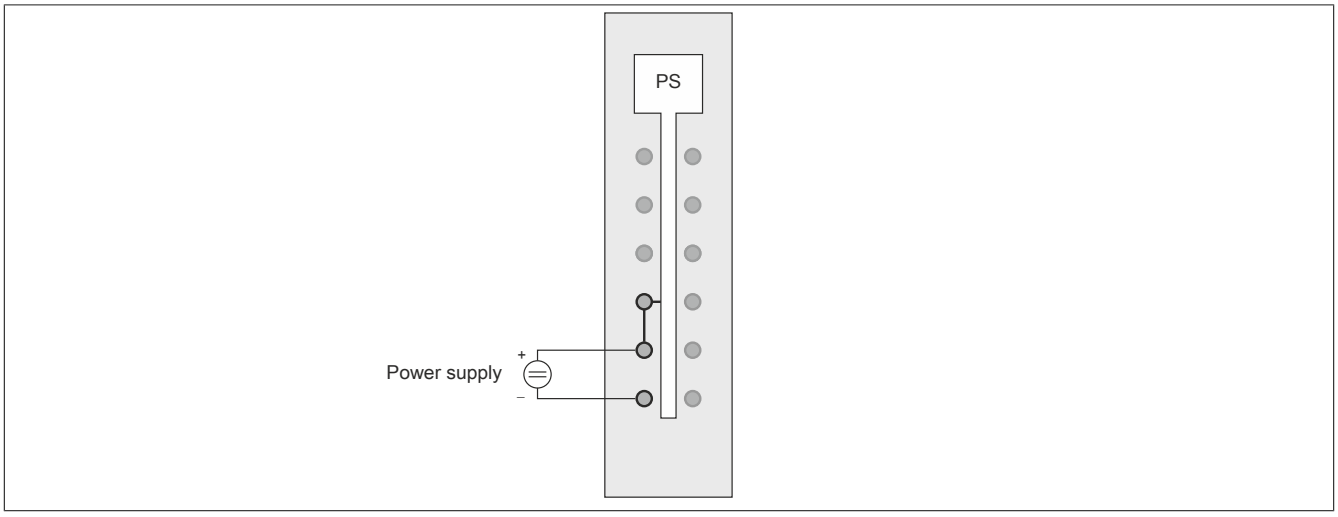
4.29.6.5 LED status indicators

Figure	LED	Color	Status	Description
	r	Green	On	Input voltage > 19.2 V

4.29.6.6 Pinout

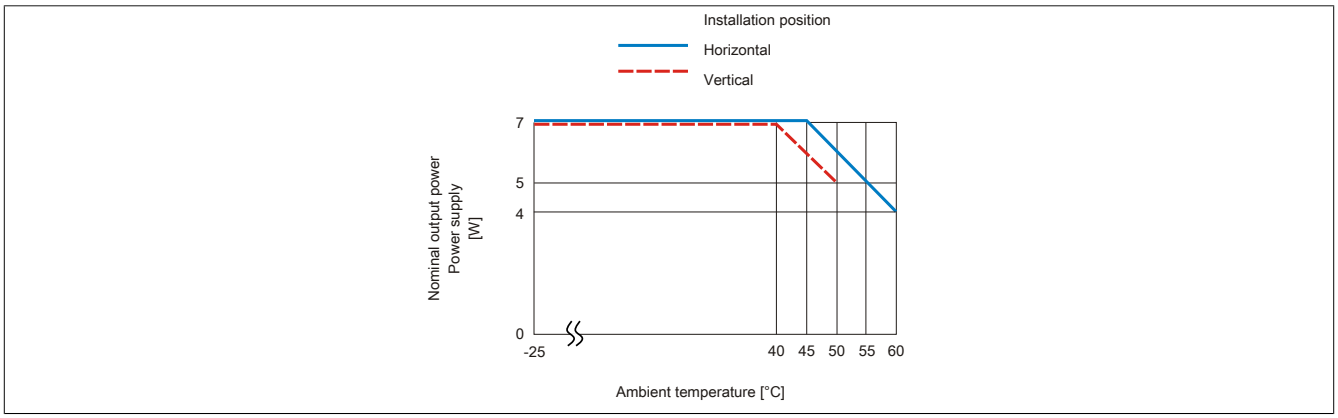


4.29.6.7 Connection example



4.29.6.8 Derating

The rated output current for the supply is 7 W. Derating must be taken into consideration based on mounting orientation.



4.30 System modules for the X20 redundancy system

The X20 redundancy system has a modular structure. In addition to the basis modules, the following system modules are also required,

- Bus base
- Hub expansion module(s)
- Power supply module for standalone hub

4.30.1 Brief information

Product ID	Short description	on page
X20HB2885	X20 hub expansion module, integrated active 2-port hub, 2x RJ45	2930
X20HB2886	X20 hub expansion module, integrated active 2-port hub, 2 fiber optic interfaces	2934
X20cHB2885	X20 hub expansion module, coated, integrated active 2-port hub, 2x RJ45	2930
X20cHB2886	X20 hub expansion module, coated, integrated active 2-port hub, 2 fiber optic interfaces	2934

4.30.2 X20(c)HB2885

4.30.2.1 General information

The X20BC8084 POWERLINK bus controller and the X20HB8884 module are equipped with an integrated link selector function. An additional 1 or 2 slots are available, depending on the bus base used. The active X20HB2885 hub expansion module can be operated in these slots.

The active hub expansion module is equipped with one integrated 2x hub and allows redundant wiring. This means that the connection between the two ports remains intact if there is a failure in the bus controller or Compact Link Selector. The status of the module and network are indicated by LEDs.

- Active hub expansion module
- 2x Fast Ethernet hub for redundant wiring
- Hot-swap-capable

4.30.2.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

	8	Termination	

4.30.3 X20(c)HB2886

4.30.3.1 General information

The X20BC8084 POWERLINK bus controller and the X20HB8884 module are equipped with an integrated link selector function. An additional 1 or 2 slots are available, depending on the bus base used. The active X20HB2886 hub expansion module can be operated in these slots. Note that the hardware revision of the X20BC8084 and the X20HB8884 must be ≥E0.

The active hub expansion module is equipped with one integrated 2x hub and allows redundant wiring. This means that the connection between the two 100 Base-FX interfaces remains intact if there is a failure in the bus controller or Compact Link Selector. The Ethernet connection is made using 62.5/125 µm or 50/125 µm fiber optic multimode cable with a duplex LC connection. The status of the module and network are indicated by LEDs.

- Active hub expansion module
- 2x 100 BASE-FX hub for redundant wiring
- Hot-swap-capable

4.30.3.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Figure	Description
	100 BASE-FX, Duplex LC female

4.30.3.8 Wiring guidelines for X20 modules with fiber optic cable

The following wiring guidelines must be observed:

- Cable fiber type: Multimode fiber with 62.5/125 µm or 50/125 µm core diameter
- On both sides: Duplex LC male connector
- Observe minimum cable flex radius (see data sheet for the cable)

4.31 Temperature modules

Temperature measurement values are converted into number values which can be processed by the PLC using temperature modules.

In the PLC, the number values are always in 16-bit 2s complement, regardless of the resolution. In this way, the resolution (number of steps) of the temperature module does not have to be considered when creating the application program.

For temperature measurements, the temperature module returns the measured value in 0.1°C steps. That means, a result of 750 corresponds to 75.0°C. The data format 0.1°C is supported as standard by all temperature modules.

Every channel on temperature module has a status LED.

4.31.1 Brief information

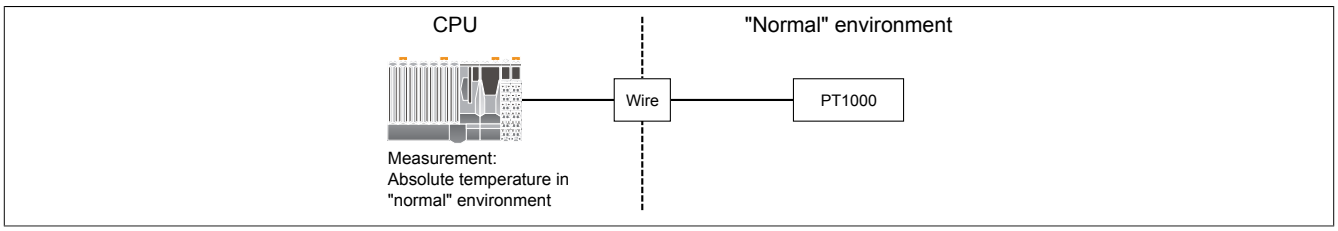
Product ID	Short description	on page
X20AT2222	X20 temperature input module, 2 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections	2939
X20AT2311	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.001°C, 4-wire connections	2949
X20AT2402	X20 temperature input module, 2 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C	2957
X20AT4222	X20 temperature input module, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections	2969
X20AT6402	X20 temperature input module, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C	2979
X20ATA312	X20 temperature input module, 2 inputs for resistance measurement, PT100, resolution 0.01°C, 4-wire connections	2991
X20ATA492	X20 temperature input module, 2 thermocouple inputs, type J, K, N, S, B, R, E, C, T, single channel electrically isolated, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately	3002
X20ATB312	X20 temperature input module, 4 inputs for resistance measurement, PT100, resolution 0.01 °C, 4-wire connections	3025
X20ATC402	X20 temperature input module, 6 thermocouple inputs, type J, K, N, S, B, R, E, C, T, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately	3036
X20cAT4222	X20 temperature input module, coated, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections	2969
X20cAT6402	X20 temperature input module, coated, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C	2979

4.31.2 Measurement methods

Depending on the area to be measured, there are two different methods for determining the temperature.

Method 1: Direct measurement using measurement resistor

The temperature module measures an electrical value that makes it possible to directly infer the current absolute temperature.

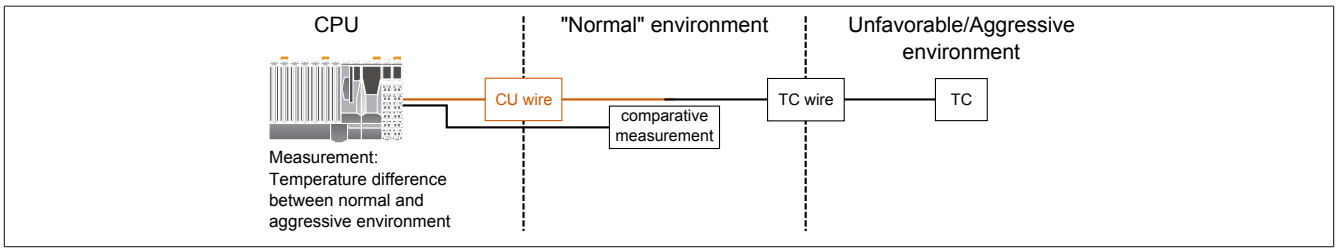


A measurement resistor often used in this method is the PT1000. Measuring the electrical resistance can be used to determine the absolute temperature at the measurement point for a temperature range of approximately -200°C to 850°C.

Method 2: Indirect measurement using thermocouples

Thermocouples are primarily used whenever it is not possible to use measurement resistors, for example because the environment directly around the measurement point contains aggressive gases.

This method of measuring bears on the basics of the thermoelectric effect. The module measures an electrical voltage, which can then be used to derive the difference in temperature.



Thermocouple modules from B&R prepare the temperature value at the measurement point as an absolute value. The measured temperature difference is referenced against another temperature that is usually measured directly at another location (see method 1).

Information:

In the best case, the temperature at the location where the thermocouple crosses an inexpensive copper cable is used as the reference or compensation value.

4.31.3 X20AT2222

4.31.3.1 General information

The module is equipped with 2 inputs for PT100/PT1000 resistance temperature measurement.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 inputs for resistance temperature measurement
- For PT100 and PT1000
- Configurable sensor type per channel
- Direct resistance measurement
- Configurable 2- or 3- wire connections per module
- Configurable filter time

4.31.3.2 Order data

Model number	Short description	Figure

ATEX Zone 2 [1]	Yes
KC	Yes
GL	Yes
GOST-R	Yes
Temperature inputs resistance measurement	
Input	Resistance measurement with constant current supply for 2- or 3-wire connections
Digital converter resolution	16-bit
Filter time	Configurable between 1 ms and 66.7 ms
Conversion time	
1 channel	20 ms with 50 Hz filter
2 channels	80 ms with 50 Hz filter
Conversion procedure	Sigma Delta
Output format	INT or UINT for resistance measurement
Sensor	
Sensor type	Configurable per channel
PT100	-200 to 850°C
PT1000	-200 to 850°C
Resistance measurement range	0.1 to 4500 Ω / 0.05 to 2250 Ω
Input filter	1st-order low pass / cutoff frequency 500 Hz
Sensor standard	IEC/EN 60751
Common-mode range	>0.7 V
Isolation voltage between channel and bus	500 V_{eff}
Linearization method	Internal
Measuring current	250 µA ±1.25%
Reference	4530 Ω ±0.1%
Permitted input signal	Short-term max. ±30 V
Max. error at 25°C	
Gain	0.037% [2]
Offset	0.0015% [3]
Max. gain drift	0.004% per °C [2]
Max. offset drift	0.00015% per °C [3]
Nonlinearity	<0.0010% [3]
Crosstalk between channels	<-93 dB
Temperature sensor resolution	
PT100	1 LSB = 0.1°C
PT1000	1 LSB = 0.1°C
Resistance measurement resolution	
G = 1	0.1 Ω
G = 2	0.05 Ω
Common-mode rejection	
50 Hz	>80 dB
DC	>95 dB
Standardized value range for resistance measurement	
G = 1	0.1 to 4500.0 Ω
G = 2	0.05 to 2250.0 Ω
Temperature sensor standardization	
PT100	-200.0 to 850.0°C
PT1000	-200.0 to 850.0°C

4.31.3.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Warning/Error on an I/O channel. Overflow or underflow of the analog inputs.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	The input is switched off
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

4.31.3.5 Pinout

Channels that are not being used should be disabled.

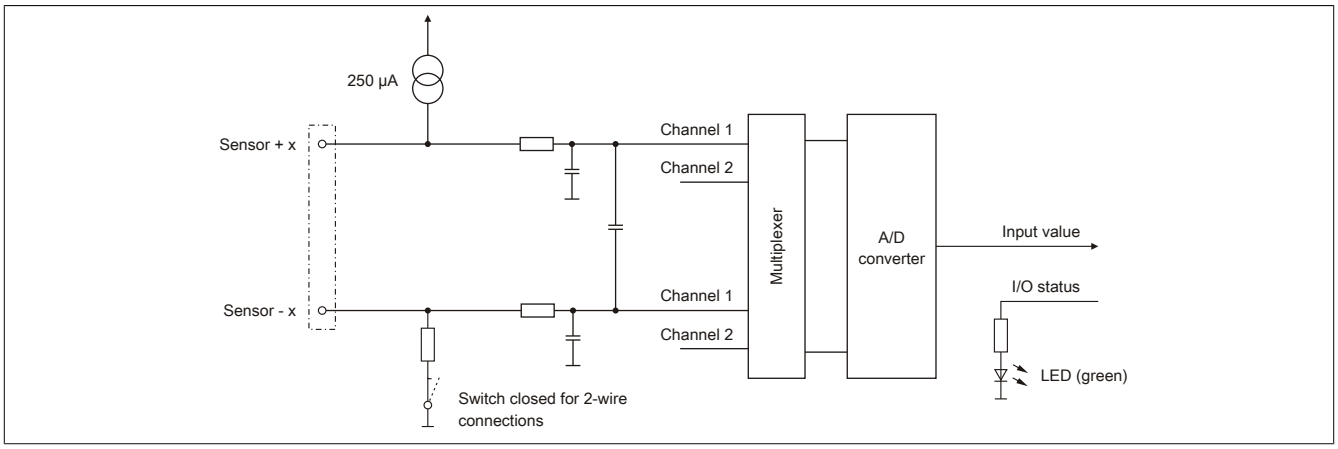
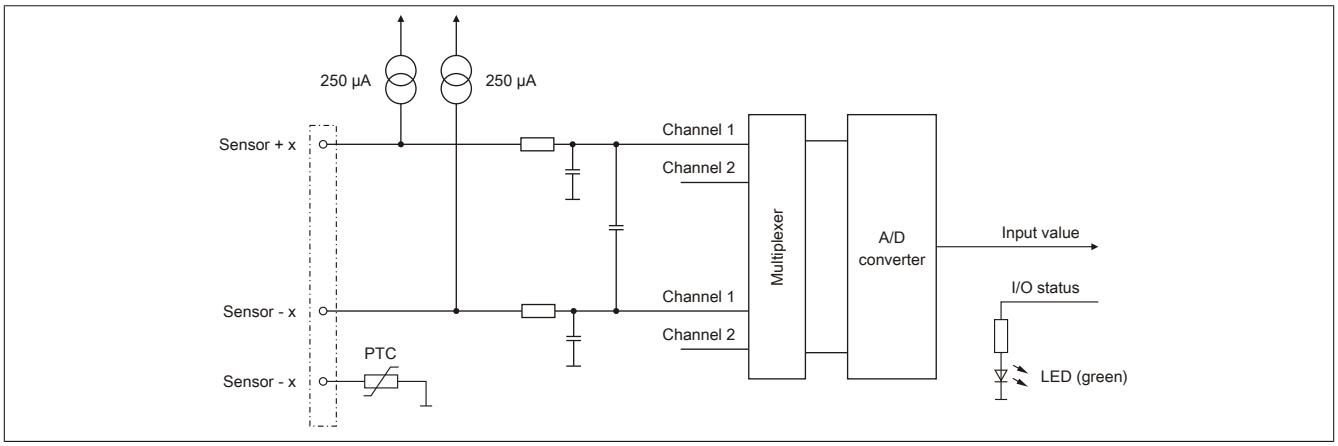
2-wire connections



3-wire connections



4.31.3.8 Register description

4.31.3.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.3.8.2 Function model 0 - "3-wire connections" and function model 1 - "2-wire connections"

For this module, the connection type is selected using function models 0 and 1.

Function model	Connection type
0	3-wire connections (standard)
1	2-wire connections

The registers used are identical for both function models:

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
16	ConfigOutput01	USINT				●
18	ConfigOutput02	USINT				●
Communication						
0	Temperature01	INT	●			
	Resistor01	UINT				
2	Temperature02	INT	●			
	Resistor02	UINT				
28	IOCycleCounter	USINT	●			
30	StatusInput01	USINT	●			

4.31.3.8.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
16	-	ConfigOutput01	USINT				●
18	-	ConfigOutput02	USINT				●
Communication							
0	0	Temperature01	INT	●			
	0	Resistor01	UINT				
2	2	Temperature02	INT	●			
	2	Resistor02	UINT				
28	-	IOCycleCounter	USINT		●		
30	-	StatusInput01	USINT		●		

1) The offset specifies the position of the register within the CAN object.

4.31.3.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.3.8.4 General information

4.31.3.8.4.1 Analog inputs

This module stores converted analog values in the registers. Different resistance or temperature measurements will result in different value ranges and data types.

Information:

Operating channels outside the specification can have an effect on neighboring channels.

4.31.3.8.4.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

4.31.3.8.4.3 Conversion time

The conversion time for the channels depends on their use. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

Channel uses	Conversion time
1 channel	1 · Filter time
n channels with the same sensor type	n · (20 ms + Filter time)
n channels with different sensor types	n · (20 ms + 2 · Filter time)

4.31.3.8.4.4 Reduced update time

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily.

The time saved is equal to:

$$\text{Time saved} = 2 \cdot 20\ \text{ms} + \text{Filter time}$$

The filter time is the conversion time for the remaining channels.

Examples

Inputs are filtered using a 60 Hz filter.

	Example 1	Example 2
Switched on inputs	1	1 to 2
Conversion time	16.7 ms	734 ms

4.31.3.8.5 Configuration

4.31.3.8.5.1 Input filter

Name:
ConfigOutput01

This register can be used to configure the filter time for all analog inputs.

Data type	Value	Filter	Filter time
USINT	0	15 Hz	66.7 ms
	1	25 Hz	40 ms
	2	30 Hz	33.3 ms
	3	50 Hz	20 ms
	4	60 Hz	16.7 ms
	5	100 Hz	10 ms
	6	500 Hz	2 ms
	7	1000 Hz	1 ms

4.31.3.8.5.2 Sensor configuration

Name:
ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON. To save time, individual channels can be switched off (see "Reduced update time").

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Channel 1	0000 - 0001	Reserved
		0010	PT100 sensor type
		0011	PT1000 sensor type
		0100	Reserved
		0101	Resistance measurement 0.1 to 4500 Ω
		0110	Resistance measurement 0.05 to 2250 Ω
		1111	Channel disabled
4 - 7	Channel 2	0000 - 0001	Reserved
		0010	PT100 sensor type
		0011	PT1000 sensor type
		0100	Reserved
		0101	Resistance measurement 0.1 to 4500 Ω
		0110	Resistance measurement 0.05 to 2250 Ω
		1111	Channel disabled

4.31.3.8.6 Communication

4.31.3.8.6.1 Analog input values

Name:
Temperature01 to Temperature02
Resistor01 to Resistor02

This register is used to indicate the analog input values depending on the configured operating mode.

Data type	Digital value	Input signal
INT	-2000 to 8500 (for -200.0 to 850.0°C)	PT100 sensor type
	-2000 to 8500 (for -200.0 to 850.0°C)	PT1000 sensor type
UINT	1 to 45000 (resolution 0.1 Ω)	Resistance measurement 0.1 to 4500 Ω
	1 to 45000 (resolution 0.05 Ω)	Resistance measurement 0.05 to 2250 Ω

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0x8000 is output.

4.31.3.8.6.2 I/O cycle counter

Name:
IOCycleCounter

The cyclic counter increases after all input data has been updated.

Data type	Value	Information
USINT	0 to 255	Repeating counter

4.31.3.8.6.3 Input status

Name:
StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7		0	

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs.

Error status	Temperature measurement Digital value for error	Resistance measurement Digital value for error
Open line	32767 (0x7FFF)	65535 (0xFFFF)
Upper limit value exceeded	32767 (0x7FFF)	65535 (0xFFFF)
Lower limit value exceeded	-32767 (0x8001)	0 (0x0000)
Invalid value	-32768 (0x8000)[1)] 32767 (0x7FFF)[2)] 65535 (0xFFFF)[3)]	65535 (0xFFFF)

1) Default value or channel was disabled in the I/O configuration.
2) After switching off the channel during operation.
3) Value in function model 254 - Bus controller.

4.31.3.8.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.31.3.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
1 input	Equal to the filter time
2 inputs	2 · 20 ms + filter time

4.31.4 X20AT2311

4.31.4.1 General information

The module is equipped with 2 inputs for PT100 4-line resistance temperature measurement.

- 2 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement
- 4-wire measurement
- Configurable filter time

2337	-	IOCycleCounter	USINT		•		
2345	-	StatusInput01	USINT		•		

1) The offset specifies the position of the register within the CAN object.

4.31.4.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.4.8.4 General information

4.31.4.8.4.1 Timing

The timing for acquiring measurement values is determined by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

4.31.4.8.4.2 Conversion time

The conversion time for the channels depends on the filter time configured in the 4.31.4.8.5.1 "ConfigOutput1" register.

Channel uses	Conversion time
All channels independent of the configuration	1x filter time

4.31.4.8.4.3 Ratio of filter time to resolution

The following table shows the maximum frequency with which the specified resolution can be achieved.

Filter / Filter time	Resolution
5 Hz / 200 ms	0001°C
50 Hz / 20 ms	001°C
1000 Hz / 1 ms	01°C

4.31.4.8.5 Configuration

4.31.4.8.5.1 Input filter

Name:
ConfigOutput01

This register can be used to configure the filter time for all analog inputs.

Data type	Value	Filter	Filter time
USINT	0	15 Hz	66.7 ms
	1	25 Hz	40 ms
	2	30 Hz	33.3 ms
	3	50 Hz	20 ms
	4	60 Hz	16.7 ms
	5	100 Hz	10 ms
	6	500 Hz	2 ms
	7	1000 Hz	1 ms
	8	10 Hz	100 ms
	9	5 Hz	200 ms
	19	25 Hz	400 ms

4.31.4.8.5.2 Sensor type and channel disabling

Name:
ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Channel 1	0000	Reserved
		0001	Sensor type PT100, resolution 1 mK
		0010	Resistance measurement 0.5 Ω to 390 Ω, resolution 1 mΩ
		0011 to 0110	Reserved
		0111	Channel disabled
		1xxx	Reserved
4 - 7	Channel 2	0000	Reserved
		0001	Sensor type PT100, resolution 1 mK
		0010	Resistance measurement 0.5 Ω to 390 Ω, resolution 1 mΩ
		0011 to 0110	Reserved
		0111	Channel disabled
		1xxx	Reserved

4.31.4.8.6 Communication

4.31.4.8.6.1 Analog measurement inputs

Name:
Temperatur01 to Temperatur02
Resistor01 to Resistor02

These registers are used to indicate the analog input values depending on the configured operating mode. Different resistance or temperature measurements will result in different value ranges and data types.

Name	Data type	Input signal	Digital value
Temperatur01 to Temperatur02	DINT	PT100 sensor type	-200000 to +850000 (for -200 to +850°C)
Resistor01 to Resistor02	UDINT	Resistance measurement 0.5 to 390 Ω	500 to 390000 (resolution 0.001 Ω)

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x80000000 is output.
- After switching the sensor type, 0x80000000 is output until the first conversion.
- If the input is not switched on, 0x80000000 is output.

4.31.4.8.6.2 I/O cycle counter

Name:
IOCycleCounter

The cyclic counter increases after all input data has been updated.

Data type	Value	Information
USINT	0 to 255	Repeating counter

4.31.4.8.6.3 Input status

Name:
StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.

After an error, it takes about 15 filter times until a valid value is available again.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

Analog value in the event of error

In addition to the status info, the error type also sets the analog value as follows:

Error status	Temperature measurement - Digital value for error	Resistance measurement - Digital value for error
Open line	+2147483647 (0x7FFFFFFF)	+4294967295 (0xFFFFFFFF)
Upper limit value exceeded	+2147483647 (0x7FFFFFFF)	+4294967295 (0xFFFFFFFF)
Lower limit value exceeded	-2147483647 (0x80000001)	-2147483647 (0x80000001)
Invalid value	-2147483648 (0x80000000)	-2147483648 (0x80000000)

4.31.4.8.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.31.4.8.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1x filter time

4.31.5 X20AT2402

4.31.5.1 General information

The module is equipped with 2 inputs for J, K, N, S, B and R thermocouple sensors. The module has an integrated terminal temperature compensation.

This module is designed for X20 6-pin terminal blocks. If needed (e.g. for logistical reasons), the 12-pin terminal block can also be used.

- 2 inputs for thermocouples
- For sensor types J, K, N, S, B, R
- Additional direct raw value measurement
- Integrated terminal temperature compensation
- Configurable filter time

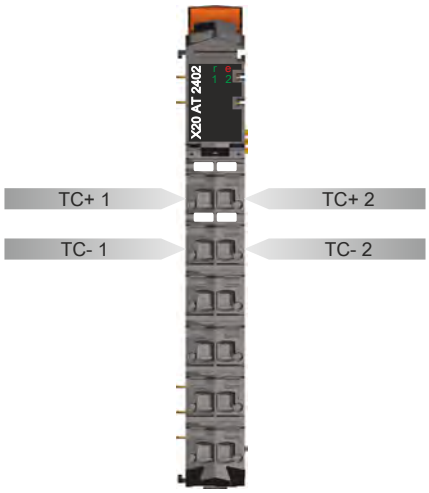
4.31.5.4 LED status indicators

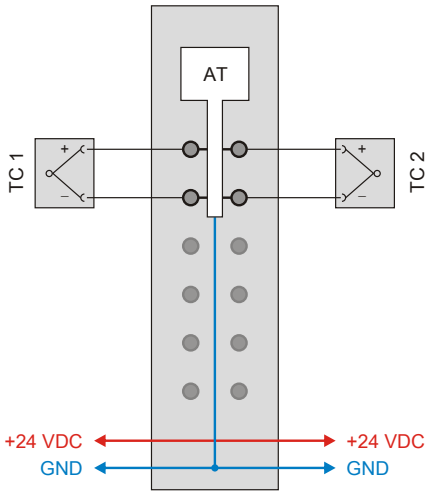
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Warning/Error on an I/O channel. Overflow or underflow of the analog inputs.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	The input is switched off
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

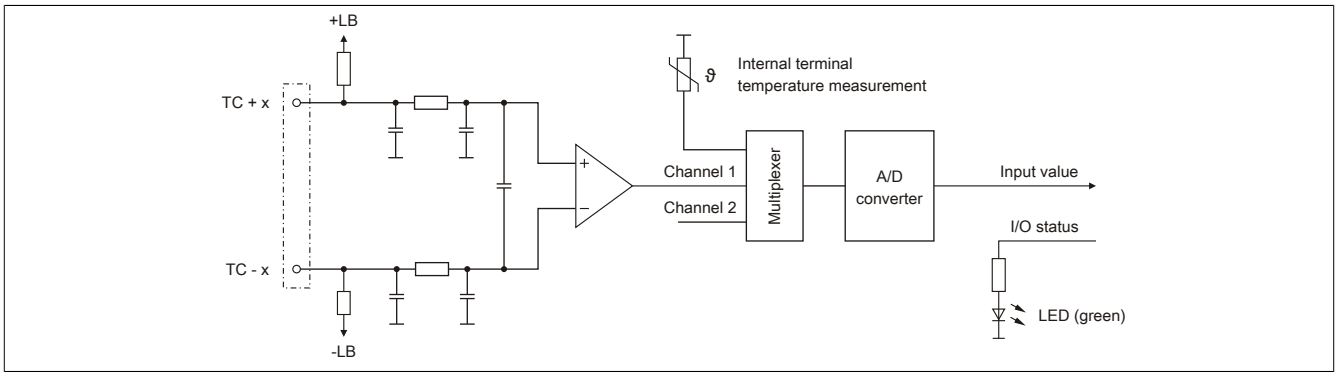
4.31.5.5 Pinout



4.31.5.6 Connection example

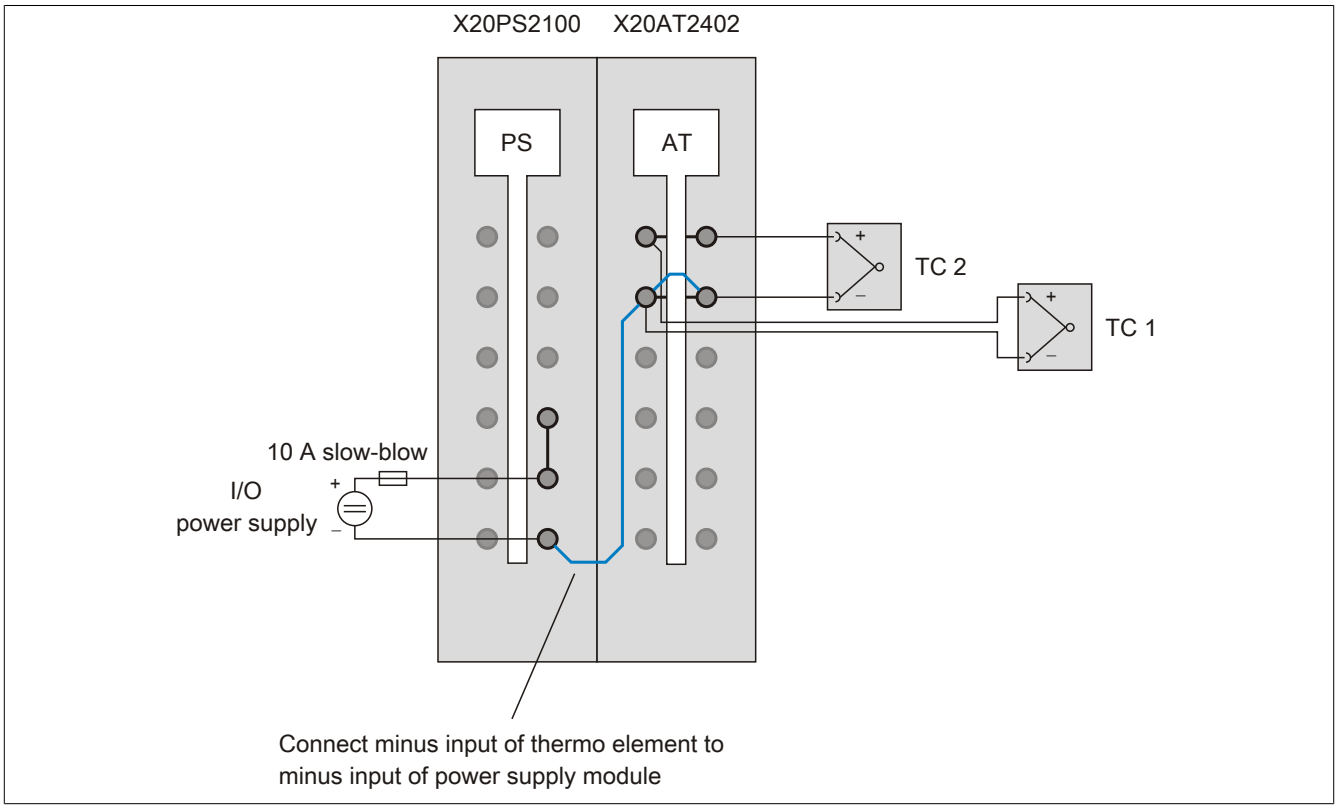


4.31.5.7 Input circuit diagram



4.31.5.8 Ceramic heating element with integrated thermo elements

We recommend connecting the minus input of the thermo element to the minus input of the supply feed module. This prevents potential measurement errors caused by ripple voltage effects in the measurement signal.



4.31.5.9 External cold junction

General information

An external cold junction temperature value can be predefined for the module for measurement value correction. This makes it possible to set up an external cold junction. The same external cold junction temperature is used for measurement value correction on all channels.

An external cold junction makes sense in the following applications and situations:

- Large distances between the controller and measurement point
- To increase precision

To bridge large distances

Setting up an external cold junction is recommended when there are large distances between the controller and the measurement point. The thermocouple voltage is routed from the external cold junction to the terminal on the X20AT2402 via copper wires. The temperature measured at the external cold junction (e.g. with PT100 - X20AT2222) is stored in the I/O area of the X20AT2402 module. The X20AT2402 uses the measured voltage and the cold junction temperature to internally calculate the needed thermocouple temperature.

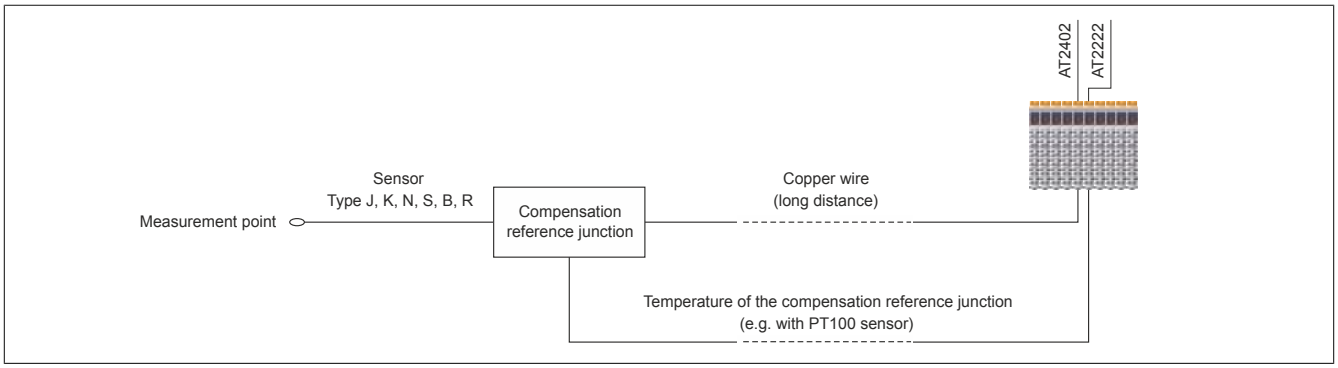


Figure 525: External cold junction for bridging large distances

Increased precision

Setting up an external cold junction is recommended to increase precision. The external cold junction is set up as described above. The installation of an external cold junction is especially helpful in the following cases:

- A module consuming more power than 1 W is connected in addition to the X20AT2402.
- No modules but the X20AT2402 are connected
- With strongly fluctuating ambient conditions (draft, temperature)

4.31.5.10 Register description

4.31.5.10.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.5.10.2 Function model 0 - default

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
24	ConfigOutput01	USINT				●
26	ConfigOutput02	USINT				●
27	ConfigOutput03	USINT				●
Communication						
0	Temperature01	INT	●			
2	Temperature02	INT	●			
28	IOCycleCounter	USINT	●			
30	StatusInput01	USINT	●			
14	CompensationTemperature	INT		●		

4.31.5.10.3 Function model 1 - External cold junction temperature

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
24	ConfigOutput01	USINT				●
26	ConfigOutput02	USINT				●
27	ConfigOutput03	USINT				●
Communication						
12	ExternalCompensationTemperature	INT			●	
0	Temperature01	INT	●			
2	Temperature02	INT	●			
28	IOCycleCounter	USINT	●			
30	StatusInput01	USINT	●			

4.31.5.10.4 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
24	-	ConfigOutput01	USINT				●
26	-	ConfigOutput02	USINT				●
27	-	ConfigOutput03	USINT				●
Communication							
0	0	Temperature01	INT	●			
2	2	Temperature02	INT	●			
28	-	IOCycleCounter	USINT		●		
30	-	StatusInput01	USINT		●		
14	-	CompensationTemperature	INT		●		

1) The offset specifies the position of the register within the CAN object.

4.31.5.10.4.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.5.10.5 General information

4.31.5.10.5.1 Raw value measurement

If a sensor type other than J, K, N, S, B or R is used, the terminal temperature must be measured on at least one input. Based on this value, the user must then implement terminal temperature compensation.

4.31.5.10.5.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All enabled inputs are converted during each conversion cycle. In addition, the terminal temperature is measured (not in function model 1).

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily. Measuring the terminal temperature is switched off in function model 1.

4.31.5.10.5.3 Conversion time

The conversion time depends on the number of channels and the function model. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

Function model	Conversion time
Model 0 - n channels	(n + 1) · (2 · Filter time + 200 µs)
Model 1 - n channels	n · (2 · Filter time + 200 µs)
Model 1 - 1 channel	Equal to the filter time

Examples

Inputs are filtered using a 50 Hz filter.

	Example 1		Example 2	
	Function model 0	Function model 1	Function model 0	Function model 1
Switched on inputs	1	1	1 - 2	1 - 2
Input conversion times	40.2 ms	20 ms	80.4 ms	80.4 ms
Conversion time for the terminal temperature	40.2 ms	-	40.2 ms	-
Total conversion time	80.4 ms	20 ms	120.6 ms	80.4 ms

4.31.5.10.6 Configuration

4.31.5.10.6.1 Input filter and ambient conditions

Name:
ConfigOutput01

This register configures input filters and ambient conditions.

Input filter

The filter time for all analog inputs is defined using the input filter parameter.

Value	Filter	Filter time	Digital converter resolution
0	15 Hz	66.7 ms	16-bit
1	25 Hz	40 ms	16-bit
2	30 Hz	33.3 ms	16-bit
3	50 Hz	20 ms	16-bit
4	60 Hz	16.7 ms	16-bit
5	100 Hz	10 ms	16-bit
6	500 Hz	2 ms	16-bit
7	1000 Hz	1 ms	16-bit

Environmental conditions

Ambient conditions are set in order to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module.

This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. Power consumption values can also be found in the technical data for the corresponding module. The higher value is used for the configuration.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Filter time	0000	15 Hz
		0001	25 Hz
		0010	30 Hz
		0011	50 Hz
		0100	60 Hz
		0101	100 Hz
		0110	500 Hz
		0111	1000 Hz
		1000 to 1111	Not permitted
4 - 7	Environmental conditions	0000	Default, no calculation for adjustment
		0001	Power dissipation less than 0.2 W
		0010	Power dissipation less than 1 W
		0011	Power dissipation more than 1 W
		0100 to 1111	Not permitted

4.31.5.10.6.2 Sensor type

Name:
ConfigOutput02

This module is designed for a wide range of sensor types. The sensor type must be configured because of the different alignment values.

Data type	Value	Information
USINT	0	Conversion switched off
	1	Sensor type J
	2	Sensor type K
	3	Sensor type S
	4	Sensor type N
	5	Conversion switched off
	6	Raw value without linearization and terminal temperature compensation: Resolution 1.0625 µV for a measurement range of ±35 mV
	7	Raw value without linearization and terminal temperature compensation: Resolution 2.125 µV for a measurement range of ±70 mV
	8 - 63	Conversion switched off
	64	Sensor type R
	65 - 71	Conversion switched off
	72	Sensor type B
	73 - 255	Conversion switched off

4.31.5.10.6.3 Channel disabling

Name:
ConfigOutput03

By default, all channels are switched on. To save time, individual channels can be switched off (see "Conversion time" on page 2964).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Off
		1	On
1	Channel 2	0	Off
		1	On
2 - 7	Reserved	0	

4.31.5.10.7 Communication

4.31.5.10.7.1 Analog inputs

Name:
Temperature01 to Temperature02

Analog input value depending on the configured sensor type:

Input signal	Digital value
Type J (FeCuNi)	-2100 to +12000 (for -210.0°C to +1200.0°C)
Type K (NiCrNi)	-2700 to +13720 (for -270.0°C to +1372.0°C)
Type N (NiCrSi)	-2700 to +13000 (for -270.0°C to +1300.0°C)
Type S (PtRhPt)	-500 to +17680 (for -50.0°C to +1768.0°C)
Type B (PtRhPt)	0 to +18200 (for 0°C to +1820.0°C)
Type R (PtRhPt)	-500 to +16640 (for -50.0°C to +1664.0°C)
Raw value without linearization and terminal temperature compensation: Resolution 1.0625 µV for a measurement range of ±35 mV	-32,768 to +32,767
Raw value without linearization and terminal temperature compensation: Resolution 2.125 µV for a measurement range of ±70 mV	-32,768 to +32,767

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0x8000 is output.

4.31.5.10.7.2 I/O cycle counter

Name:
IOCycleCounter

The cyclic counter increases after all input data has been updated.

Data type	Value	Information
USINT	0 to 255	Repeating counter

4.31.5.10.7.3 Input status

The module's inputs are monitored. A change in the monitoring status generates an error message.

In addition to the status info, the error type also sets the analog value as follows:

Error status	Digital value for error
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

Name:
StatusInput01

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

4.31.5.10.7.4 Reads the internal cold junction temperature

Name:
CompensationTemperature

The internal cold junction temperature is stored in this register.

Data type	Value	Information
INT	-250 to 850	Internal cold junction temperature (PT1000): -25.0 to 85.0°C

4.31.5.10.7.5 Defines the external cold junction temperature

Name:
ExternalCompensationTemperature

The external cold junction temperature is defined in this register.

Data type	Value	Information
INT	-250 to 850	External cold junction temperature: -25.0 to 85.0°C

4.31.5.10.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.31.5.10.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

For the formulas listed in the table, 'n' corresponds to the number of channels that are switched on.

Function model 0	
n inputs	(n + 1) · (Filter time + 200 µs)

Function model 1	
1 input	Equal to the filter time
n inputs	n · (Filter time + 200 µs)

4.31.6 X20(c)AT4222

4.31.6.1 General information

The module is equipped with 4 inputs for PT100/PT1000 resistance temperature measurement.

- 4 inputs for resistance temperature measurement
- For PT100 and PT1000
- Configurable sensor type per channel
- Direct resistance measurement
- Configurable 2- or 3- wire connections per module
- Configurable filter time

4.31.6.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.31.6.5 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Warning/Error on an I/O channel. Overflow or underflow of the analog inputs.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 4	Green	Off	The input is switched off
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

4.31.6.6 Pinout

Channels that are not being used should be disabled.

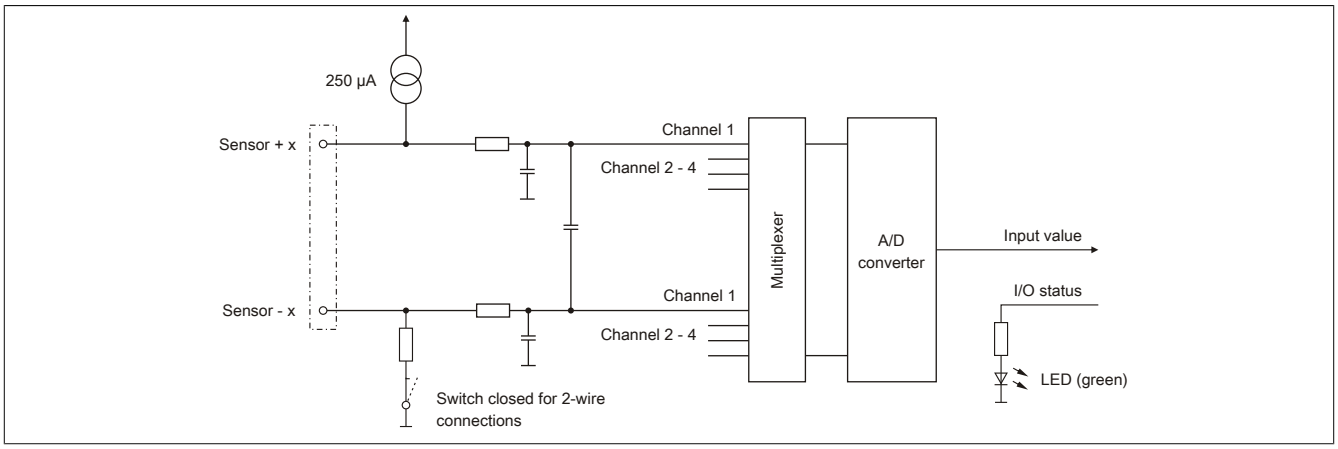
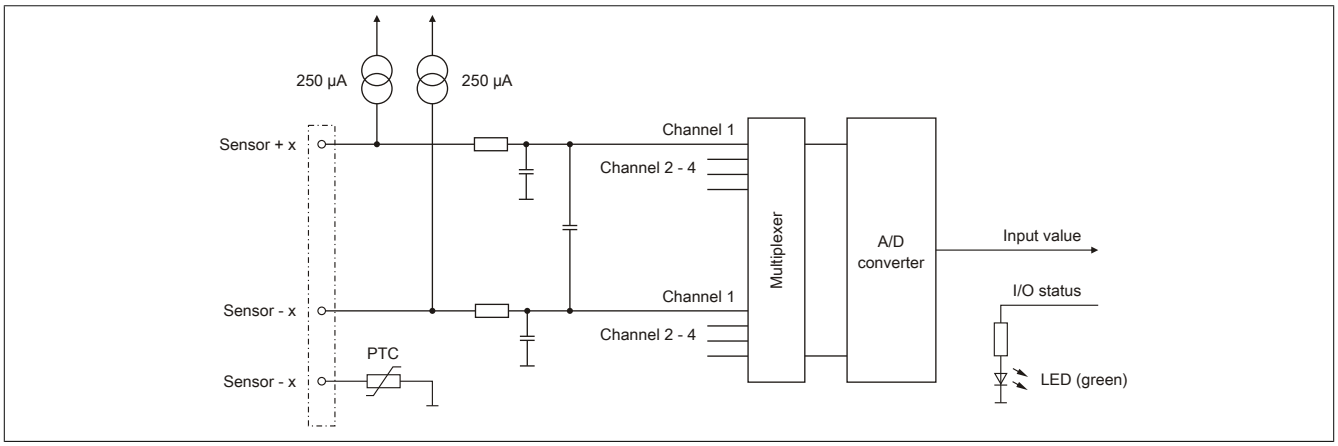
2-wire connections



3-wire connections



4.31.6.9 Register description

4.31.6.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.6.9.2 Function model 0 - "3-wire connections" and function model 1 - "2-wire connections"

For this module, the connection type is selected using function models 0 and 1.

Function model	Connection type
0	3-wire connections (standard)
1	2-wire connections

The registers used are identical for both function models:

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
16	ConfigOutput01	USINT				●
18	ConfigOutput02	UINT				●
Communication						
0	Temperature01	INT	●			
	Resistor01	UINT				
2	Temperature02	INT	●			
	Resistor02	UINT				
4	Temperature03	INT	●			
	Resistor03	UINT				
6	Temperature04	INT	●			
	Resistor04	UINT				
28	IOCycleCounter	USINT	●			
30	StatusInput01	USINT	●			

4.31.6.9.3 Function model 254 - Bus controller

Register	Offset[1)]	Name	Data type	Read		Write	
				Cyclic	Acyclic	Cyclic	Acyclic
Configuration							
16	-	ConfigOutput01	USINT				●
18	-	ConfigOutput02	UINT				●
Communication							
0	0	Temperature01	INT	●			
	0	Resistor01	UINT				
2	2	Temperature02	INT	●			
	2	Resistor02	UINT				
4	4	Temperature03	INT	●			
	4	Resistor03	UINT				
6	6	Temperature04	INT	●			
	6	Resistor04	UINT				
28	-	IOCycleCounter	USINT		●		
30	-	StatusInput01	USINT		●		

1) The offset specifies the position of the register within the CAN object.

4.31.6.9.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.6.9.4 General information

4.31.6.9.4.1 Analog inputs

This module stores converted analog values in the registers. Different resistance or temperature measurements will result in different value ranges and data types.

Information:

Operating channels outside the specification can have an effect on neighboring channels.

4.31.6.9.4.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All switched-on inputs are converted during each conversion cycle and transferred halfway through the X2X Link cycle.

4.31.6.9.4.3 Conversion time

The conversion time for the channels depends on their use. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

Channel uses	Conversion time
1 channel	1 · Filter time
n channels with the same sensor type	n · (20 ms + Filter time)
n channels with different sensor types	n · (20 ms + 2 · Filter time)

4.31.6.9.4.4 Reduced update time

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily.

Calculating the time saved

The amount of time saved can be calculated with the following formula. And "n" corresponds to the number of inputs that are switched off.

$$\text{Time saved} = n \cdot (20\ \text{ms} + \text{filter time})$$

Examples

Inputs are filtered using a 60 Hz filter.

	Example 1	Example 2	Example 3
Switched on inputs	1	1 and 3	1 to 4
Conversion time	16.7 ms	73.4 ms	146.8 ms

4.31.6.9.5 Configuration

4.31.6.9.5.1 Input filter

Name:
ConfigOutput01

This register can be used to configure the filter time for all analog inputs.

Data type	Value	Filter	Filter time
USINT	0	15 Hz	66.7 ms
	1	25 Hz	40 ms
	2	30 Hz	33.3 ms
	3	50 Hz	20 ms
	4	60 Hz	16.7 ms
	5	100 Hz	10 ms
	6	500 Hz	2 ms
	7	1000 Hz	1 ms

4.31.6.9.5.2 Sensor configuration

Name:
ConfigOutput02

This register can be used to configure the sensor type for individual channels.

This module is designed for temperature and resistance measurement. The sensor type must be specified because of the different calibration values for temperature and resistance.

The default setting for all channels is ON. To save time, individual channels can be switched off (see "Reduced update time").

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 3	Channel 1	0000 - 0001	Reserved
		0010	PT100 sensor type
		0011	PT1000 sensor type
		0100	Reserved
		0101	Resistance measurement 0.1 to 4500 Ω
		0110	Resistance measurement 0.05 to 2250 Ω
		1111	Channel disabled
...		...	
12 - 15	Channel 4	0000 - 0001	Reserved
		0010	PT100 sensor type
		0011	PT1000 sensor type
		0100	Reserved
		0101	Resistance measurement 0.1 to 4500 Ω
		0110	Resistance measurement 0.05 to 2250 Ω
		1111	Channel disabled

4.31.6.9.6 Communication

4.31.6.9.6.1 Analog input values

Name:
Temperature01 to Temperature04
Resistor01 to Resistor04

This register is used to indicate the analog input values depending on the configured operating mode.

Data type	Digital value	Input signal
INT	-2000 to 8500 (for -200.0 to 850.0°C)	PT100 sensor type
	-2000 to 8500 (for -200.0 to 850.0°C)	PT1000 sensor type
UINT	1 to 45000 (resolution 0.1 Ω)	Resistance measurement 0.1 to 4500 Ω
	1 to 45000 (resolution 0.05 Ω)	Resistance measurement 0.05 to 2250 Ω

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0x8000 is output.

4.31.6.9.6.2 I/O cycle counter

Name:
IOCycleCounter

The cyclic counter increases after all input data has been updated.

Data type	Value	Information
USINT	0 to 255	Repeating counter

4.31.6.9.6.3 Input status

Name:
StatusInput01

The module's inputs are monitored. A change in the monitoring status generates an error message.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
...		...	
6 - 7	Channel 4	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line

Limiting the analog value

In addition to the status information, the analog value is set to the values listed below by default when an error occurs.

Error status	Temperature measurement Digital value for error	Resistance measurement Digital value for error
Open line	32767 (0x7FFF)	65535 (0xFFFF)
Upper limit value exceeded	32767 (0x7FFF)	65535 (0xFFFF)
Lower limit value exceeded	-32767 (0x8001)	0 (0x0000)
Invalid value	-32768 (0x8000)[1)] 32767 (0x7FFF)[2)] 65535 (0xFFFF)[3)]	65535 (0xFFFF)

1) Default value or channel was disabled in the I/O configuration.
2) After switching off the channel during operation.
3) Value in function model 254 - Bus controller.

4.31.6.9.7 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
100 µs

4.31.6.9.8 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time	
1 input	Equal to the filter time
n inputs	n · (20 ms + filter time)

4.31.7 X20(c)AT6402

4.31.7.1 General information

The module is equipped with 6 inputs for J, K, N, S, B and R thermocouple sensors. The module has an integrated terminal temperature compensation.

- 6 inputs for thermocouples
- For sensor types J, K, N, S, B, R
- Additional direct raw value measurement
- Integrated terminal temperature compensation
- Configurable filter time

4.31.7.2 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

For simplification purposes, only images and module IDs of uncoated modules are used in this data sheet.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

4.31.7.3 Order data

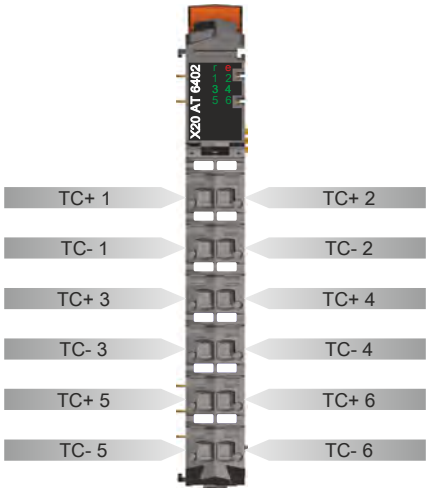
4.31.7.5 LED status indicators

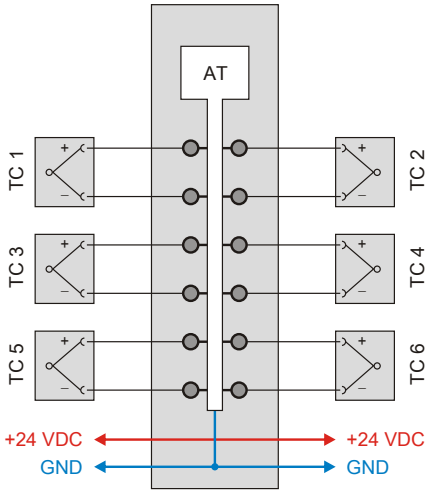
For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	r	Green	Off	No power to module
			Single flash	RESET mode
			Blinking	PREOPERATIONAL mode
			On	RUN mode
	e	Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	Warning/Error on an I/O channel. Overflow or underflow of the analog inputs.
	e + r	Red on / Green single flash		Invalid firmware
	1 - 6	Green	Off	The input is switched off
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

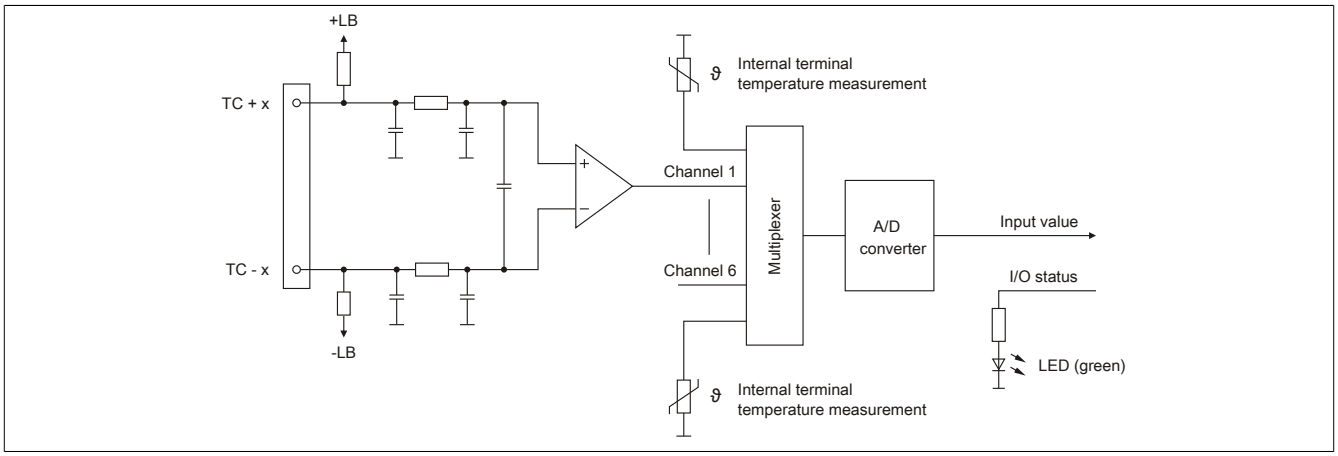
4.31.7.6 Pinout



4.31.7.7 Connection example

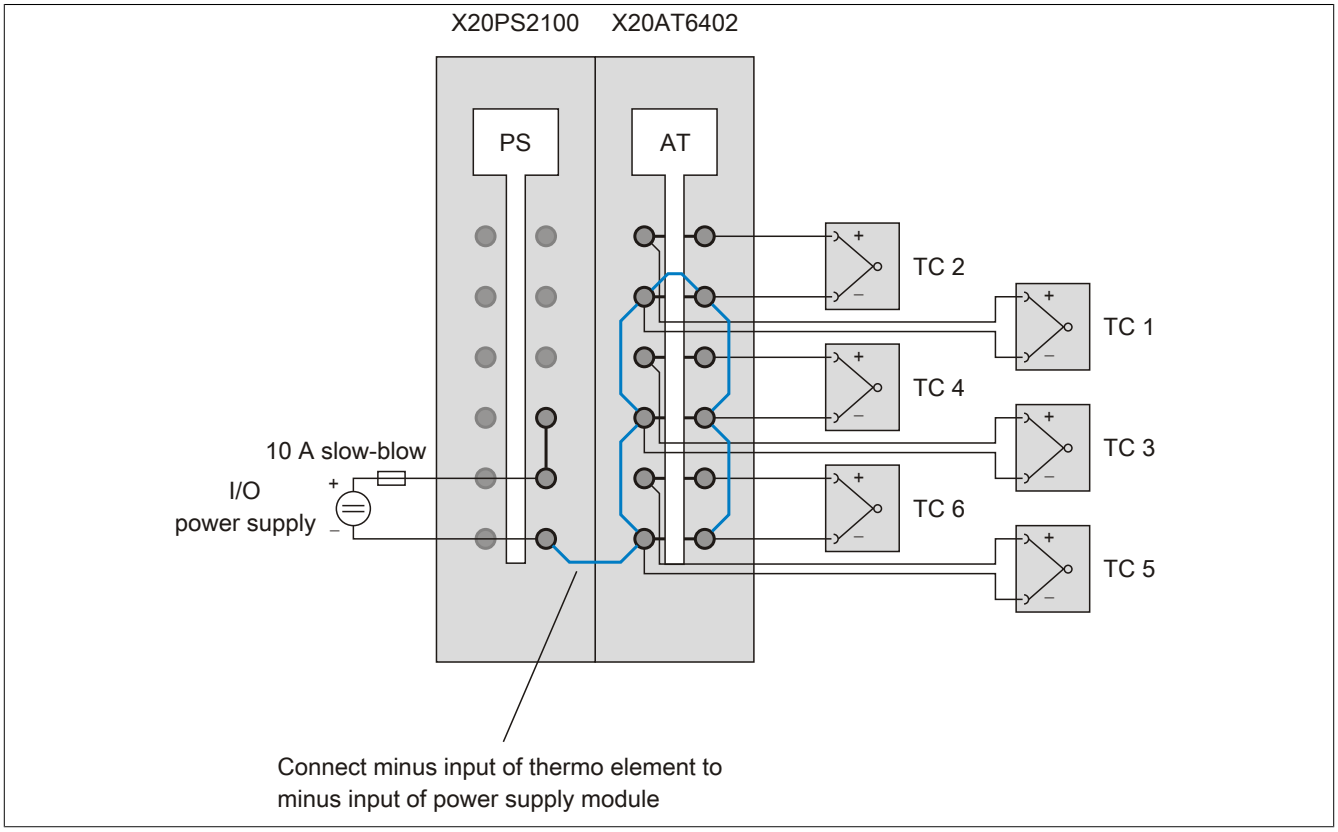


4.31.7.8 Input circuit diagram



4.31.7.9 Ceramic heating element with integrated thermo elements

We recommend connecting the minus input of the thermo element to the minus input of the supply feed module. This prevents potential measurement errors caused by ripple voltage effects in the measurement signal.



4.31.7.10 External cold junction

General information

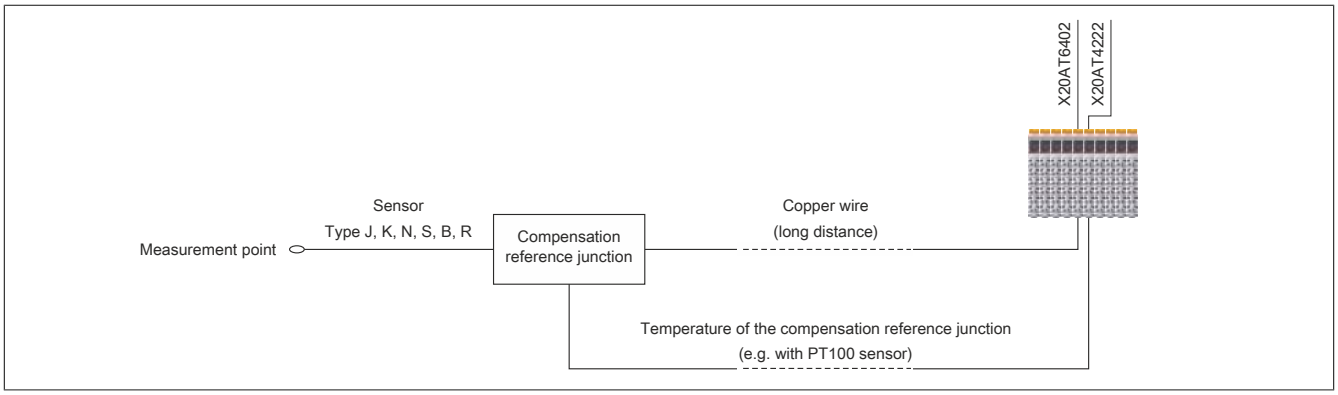
An external cold junction temperature value can be predefined for the module for measurement value correction. This makes it possible to set up an external cold junction. The same external cold junction temperature is used for measurement value correction on all channels.

An external cold junction makes sense in the following applications and situations:

- Large distances between the controller and measurement point
- To increase precision

To bridge large distances

Setting up an external cold junction is recommended when there are large distances between the controller and the measurement point. The thermocouple voltage is routed from the external cold junction to the terminal on the X20AT6402 via copper wires. The temperature measured at the external cold junction (e.g. with PT100 - X20AT4222) is stored in the I/O area of the X20AT6402 module. The X20AT6402 uses the measured voltage and the cold junction temperature to internally calculate the needed thermocouple temperature.



Increased precision

Setting up an external cold junction is recommended to increase precision. The external cold junction is set up as described above. The installation of an external cold junction is especially helpful in the following cases:

- A module consuming more power than 1 W is connected in addition to the X20AT6402.
- No modules but the X20AT6402 are connected
- With strongly fluctuating ambient conditions (draft, temperature)

4.31.7.11 Register description

4.31.7.11.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.7.11.2 Function model 0 - default

1) The offset specifies the position of the register within the CAN object.

4.31.7.11.4.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.31.7.11.5 General information

4.31.7.11.5.1 Raw value measurement

If a sensor type other than J, K, N, S, B or R is used, the terminal temperature must be measured on at least one input. Based on this value, the user must then implement terminal temperature compensation.

4.31.7.11.5.2 Timing

The timing for acquiring measurement values is determined by the converter hardware. All enabled inputs are converted during each conversion cycle. In addition, the terminal temperature is measured (not in function model 1).

Any inputs that are not needed can be switched off, which reduces the I/O update time. Inputs can also be only switched off temporarily. Measuring the terminal temperature is switched off in function model 1.

4.31.7.11.5.3 Conversion time

The conversion time depends on the number of channels and the function model. For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

Function model	Conversion time
Model 0 - n channels	(n + 1) · (2 · Filter time + 200 µs)
Model 1 - n channels	n · (2 · Filter time + 200 µs)
Model 1 - 1 channel	Equal to the filter time

Examples

Inputs are filtered using a 50 Hz filter.

	Example 1		Example 2	
	Function model 0	Function model 1	Function model 0	Function model 1
Switched on inputs	1	1	1 - 6	1 - 6
Input conversion times	40.2 ms	20 ms	241.2 ms	241.2 ms
Conversion time for the terminal temperature	40.2 ms	-	40.2 ms	-
Total conversion time	80.4 ms	20 ms	281.4 ms	241.2 ms

4.31.7.11.6 Configuration

4.31.7.11.6.1 Input filter and ambient conditions

Name:
ConfigOutput01

This register configures input filters and ambient conditions.

Input filter

The filter time for all analog inputs is defined using the input filter parameter.

Value	Filter	Filter time	Digital converter resolution
0	15 Hz	66.7 ms	16-bit
1	25 Hz	40 ms	16-bit
2	30 Hz	33.3 ms	16-bit
3	50 Hz	20 ms	16-bit
4	60 Hz	16.7 ms	16-bit
5	100 Hz	10 ms	16-bit
6	500 Hz	2 ms	16-bit
7	1000 Hz	1 ms	16-bit

Environmental conditions

Ambient conditions are set in order to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module.

This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. Power consumption values can also be found in the technical data for the corresponding module. The higher value is used for the configuration.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0 - 3	Filter time	0000	15 Hz
		0001	25 Hz
		0010	30 Hz
		0011	50 Hz
		0100	60 Hz
		0101	100 Hz
		0110	500 Hz
		0111	1000 Hz
		1000 to 1111	Not permitted
4 - 7	Environmental conditions	0000	Default, no calculation for adjustment
		0001	Power dissipation less than 0.2 W
		0010	Power dissipation less than 1 W
		0011	Power dissipation more than 1 W
		0100 to 1111	Not permitted

4.31.7.11.6.2 Sensor type

Name:
ConfigOutput02

This module is designed for a wide range of sensor types. The sensor type must be configured because of the different alignment values.

Data type	Value	Information
USINT	0	Conversion switched off
	1	Sensor type J
	2	Sensor type K
	3	Sensor type S
	4	Sensor type N
	5	Conversion switched off
	6	Raw value without linearization and terminal temperature compensation: Resolution 1.0625 µV for a measurement range of ±35 mV
	7	Raw value without linearization and terminal temperature compensation: Resolution 2.125 µV for a measurement range of ±70 mV
	8 - 63	Conversion switched off
	64	Sensor type R
	65 - 71	Conversion switched off
	72	Sensor type B
	73 - 255	Conversion switched off

4.31.7.11.6.3 Channel disabling

Name:
ConfigOutput03

By default, all channels are switched on. To save time, individual channels can be switched off (see "Conversion time" on page 2986).

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Description	Value	Information
0	Channel 1	0	Off
		1	On
1	Channel 2	0	Off
		1	On
2	Channel 3	0	Off
		1	On
3	Channel 4	0	Off
		1	On
4	Channel 5	0	Off
		1	On
5	Channel 6	0	Off
		1	On
6 - 7	Reserved	0	

4.31.7.11.7 Communication

4.31.7.11.7.1 Analog inputs

Name:
Temperature01 to Temperature06

Analog input value depending on the configured sensor type:

Input signal	Digital value
Type J (FeCuNi)	-2100 to +12000 (for -210.0°C to +1200.0°C)
Type K (NiCrNi)	-2700 to +13720 (for -270.0°C to +1372.0°C)
Type N (NiCrSi)	-2700 to +13000 (for -270.0°C to +1300.0°C)
Type S (PtRhPt)	-500 to +17680 (for -50.0°C to +1768.0°C)
Type B (PtRhPt)	0 to +18200 (for 0°C to +1820.0°C)
Type R (PtRhPt)	-500 to +16640 (for -50.0°C to +1664.0°C)
Raw value without linearization and terminal temperature compensation: Resolution 1.0625 µV for a measurement range of ±35 mV	-32,768 to +32,767
Raw value without linearization and terminal temperature compensation: Resolution 2.125 µV for a measurement range of ±70 mV	-32,768 to +32,767

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is not switched on, 0x8000 is output.

4.31.7.11.7.2 I/O cycle counter

Name:
IOCycleCounter

The cyclic counter increases after all input data has been updated.

Data type	Value	Information
USINT	0 to 255	Repeating counter

4.31.7.11.7.3 Input status

The module's inputs are monitored. A change in the monitoring status generates an error message.

In addition to the status info, the error type also sets the analog value as follows:

Error status	Digital value for error
Open line	+32767 (0x7FFF)
Upper limit value exceeded	+32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value	-32768 (0x8000)

Status of inputs 1 to 4

Name:
StatusInput01

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 1	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 2	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 5	Channel 3	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
6 - 7	Channel 4	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line

Status of inputs 5 to 6

Name:
StatusInput02

Bit structure:

Bit	Description	Value	Information
0 - 1	Channel 5	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
2 - 3	Channel 6	00	No error
		01	Lower limit value exceeded
		10	Upper limit value exceeded
		11	Open line
4 - 7	Reserved	0	

4.31.7.11.7.4 Reads the internal cold junction temperature

Name:
CompensationTemperature

The internal cold junction temperature is stored in this register.

Data type	Value	Information
INT	-250 to 850	Internal cold junction temperature (PT1000): -25.0 to 85.0°C

4.31.7.11.7.5 Defines the external cold junction temperature

Name:
ExternalCompensationTemperature

The external cold junction temperature is defined in this register.

Data type	Value	Information
INT	-250 to 850	External cold junction temperature: -25.0 to 85.0°C

4.31.7.11.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
150 µs

4.31.7.11.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

For the formulas listed in the table, 'n' corresponds to the number of channels that are switched on.

Function model 0	
n inputs	(n + 1) · (Filter time + 200 µs)

Function model 1	
1 input	Equal to the filter time
n inputs	n · (Filter time + 200 µs)

4.31.8 X20ATA312

4.31.8.1 General information

The module is equipped with 2 inputs for PT100 4-line resistance temperature measurement.

- 2 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement as well
- 4-wire measurement
- Filter time can be configured

4.31.8.2 Order data

Model number	Short description	Figure

4.31.8.3 Technical data

Product ID	X20ATA312
Short description	
I/O module	2 inputs for PT100 resistance temperature measurement
General information	
B&R ID code	0xE0E4
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Inputs	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	0.4 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
Temperature inputs resistance measurement	
Input	Resistance measurement with constant current supply for 4-wire connections
Digital converter resolution	24-bit
Filter time	1 to 200 ms
Conversion time	
1 channel	20 ms with 50 Hz filter
2 channels	40 ms per channel with 50 Hz filter
Conversion procedure	Sigma-delta
Output format	DINT or UDINT for resistance measurement
Resistance measurement range	0.5 to 390 Ω
Temperature sensor resolution	1 LSB = 0.01°C
Resistance measurement resolution	0.001 Ω
Input filter	1st-order low pass / cutoff frequency 1050 Hz
Sensor standard	IEC/EN 60751

Table 700: X20ATA312 - Technical data

Product ID	X20ATA312
Isolation voltage between channel and bus	500 V_{eff}
Linearization method	Internal
Measuring current	1 mA
Temperature sensor normalization	-200 to 850°C
Reference	1568 Ω ±0.1%
Temperature measurement range	-200 to 850°C
Permitted input signal	Short-term max. 28.8 V
Max. error at 25°C 2)	
Gain	0.0059% 3)
Offset	0.0015% 4)

Mechanical characteristics	
Note	Order 1x X20TB12 or X20TB1F terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 700: X20ATA312 - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) To ensure accuracy, modules with a power loss <1.2 W must be inserted to the left and right of this module.
3) Based on the current resistance value.
4) Based on the entire resistance measurement range.

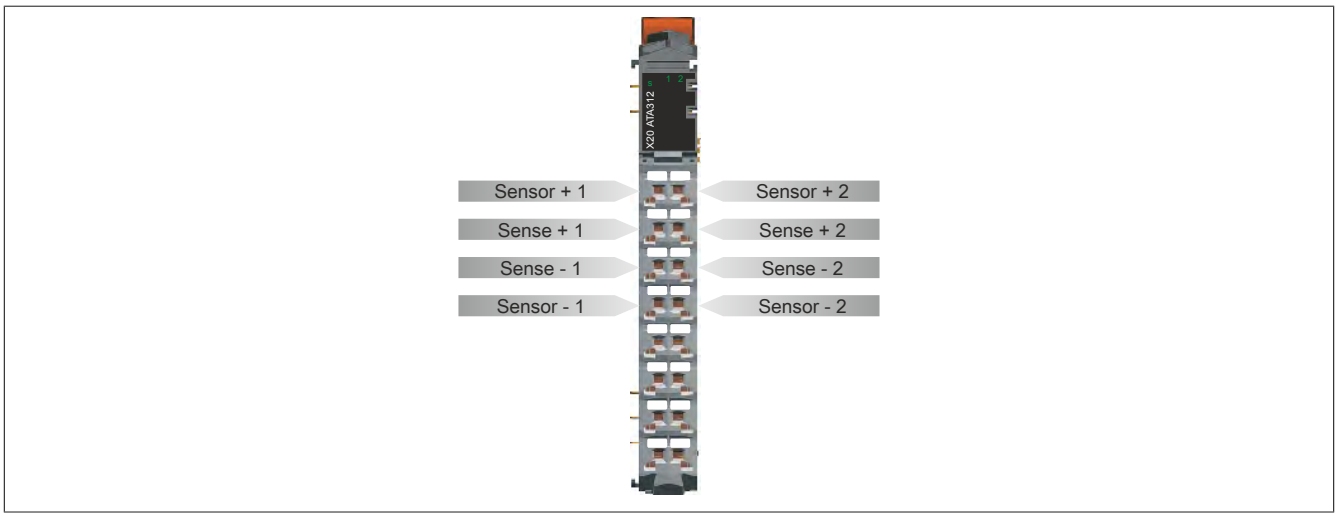
4.31.8.4 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

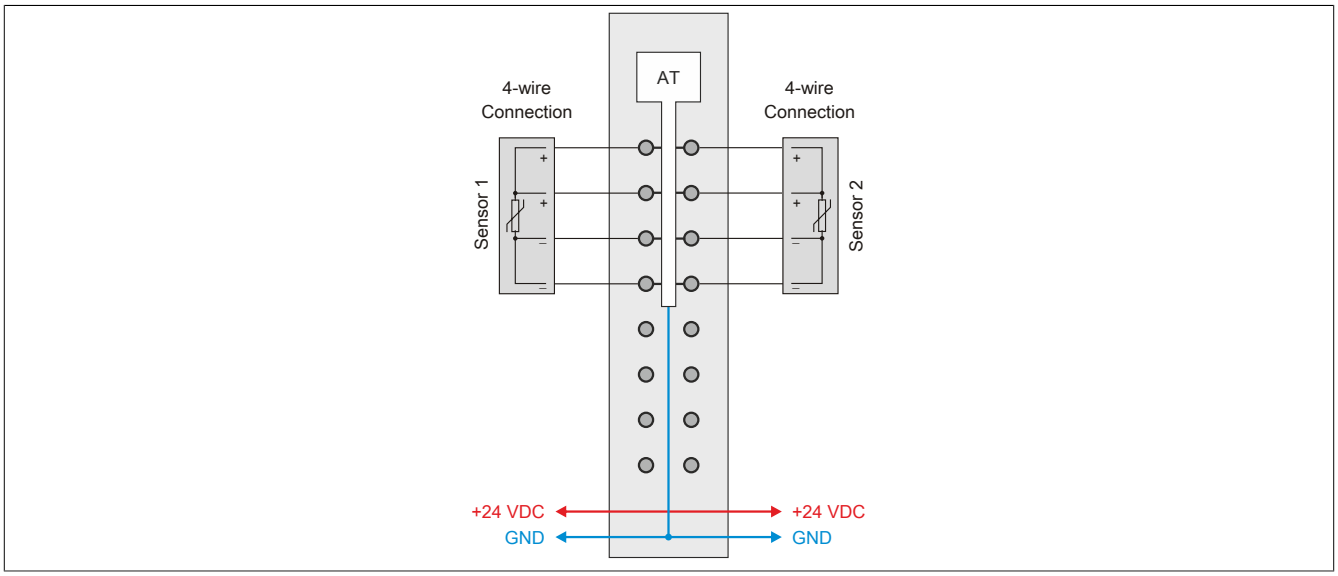
Image	LED	Color	Status	Description
	s	Green	Off	Module supply not connected
			Single flash	Reset mode
			Double flash	Boot mode (Updating firmware)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Parameter or conversion error[2]
		Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	Input turned off or not supplied
			Single flash	Parameter error[2]
			Double flash	Conversion error[2]
			Blinking	Overflow, underflow or open line
			On	A/D converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Parameter and conversion errors are indicated on both the red s-LED and the channel LED for the respective output at the same time.

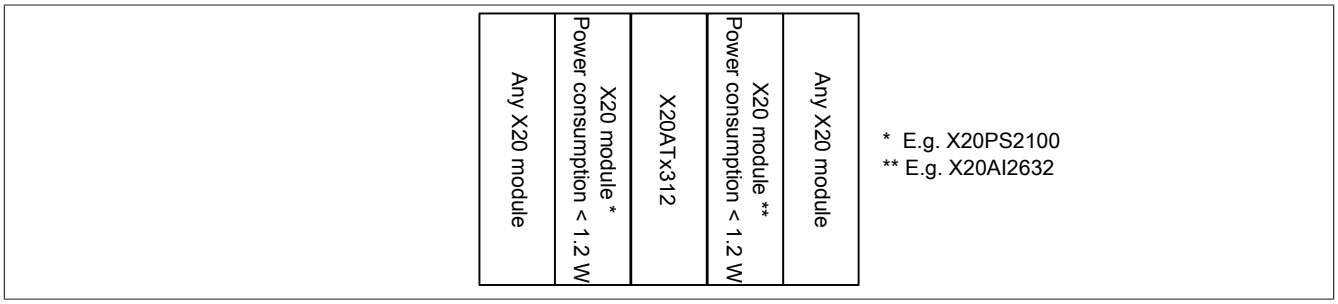
4.31.8.5 Pinout



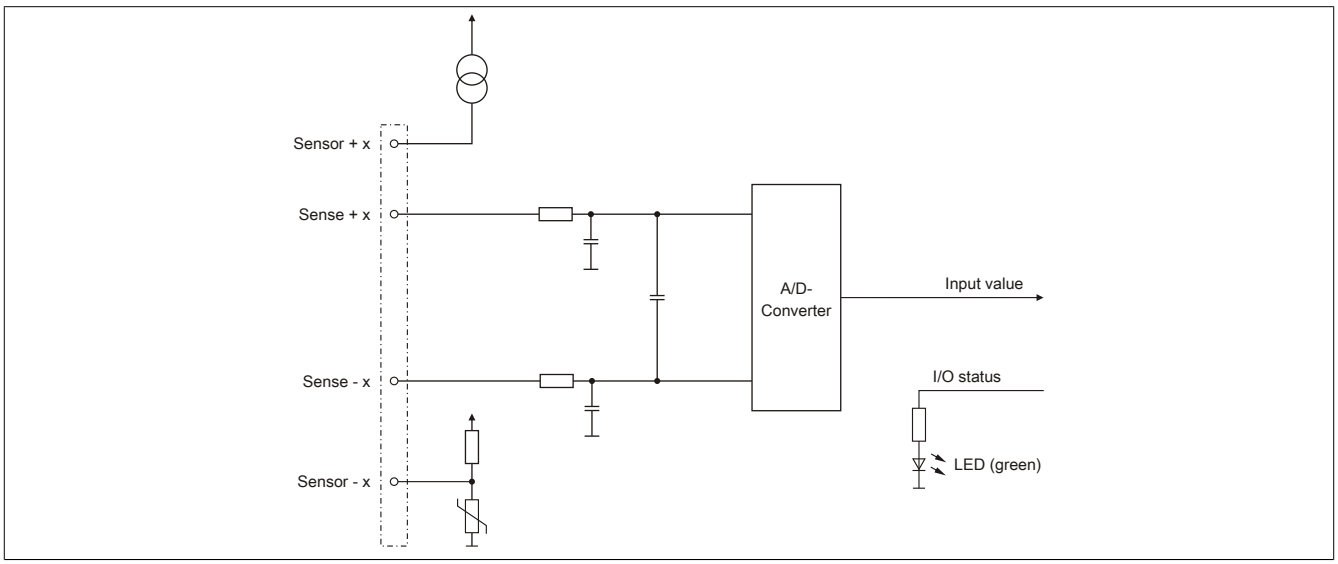
4.31.8.6 Connection example



To ensure accuracy, modules with a power consumption <1.2 W must be inserted to the left and right of this modules.



4.31.8.7 Input circuit diagram



4.31.8.8 Register description

4.31.8.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.8.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
130	InputFilter	UINT				•
134	ModeADC	UINT				•
514	SensorType01	UINT				•

1) The offset specifies where the register is within the CAN object.

4.31.8.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.8.8.4 Configuration of the A/D converter

4.31.8.8.4.1 Setting the conversion rate

Name:
InputFilter

This register can be used to set the conversion rate for the Analog/Digital converter.

Data type	Value
UINT	5 to 1023

Information:

The lower the conversion interval is set, the more precisely the value can be converted. However, this also increases the I/O update time.

4.31.8.8.4.2 A/D converter operating mode

Name:
ModeADC

This register can be used to set the operating mode for the Analog/Digital converter.

The individual options allow faster digitalization of the analog values, but this also reduces the precision of the measured values. The default value is 0.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	Chopper mode	0	Alternating amplification of the analog value
		1	Chopper mode off
1	Order of the SINC filter	0	SINC4
		1	SINC3
2 - 15	Reserved	-	-

The following rules apply:

ConversionTime(SINC3) = ConversionTime(SINC4) - 1 x ConversionCycle
ConversionTime(without Chop) = 0.5 x ConversionTime(Chop)

4.31.8.8.5 Configuring the measurement channels

Each temperature measurement channel can be configured independently. All the registers required for this purpose by each channel are arranged separately.

4.31.8.8.5.1 General channel configuration

Name:
SensorType01 to SensorType02

This register defines the basic behavior of the channel.
The default value is 0x81.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	Sensor type with unit and resolution	001	PT100 [10 mK/bit] - Temperature measurement
		010	PT100 [1 mΩ/bit] - Resistance measurement
		011 to 111	Reserved
3 - 4	Reserved	-	
5	Replacement value strategy	0	Static replacement
		1	Retain last valid value
6	Monitoring the user-defined limit values	0	Switch off additional limits
		1	Switch on additional limits
7	Channel (on/off)	0	Switch off the entire channel
		1	Switch on the channel
8 - 15	Reserved	-	

4.31.8.8.6 Configuring the replacement value strategy

If a measured value is detected that is outside the permitted value range, the behavior of the input register must still remain clearly defined. The module provides the user two different options for this purpose.

Retain last valid value

With this strategy, the determined measured value is stored temporarily for a specific time and written to the input register after a delay. If an invalid measured value is detected, this value and all values that have been stored temporarily are discarded. The last valid input register value is retained. To update the value in the input register, there must be enough valid values stored in the temporary buffer. The number needed is determined by the time period specified in "PreparationInterval0x".

Replace with static value

With this strategy, the measured value is written to the input register without delay. If an invalid value occurs, it is replaced by a static value that has been predefined by the user.

4.31.8.8.6.1 Preparation interval

Name:
PreparationInterval01 to PreparationInterval02

This register defines the time interval in which the measured value is checked before being passed on.

Data type	Value
UINT	0 to 65535 (x 0.1 ms)

Information:

This register must be defined if the replacement value strategy "Retain last valid value" was selected in register "SensorType0x".

4.31.8.8.6.2 Static replacement value for upper limit

Name:
ReplaceUpper01 to ReplaceUpper02

This register is used to defined a replacement value that is output in place of the invalid measured value if the upper limit is violated.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "SensorType0x".

4.31.8.8.6.3 Static replacement value for lower limit

Name:
ReplaceLower01 to ReplaceLower02

This register is used to defined a replacement value that is output in place of the invalid measured value if the lower limit is violated.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "SensorType0x".

4.31.8.8.7 Configuring the user-defined limit values

This module provides the user the option to specify user-defined limits. If the valid measurement range is reduced in this way, the behavior of the replacement value strategy is more likely to be applied.

Valid measurement range

The valid range is derived from the properties of the sensor being used or the hardware and firmware of the respective B&R module. These values cannot be changed by the user.

Valid range of values

The range of values is always within the valid measurement range. The range of values can be adapted to the requirements of the application by specifying the upper and lower limit value.

4.31.8.8.7.1 Upper limit value

Name:
UpperLimit01 to UpperLimit02

This register specifies the upper limit value. The values entered should be within the valid measurement range.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.8.8.7.2 Lower limit value

Name:
LowerLimit01 to LowerLimit02

This register specifies the lower limit value. The values entered should be within the valid measurement range.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.8.8.7.3 Hysteresis

Name
Hysteresis01 to Hysteresis02

A hysteresis can be set in order to avoid frequent status changes in the measurement range close to the limit value. Here, a small section is defined at the edge of the valid range of values where the measured values retain the status (valid or invalid) of the previous measured value.

Data type	Value
UINT	0 to 65535

4.31.8.8.8 Configuring status messages

Errors are detected by the module and sent to the application. When using Function model 0 - Standard, the trigger behavior of these error messages can be influenced by the "Delay" register.

In Automation Studio, an error message can be read either packed as the entire register or individually as bits.

4.31.8.8.8.1 Delaying error messages

Name:
ErrorDelay01 to ErrorDelay02

In order to avoid false alarms due to short-term measurement variations, the status messages sent to the PLC can be delayed. This register determines the number of A/D conversions in which an error must exist before an error message is sent.

Data type	Value
UINT	0 to 65535 [A/D conversions]

4.31.8.8.8.2 Delaying the sum error message

Name:
SumErrorDelay01 to SumErrorDelay02

This register can be used to set the delay used when sending bit 5 of the "Status0x" register to the PLC independent of the other status messages.

Data type	Value
UINT	0 to 65535

4.31.8.8.9 Communication

The received temperature data is assigned a timestamp and, depending on the configuration, made available with different register names and data types.

4.31.8.8.9.1 Measured value – Temperature

Name:
Temperature01 to Temperature02

If the channel is configured for resistance measurement, the current temperature value is made available in this register.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.8.8.9.2 Measured value – Resistance

Name:
Resistor01 to Resistor02

If the channel is configured for resistance measurement, the current resistance value is made available in this register.

Data type	Value
UDINT	0 to 4,294,967,295

4.31.8.8.9.3 Measured value – Unweighted

Name:
Measurand01 to Measurand02

When using the AsIoAcc library, the unweighted measurement can be accessed via this register. This refers to a measured value that is within the valid measurement range and has not yet been compared with the user-defined limits.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

If no user-defined limits are configured, the value of this register does not differ from the temperature or resistance value.

4.31.8.8.9.4 Cycle counter

Name:
IOCycleCounter01 to IOCycleCounter02

This register is used to provide a continuous counter for the application that is incremented each time a temperature value is read.

Data type	Value
USINT	0 to 32767 [A/D conversions]
UINT	0 to 65535 [A/D conversions]

4.31.8.8.9.5 Sampling time - Timestamp

Name:
Sampletime01 to Sampletime02

This register is used to provide the application the net time until the temperature will be evaluated.

Data type	Value
INT	-32,768 to 32,767 [µs]
DINT	-2,147,483,648 to 2,147,483,647 [µs]

Information:

The SDC library requires a 16-bit value for the sampling time. It is therefore also prepared as a 16-bit value.

4.31.8.8.9.6 Status messages

Name:
Status01 to Status02

The register bits are set if an error has been diagnosed and the error remains longer than the delay configured in the "ErrorDelay0x" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Underrun01 to Underrun02	0	No error
		1	Value below the permitted range
1	Overrun01 to Overrun02	0	No error
		1	Value above the permitted range
2	OpenLine01 to OpenLine02	0	No error
		1	Sensor is not connected correctly
3	Reserved	-	
4	ConverterFault01 to ConverterFault02	0	No error
		1	Invalid A/D converter output
5	SumFault01 to SumFault02	0	No error
		1	Composite error
6	ParameterFault01 to ParameterFault02	0	No error
		1	The 4.31.8.8.5.1 "SensorType0x" register is faulty
7	IoSupplyFault01 to IoSupplyFault02	0	No error
		1	The I/O supply voltage is faulty

4.31.8.8.9.7 Status messages for function model 254

Name:
Status01To02

The bits in this register are set if an error has been detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Underrun on channel 01	0	No error
		1	Value below the permitted range
1	Overrun on channel 01	0	No error
		1	Value above the permitted range
2	Underrun on channel 02	0	No error
		1	Value below the permitted range
3	Overrun on channel 02	0	No error
		1	Value above the permitted range
4 - 7	Reserved	-	

Information:

If an open line is detected on a channel, then both error messages will be displayed at the same time.

4.31.8.8.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.31.8.8.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.31.9 X20ATA492

4.31.9.1 General information

The module is equipped with 2 inputs for J, K, N, S, B, R, E, C and T thermocouple sensors. The 2 measurement channels are electrically isolated from each other.

This module can also be equipped with the X20TB1E thermocouple terminal block with integrated PT1000 temperature sensors. This makes it possible to achieve optimal terminal temperature compensation.

- Single-channel electrical isolation
- Integrated terminal temperature compensation
- 2x PT1000 sensor integrated in the terminal
- 2x external PT1000 sensor can be connected, 2-wire or 4-wire connections

4.31.9.2 Order data

Model number	Short description	Figure
	Temperature measurement	
X20ATA492	X20 temperature input module, 2 thermocouple inputs, type J, K, N, S, B, R, E, C, T, single channel electrically isolated, 2x PT1000 integrated for terminal temperature compensation, with 1x X20TB1E terminal block, order terminal block separately	
	Required accessories	
	Bus modules	
X20BM11	X20 bus module, 24 VDC keyed, internal I/O supply continuous	
	Terminal blocks	
X20TB1E	X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation	
X20TB1F	X20 terminal block, 16-pin, 24 VDC keyed	

Table 701: X20ATA492 - Order data

4.31.9.3 Technical data

Product ID	X20ATA492
Short description	
I/O module	2 inputs for thermocouples
General information	
B&R ID code	0xBB98
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Inputs	Yes, using status LED and software
Power consumption	
Bus	0.35 W
Internal I/O	0.5 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	Yes
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
KC	Yes
GOST-R	Yes
Thermocouple temperature inputs	
Input	Thermocouple
Digital converter resolution	16-bit
Filter time	Configurable between 1 ms and 66.7 ms
Conversion time	
Internal terminal temperature comp.	2 * 4 * x ms [2)]
External terminal temperature comp.	x ms [2)]
Remote temperature comp.	2 * 4 * x ms [2)]
Output format	INT
Measurement range	
Sensor temperature	
Type J: Fe-CuNi	-210 to 1200°C
Type K: NiCr-Ni	-270 to 1372°C
Type N: NiCrSi-NiSi	-270 to 1298°C
Type S: PtRh10-Pt	-50 to 1768°C
Type B: PtRh30-PtRh6	0 to 1820°C
Type R: PtRh13-Pt	-50 to 1760°C
Type E: NiCr-CuNi	-270 to 997°C
Type C: WRe5-WRe26	0 to 2310°C
Type T: Cu-CuNi	-270 to 400°C
Terminal temperature	-40 to 130°C
Voltage	±65.534 mV
Sensor standard	EN 60584
Resolution	
Sensor temperature	1 LSB = 0.1°C
Terminal temperature	1 LSB = 0.1°C
Voltage	Depending on gain, 1 LSB = 1 µV or 2 µV
Normalization	
Type J	-210 to 1200°C
Type K	-270 to 1372°C
Type N	-270 to 1298°C
Type S	-50 to 1768°C
Type B	0 to 1820°C
Type R	-50 to 1760°C
Type E	-270 to 997°C
Type C	0 to 2310°C
Type T	-270 to 400°C
Terminal temperature (PT1000)	-40 to 130°C
Voltage	Depending on gain ±32.767 mV or ±65.534 mV
Monitoring	
Range exceeded (neg.)	0x8001
Above upper range limit	0x7FFF
Open line	0x7FFF
Open inputs	0x7FFF
General error	0x8000
Conversion procedure	Sigma-delta
Linearization method	Internal
Permitted input signal	Max. ±5 V
Input filter	1st-order low pass / cutoff frequency 500 Hz

3) Based on the current measured value.
4) Based on the entire measurement range.

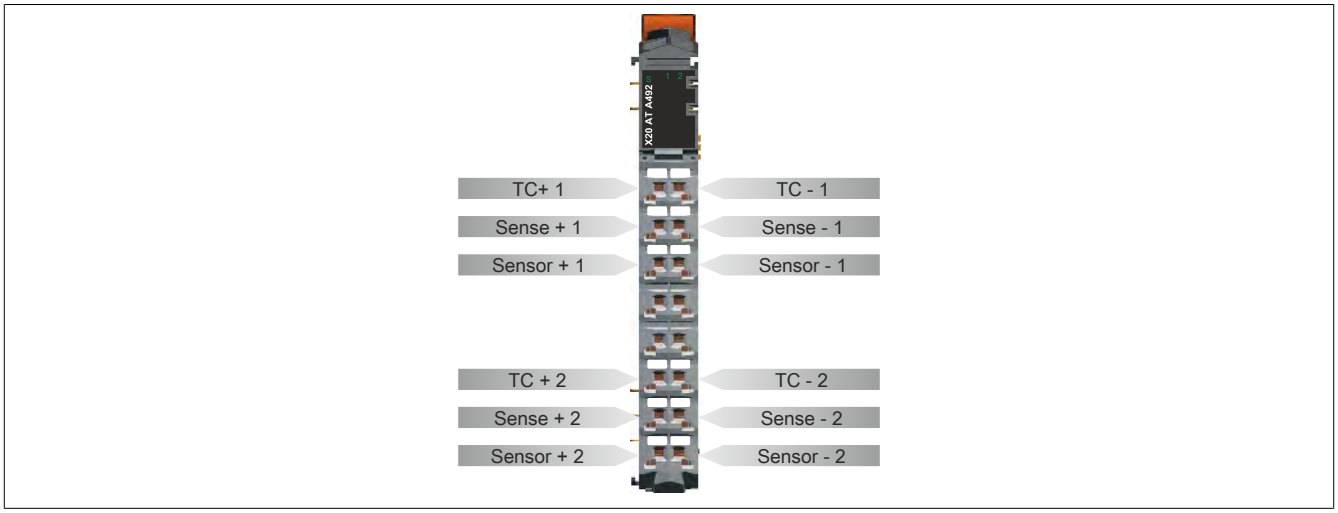
4.31.9.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	S	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	A parameter or conversion error has occurred. This status is output in addition to a single/double flash on the channel LED of the analog input where the error occurs.
		Red on / Green single flash		Invalid firmware
	1 - 2	Green	Off	Input turned off or not supplied
			Single flash	A parameter error has occurred. A single flash is output on the red "s" module status LED.
			Double flash	A conversion error has occurred. A single flash is output on the red "s" module status LED.
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

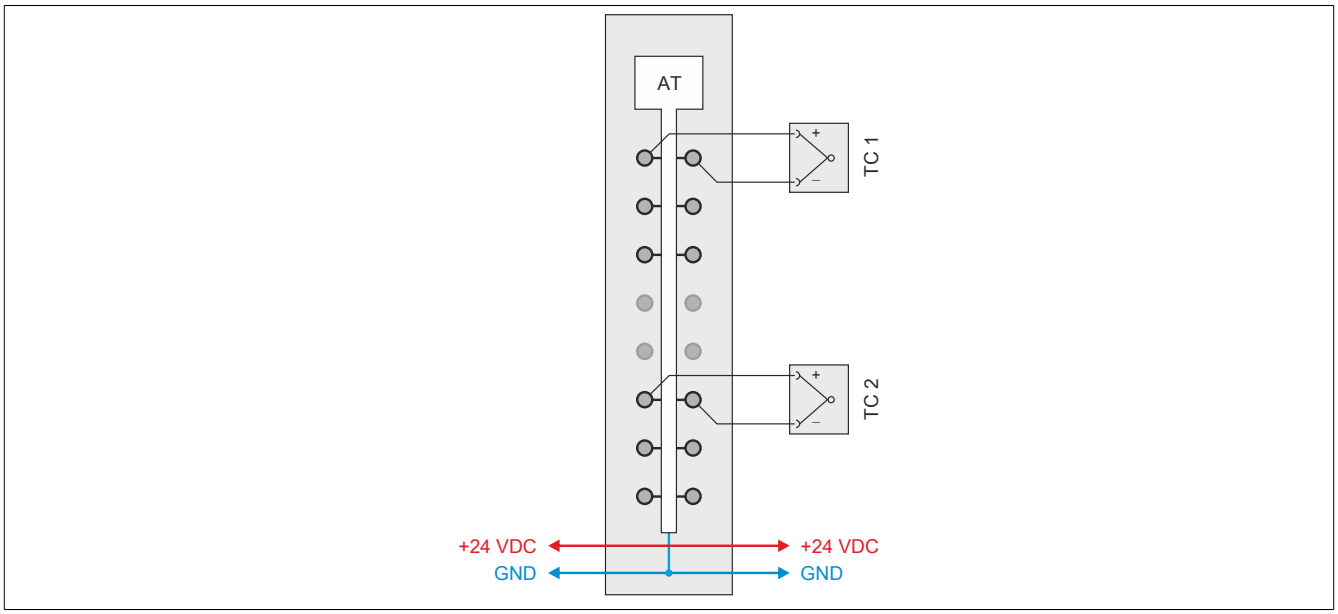
4.31.9.5 Pinout



4.31.9.6 Connection examples

Internal temperature compensation

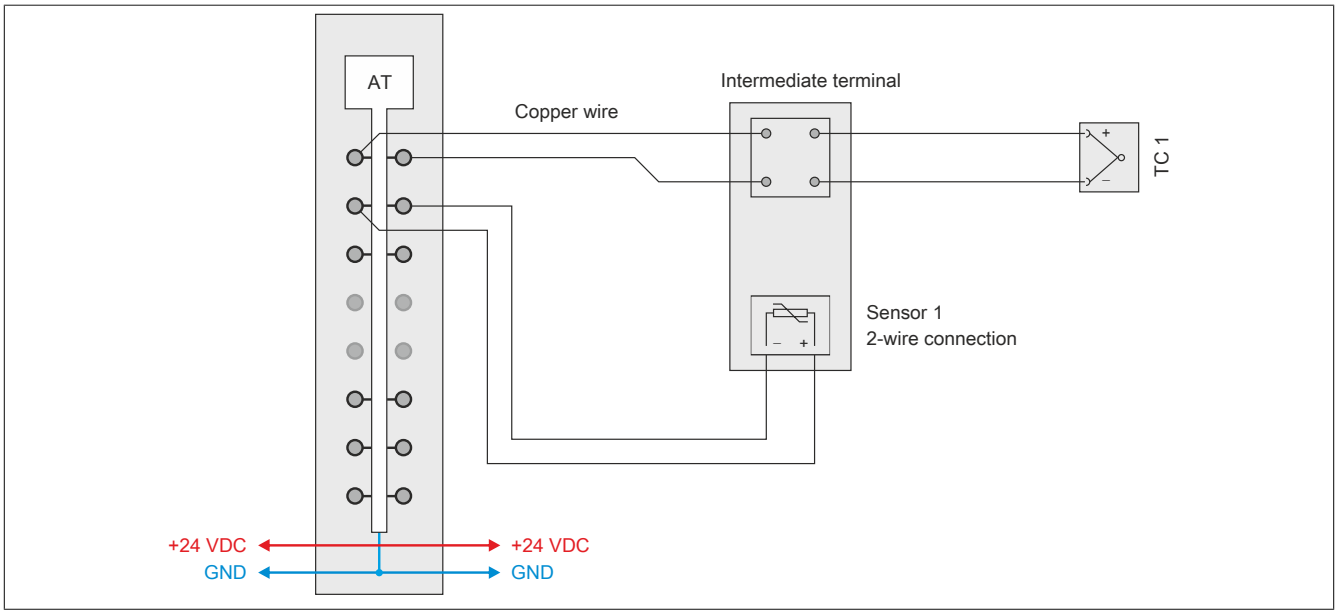
The thermocouple terminal block X20TB1E with integrated PT1000 sensors is used for internal temperature compensation.



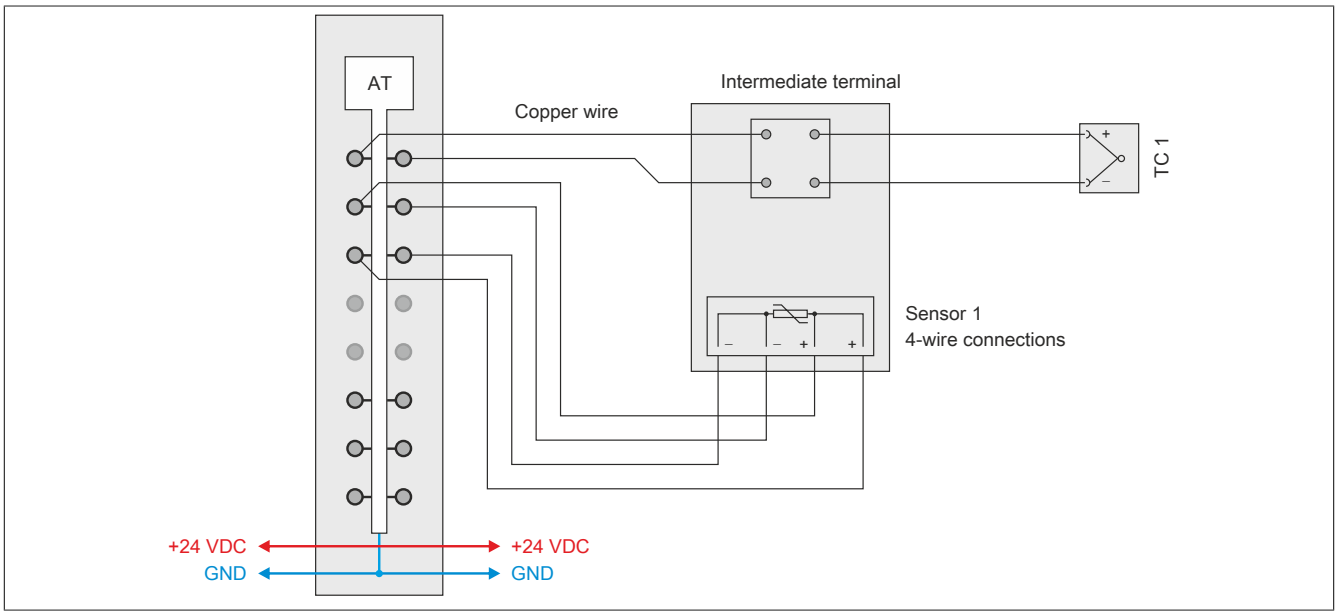
Remote temperature compensation

The 16x standard terminal X20TB1F is used for remote temperature compensation. The external PT1000 sensors are connected to the module using 2-wire or 4-wire connections.

2-wire connections



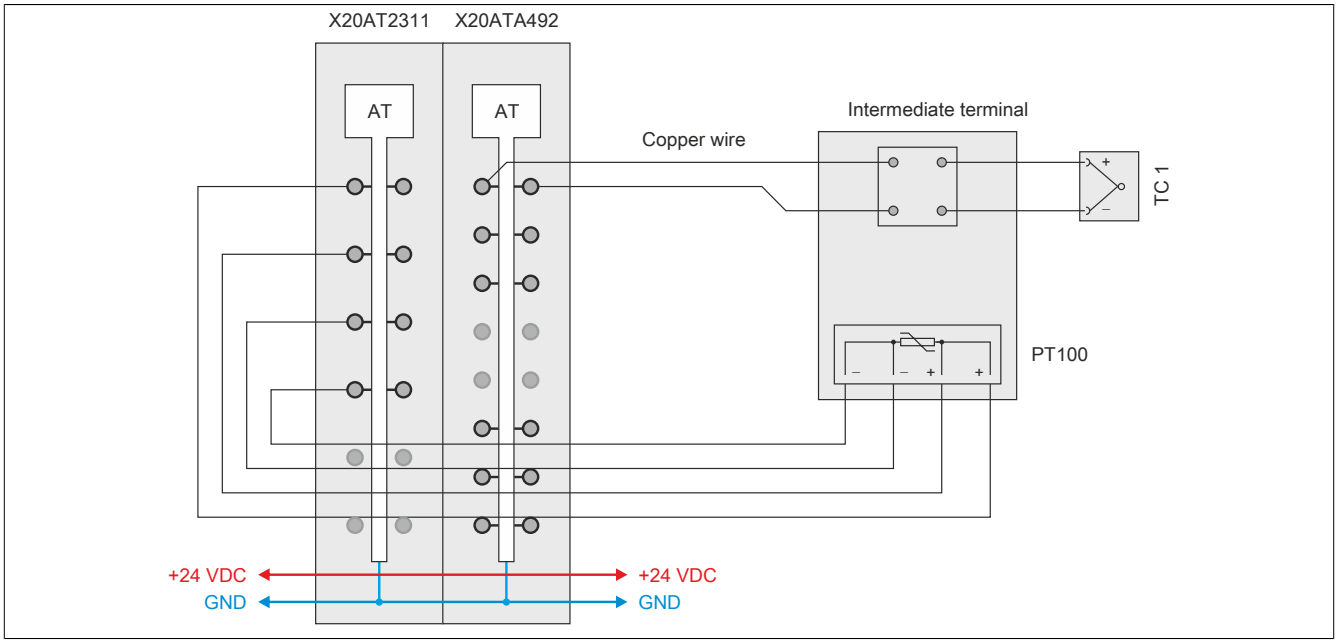
4-wire connections



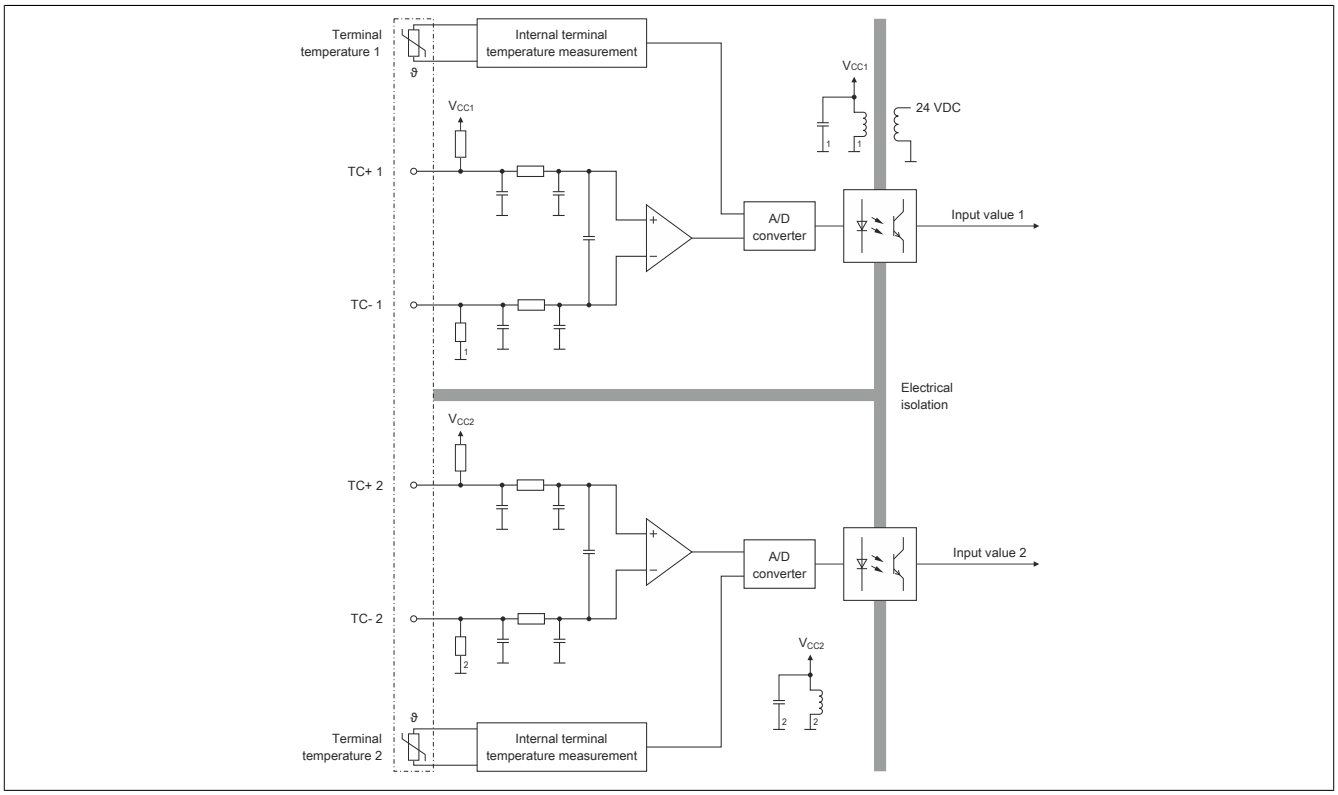
External temperature compensation

External compensation does not require the PT1000 values to be converted internally in the module. Instead, the reference temperatures have to be pre-processed in the program before being stored in the module. A separate register is available for each temperature channel to transfer an externally pre-processed compensation value.

In the following example, the compensation value is determined using the X20AT2311 temperature input module and a PT100 sensor on the intermediate terminal. The cold junction temperature determined externally is then made available to the X20ATA492 module via the respective I/O data points.



4.31.9.7 Input circuit diagram



4.31.9.8 Increased precision

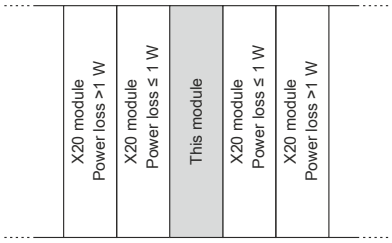
4.31.9.8.1 Internal temperature compensation

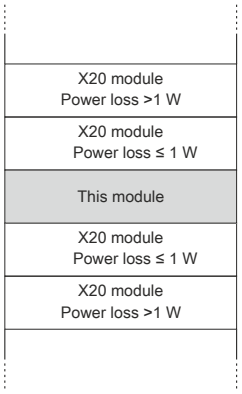
When using internal terminal temperature compensation, a temperature model must be defined in order to increase precision. A temperature model should be selected according to the following criteria:

- Thermal power loss of neighboring modules
- X20 system - Mounting orientation

4.31.9.8.1.1 Neighboring modules with low thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

Horizontal installation	Vertical installation
	




The following temperature model must be set in the Cfo_SensorTypeCh0x register.

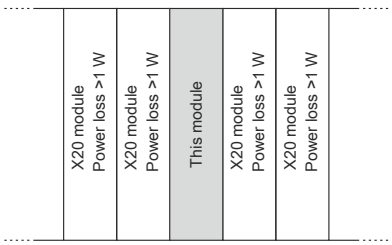
Bit 6 and 7	Temperature model	Bit 6 and 7	Temperature model
00	Horizontal installation, low thermal radiance <1W	10	Vertical installation, low thermal radiance <1W

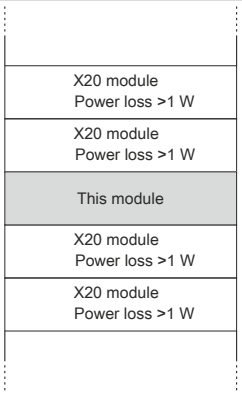
Information:

The best results are achieved by placing a dummy module on both sides.

4.31.9.8.1.2 Neighboring modules with higher thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

Horizontal installation	Vertical installation
	




The following temperature model must be set in the Cfo_SensorTypeCh0x register.

Bit 6 and 7	Temperature model	Bit 6 and 7	Temperature model
01	Horizontal installation, high thermal radiance >1 W	11	Vertical installation, high thermal radiance >1 W

4.31.9.8.2 Remote or external terminal temperature compensation

Setting up a remote or external cold junction can provide the most accurate temperature measurement in a machine or system.

The installation of a remote or external cold junction is especially helpful in the following cases.

- There is no module next to the temperature module
- With strongly fluctuating ambient conditions (draft, temperature)
- External fan is used in the control cabinet

4.31.9.9 Register description

4.31.9.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

Table 706: Variable mapping in Automation Studio (CANIO)

4.31.9.9.6 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.9.9.7 Temperature measurement

4.31.9.9.7.1 Data registers

The module stores converted analog values in the registers. The configured sensor type will affect the value ranges.

The channels for Group 01 – temperature sensor and cold junction temperature, respectively – are electrically isolated from Group 02. The channels for both groups are operated at the same time by a separate analog converter. If the terminal is not used with integrated measuring resistance, it is important to make sure that the sensor and the corresponding cold junction are connected properly in the external wiring.

4.31.9.9.7.2 "Temperature0x" and "TemperatureEvaluated0x" registers

Analog input value depending on the configured sensor type:

Input signal	Digital value
Type J (Fe-CuNi)	-2100 to 12000 (for -210.0 to 1200.0°C)
Type K (NiCr-Ni)	-2700 to 13720 (for -270.0 to 1372.0°C)
Type N (NiCrSi-NiSi)	-2700 to 12980 (for -270.0 to 1298.0°C)
Type S (PtRh10-Pt)	-500 to 17680 (for -50.0 to 1768.0°C)
Type R (PtRh13-Pt)	-500 to 17600 (for -50.0 to 1760.0°C)
Type C (WRe5-WRe26)	0 to 23100 (for 0 to 2310.0°C)
Type T (Cu-CuNi)	-2700 to 4000 (for -270.0 to 400.0°C)
Type B (PtRh30-PtRh6)	0 to 18200 (for 0 to 1820.0°C)
Type E (NiCr-CuNi)	-2700 to 9970 (for -270.0 to 997.0°C)
Voltage without linearization and terminal temperature compensation Resolution 1.0625 µV for a measurement range of ±35 mV	-32,768 to 32,767
Voltage without linearization and terminal temperature compensation Resolution 2.125 µV for a measurement range of ±70 mV	-32,768 to 32,767

Table 707: "Temperature01", "Temperature02", "TemperatureEvaluated01" and "TemperatureEvaluated02" registers

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8000 is output

4.31.9.9.7.3 Voltage measurement

If a sensor type different than the module's integrated sensor is used, then the terminal temperature must be measured on the corresponding cold junction input. Based on this value, the user must then implement terminal temperature compensation in the application.

4.31.9.9.7.4 Timing

The timing for acquiring measurement values is determined by the converter hardware and the configured filter time. All enabled inputs are converted by the two analog converters during each conversion cycle.

The temperature input and the cold junction temperature of the corresponding galvanic measurement group are counted as channels. The maximum number of channels to calculate is therefore n = 2.

Any inputs that are not needed can be switched off, which reduces the I/O update time. To generate a temperature value with the configured filter time as the I/O update time, the temperature compensation must be configured using an externally specified cold junction value.

The conversion time depends on the number of channels. For the formula listed in the table, "n" corresponds to the number of channels that are switched on.

Number of channels	Conversion time
n channels	n * defined filter time

Table 708: Conversion time calculation

4.31.9.9.7.5 "CompensationValue0x" registers

The two internal cold junction temperatures on the module can be read in standard operation. These are not available when using an internal temperature model for compensation.

Analog input value:

Input signal	Digital value
Compensation temperature (PT1000)	-250 to 850 (for -25.0 to 85.0°C)

Table 709: "CompensationValue01" and "CompensationValue02" registers

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8000 is output

4.31.9.9.7.6 "ExternalCompensationTemperature0x" registers

For the module, it is possible to specify external cold junction temperatures to be used for measurement correction.

Output value:

Description	Digital value
External compensation temperature	-250 to 850 (for -25.0 to 85.0°C)

Table 710: "ExternalCompensationTemperature01" and "ExternalCompensationTemperature02" registers

4.31.9.9.7.7 "SampleTime0x", "SampleTime0x_16bit" and "SampleTime0x_32bit" registers and data points

These registers and data points return the timestamp of the values currently being read as signed 2- or 4-byte values in µs.

Data type	Description
INT	-32,768 to 32,767 ... Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647 ... Nettime timestamp of the current input value

Table 711: "SampleTime01", "SampleTime02", "SampleTime01_16bit", "SampleTime02_16bit", "SampleTime01_32bit" and "SampleTime02_32bit" registers and data points

4.31.9.9.7.8 "IOCycleCount0x", "IOCycleCount0x_08bit" and "IOCycleCount0x_16bit" registers and data points

These registers and data points are cyclic counters. They are incremented as soon as the module has converted all enabled values. When there is a difference of ≥1 compared to the previous cycle, the defined filter time has elapsed and new values are provided.

Data type	Description
USINT	-128 to 127 ... Conversion cycle counter
INT	-32,768 to 32,767 ... Conversion cycle counter

Table 712: "IOCycleCount01", "IOCycleCount02", "IOCycleCount01_08bit", "IOCycleCount02_08bit", "IOCycleCount01_16bit" and "IOCycleCount02_16bit" registers and data points

4.31.9.9.8 Configuration

4.31.9.9.8.1 Configuration registers

The following registers are used to configure the necessary operating settings for the temperature inputs and the cold junction readings.

4.31.9.9.8.2 "Cfo_SensorTypeCh0x" registers

These registers are used to set the configuration accordingly for temperature channel and cold junction measurement 01 and 02.

Data type UINT Bit	Name		Information
0 - 5	Defines sensor	000000	Sensor type J (default)
		000001	Sensor type K
		000010	Sensor type N
		000011	Sensor type S
		000100	Sensor type R
		000101	Sensor type C
		000110	Sensor type T
		000111	Sensor type B
		001000	Sensor type E
		111101	Voltage without linearization and terminal temperature compensation Resolution 1.0625 µV for a measurement range of ±35 mV
		111110	Voltage without linearization and terminal temperature compensation Resolution 2.125 µV for a measurement range of ±70 mV
6 - 7	Selection of temperature model	00	Horizontal installation, low thermal radiance ≤1 W
		01	Horizontal installation, high thermal radiance >1 W
		10	Vertical installation, low thermal radiance ≤1 W
		11	Vertical installation, high thermal radiance >1 W
8 - 9	Cold junction type	00	Cold junction sensor PT1000
		01	Reserved
		10	Reserved
		11	Cold junction conversion disabled
10	Unit for cold junction value	0	Standardization / display 0.1°C
		1	Standardization / display 0.1°C Ω
11	Cold junction value input	0	Measurement of the internal cold junction
		1	External specific via analog output value
12	Internal terminal compensation according to temperature model	0	Mode disabled
		1	Internal compensation mode according to the configured temperature model (see bits 6 and 7)
13	Replacement value strategy	0	Use replacement values if error occurs
		1	Keep the last valid converted value (see Cfo_PreparationIntervalCh0x)
14	User limit value monitoring[1)]	0	User limit value monitoring disabled
		1	User limit value monitoring enabled
15	Channel activation	0	Channel disabled
		1	Channel enabled

Table 713: "Cfo_SensorTypeCh01" and "Cfo_SensorTypeCh02" registers

1) Signal monitoring and generation of error states for underflow, overflow and open line are already automatically enabled on the module; however, the user limit values are not applied until bit 14 is set. Likewise, the replacement value strategy is only enabled if this bit is set.

Operating mode - Internal terminal compensation according to temperature model

If this mode is selected, it is important to make sure that both PT1000 cold junction sensors are configured and connected!

Selection of temperature model when internal compensation is used

This setting is used to adjust the internal terminal temperature characteristic curve to the type and amount of generated heat dissipated to the module. This selection is based on the power consumption of the modules connected immediately to the left and right on the X2X Link. This data can be found in the modules' data sheet. The higher value is used for the configuration.

4.31.9.9.8.3 "Cfo_InputFilterCh0x" registers

These registers are used to configure the filter/sampling time for a galvanic group. The defined filter/sampling time applies to the temperature input as well as the input for the terminal temperature measurement within a group.

Data type UINT Value	Description
4	Filter time 1 ms [1 kHz]
9	Filter time 2 ms [500 Hz]
48	Filter time 10 ms [100 Hz]
80	Filter time 16.67 ms [60 Hz]
96	Filter time 20 ms [50 Hz]
160	Filter time 33.3 ms [30 Hz]
192	Filter time 40 ms [25 Hz]
480	Filter time 100 ms [10 Hz]
960	Filter time 200 ms [5 Hz]

Table 714: "Cfo_InputFilterCh01" and "Cfo_InputFilterCh02" registers

4.31.9.9.8.4 "Cfo_LowerLimitCh0x" registers

These registers are used to define the lower user limit value for the respective temperature channel. If limit value monitoring is active, the corresponding error status is output after a configured delay when falling below this temperature value. When this error state occurs, the "TemperatureEvaluated0x" channel is evaluated according to the replacement value strategy.

Data type	Description
INT	-32,767 to 32,767 ... Lower limit value: 32,767 (default)

Table 715: "Cfo_LowerLimitCh01" and "Cfo_LowerLimitCh02" registers

4.31.9.9.8.5 "Cfo_UpperLimitCh0x" registers

These registers are used to define the upper user limit value for the respective temperature channel. If limit value monitoring is active, the corresponding error status is output after a configured delay when exceeding this temperature value. When this error state occurs, the "TemperatureEvaluated0x" channel is evaluated according to the replacement value strategy.

Data type	Description
INT	-32,767 to 32,767 ... Upper limit value: 32,767 (default)

Table 716: "Cfo_UpperLimitCh01" and "Cfo_UpperLimitCh02" registers

4.31.9.9.8.6 "Cfo_HysteresisCh0x" registers

These registers are used to configure the error hysteresis for the respective temperature channel. The error status is cleared if the actual temperature value changes by at least this hysteresis value in the allowed direction from the limit value.

Data type	Description
INT	-32,767 to 32,767 ... Hysteresis: 16 (default)

Table 717: "Cfo_HysteresisCh01" and "Cfo_HysteresisCh02" registers

4.31.9.9.8.7 "Cfo_ReplaceLowerCh0x" registers

These registers are used to define the lower replacement value for the respective temperature channel. If limit value monitoring is active in the replacement value strategy mode (see section 4.31.9.9.8.2 ""Cfo_SensorTypeCh0x" registers" on page 3017) and an underflow error occurs, the respective error status is generated after the configured delay and the temperature value in the "TemperatureEvaluated0x" register is kept at this replacement value.

Data type	Description
INT	-32,767 to 32,767 ... Lower replacement value: 32,767 (default)

Table 718: "Cfo_ReplaceLowerCh01" and "Cfo_ReplaceLowerCh02" registers

4.31.9.9.8.8 "Cfo_ReplaceUpperCh0x" registers

These registers are used to define the upper replacement value for the respective temperature channel. If limit value monitoring is active in the replacement value strategy mode (see section 4.31.9.9.8.2 ""Cfo_SensorTypeCh0x" registers" on page 3017) and an overflow error occurs, the respective error status is generated after the configured delay and the temperature value in the "TemperatureEvaluated0x" register is kept at this replacement value.

Data type	Description
INT	-32,767 to 32,767 ... Upper replacement value: 32,767 (default)

Table 719: "Cfo_ReplaceUpperCh01" to "Cfo_ReplaceUpperCh02" registers

4.31.9.9.8.9 "Cfo_PreparationIntervalCh0x" registers

These registers are used to configure the preparation interval for the respective temperature channel. This parameter becomes active if "Keep the last valid converted value" (see section 4.31.9.9.8.2 ""Cfo_SensorTypeCh0x" registers" on page 3017) has been selected for the replacement value strategy.

The module continues to sample and convert the temperature based on the configured filter/sampling time. The measured value must first be checked to ensure that a permissible value is being shown. If the value is valid, then the measurement value that was sampled two preparation intervals prior is always output.

Data type	Description
UINT	0 to 65,535 ... Interval time: 0 ms (default)

Table 720: "Cfo_PreparationIntervalCh01" and "Cfo_PreparationIntervalCh02" registers

"Application" Value being measured (analog)	Procedure: • Measurement values are acquired according to the configured input filter. After the sampling time elapses, a new digitally converted value is stored in the measurement value memory. After the configured interval time elapses, the current contents of the measurement value memory are checked. • If a permissible value is present, then the contents of the buffer memory are transferred to the display memory and the contents of the measurement value memory are transferred to the buffer. • If the check turns up an impermissible value, then the contents of the measurement value memory are discarded. The copy direction between the display and buffer memory reverses and the last valid value continues to be output.
↓ Condition: - Sampling time elapsed	
"Measurement value memory" Measurement value (digital)	
↓ Condition: - PreparationInterval elapsed - Measurement value permissible	
"Cache" of last valid value	
↓ Condition: - PreparationInterval elapsed - Measurement value permissible	
"Display memory" Previous valid/displayed value	

Information:

If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can take twice the interval time plus the configured I/O update time.

Table 721: How the preparation interval works

4.31.9.9.8.10 "Cfo_ErrorDelayCh0x" registers

These registers are used to configure the delay for generating an error. This delay applies to underflow, overflow and open line errors and can be used to hide temporary measurement value overshoots, for example.

Data type	Description
UINT	0 to 10 ... Error formation delay: 2 conversion cycles (default)

Table 722: "Cfo_ErrorDelayCh01" and "Cfo_ErrorDelayCh02" registers

4.31.9.9.8.11 "Cfo_SumErrorDelayCh0x" registers

These registers are used to configure the delay for the composite error status. The composite error status is made up of all other error statuses.

Data type	Description
UINT	0 to 65,535 ... Composite error bit delay time: 4000 ms (default)

Table 723: "Cfo_SumErrorDelayCh01" and "Cfo_SumErrorDelayCh02" registers

4.31.9.9.9 Error handling

4.31.9.9.9.1 "StatusInput0x" registers

The module's temperature inputs are monitored. A change in the monitoring status generates an error message. Some error information is only enabled after a configurable delay [ms] (as with the composite error) or after a configurable delay as a multiple of the conversion cycle when underflow, overflow or open lines occurs.

Data type USINT Bit	Name		Information
0	Underflow monitoring for channel 0x	0	No error
		1	Underflow
1	Overflow monitoring for channel 0x	0	No error
		1	Overrun
2	Open line monitoring for channel 0x	0	No error
		1	Open line
3	Composite message: Terminal temperature measurement error for channel 0x	0	No error
		1	Error during terminal temperature measurement
4	Conversion monitoring for channel 0x	0	No error
		1	Conversion error
5	Composite error monitoring for channel 0x	0	No error
		1	Composite error
6	Parameter monitoring for channel 0x	0	No error
		1	Parameter error
7	I/O supply monitoring for channel 0x	0	No error
		1	I/O supply error

Table 724: "StatusInput01" and "StatusInput02" registers

In addition to the status info, the error type also sets the analog value to the following values:

Error type	Digital value for error
Open circuit	32767 (0x7FFF)
Upper limit value exceeded	32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value or I/O supply error	-32768 (0x8000)

Table 725: Display values in error state

4.31.9.9.9.2 "Underflow0x" data points

These data points generate the error status when the signal falls below the minimum value on the respective temperature channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Underflow monitoring for channel 0x	0	No error
		1	Underflow

Table 726: "Underflow01" and "Underflow02" data points

4.31.9.9.9.3 "Overflow0x" data points

These data points generate the error status when the signal exceeds the maximum value on the respective temperature channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Overflow monitoring for channel 0x	0	No error
		1	Overrun

Table 727: "Overflow01" and "Overflow02" data points

4.31.9.9.9.4 "OpenLine0x" data points

These data points generate the error status when an open line is detected on the respective temperature channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Open line monitoring for channel 0x	0	No error
		1	Open line

Table 728: "OpenLine01" and "OpenLine02" data points

4.31.9.9.9.5 "CompTemperaturError0x" data points

These data points generate the error status (composite message) for the cold junction temperature measurement on the respective channel. For more detailed information, see section 4.31.9.9.9.10 ""CompensationStatus0x" registers" on page 3022.

BOOL	Name		Information
x	Composite message: Terminal temperature measurement error for channel 0x	0	No error
		1	Terminal temperature measurement error

Table 729: "CompTemperaturError01" and "CompTemperaturError02" data points

4.31.9.9.9.6 "ConversionError0x" data points

These data points generate the error status for the respective temperature channel. The error is triggered when the conversion time is exceeded on the hardware.

BOOL	Name		Information
x	Conversion monitoring for channel 0x	0	No error
		1	Conversion error

Table 730: "ConversionError01" and "ConversionError02" data points

4.31.9.9.9.7 "SumError0x" data points

These data points generate the composite error for the respective temperature channel. This error information is enabled after the configurable delay time [ms] has elapsed. Linking this error information to an application makes it possible to hide temporary temperature value overflows and underflows, for example.

BOOL	Name		Information
x	Composite error monitoring for channel 0x	0	No error
		1	Composite error

Table 731: "SumError01" and "SumError02" data points

4.31.9.9.9.8 "ParameterError0x" data points

These data points generate the parameter error for the respective temperature channel. This error state is triggered by configuring a sensor type that is not allowed.

BOOL	Name		Information
x	Parameter monitoring for channel 0x	0	No error
		1	Parameter error

Table 732: "ParameterError01" and "ParameterError02" data points

4.31.9.9.9.9 "IoSuppError0x" data points

If the supply falls below 20 VDC, then the I/O power supply error is generated in these data points for the respective temperature channel. The following actions also take place:

- Channel LEDs are turned off
- Temperature values are set to an invalid value = 0x8000
- IOCycleCount0x and SampleTime0x stop changing

BOOL	Name		Information
x	I/O supply monitoring for channel 0x	0	No error
		1	I/O supply error

Table 733: "IoSuppError01" and "IoSuppError02" data points

4.31.9.9.9.10 "CompensationStatus0x" registers

The module's cold junction temperature inputs are monitored. A change in the monitoring status generates an error message. Some error information is only enabled after a configurable delay [ms] (as with the composite error) or after a configurable delay as a multiple of the conversion cycle when underflow, overflow or open lines occurs.

Data type USINT Bit	Name		Information
0	Underflow monitoring for cold junction 0x	0	No error
		1	Underflow
1	Overflow monitoring for cold junction 0x	0	No error
		1	Overrun
2	Open line monitoring for cold junction 0x	0	No error
		1	Open line
3	Composite message: Terminal temperature measurement error for cold junction 0x	0	No error
		1	Error during terminal temperature measurement
4	Conversion monitoring for cold junction 0x	0	No error
		1	Conversion error
5	Composite error monitoring for cold junction 0x	0	No error
		1	Composite error
6	Parameter monitoring for cold junction 0x	0	No error
		1	Parameter error
7	I/O supply monitoring for cold junction 0x	0	No error
		1	I/O supply error

Table 734: "CompensationStatus01" and "CompensationStatus02" registers

In addition to the status info, the error type also sets the analog value to the following values:

Error type	Digital value for error
Open circuit	32767 (0x7FFF)
Upper limit value exceeded	32767 (0x7FFF)
Lower limit value exceeded	-32767 (0x8001)
Invalid value or I/O supply error	-32768 (0x8000)

Table 735: Display values in error state

4.31.9.9.9.11 "CompUnderflow0x" data points

These data points generate the error status when the signal falls below the minimum value on the respective cold junction channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Underflow monitoring for cold junction 0x	0	No error
		1	Underflow

Table 736: "CompUnderflow01" and "CompUnderflow02" data points

4.31.9.9.9.12 "CompOverflow0x" data points

These data points generate the error status when the signal exceeds the maximum value on the respective cold junction channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Overflow monitoring for cold junction 0x	0	No error
		1	Overrun

Table 737: "CompOverflow01" and "CompOverflow02" data points

4.31.9.9.9.13 "CompOpenLine0x" data points

These data points generate the error status when an open line is detected on the respective cold junction channel. This error information is enabled as a multiple of the converter cycle only after the configurable delay time.

BOOL	Name		Information
x	Open line monitoring for cold junction 0x	0	No error
		1	Open line

Table 738: "CompOpenLine01" and "CompOpenLine02" data points

4.31.9.9.9.14 "CompConversionError0x" data points

These data points generate the error status for the respective cold junction channel. The error is triggered when the conversion time is exceeded on the hardware.

BOOL	Name		Information
x	Conversion monitoring for cold junction 0x	0	No error
		1	Conversion error

Table 739: "CompConversionError01" and "CompConversionError02" data points

4.31.9.9.9.15 "CompSumError0x" data points

These data points generate the composite error for the respective cold junction channel. This error information is enabled after the configurable delay time [ms] has elapsed. Linking this error information to an application makes it possible to hide temporary temperature value overflows and underflows, for example.

BOOL	Name		Information
x	Composite error monitoring for cold junction 0x	0	No error
		1	Composite error

Table 740: "CompSumError01" and "CompSumError02" data points

4.31.9.9.9.16 "CompParameterError0x" data points

These data points generate the parameter error for the respective cold junction channel. This error state is triggered by configuring a sensor type that is not allowed.

BOOL	Name		Information
x	Parameter monitoring for cold junction 0x	0	No error
		1	Parameter error

Table 741: "CompParameterError01" and "CompParameterError02" data points

4.31.9.9.9.17 "CompIoSuppError0x" data points

If the supply falls below 20 VDC, then the I/O power supply error is generated in these data points for the respective cold junction channel. The following actions also take place:

- Channel LEDs are turned off
- Temperature values are set to an invalid value = 0x8000
- IOCycleCount0x and SampleTime0x stop changing

BOOL	Name		Information
x	I/O supply monitoring for cold junction 0x	0	No error
		1	I/O supply error

Table 742: "CompIoSuppError01" and "CompIoSuppError02" data points

4.31.9.9.10 Function models

A function model specifies the registers on the module (storage model) that are available for the application. Only these registers are processed on the module during each cycle and transferred cyclically via the bus. In this way, it is possible to minimize the cycle time by selecting the correct function model.

Function model	Number	Automation Studio	CANopen	DeviceNet	Modbus/TCP	CAN I/O
Default	0	•				
Bus controllers	254		•	•	•	•

Table 743: Overview of possible function models

4.31.9.9.11 B&R ID code

Code for module identification (0xBB98).

4.31.9.9.12 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without communication errors occurring. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.31.9.9.13 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

For the formulas listed in the table, "n" corresponds to the number of channels that are switched on.

Minimum I/O update time	
Normal operation "n" channels	n * defined filter time
Replacement value mode: "Keep the last valid converted value" n channels	Sampling interval + (n * defined filter time)

4.31.10 X20ATB312

4.31.10.1 General information

The module is equipped with 4 inputs for PT100 4-line resistance temperature measurement.

- 4 inputs for resistance temperature measurement
- PT100 sensor
- Direct resistance measurement as well
- 4-wire measurement
- Filter time can be configured

4.31.10.2 Order data

Model number	Short description	Figure

4.31.10.3 Technical data

Product ID	X20ATB312
Short description	
I/O module	4 inputs for PT100 resistance temperature measurement
General information	
B&R ID code	0xE0EF
Status indicators	I/O function per channel, operating state, module status
Diagnostics	
Module run/error	Yes, using status LED and software
Inputs	Yes, using status LED and software
Power consumption	
Bus	0.01 W
Internal I/O	0.6 W
Additional power dissipation caused by the actuators (resistive) [W]	-
Electrical isolation	
Channel - Bus	Yes
Channel - Channel	No
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1)]	Yes
Temperature inputs resistance measurement	
Input	Resistance measurement with constant current supply for 4-wire connections
Digital converter resolution	24-bit
Filter time	1 to 200 ms
Conversion time [2)]	
1 channel	20 ms with 50 Hz filter
2 channels	40 ms per channel with 50 Hz filter
Conversion procedure	Sigma-delta
Output format	DINT or UDINT for resistance measurement
Resistance measurement range	0.5 to 390 Ω
Temperature sensor resolution	1 LSB = 0.01°C
Resistance measurement resolution	0.001 Ω
Input filter	1st-order low pass / cutoff frequency 1050 Hz
Sensor standard	IEC/EN 60751

Table 745: X20ATB312 - Technical data

Product ID	X20ATB312
Isolation voltage between channel and bus	500 V_{eff}
Linearization method	Internal
Measuring current	1 mA
Temperature sensor normalization	-200 to 850°C
Reference	1568 Ω ±0.1%
Temperature measurement range	-200 to 850°C
Permitted input signal	Short-term max. 28.8 V
Max. error at 25°C [3]	
Gain	0.0059% [4]
Offset	0.0015% [5]
Max. gain drift	<0.00065% per °C [4]
Max. offset drift	<0.000025% per °C [5]
Nonlinearity	<0.001% [5]
Standardized value range for resistance measurement	19 to 390 Ω
Temperature measurement monitoring	
Range exceeded (neg.)	0x80000001
Above upper range limit	0x7FFFFFFF
Open line	0x7FFFFFFF
General error	0x80000000

Transport	5 to 95%, non-condensing
Mechanical characteristics	
Note	Order 1x X20TB12 or X20TB1F terminal block separately Order 1x X20BM11 bus module separately
Spacing	$12.5^{+0.2}$ mm

Table 745: X20ATB312 - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) The module is equipped with two independent converters (sensor 1 and 2, sensor 3 and 4). The conversion time is valid for the number of channels connected to the corresponding converter.
3) To ensure accuracy, modules with a power loss <1.2 W must be inserted to the left and right of this module.
4) Based on the current resistance value.
5) Based on the entire resistance measurement range.

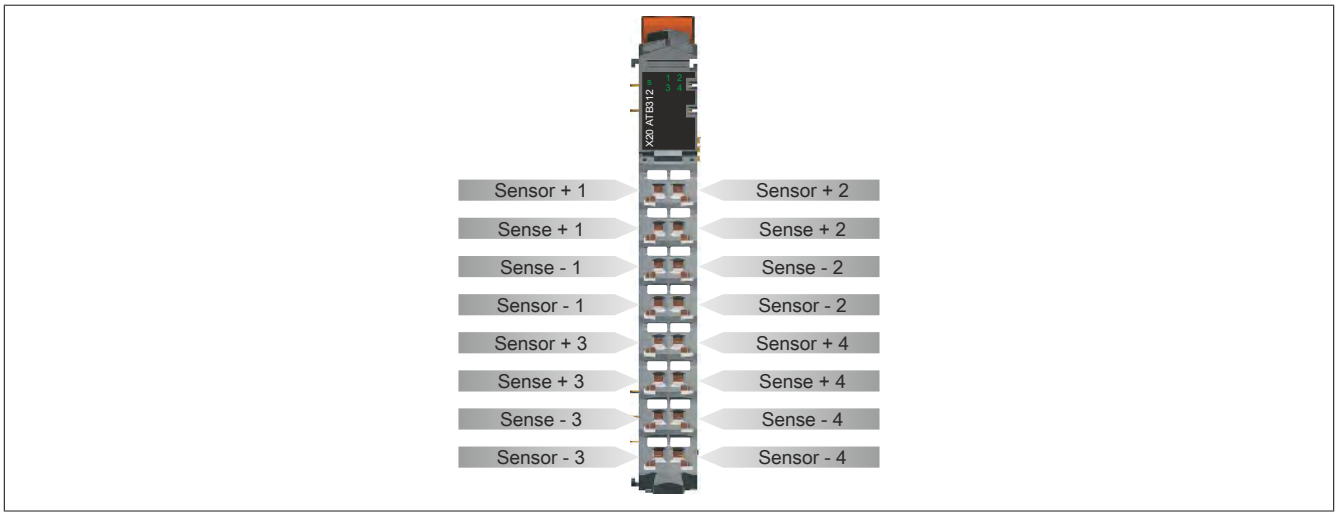
4.31.10.4 Status LEDs

For a description of the various operating modes, see section 2.11.1 "re LEDs".

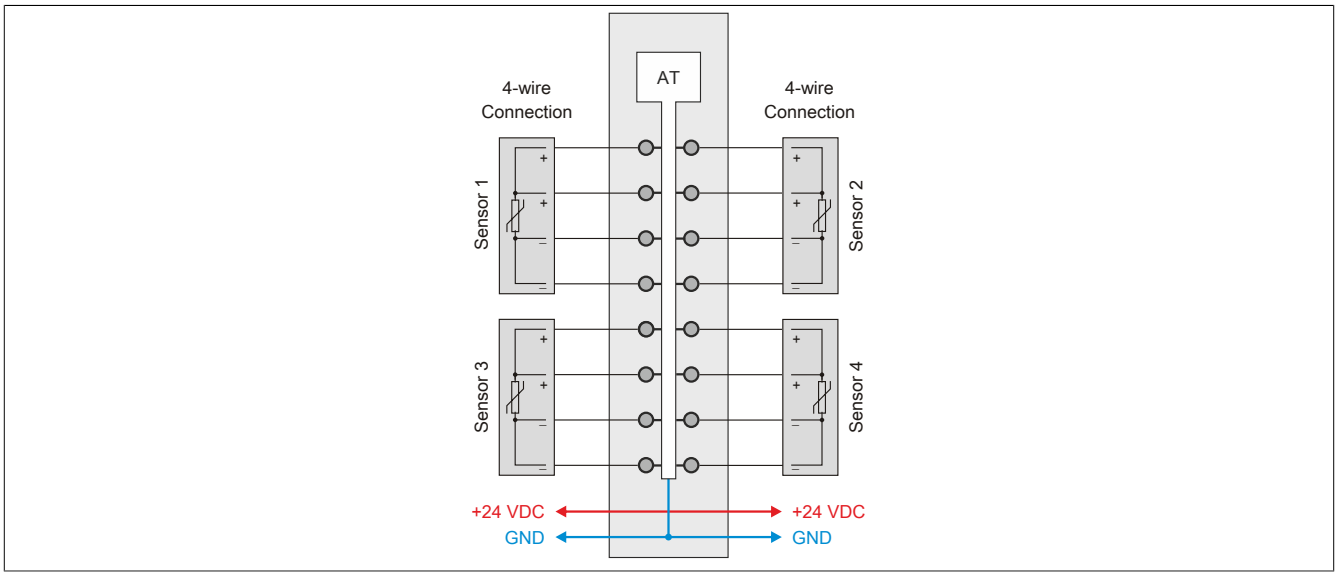
Image	LED	Color	Status	Description
	s	Green	Off	Module supply not connected
			Single flash	Reset mode
			Double flash	Boot mode (Updating firmware)[1]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	Module supply not connected or everything OK
			On	Error or reset status
			Single flash	Parameter or conversion error[2]
		Red on / Green single flash		Invalid firmware
	1 - 4	Green	Off	Input turned off or not supplied
			Single flash	Parameter error[2]
			Double flash	Conversion error[2]
			Blinking	Overflow, underflow or open line
			On	A/D converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.
2) Parameter and conversion errors are indicated on both the red s-LED and the channel LED for the respective output at the same time.

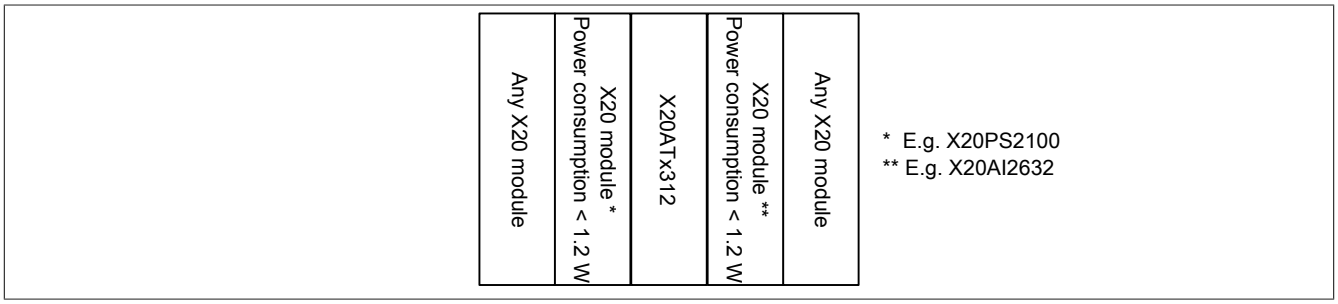
4.31.10.5 Pinout



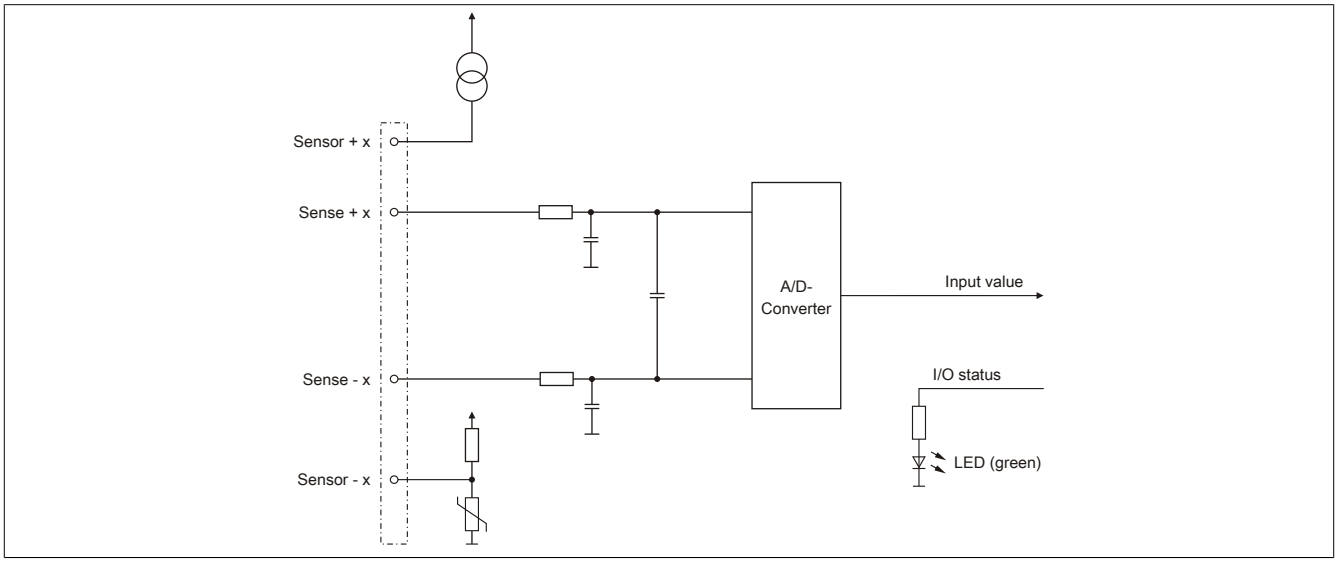
4.31.10.6 Connection example



To ensure accuracy, modules with a power consumption <1.2 W must be inserted to the left and right of this modules.



4.31.10.7 Input circuit diagram



4.31.10.8 Register description

4.31.10.8.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.10.8.2 Function model 0 - Standard

Register	Name	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Configuration						
130	InputFilter	UINT				•
134	ModeADC	UINT				•
Index * 64 + 450	SensorType0x (Index x = 1 to 4)	UINT				•

1) The offset specifies where the register is within the CAN object.

4.31.10.8.3.1 CAN I/O bus controller

The module occupies 1 analog logical slot on CAN-I/O 1.

4.31.10.8.4 Configuration of the A/D converter

4.31.10.8.4.1 Setting the conversion rate

Name:
InputFilter

This register can be used to set the conversion rate for the Analog/Digital converter.

Data type	Value
UINT	5 to 1023

Information:

The lower the conversion interval is set, the more precisely the value can be converted. However, this also increases the I/O update time.

4.31.10.8.4.2 A/D converter operating mode

Name:
ModeADC

This register can be used to set the operating mode for the Analog/Digital converter.

The individual options allow faster digitalization of the analog values, but this also reduces the precision of the measured values. The default value is 0.

Data type	Value
UINT	See bit structure

Bit structure:

Bit	Name	Value	Information
0	Chopper mode	0	Alternating amplification of the analog value
		1	Chopper mode off
1	Order of the SINC filter	0	SINC4
		1	SINC3
2 - 15	Reserved	-	-

The following rules apply:

ConversionTime(SINC3) = ConversionTime(SINC4) - 1 x ConversionCycle
ConversionTime(without Chop) = 0.5 x ConversionTime(Chop)

4.31.10.8.5 Configuring the measurement channels

Each temperature measurement channel can be configured independently. All the registers required for this purpose by each channel are arranged separately.

4.31.10.8.5.1 Channel parameters

Name:
SensorType01 to SensorType04

This register defines the basic behavior of the channel.
The default value is 0x81.

Data type	Value
UINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0 - 2	Sensor type with unit and resolution	001	PT100 [10 mK/bit] - Temperature measurement
		010	PT100 [1 mΩ/bit] - Resistance measurement
		011 to 111	Reserved
3 - 4	Reserved	-	
5	Replacement value strategy	0	Static replacement
		1	Retain last valid value
6	Monitoring the user-defined limit values	0	Switch off additional limits
		1	Switch on additional limits
7	Channel (on/off)	0	Switch off the entire channel
		1	Switch on the channel
8 - 15	Reserved	-	

4.31.10.8.6 Configuring the replacement value strategy

If a measured value is detected that is outside the permitted value range, the behavior of the input register must still remain clearly defined. The module provides the user two different options for this purpose.

Retain last valid value

With this strategy, the determined measured value is stored temporarily for a specific time and written to the input register after a delay. If an invalid measured value is detected, this value and all values that have been stored temporarily are discarded. The last valid input register value is retained. To update the value in the input register, there must be enough valid values stored in the temporary buffer. The number needed is determined by the time period specified in "PreparationInterval0x".

Replace with static value

With this strategy, the measured value is written to the input register without delay. If an invalid value occurs, it is replaced by a static value that has been predefined by the user.

4.31.10.8.6.1 Preparation interval

Name:
PreparationInterval01 to PreparationInterval04

This register defines the time interval in which the measured value is checked before being passed on.

Data type	Value
UINT	0 to 65535 (x 0.1 ms)

Information:

This register must be defined if the replacement value strategy "Retain last valid value" was selected in register "SensorType0x".

4.31.10.8.6.2 Static replacement value when exceeding the upper limit

Name:
ReplaceUpper01 to ReplaceUpper04

This register is used to defined a replacement value that is output in place of the invalid measured value if the upper limit is violated.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "SensorType0x".

4.31.10.8.6.3 Static replacement value when falling below the lower limit

Name:
ReplaceLower01 to ReplaceLower04

This register is used to defined a replacement value that is output in place of the invalid measured value if the lower limit is violated.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

This register must be defined if the replacement value strategy "Replace with static value" was selected in register "SensorType0x".

4.31.10.8.7 Configuring the user-defined limit values

This module provides the user the option to specify user-defined limits. If the valid measurement range is reduced in this way, the behavior of the replacement value strategy is more likely to be applied.

Valid measurement range

The valid range is derived from the properties of the sensor being used or the hardware and firmware of the respective B&R module. These values cannot be changed by the user.

Valid range of values

The range of values is always within the valid measurement range. The range of values can be adapted to the requirements of the application by specifying the upper and lower limit value.

4.31.10.8.7.1 Upper limit value

Name:
UpperLimit01 to UpperLimit04

This register specifies the upper limit value. The values entered should be within the valid measurement range.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.10.8.7.2 Lower limit value

Name:
LowerLimit01 to LowerLimit04

This register specifies the lower limit value. The values entered should be within the valid measurement range.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.10.8.7.3 Hysteresis

Name
Hysteresis01 to Hysteresis04

A hysteresis can be set in order to avoid frequent status changes in the measurement range close to the limit value. Here, a small section is defined at the edge of the valid range of values where the measured values retain the status (valid or invalid) of the previous measured value.

Data type	Value
UINT	0 to 65535

4.31.10.8.8 Configuring status messages

Errors are detected by the module and sent to the application. When using Function model 0 - Standard, the trigger behavior of these error messages can be influenced by the "Delay" register.

In Automation Studio, an error message can be read either packed as the entire register or individually as bits.

4.31.10.8.8.1 Delaying error messages

Name:
ErrorDelay01 to ErrorDelay04

In order to avoid false alarms due to short-term measurement variations, the status messages sent to the PLC can be delayed. This register determines the number of A/D conversions in which an error must exist before an error message is sent.

Data type	Value
UINT	0 to 65535 [A/D conversions]

4.31.10.8.8.2 Delaying the sum error message

Name:
SumErrorDelay01 to SumErrorDelay04

This register can be used to set the delay used when sending bit 5 of the "Status0x" register to the PLC independent of the other status messages.

The sum error can be delayed separately, independent of all other status messages.

Data type	Value
UINT	0 to 65535 [ms]

4.31.10.8.9 Communication

The received temperature data is assigned a timestamp and, depending on the configuration, made available with different register names and data types.

4.31.10.8.9.1 Measured value – Temperature

Name:
Temperature01 to Temperature04

If the channel is configured for resistance measurement, the current temperature value is made available in this register.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

4.31.10.8.9.2 Measured value – Resistance

Name:
Resistor01 to Resistor04

If the channel is configured for resistance measurement, the current resistance value is made available in this register.

Data type	Value
UDINT	0 to 4,294,967,295

4.31.10.8.9.3 Measured value – Unweighted

Name:
Measurand01 to Measurand04

When using the AsIoAcc library, the unweighted measurement can be accessed via this register. This refers to a measured value that is within the valid measurement range and has not yet been compared with the user-defined limits.

Data type	Value
DINT	-2,147,483,648 to 2,147,483,647

Information:

If no user-defined limits are configured, the value of this register does not differ from the temperature or resistance value.

4.31.10.8.9.4 Cycle counter

Name:
IOCycleCounter01 to IOCycleCounter04

This register is used to provide a continuous counter for the application that is incremented each time a temperature value is read.

Data type	Value
USINT	0 to 32767 [A/D conversions]
UINT	0 to 65535 [A/D conversions]

4.31.10.8.9.5 Sampling time

Name:
Sampletime01 to Sampletime04

This register is used to provide the application the net time until the temperature will be evaluated.

Data type	Value
INT	-32,768 to 32,767 [µs]
DINT	-2,147,483,648 to 2,147,483,647 [µs]

Information:

The SDC library requires a 16-bit value for the sampling time. It is therefore also prepared as a 16-bit value.

4.31.10.8.9.6 Status messages

Name:
Status01 to Status04

The register bits are set if an error has been diagnosed and the error remains longer than the delay configured in the "ErrorDelay0x" register.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Underrun01 to Underrun04	0	No error
		1	Value below the permitted range
1	Overrun01 to Overrun04	0	No error
		1	Value above the permitted range
2	OpenLine01 to OpenLine04	0	No error
		1	Sensor is not connected correctly
3	Reserved	-	
4	ConverterFault01 to ConverterFault04	0	No error
		1	Invalid A/D converter output
5	SumFault01 to SumFault04	0	No error
		1	Composite error
6	ParameterFault01 to ParameterFault04	0	No error
		1	The 4.31.10.8.5.1 "SensorType0x" register is faulty
7	IoSupplyFault01 to IoSupplyFault04	0	No error
		1	The supply voltage (I/O) is faulty

4.31.10.8.9.7 Status messages for function model 254

Name:
Status01To04

The bits in this register are set if an error has been detected.

Data type	Value
USINT	See bit structure.

Bit structure:

Bit	Name	Value	Information
0	Underrun on channel 01	0	No error
		1	Value below the permitted range
1	Overrun on channel 01	0	No error
		1	Value above the permitted range
...		...	
6	Underrun on channel 04	0	No error
		1	Value below the permitted range
7	Overrun on channel 04	0	No error
		1	Value above the permitted range

Information:

If an open line is detected on a channel, then both error messages will be displayed at the same time.

4.31.10.8.10 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.31.10.8.11 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.31.11 X20ATC402

4.31.11.1 General information

The module is equipped with 6 inputs for J, K, N, S, B, R, E, C and T thermocouple sensors.

This module can also be equipped with the X20TB1E thermocouple terminal block with integrated PT1000 temperature sensors. This makes it possible to achieve optimal terminal temperature compensation.

- 6 channels for thermocouples
- For sensor types J, K, N, S, B, R, E, C, T, raw value measurement
- Integrated terminal temperature compensation
- 2x PT1000 sensor integrated in the terminal (X20TB1E)
- 2x external PT1000 sensor can be connected (X20TB1F)
- Configurable filter time

4.31.11.2 Order data

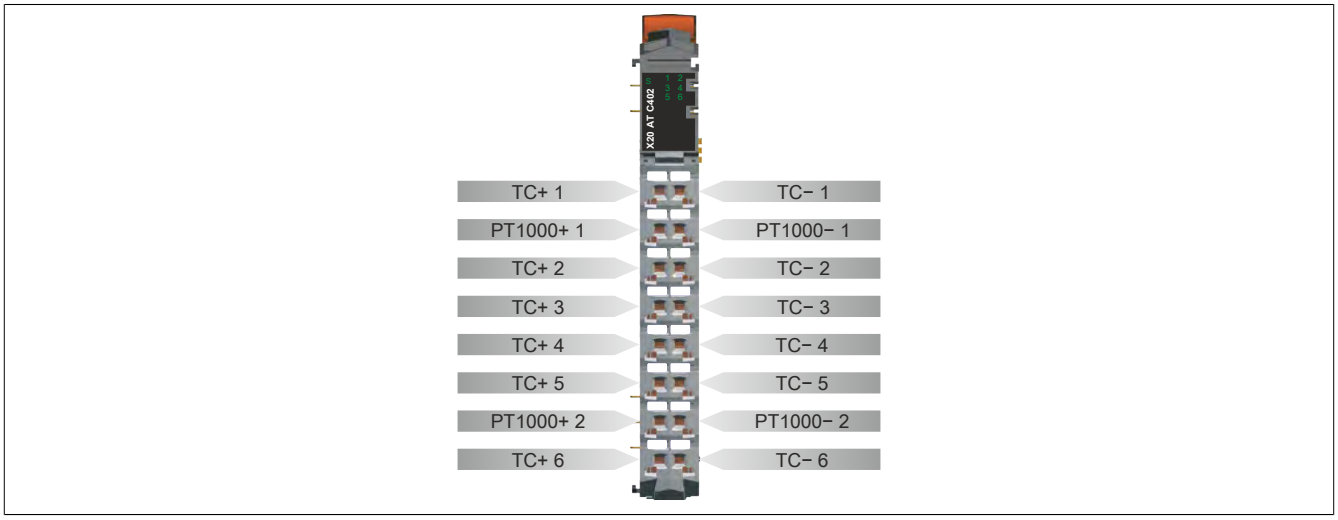
4.31.11.4 LED status indicators

For a description of the various operating modes, see section 2.11.1 "re LEDs".

Figure	LED	Color	Status	Description
	S	Green	Off	No power to module
			Single flash	RESET mode
			Double flash	BOOT mode (during firmware update)[1)]
			Blinking	PREOPERATIONAL mode
			On	RUN mode
		Red	Off	No power to module or everything OK
			On	Error or reset status
			Single flash	A parameter or conversion error has occurred. This status is output in addition to a single/double flash on the channel LED of the analog input where the error occurs.
		Red on / Green single flash		Invalid firmware
	1 - 6	Green	Off	Input turned off or not supplied
			Single flash	A parameter error has occurred. A single flash is output on the red "s" module status LED.
			Double flash	A conversion error has occurred. A single flash is output on the red "s" module status LED.
			Blinking	Overflow, underflow or open line
			On	Analog/digital converter running, value OK

1) Depending on the configuration, a firmware update can take up to several minutes.

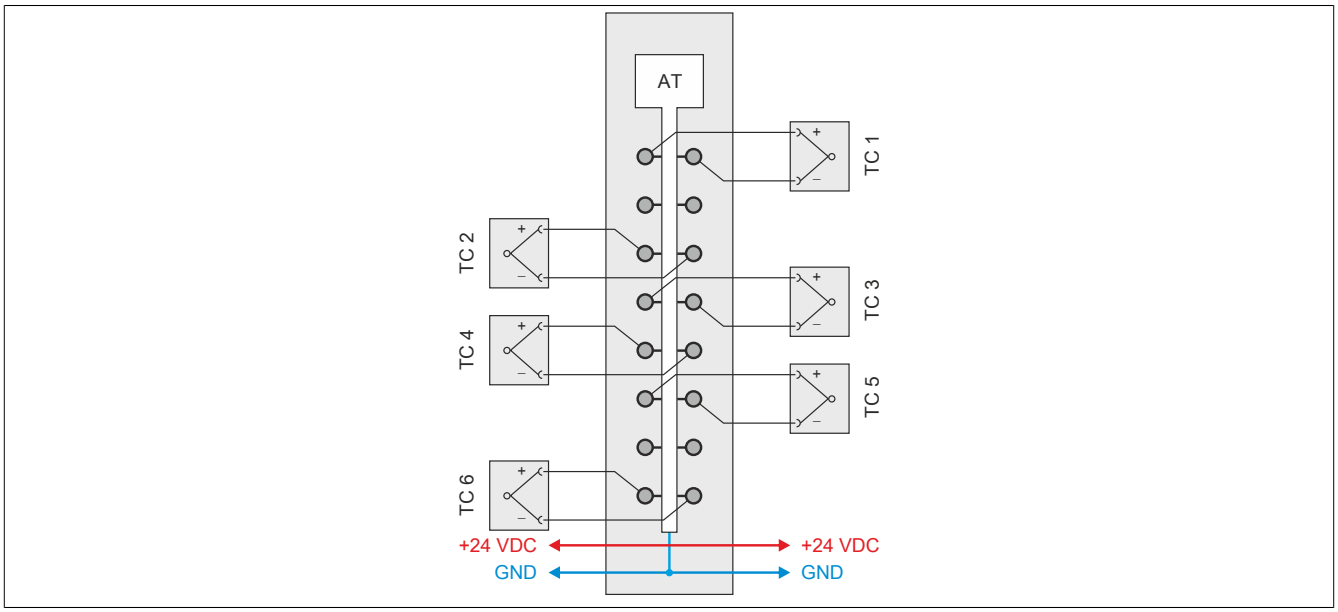
4.31.11.5 Pinout



4.31.11.6 Connection examples

Internal temperature compensation

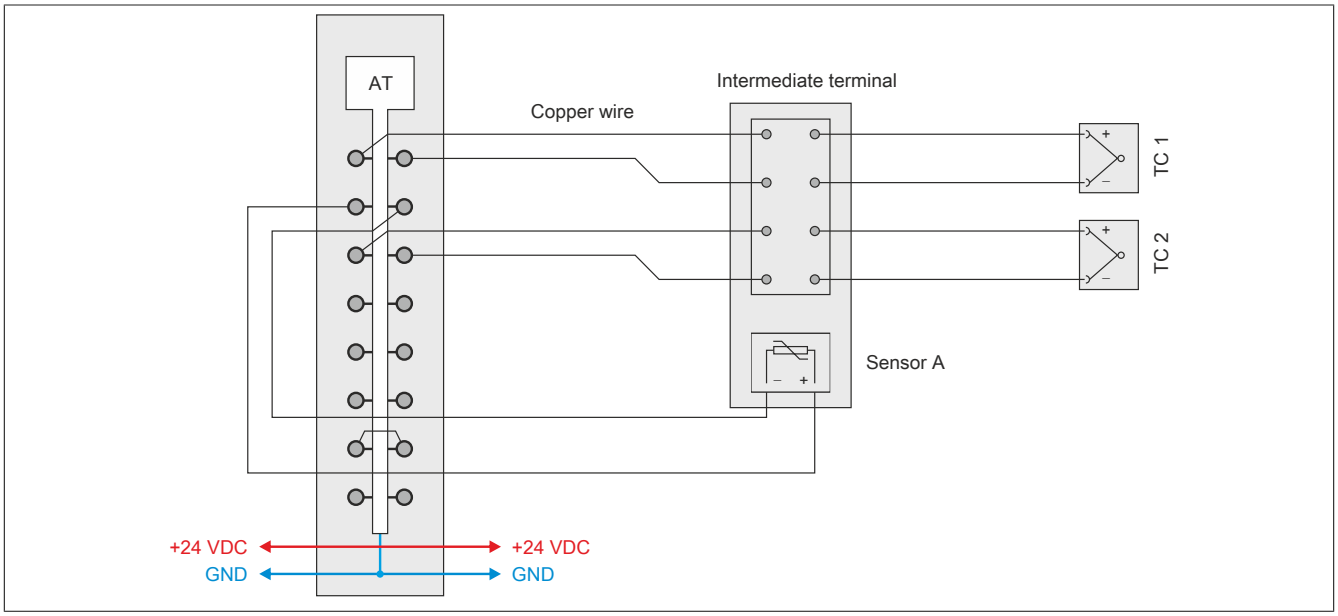
The thermocouple terminal block X20TB1E with integrated PT1000 sensors is used for internal temperature compensation.



Remote temperature compensation

The 16x standard terminal X20TB1F is used for remote temperature compensation. The external PT1000 sensors are connected to the module using 2-wire connections.

If Sensor B is not needed for temperature compensation, then the terminal points need to be bypassed.

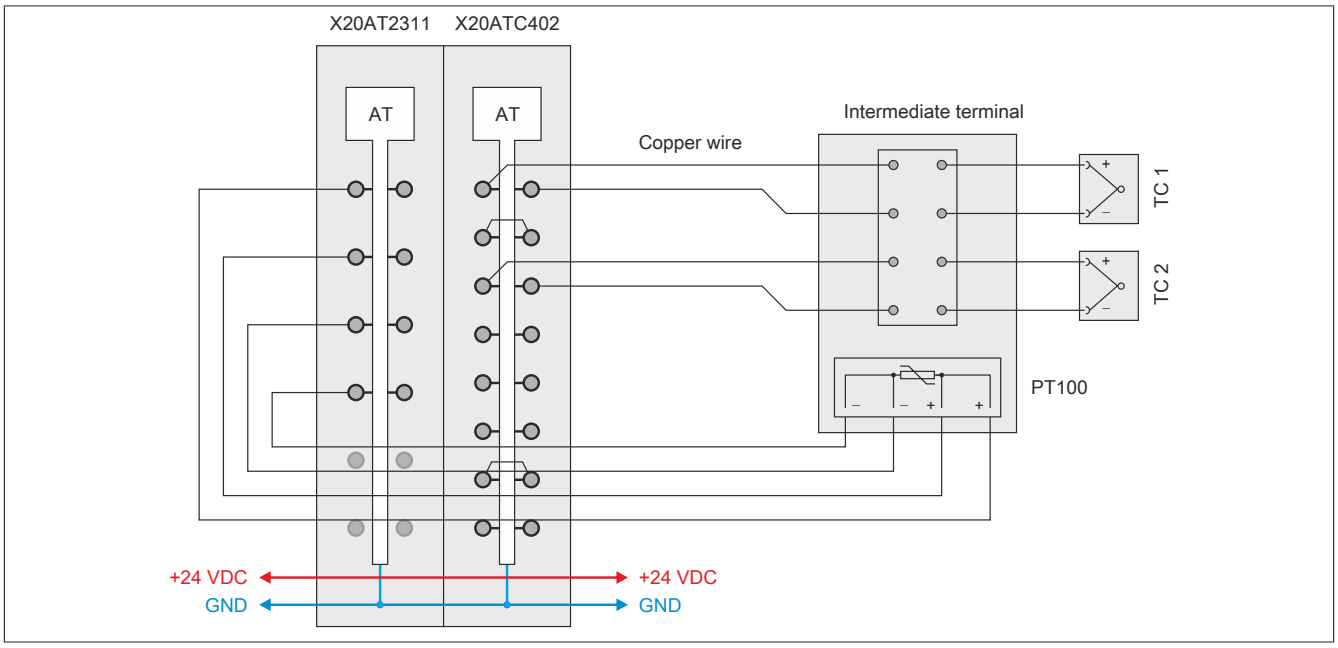


External temperature compensation

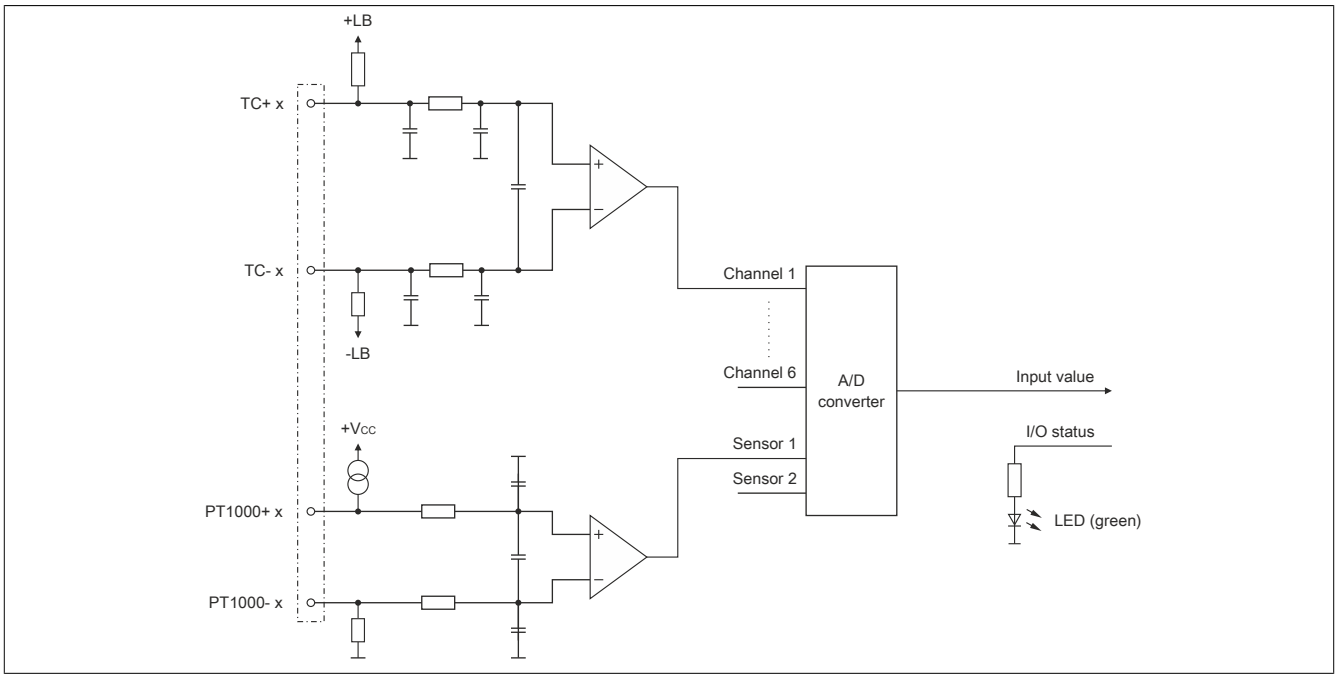
External compensation does not require the PT1000 values to be converted internally in the module. Instead, the reference temperatures have to be pre-processed in the program before being stored in the module. A separate register is available for each temperature channel to transfer an externally pre-processed compensation value.

In the following example, the compensation value is determined using the X20AT2311 temperature input module and a PT100 sensor on the intermediate terminal. The cold junction temperature determined externally is then made available to the X20ATC402 module via the respective I/O data points.

Since sensors A and B aren't needed for temperature compensation, the respective terminal points need to be bypassed.



4.31.11.7 Input circuit diagram



4.31.11.8 Increased precision

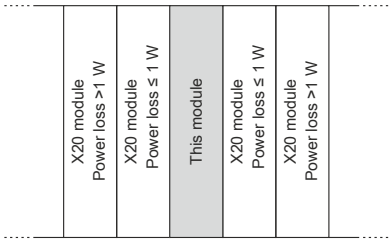
4.31.11.8.1 Internal temperature compensation

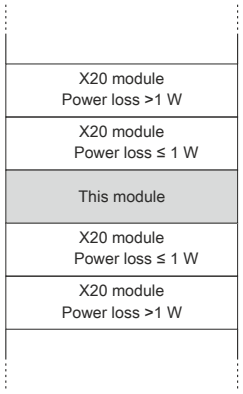
When using internal terminal temperature compensation, a temperature model must be defined in order to increase precision. A temperature model should be selected according to the following criteria:

- Thermal power loss of neighboring modules
- X20 system - Mounting orientation

4.31.11.8.1.1 Neighboring modules with low thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

Horizontal installation	Vertical installation
	




The following temperature model must be set in the Cfo_SensorTypeCh0x register.

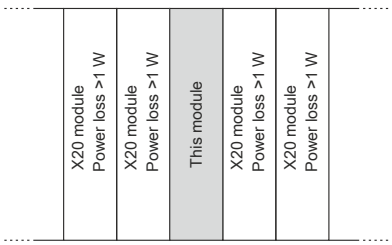
Bit 6 and 7	Temperature model	Bit 6 and 7	Temperature model
00	Horizontal installation, low thermal radiance <1W	10	Vertical installation, low thermal radiance <1W

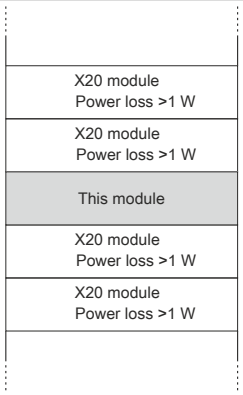
Information:

The best results are achieved by placing a dummy module on both sides.

4.31.11.8.1.2 Neighboring modules with higher thermal power loss

The temperature model listed in the table must be configured according to the mounting orientation.

Horizontal installation	Vertical installation
	




The following temperature model must be set in the Cfo_SensorTypeCh0x register.

Bit 6 and 7	Temperature model	Bit 6 and 7	Temperature model
01	Horizontal installation, high thermal radiance >1 W	11	Vertical installation, high thermal radiance >1 W

4.31.11.8.2 Remote or external terminal temperature compensation

Setting up a remote or external cold junction can provide the most accurate temperature measurement in a machine or system.

The installation of a remote or external cold junction is especially helpful in the following cases.

- There is no module next to the temperature module
- With strongly fluctuating ambient conditions (draft, temperature)
- External fan is used in the control cabinet

4.31.11.9 Register description

4.31.11.9.1 General data points

In addition to the registers listed in the register description, the module also has other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

The general data points are described in section 4.33 "General data points".

4.31.11.9.2 Function model 0 - Standard

Register	Product ID	Data type	Read		Write	
			Cyclic	Acyclic	Cyclic	Acyclic
Module configuration						
1026	Cfo_InputFilter	UINT				•

4.31.11.9.3.1 CAN I/O bus controller

The module occupies 2 analog logical slots on CAN-I/O.

4.31.11.9.4 Module configuration

The X20ATC402 is an I/O module for temperature measurement. It has six non electrically isolated channels. The module requires a 16-pin standard terminal or the 16-pin terminal with 2 integrated PT1000 inputs for temperature compensation. The remaining six channels can be equipped with thermocouples and record the difference in temperature between the reference point (e.g. the terminal) and the actual measurement point.

4.31.11.9.4.1 I/O update time

The analog/digital converter must convert up to eight values. After switching between two inputs there are four measurements in order to obtain a meaningful value. Since not all inputs need to be used, the actual I/O update time may vary greatly.

The following formula can be used to calculate the I/O update time:

Conversion rate * 4 * (number of converted compensation values + number of converted temperature differences)

4.31.11.9.4.2 InputFilter

Designations (pChannelName):
Cfo_InputFilter

The "Filter" register allows the user to set the conversion interval for the analog/digital converter.

Data type	Values [msec]
UINT	0…65535

Information:

The lower the conversion interval is set, the more precisely the value can be converted. However, this also increases the I/O update time.

The following formula applies:

Conversion rate = (4920000/1024) * InputFilter

4.31.11.9.5 Compensation

The measurement process is based on the interaction between the temperature sensors and the thermocouples. Each thermocouple measures the difference in temperature between the measurement point and the terminal. To calculate the absolute temperature, the measurement value must be placed in relation to a compensation value. The compensation value can be provided to the module via cyclic data points or read in via PT1000 temperature sensors.

4.31.11.9.5.1 Internal compensation

The input channels of the PT1000 temperature sensor are used for internal compensation.
When using the 16-pin standard terminal (X20TB1F), the reference point for compensation measurements can be moved from the terminal to a thermally isolated location. Using such a "remote terminal" makes it possible to achieve very precise measurement results. There are two of each configuration register required for this, which allows the two measurements to be configured independently of one another. The reference temperatures can be displayed and calibrated using an offset value.

Information:

To avoid unnecessary traffic on the X2X bus, the compensation registers should only be transferred cyclically during the fine-tuning process and for service and maintenance purposes. The information is generally not required during normal operation.

Alternatively, the module can be operated with a special 16-pin terminal (X20TB1E). This is equipped with two PT1000 temperature sensors and is used to determine the default values. To allow for this compensation method, extra temperature distribution models have been built into the module.

ClampType

Designations (pChannelName):
Cfo_ClampTypeA
Cfo_ClampTypeB

The ClampType register specifies the type of sensor and registers the conversion of the compensation value on the ADC.

Data type	Values
UINT	See bit structure Bus controller default: 0

Bit structure:

Bit	Product ID		Note
0	Sensor type	0	PT1000
1	Compensation channel (on/off)	0	Channel not converted by the ADC
		1	Channel registered on the ADC
2	Compensation value (see CompensationValue)	0	Prepare as temperature value
		1	Prepare as resistance value
3	Reserved	-	
4	Installation parameter	0	Horizontal installation
		1	Vertical installation
5	Thermal radiance	0	Low
		1	High
6…15	Reserved	-	

Four different temperature distribution models have been built into the module, optimized for the various ways the module can be installed. The respective model is selected using the following bits:

Installation parameter:
If the X2X bus modules are installed next to each other, the installation parameter should be set to 0.
If the X2X bus modules are installed above and below each other, the installation parameter should be set to 1.

Thermal radiance:
If an active module that generates additional heat is installed in the immediate vicinity of the temperature module, then this parameter should be set to 1.

CompensationValue

Designations (pChannelName):
CompensationValueA
CompensationValueB

The "CompensationValue" registers can be used to read the compensation value. Depending on how the "ClampType" register is set, it is output as either a temperature or resistance value.

Data type	Values [0.1°C or 0.1 Ohm]
INT	-32767…32767

ClampOffset

Designations (pChannelName):
Cfo_ClampOffsetA
Cfo_ClampOffsetB

The "ClampOffset" registers define the offsets that are deducted from the respective compensation values.

Data type	Values [0.1 Ohm]
INT	-32767…32767 Bus controller default: 0

CompensationStatus

Designations (pChannelName):
CompensationStatusA
CompensationStatusB

The "CompensationStatus" registers provide information about the current status of the respective compensation value. The structure is based on the status registers of the six measurement channels.

Data type	Values
USINT	See bit structure

Bit structure:

Bit	Product ID		Note
0	UnderrunA UnderrunB	0	No error
		1	Value below the permitted range
1	OverrunA OverrunB	0	No error
		1	Value above the permitted range
2	OpenLineA OpenLineB	0	No error
		1	Open line
3	(Compensation error)	-	no meaning
4	ConverterFaultA ConverterFaultB	0	No error
		1	Converter error
5	SumFaultA SumFaultB	0	No error
		1	Immediate composite error
6	ParameterFaultA ParameterFaultB	0	No error
		1	Setting for "ClampType" register not permitted
7	Reserved	-	

4.31.11.9.5.2 External compensation

With external compensation, there is no need for internal conversion of the PT1000 values in the module. Instead, the reference temperatures have to be pre-processed in the program before being stored in the module. Additional output registers are provided in the I/O mapping to allow for the exchange.

ExternalCompensation

Designations (pChannelName):
ExternalCompensation01
ExternalCompensation[02…06]

The "ExternalCompensation" registers can be used to send an externally generated compensation value from the PLC program to the module. There is a separate register for each temperature channel.

Data type	Values [0.1°C]
INT	-32767…32767

4.31.11.9.6 Temperature measurement - Configuration

The temperature measurement channels can be configured independently of each other. All the registers required for each channel are arranged separately.
The "SensorType" register needs to be adjusted in order to enable a temperature channel. The rest of the registers complement this configuration and only need to be defined as required.

4.31.11.9.6.1 SensorType

Designations (pChannelName):
Cfo_SensorType01
Cfo_SensorType[02...06]

The "SensorType" registers control the basic functionality of a temperature channel.

Data type	Values
UINT	See bit structure

Bit structure:

Bit	Product ID		Note
0…5	Standardization		Sensor type used
6…7	Reserved	-	
8…11	Method of compensation		Reference point
12	Reserved	-	
13	Replacement value	0	Replace with static preset value
		1	Retain last valid value
14	Additional user limits	0	Valid value range for sensor type
		1	Additional restrictions to value range
15	Temperature channel (on/off)	0	Channel not converted by the ADC
		1	Channel registered on the ADC

Sensor type:
00…000000 - Sensor J (Fe-CuNi)
01…000001 - Sensor K (NiCr-Ni)
02…000010 - Sensor N (NiCrSi-NiSi)
03…000011 - Sensor S (PtRh10-Pt)
04…000100 - Sensor R (PtRh13-Pt)
05…000101 - Sensor C (WRe5-WRe26)
06…000110 - Sensor T (Cu-CuNi)
07…000111 - Sensor B (PtRh30-PtRh6)
08…001000 - Sensor E (NiCr-CuNi)
Raw values without linearization and temperature compensation
61…111101 - RawValue1; Resolution 1.0625 µV; Measurement range ±35 mV
62…111110 - RawValue2; Resolution 2.125 µV; Measurement range ±70 mV

Reference point:
0…0000 - Compensation A
1…0001 - Compensation B
4…0100 - Temperature model implemented for special terminal
8…1000 - External compensation

4.31.11.9.6.2 PreparationInterval

Name (pChannelName):
Cfo_PreparationInterval01
Cfo_PreparationInterval[02…06]

If the last valid measurement value should be kept when violating the limit value, then PreparationInterval must be defined. The measurement values continue to be acquired and converted according to the configured I/O update time. They are then checked and discarded if they do not meet the specifications. When an error does not occur, therefore, the measurement value acquired two preparation intervals ago is constantly output.

Data type	Values [0.1 ms]
UINT	0…65535

How it works:
Measured values are converted at the configured conversion rate and saved to measurement value memory. The current contents of the measurement value memory are checked within the configured interval. If a permissible value is present, then the contents of the buffer memory are passed to output memory and the contents of the measurement value memory are passed to the buffer.
If the check turns up an impermissible value, then the contents of the measurement value memory are discarded. The copy direction between the output and buffer memory reverses and the last valid value continues to be output.

"Application" for the value being measured (analog)	
↓	Condition: - Conversion interval (ADC) elapsed
"Measurement value memory" Measurement value (digital)	
↓	Condition: - PreparationInterval elapsed - Measurement value permissible
"Buffer" Last valid value	
↓	Condition: - PreparationInterval elapsed - Measurement value permissible
"Output memory" Next-to-last valid/ displayed value	

Information:

If configured to keep the last valid value, the delay time from measuring to outputting the value will be at least twice the preparation interval. In the worst case scenario, this can also take twice the interval time plus the configured ADC conversion rate.

Information:

The registers are only set for the channel when "SensorType" bit 13 is set.

4.31.11.9.6.3 ReplaceUpper, ReplaceLower

Names (pChannelName):
Cfo_ReplaceUpper01
Cfo_ReplaceUpper[02…06]

Cfo_ReplaceLower01
Cfo_ReplaceLower[02…06]

The "Replace" register is used to define the static values to be displayed instead of the current measurement value when the limit is violated.

Data type	Values
INT	-32767…32767

Information:

The registers are only set for the channel when "SensorType" bit 13 is not set.

4.31.11.9.6.4 UpperLimit, LowerLimit

Condition: The registers are only set for the channel when "ClampType" bit 14 is set.

Names (pChannelName):
Cfo_UpperLimit01
Cfo_UpperLimit[02…06]

Cfo_LowerLimit01
Cfo_LowerLimit[02…06]

If the value range needs to be restricted further, the "UpperLimit" and "LowerLimit registers can be used to enter new user-specific limit values.

Data type	Values
INT	-32767…32767
UINT	0...65535

4.31.11.9.6.5 Hysteresis

Designations (pChannelName):
Cfo_Hysteresis01
Cfo_Hysteresis[02…06]

If the user-specific limit values are being used, then a hysteresis range should also be defined. The "Hysteresis" registers configure how far a limit value can be exceeded before a response is triggered.

Data type	Values
INT	-32767…32767
UINT	0...65535

Information:

The registers are only set for the channel when "ClampType" bit 14 is set.

4.31.11.9.6.6 ErrorDelay

Names (pChannelName):
Cfo_ErrorDelay01
Cfo_ErrorDelay[02…06]

This register specifies the number of consecutive conversion procedures where an error is pending until the corresponding individual error status bit is set. The delay applies to underflow, overflow and open circuit errors. This delay can be used to hide temporary measurement value deviations, for example.

Data type	Values
UINT	0…65535

4.31.11.9.6.7 SumErrorDelay

Names (pChannelName):
Cfo_SumErrorDelay01
Cfo_SumErrorDelay[02…06]

A "SumErrorDelay" register can be used to set the time that an error must remain pending before the composite error bit is set.

Data type	Values
UINT	0…65535

4.31.11.9.7 Temperature measurement

The received temperature data is prepared in two different formats and given a time stamp. For each channel there are two separate registers for transmitting the measurement values to the PLC. The user is free to select the format that best fits the application at hand.

4.31.11.9.7.1 TemperatureEvaluated, Measurand

Designations (pChannelName):
TemperatureEvaluated01
TemperatureEvaluated[02…06]

TemperatureEvaluated01_CANIO
TemperatureEvaluated[02…06]_CANIO

Measurand01
Measurand[02...06]

Analog input value with respect to sensor type:

Input signal	Digital value
Type J (Fe-CuNi)	-2100 to 12000 (for -210.0 to 1200.0°C)
Type K (NiCr-Ni)	-2700 to 13720 (for -270.0 to 1372.0°C)
Type N (NiCrSi-NiSi)	-2700 to 12980 (for -270.0 to 1298.0°C)
Type S (PtRh10-Pt)	-500 to 17680 (for -50.0 to 1768.0°C)
Type R (PtRh13-Pt)	-500 to 17600 (for -50.0 to 1760.0°C)
Type C (WRe5-WRe26)	0 to 23100 (for 0 to 2310.0°C)
Type T (Cu-CuNi)	-2700 to 4000 (for -270.0 to 400.0°C)
Type B (PtRh30-PtRh6)	0 to 18200 (for 0 to 1820.0°C)
Type E (NiCr-CuNi)	-2700 to 9970 (for -270.0 to 997.0°C)
Voltage without linearization and terminal temperature compensation Resolution 1.0625 µV for a measurement range of ±35 mV	-32768 to 32767
Voltage without linearization and terminal temperature compensation Resolution 2.125 µV for a measurement range of ±70 mV	-32768 to 32767

In order for the user to always be supplied with a defined output value, the following must be taken into consideration:

- Up to the first conversion, 0x8000 is output.
- After switching the sensor type, 0x8000 is output until the first conversion.
- If the input is switched off, 0x8000 is output.
- If an I/O voltage supply failure occurs, 0x8000 is output

4.31.11.9.7.2 SampleTime

Names (pChannelName):
SampleTime01_16bit
SampleTime[02…06]_16bit

SampleTime01_32bit
SampleTime[02…06]_32bit

These registers return the timestamp for when the module reads the current channel mapping. The values are provided as signed 2-byte or 4-byte values.

Data type	Values [µs]	Information
INT	-32,768 to 32767	Nettime timestamp of the current input value
DINT	-2,147,483,648 to 2,147,483,647	Nettime timestamp of the current input value

4.31.11.9.7.3 IOCycleCounter

Designations (pChannelName):
IOCycleCounter01_8bit
IOCycleCounter[02…06]_8bit

IOCycleCounter01_16bit
IOCycleCounter[02…06]_16bit

The "IOCycleCounter" is a cyclic counter that is incremented each time a value is converted. It can be used as either a 1-byte or 2-byte counter.

Data type	Values
USINT	0...255
UINT	0…65535

4.31.11.9.7.4 Error management

The module can diagnose various error states. Detected errors can be read out via the status registers and the individual error bits. If an error only occurs briefly, the error status is reset automatically. The error management method must be tailored to the particular function model being used.

Status messages in function model 0

When using function model 0 (e.g. operation with X20 CPU) six different error sources can be analyzed. The "Delay" registers allow the user to control how errors are triggered on each channel. Error messages can be called either in packages or bit-wise.

Status

Names (pChannelName):
Status01
Status[02…06]

The current error status of the module channels is displayed in this register, regardless of the configured replacement value strategy. Some error information may be delayed according to the previously configured condition.

Data type	Values
USINT	See bit structure

Bit structure:

Bit	Name		Information
0	Underrun01 Underrun[02...06]	0	No error
		1	Value below the permitted range
1	Overrun01 Overrun[02...06]	0	No error
		1	Value above the permitted range
2	OpenLine01 OpenLine[02...06]	0	No error
		1	Open line
3	CompensationFault01 CompensationFault[02...06]	0	No error
		1	Compensation error
4	ConverterFault01 ConverterFault[02...06]	0	No error
		1	Conversion error
5	SumFault01 SumFault[02...06]	0	No error
		1	Immediate composite error
6	ParameterFault01 ParameterFault[02...06]	0	No error
		1	Setting for "ClampType" register not permitted
7	Reserved	-	

Status messages in function model 254 (CANIO)

In function model 254 there is no configuration required in advance to activate error detection. It is always activated during startup. To streamline the transfer, however, only the four basic diagnostics were implemented.

ModuleStatus (CANIO)

Designations (pChannelName):
ModuleStatus01To04
ModuleStatus05To06

The bits of the "ModuleStatus" registers are set when one of the implemented error diagnostics is triggered.

Data type	Values
USINT	See bit structures I and II

Bit structure I:

Bit	Product ID		Note
0…1	Channel 1	0 - 3	See error description
2…3	Channel 2	0 - 3	See error description
4…5	Channel 3	0 - 3	See error description
6…7	Channel 4	0 - 3	See error description

Bit strucrture II:

Bit	Product ID		Note
0…1	Channel 5	0 - 3	See error description
2…3	Channel 6	0 - 3	See error description
4…7	Reserved	-	

Error description:
0…00 - No error
1…01 - Underflow (lower value limit violated)
2…10 - Overflow (upper value limit violated)
3…11 - Open line

4.31.11.9.8 Minimum cycle time

The minimum cycle time defines how far the bus cycle can be reduced without causing a communication error or impaired functionality. It should be noted that very fast cycles decrease the idle time available for handling monitoring, diagnostics and acyclic commands.

Minimum cycle time
200 µs

4.31.11.9.9 Minimum I/O update time

The minimum I/O update time defines how far the bus cycle can be reduced while still allowing an I/O update to take place in each cycle.

Minimum I/O update time
1 ms

4.32 Terminal blocks

Various terminal blocks are available for wiring X20 modules.

4.32.1 Brief information

Product ID	Short description	on page
X20TB06	X20 terminal block, 6-pin, 24 VDC keyed	3057
X20TB12	X20 terminal block, 12-pin, 24 VDC keyed	3057
X20TB1E	X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation	3059
X20TB1F	X20 terminal block, 16-pin, 24 VDC keyed	3061
X20TB32	X20 terminal block, 12-pin, 240 VAC keyed	3063

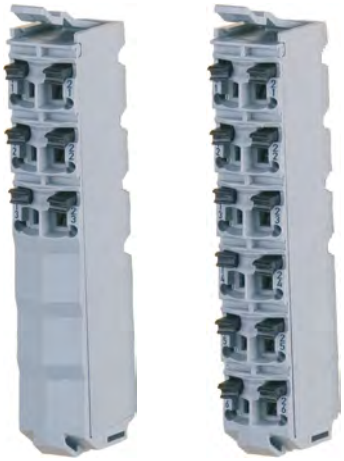
4.32.2 X20TB06/X20TB12

4.32.2.1 General information

The X20 24 VDC modules are wired using the X20TB06 and X20TB12 terminal blocks.

- Tool-free wiring with push-in technology
- Simple wire release using lever
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded

4.32.2.2 Order data



X20TB06 X20TB12

Model number	Short description

Relative humidity		
Operation	Corresponds to the X20 module used	

Table 749: X20TB06, X20TB12 - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) Take the respective limit data for the I/O modules into consideration!
3) Identical for operation, storage and transport.

Warning!

It is possible to come into contact with parts that carry voltage when the clamping block is disconnected. For this reason, working on a disconnected clamping block is not permitted at voltages of 50 V or higher.

4.32.2.4 Contact holding force

To ensure that cables maintain a secure contact with the terminal block, they must not be under too much stress. If the holding force is exceeded, the cable will come loose from the terminal block and cause a malfunction.

	Fine strand wires			Solid wires				With wire end sleeves	
Cables in mm²	0.25	1.5	2.5	0.08	0.25	1.5	2.5	0.25	1.5
Standard spec. (min. value in Newton)	12.5	40	50	4	12.5	40	50	12.5	40

Information:

Fine strand wires must be twisted to provide sufficient holding force.

4.32.3 X20TB1E

4.32.3.1 General information

The X20TB1E terminal block is equipped with two integrated PT1000 sensors. It is therefore optimally suited for internal terminal temperature compensation. The terminal block can be used on all thermocouple modules with 12 connections.

- Integrated terminal temperature compensation
- Tool-free wiring with push-in technology
- Simple wire release using a screwdriver
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded

4.32.3.2 Order data

Model number	Short description	Figure
	Terminal blocks	
X20TB1E	X20 terminal block, 12-pin, 24 VDC keyed, 2x PT1000 integrated for terminal temperature compensation	

Table 750: X20TB1E - Order data

4.32.3.3 Technical data

Product ID	X20TB1E
General information	
Certification	
CE	Yes
cULus	Yes
ATEX Zone 2 [1]	Yes
GL	Yes
LR	Yes
GOST-R	Yes
Terminal block	
Number of pins	12
Type of terminal clamp	Push-in terminal
Push-in force per contact	Typ. 10 N
Cable type	Only copper wires (no aluminum wires!)
Wire stripping length	7 to 9 mm
Connection cross section	
Solid wires	0.08 to 1.50 mm² / 28 to 16 AWG
Fine strand wires	0.25 to 1.50 mm² / 24 to 16 AWG
With wire end sleeves	0.25 to 0.75 mm² / 24 to 20 AWG
Distance between contacts	
Left - Right	4.2 mm
Above - Below	8.25 mm
Terminal temperature compensation	2x PT1000 integrated in the terminal
Electrical characteristics	
Nominal voltage	24 VDC
Max. voltage	50 VDC
Nominal current [2]	2 A / contact
Contact resistance	≤5 mΩ
Environmental conditions [3]	
Temperature	
Operation	Corresponds to the X20 module used
Relative humidity	
Operation	Corresponds to the X20 module used

Table 751: X20TB1E - Technical data

1) Ta min.: 0°C
   Ta max.: See environmental conditions
2) Take the respective limit data for the I/O modules into consideration!
3) Identical for operation, storage and transport.

Warning!

It is possible to come into contact with parts that carry voltage when the clamping block is disconnected. For this reason, working on a disconnected clamping block is not permitted at voltages of 50 V or higher.

4.32.3.4 Contact holding force

To ensure that cables maintain a secure contact with the terminal block, they must not be under too much stress. If the holding force is exceeded, the cable will come loose from the terminal block and cause a malfunction.

	Fine strand wires			Solid wires				With wire end sleeves	
Cables in mm²	0.25	1.5	2.5	0.08	0.25	1.5	2.5	0.25	1.5
Standard spec. (min. value in Newton)	12.5	40	50	4	12.5	40	50	12.5	40

Information:

Fine strand wires must be twisted to provide sufficient holding force.

4.32.4 X20TB1F

4.32.4.1 General information

X20 24 VDC modules with 16 connections are wired using the X20TB1F terminal block.

- Tool-free wiring with push-in technology
- Simple wire release using a screwdriver
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded

4.32.4.2 Order data

   Ta max.: See environmental conditions
2) Take the respective limit data for the I/O modules into consideration!
3) Identical for operation, storage and transport.

Warning!

It is possible to come into contact with parts that carry voltage when the clamping block is disconnected. For this reason, working on a disconnected clamping block is not permitted at voltages of 50 V or higher.

4.32.4.4 Contact holding force

To ensure that cables maintain a secure contact with the terminal block, they must not be under too much stress. If the holding force is exceeded, the cable will come loose from the terminal block and cause a malfunction.

	Fine strand wires			Solid wires				With wire end sleeves	
Cables in mm²	0.25	1.5	2.5	0.08	0.25	1.5	2.5	0.25	1.5
Standard spec. (min. value in Newton)	12.5	40	50	4	12.5	40	50	12.5	40

Information:

Fine strand wires must be twisted to provide sufficient holding force.

4.32.5 X20TB32

4.32.5.1 General information

The X20 240 VAC modules are wired using X20TB32 terminal blocks.

- Tool-free wiring with push-in technology
- Simple wire release using lever
- Ability to label each terminal
- Plain text labeling also possible
- Test access for standard probes
- Can be customer-coded
- Special color
- 240 V coding

4.32.5.2 Order data

3) Identical for operation, storage and transport.

Warning!

It is possible to come into contact with parts that carry voltage when the clamping block is disconnected. For this reason, working on a disconnected clamping block is not permitted at voltages of 50 V or higher.

4.32.5.4 Contact holding force

To ensure that cables maintain a secure contact with the terminal block, they must not be under too much stress. If the holding force is exceeded, the cable will come loose from the terminal block and cause a malfunction.

	Fine strand wires			Solid wires				With wire end sleeves	
Cables in mm²	0.25	1.5	2.5	0.08	0.25	1.5	2.5	0.25	1.5
Standard spec. (min. value in Newton)	12.5	40	50	4	12.5	40	50	12.5	40

Information:

Fine strand wires must be twisted to provide sufficient holding force.

4.33 General data points

In addition to the registers listed in the register description, X20 modules also have other more general data points. These registers are not specific to the module but contain general information such as serial number and hardware version.

4.33.1 FirmwareVersion

Name:
FirmwareVersion

The firmware version of the module can be read using this data point.

The last two positions correspond to the number after the decimal point.

Example: 345 corresponds to 3.45.

Data type	Value	Information
UINT	1 to 99	Release version of older modules or developmental versions of new modules
	100 to 29999	Release version
	30000 to 59999	Test version

4.33.2 HardwareVariant

Name:
HardwareVariant

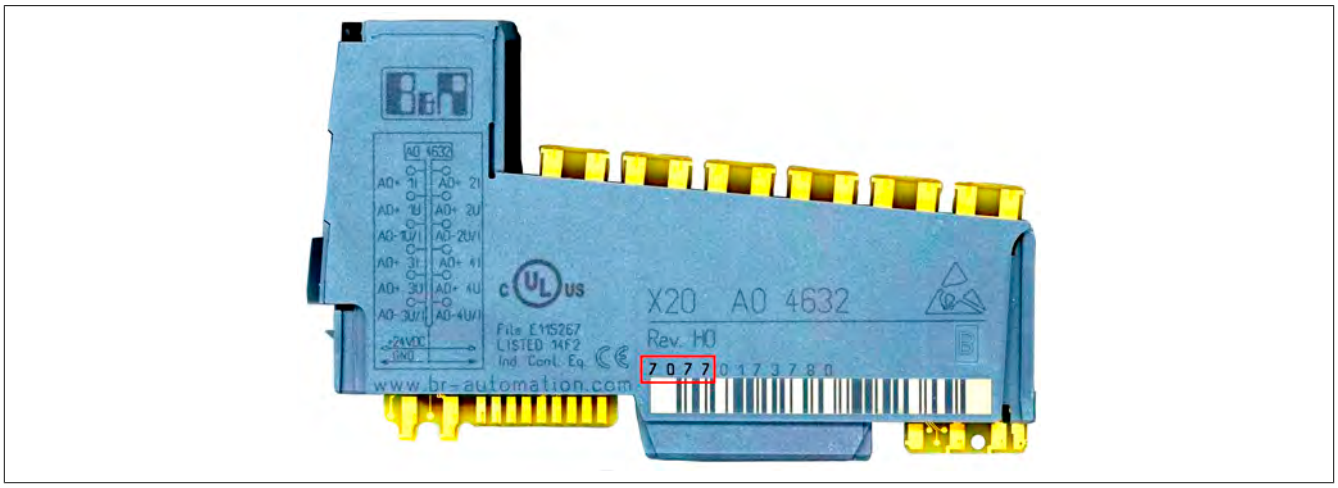
The hardware variant of the module can be read using this data point.

Data type	Value
UINT	0 to 65535

4.33.3 ModuleID

Name:
ModuleID

The module ID of the module can be read using this data point. The module hardware ID can be found in the respective module documentation. In addition, a serial number is printed on each electronics module; the module hardware ID corresponds to the first four positions of the serial number. (See figure: Hardware ID is additionally colored black.)



Data type	Value
UINT	0 to 65535

Information:

IDs beginning from 9999 are printed as hexadecimal numbers and must be converted to their decimal values for comparison!

4.33.4 SerialNumber

Name:
SerialNumber

The module's unique serial number can be read using this data point.

The complete serial number is made up of ModuleID and SerialNumber as follows: Serial number = (Hardware ID * 1E+7) + SerialNumber

The serial number is printed in decimal form on the module's housing.

Example

Hardware ID = (decimal) 1213

Serial number = (decimal) 67671339

Serial number = 1213 * 10000000 + 671339 = 12130671339

Data type	Value
UDINT	0 to 4,294,967,295

4.33.5 ModuleOK

Name:
ModuleOK

Whether the module is physically present in the slot or not can be read from this register.

Data type	Value	Information
BOOL	0	Module not ready for operation
	1	Module connected and configured

4.33.6 StaleData

Name:
StaleData

Whether the transferred data originates from the current cycle or a previous cycle can be read using this data point.

This error can result from cycle times that are too short or disturbances in module communication, for example.

Information:

This data point is only valid if ModuleOK = 1.

Data type	Value	Information
BOOL	0	Data originates from the current cycle
	1	Data does not originate from the current cycle

5 Coated modules

Coated modules are X20 modules with a protective coating for the electronics component. This coating protects X20c modules from condensation and corrosive gases.
The modules' electronics are fully compatible with the corresponding X20 modules.

The coating has been certified according to the following standards:

- Condensation: BMW GS 95011-4, 2x 1 cycle
- Corrosive gas: EN 60068-2-60, Method 4, Exposure 21 days

Differences between coated and uncoated modules

- Suitable for operation in adverse atmospheric environments
- Suitable for operation in 100% humidity, condensing
- Coated modules have a different Module ID than the corresponding uncoated variants

5.1 Module overview: Alphabetically

Order data	Short description
X20cAI2438	X20 analog input module, coated, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports the HART protocol
X20cAI4622	X20 analog input module, coated, 4 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20cAI4632	X20 analog input module, coated, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20cAI4632-1	X20 analog input module, coated, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20cAO2437	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated
X20cAO2438	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol
X20cAO4622	X20 analog output module, coated, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20cAO4632	X20 analog output module, coated, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20cAO4632-1	X20 analog output module, coated, 4 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution
X20cAP3121	X20 energy metering module, coated, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 1 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed
X20cAT4222	X20 temperature input module, coated, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20cAT6402	X20 temperature input module, coated, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C
X20cBB80	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20cBB81	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cBB82	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cBC0083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC0087	X20 bus controller, coated, Modbus/TCP or Modbus/UDP interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC0088	X20 bus controller, coated, 1 EtherNet/IP interface, integrated switch, web interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC00E3	X20 bus controller, coated, 1 PROFINET RT interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC1083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20cBC8083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20cBC8084	X20 bus controller, coated, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20cBM01	X20 power supply bus module, coated, 24 VDC keyed, internal I/O supply interrupted to the left
X20cBM11	X20 bus module, coated, 24 VDC keyed, internal I/O supply continuous
X20cBM12	X20 bus module, coated, 240 VAC keyed, internal I/O supply continuous
X20cBM31	X20 bus module, coated, for double-width modules, 24 VDC keyed, internal I/O supply continuous
X20cBM32	X20 bus module, coated, for double-width modules, 240 VAC keyed, internal I/O supply continuous
X20cBR9300	X20 bus receiver, coated, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20cBT9100	X20 bus transmitter, coated, X2X Link, supply for internal I/O supply

Coated modules

Order data	Short description
X20cCP1584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP1586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP3584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP3586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCS1020	X20 interface module, coated, 1 RS232 interface, max. 115.2 kbit/s
X20cCS1030	X20 interface module, coated, 1 RS422/485 interface, max. 115.2 Mbit/s
X20cDC1198	X20 digital counter module, coated, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit
X20cDC1396	X20 digital counter module, coated, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20cDC2395	X20 digital counter module, coated, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function
X20cDI4371	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20cDI4375	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, open line and short circuit detection, 3-wire connections
X20cDI4760	X20 digital input module, coated, 4 NAMUR inputs, 8.05 V
X20cDI6371	X20 digital input module, coated, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20cDI6372	X20 digital input module, coated, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections
X20cDI9371	X20 digital input module, coated, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20cDI9372	X20 digital input module, coated, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections
X20cDM9324	X20 digital mixed module, coated, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20cDO2633	X20 digital output module, coated, 2 triac outputs, 12 to 240 VAC, 2 A, L switching, phase angle control, 240 V keyed
X20cDO4322	X20 digital output module, coated, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20cDO4332	X20 digital output module, coated, 4 outputs, 24 VDC, 2 A, source, 3-wire connections
X20cDO4633	X20 digital output module, coated, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed
X20cDO4649	X20 digital output module, coated, 4 relays, N.O. contacts, 240 VAC / 5 A
X20cDO6321	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections
X20cDO6322	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20cDO6639	X20 digital output module, coated, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A
X20cDO8331	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections
X20cDO8332	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections
X20cDO9321	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections
X20cDO9322	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20cDS1119	X20 multifunctional digital signal processor, coated, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module
X20cHB1881	X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable
X20cHB2880	X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45
X20cHB2881	X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable
X20cHB2885	X20 hub expansion module, coated, integrated active 2-port hub, 2x RJ45
X20cHB2886	X20 hub expansion module, coated, integrated active 2-port hub, 2 fiber optic interfaces
X20cHB8815	X20 POWERLINK - TCP/IP gateway, coated, can be expanded with active hub modules, 2x RJ45
X20cHB8880	X20 base hub module, coated, integrated 2-port hub, 2x RJ45
X20cHB8884	X20 compact link selector, coated, 2x RJ45, order bus base, power supply module and terminal block separately.
X20cIF1030	X20 interface module, coated, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated
X20cIF1041-1	X20 interface module, coated, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately
X20cIF1061-1	X20 interface module coated, for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated
X20cIF1063-1	X20 interface module, coated, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20cIF1072	X20 interface module, coated, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20cIF1082-2	X20 interface module, coated, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function
X20cIF10D3-1	X20 interface module, coated, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20cIF10E3-1	X20 interface module, coated, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20cIF10X0	X20 interface module, coated, 1 redundancy link interface 1000 Base-FX, CPU-CPU data synchronization for controller redundancy
X20cIF2181-2	X20 interface module, coated, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45
X20cPD2113	X20 potential distributor, coated, 6x GND, 6x 24 VDC, with supply option, integrated microfuse
X20cPS2100	X20 power supply module, coated, for internal I/O supply
X20cPS2110	X20 power supply module, coated, for internal I/O supply, integrated microfuse
X20cPS3300	X20 power supply module, coated, for X2X Link and internal I/O supply
X20cPS3310	X20 power supply module, coated, for X2X Link and internal I/O supply integrated microfuse
X20cPS8002	X20 power supply module, coated, for standalone hub and compact link selector
X20cPS9400	X20 power supply module, coated, for bus controller and internal I/O supply, X2X Link supply

5.2 Module overview: Grouped

5.2.1 CPUs

Order data	Short description
X20cCP1584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP1586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 1 insert slot for X20 interface modules, 2 USB ports, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot cover and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP3584	X20 CPU, coated, ATOM 0.6 GHz, 256 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.
X20cCP3586	X20 CPU, coated, ATOM 1.6 GHz, 512 MB DDR2 RAM, 1 MB SRAM, removable application memory: CompactFlash, 3 insert slots for X20 interface modules, 2 USB interfaces, 1 RS232 interface, 1 Ethernet interface 10/100/1000 Base-T, 1 POWERLINK interface, incl. supply module, 1 X20TB12 terminal block, slot covers and X20 locking plate (right) X20AC0SR1 included, order application memory separately.

5.2.2 Other modules

Analog inputs

Order data	Short description
X20cAI2438	X20 analog input module, coated, 2 inputs, 4-20 mA, 16-bit converter resolution, single channel electrically isolated and with separate sensor supply, supports the HART protocol
X20cAI4622	X20 analog input module, coated, 4 inputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution, configurable input filter
X20cAI4632	X20 analog input module, coated, 4 inputs, ±10 V or 0 to 20 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20cAI4632-1	X20 analog input module, coated, 4 inputs, ±11 V or 0 to 22 mA, 16-bit converter resolution, configurable input filter, oscilloscope functions
X20cAP3121	X20 energy metering module, coated, 3 analog inputs, 480 VAC, 50/60 Hz, 4 analog inputs, 1 A AC, calculates effective, reactive and apparent power/energy, calculates root mean square values, 240 V keyed

Analog outputs

Order data	Short description
X20cAO2437	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated
X20cAO2438	X20 analog output module, coated, 2 outputs, 4 to 20 mA / 0 to 20 mA or 0 to 24 mA, 16-bit converter resolution, single channel electrically isolated, supports HART protocol
X20cAO4622	X20 analog output module, coated, 4 outputs, ±10 V or 0 to 20 mA / 4 to 20 mA, 13-bit converter resolution
X20cAO4632	X20 analog output module, coated, 4 outputs, ±10 V or 0 to 20 mA, 16-bit converter resolution
X20cAO4632-1	X20 analog output module, coated, 4 outputs, ±11 V or 0 to 22 mA, 16-bit converter resolution

Bus Controllers

Order data	Short description
X20cBC0083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC0087	X20 bus controller, coated, Modbus/TCP or Modbus/UDP interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC0088	X20 bus controller, coated, 1 EtherNet/IP interface, integrated switch, web interface, 2x RJ45, order bus base, power supply module and terminal block separately
X20cBC00E3	X20 bus controller, coated, 1 PROFINET RT interface, integrated 2-port switch, 2x RJ45, order bus base, power supply module and terminal block separately

Bus modules

Order data	Short description
X20cBM01	X20 power supply bus module, coated, 24 VDC keyed, internal I/O supply interrupted to the left
X20cBM11	X20 bus module, coated, 24 VDC keyed, internal I/O supply continuous
X20cBM12	X20 bus module, coated, 240 VAC keyed, internal I/O supply continuous
X20cBM31	X20 bus module, coated, for double-width modules, 24 VDC keyed, internal I/O supply continuous
X20cBM32	X20 bus module, coated, for double-width modules, 240 VAC keyed, internal I/O supply continuous

Bus receivers and transmitters

Order data	Short description
X20cBR9300	X20 bus receiver, coated, X2X Link, supply for X2X Link and internal I/O supply, X20 locking plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20cBT9100	X20 bus transmitter, coated, X2X Link, supply for internal I/O supply

Counter functions

Order data	Short description
X20cDC1198	X20 digital counter module, coated, 1 SSI absolute encoders, 5 V, 1 Mbit/s, 32-bit
X20cDC1396	X20 digital counter module, coated, 1 ABR incremental encoders, 24 V, 100 kHz input frequency, 4x evaluation
X20cDC2395	X20 digital counter module, coated, 1 SSI absolute encoder, 24 V, 1 ABR incremental encoder, 24 V, 2 AB incremental encoders, 24 V, 4 event counters or 2 PWM, local time measurement function

Digital inputs

Order data	Short description
X20cDI4371	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, 3-wire connections
X20cDI4375	X20 digital input module, coated, 4 inputs, 24 VDC, sink, configurable input filter, open line and short circuit detection, 3-wire connections
X20cDI4760	X20 digital input module, coated, 4 NAMUR inputs, 8.05 V
X20cDI6371	X20 digital input module, coated, 6 inputs, 24 VDC, sink, configurable input filter, 2-wire connections
X20cDI6372	X20 digital input module, coated, 6 inputs, 24 VDC, source, configurable input filter, 2-wire connections
X20cDI9371	X20 digital input module, coated, 12 inputs, 24 VDC, sink, configurable input filter, 1-wire connections
X20cDI9372	X20 digital input module, coated, 12 inputs, 24 VDC, source, configurable input filter, 1-wire connections
X20cDM9324	X20 digital mixed module, coated, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20cDS1119	X20 multifunctional digital signal processor, coated, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module

Digital inputs/outputs

Order data	Short description
X20cDM9324	X20 digital mixed module, coated, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source, 1-wire connections

Digital outputs

Order data	Short description
X20cDO4322	X20 digital output module, coated, 4 outputs, 24 VDC, 0.5 A, source, 3-wire connections
X20cDO4332	X20 digital output module, coated, 4 outputs, 24 VDC, 2 A, source, 3-wire connections
X20cDO4633	X20 digital output module, coated, 4 triac outputs, 12 to 240 VAC, 1 A, L switching, phase angle control, 240 V keyed
X20cDO4649	X20 digital output module, coated, 4 relays, N.O. contacts, 240 VAC / 5 A
X20cDO6321	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, sink, 2-wire connections
X20cDO6322	X20 digital output module, coated, 6 outputs, 24 VDC, 0.5 A, source, 2-wire connections
X20cDO6529	X20 digital output module, coated, 6 relays, normally open contacts, 115 VAC / 0.5 A, 30 VDC / 1 A
X20cDO6639	X20 digital output module, coated, 6 relays, normally open contacts, 240 VAC / 2 A, 30 VDC / 2 A
X20cDO8331	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, sink, supply directly on module, 1-wire connections
X20cDO8332	X20 digital output module, coated, 8 outputs, 24 VDC, 2 A, source, supply directly on module, 1-wire connections
X20cDO9321	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, sink, 1-wire connections
X20cDO9322	X20 digital output module, coated, 12 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20cDM9324	X20 digital mixed module, coated, 8 inputs, 24 VDC, sink, configurable input filter, 4 outputs, 24 VDC, 0.5 A, source, 1-wire connections
X20cDS1119	X20 multifunctional digital signal processor, coated, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module

Digital signal processing and preparation

Order data	Short description
X20cDS1119	X20 multifunctional digital signal processor, coated, 3 digital channels 5 V (symmetric) configurable as inputs or outputs, 2 digital input channels 24 V (asymmetric), max. 2 event counters, 1 universal counter pair configurable as A/B or up/down counter, linear movement generator (A/B, direction/frequency) with 1 reference pulse, 1 SSI absolute encoder, NetTime module

Electronics module communication

Order data	Short description
X20cCS1020	X20 interface module, coated, 1 RS232 interface, max. 115.2 kbit/s
X20cCS1030	X20 interface module, coated, 1 RS422/485 interface, max. 115.2 Mbit/s

Expandable bus controllers

Order data	Short description
X20cBC1083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 interface module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20cBC8083	X20 bus controller, coated, 1 POWERLINK interface, integrated 2-port hub, supports X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately
X20cBC8084	X20 bus controller, coated, 1 POWERLINK interface, 1x link selector, for POWERLINK cable redundancy, supports active X20 hub module expansions, 2 RJ45, order bus base, power supply module and terminal block separately

Expandable bus controllers System modules

Order data	Short description
X20cBB81	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cBB82	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cHB1881	X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable
X20cHB2880	X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45
X20cHB2881	X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable
X20cHB2886	X20 hub expansion module, coated, integrated active 2-port hub, 2 fiber optic interfaces
X20cIF1061-1	X20 interface module coated, for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated
X20cIF1063-1	X20 interface module, coated, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20cIF10D3-1	X20 interface module, coated, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20cIF10E3-1	X20 interface module, coated, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20cPS9400	X20 power supply module, coated, for bus controller and internal I/O supply, X2X Link supply

Interface module communication

Order data	Short description
X20cIF1030	X20 interface module, coated, 1 RS422/485 interface, max. 115.2 kbit/s, electrically isolated
X20cIF1041-1	X20 interface module, coated, for DTM configuration, 1 CANopen master interface, electrically isolated, order 1x TB2105 terminal block separately
X20cIF1061-1	X20 interface module coated, for DTM configuration, 1 PROFIBUS DP V0/V1 master interface, electrically isolated
X20cIF1063-1	X20 interface module, coated, for DTM configuration, 1 PROFIBUS DP V1 slave interface, electrically isolated
X20cIF1072	X20 interface module, coated, 1 CAN bus interface, max. 1 Mbit/s, electrically isolated, order 1x TB2105 terminal block separately
X20cIF1082-2	X20 interface module, coated, 1 POWERLINK interface, managing or controlled node, integrated 2-port hub, ring redundancy function PRC function
X20cIF10D3-1	X20 interface module, coated, for DTM configuration, 1 EtherNet/IP adapter (slave) interface, electrically isolated
X20cIF10E3-1	X20 interface module, coated, for DTM configuration, 1 PROFINET RT device (slave) interface, electrically isolated
X20cIF10X0	X20 interface module, coated, 1 redundancy link interface 1000 Base-FX, CPU-CPU data synchronization for controller redundancy
X20cIF2181-2	X20 interface module, coated, 1x link selector for POWERLINK cable redundancy, POWERLINK functions: - Managing node - Controlled node for iCN operation - Redundant managing node for controller redundancy - Ring redundancy - 2x hub - Multi ASend - PRC function 2x RJ45

Hub system

Order data	Short description
X20cHB8815	X20 POWERLINK - TCP/IP gateway, coated, can be expanded with active hub modules, 2x RJ45
X20cHB8880	X20 base hub module, coated, integrated 2-port hub, 2x RJ45

Other functions

Order data	Short description
X20cPD2113	X20 potential distributor, coated, 6x GND, 6x 24 VDC, with supply option, integrated microfuse

Power supply modules

Order data	Short description
X20cPS2100	X20 power supply module, coated, for internal I/O supply
X20cPS2110	X20 power supply module, coated, for internal I/O supply, integrated microfuse
X20cPS3300	X20 power supply module, coated, for X2X Link and internal I/O supply
X20cPS3310	X20 power supply module, coated, for X2X Link and internal I/O supply integrated microfuse

Redundancy system

Order data	Short description
X20cHB8884	X20 compact link selector, coated, 2x RJ45, order bus base, power supply module and terminal block separately.

System modules for the X20 hub system

Order data	Short description
X20cBB80	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, X20 end plates (left and right) X20AC0SL1/ X20AC0SR1 included
X20cBB81	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with one expansion slot for an X20 add-on module (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cBB82	X20 bus base, coated, for X20 base module (BC, HB, etc.) and X20 power supply module, with two expansion slots for two X20 add-on modules (IF, HB, etc.), X20 locking plates (left and right) X20AC0SL1/X20AC0SR1 included
X20cHB1881	X20 hub expansion module, coated, integrated 1-port hub, for fiber optic cable
X20cHB2880	X20 hub expansion module, coated, integrated 2-port hub, 2x RJ45
X20cHB2881	X20 hub expansion module, coated, integrated 2-port hub, for fiber optic cable
X20cPS8002	X20 power supply module, coated, for standalone hub and compact link selector
X20cPS9400	X20 power supply module, coated, for bus controller and internal I/O supply, X2X Link supply

System modules for the X20 redundancy system

Order data	Short description
X20cHB2885	X20 hub expansion module, coated, integrated active 2-port hub, 2x RJ45
X20cHB2886	X20 hub expansion module, coated, integrated active 2-port hub, 2 fiber optic interfaces

Temperature measurement

Order data	Short description
X20cAT4222	X20 temperature input module, coated, 4 inputs for resistance measurement, PT100, PT1000, resolution 0.1°C, 3-wire connections
X20cAT6402	X20 temperature input module, coated, 6 thermocouple inputs, Type J, K, N, S, B, R, resolution 0.1°C

6 Accessories

6.1 Additional equipment for X20 modules

Accessories available for the X20 modules include a plain text tag, an accessory locking clip and a tag holder. Installation of these accessories is described in the section 7.7 "Installing accessories".

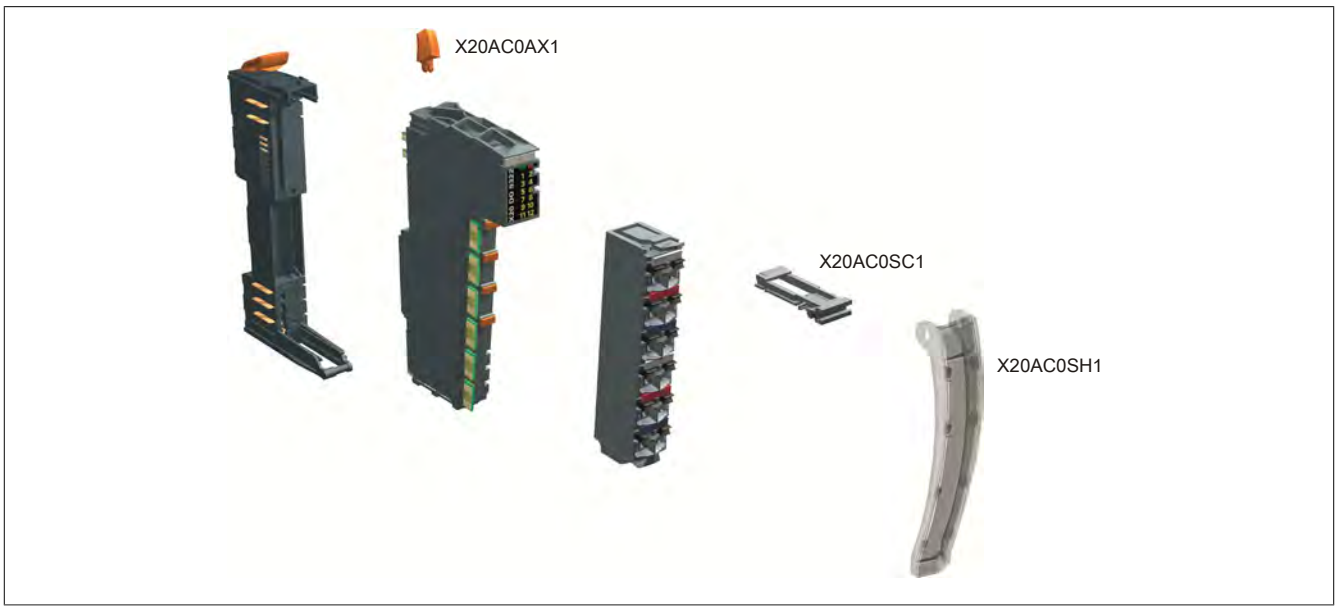


Figure 526: Additional equipment for X20 modules

6.1.1 Tag holders, terminal locking clips

Model number	Short description	Figure
	Tag holders, terminal locking clips	
X20AC0SC1	X20 terminal locking clip and tag holder for plain text tag	
X20AC0SC1.0100	X20 terminal locking clip and tag holder for plain text tag, 100 pcs. per package	

6.1.2 Plain text tags

Model number	Short description	Figure
	Plain text tags	
X20AC0SH1	X20 plain text tag	
X20AC0SH1.0100	X20 plain text tag, 100 pcs.	
	X20 slide-in labels	
X20AC0LB1.0100	X20 slide-in labels for X20 plain text tag, paper, white, perforated, 84 labels on A4 sheets, 100 sheets per package	

6.1.3 Accessory locking clips

Model number	Short description	Figure
	Accessory locking clips	
X20AC0AX1	X20 accessory locking clip	
X20AC0AX1.0100	X20 accessory locking clip, 100 pcs. per package	

6.2 Locking plates

The locking plate protects the modules on the outside against dirt and damage.

Model number	Short description	Figure
	Locking plates	
X20AC0SL1	X20 locking plate, left	
X20AC0SR1	X20 locking plate, right	
X20AC0SL1.0010	X20 locking plate, left, 10 pcs. per package	
X20AC0SR1.0010	X20 locking plate, right, 10 pcs. per package	

6.3 Cable shield clamp

For information on use, see section 3.6.2 "X20 cable shield clamp".

Model number	Short description	Figure
	Cable shield clamp	
X20AC0SG1.0010	X20 cable shield grounding clamp, 10 pcs. per package	
X20AC0SG1.0100	X20 cable shield grounding clamp, 100 pcs. per package	

6.4 Shielding bracket

The X20 shielding bracket provides an easy and space-saving way to ground the cable shielding (see section 3.6.3 "X20 shielding bracket").

Model number	Short description	Figure
	Undefined	
X20AC0SF7.0010	X20 shielding bracket 66mm	
X20AC0SF9.0010	X20 shielding bracket 88mm	

Table 756: X20AC0SF7.0010, X20AC0SF9.0010 - Order data

6.5 Terminal labeling

Each terminal connection is identified clearly directly on the terminal. It is also possible to attach tags to label the terminals individually.

The labeling tool is needed for attachment (see 7.8 "Label tags").

X20AC0M0x / X20AC0M1x

X20AC0M21

	Blank X20 tag labels (10.4 x 2.4 mm)
X20AC0M01	Blank X20 tag labels, white, set for 16 modules
X20AC0M02	Blank X20 tag labels, red, set for 16 modules
X20AC0M03	Blank X20 tag labels, blue, set for 16 modules
X20AC0M04	Blank X20 tag labels, orange, set for 16 modules
	Printed X20 tag labels (10.4 x 2.4 mm)
X20AC0M11	Printed X20 tag labels, white, set for 16 modules, label text: Module (modules 1 to 16), terminal (1 to 192)
X20AC0M12	Printed X20 tag labels, red, set for 16 modules, label text: +24 V
X20AC0M13	Printed X20 tag labels, blue, set for 16 modules, label text: GND
X20AC0M14	Printed X20 tag labels, orange, set for 16 modules, label text: Module (modules 1 to 16), terminal (1 to 192)
	Blank X20 tag labels, 10 pcs. per package (10.4 x 2.4 mm)
X20AC0M01.0010	Blank X20 tag labels, white, set for 16 modules, 10 pcs. per package
X20AC0M02.0010	Blank X20 tag labels, red, set for 16 modules, 10 pcs. per package
X20AC0M03.0010	Blank X20 tag labels, blue, set for 16 modules, 10 pcs. per package
X20AC0M04.0010	Blank X20 tag labels, orange, set for 16 modules, 10 pcs. per package
	Printed X20 tag labels, 10 pcs. per package (10.4 x 2.4 mm)
X20AC0M11.0010	Printed X20 tag labels, white, set for 16 modules, 10 pcs. per package, label text: Module (modules 1 to 16), terminal (1 to 192)
X20AC0M12.0010	Printed X20 tag labels, red, set for 16 modules, 10 pcs. per package, label text: +24 V
X20AC0M13.0010	Printed X20 tag labels, blue, set for 16 modules, 10 pcs. per package, label text: GND
X20AC0M14.0010	Printed X20 tag labels, orange, set for 16 modules, 10 pcs. per package, label text: Module (modules 1 to 16), terminal (1 to 192)
	Blank X20 tag labels, large (10.4 x 7.0 mm)
X20AC0M21	Blank X20 tag labels, large white, set for 48 modules
X20AC0M21.0010	Blank X20 tag labels, large white, set for 48 modules, 10 pcs. per package

6.6 Labeling tool

The labeling tool is needed to attach the tag labels.

Model number	Short description	Figure
	Labeling tool	
X20AC0MT1	X20 labeling tool for X20 tag labels	

6.7 Screwdriver

The screwdriver was developed specially for use with terminal blocks X20TB1E and X20TB1F to prevent damage to the terminals.

Model number	Short description	Figure
	Screwdriver	
X20AC0SD1	B&R screwdriver	

Table 757: X20AC0SD1 - Order data

6.8 POWERLINK cables

Pre-assembled POWERLINK cables with various lengths and connector combinations (RJ45 to RJ45, RJ45 to M12) ensure quick connectivity, thus saving time setting up the system.

6.8.1 RJ45 to RJ45

Not for use in cable drag chains

Model number	Short description	Figure

6.9.3 General specifications for X2X Link cables

When using a non-B&R cable for field wiring, it is important that the cable satisfies the following general specifications. For X2X Link segments up to 30 m, any cable that meets these specifications can be used. Cable lengths over this value must be inspected and approved by B&R.

	Data line	Supply line
Wires	2 x 0.25 mm² (AWG 24), stranded wire	2 x 0.34 mm² (AWG 22), stranded wire
Cable construction	Pair stranding, paired shield, aluminum foil	
Conductor resistance	Approx. 90 Ω/km	Approx. 55 Ω/km
Wave impedance	120 - 150 Ω	
Operating capacitance	<40 pF/m	
Cable shield	Tinned copper wire braiding, optical coverage ≥85%	

Table 765: General specifications for X2X Link cables

7 Mechanical handling

7.1 Solid mechanics

With all the advantages that the three-part modularity of the X20 system offers, one emphasis has always been solid mechanical design.

Its robust design, long guides and strengthened housing guarantee the stability it needs in industrial environments. These features allow the X20 system to be mounted on a top-hat rail with the same ease as a rack system. They also make it just as simple to remove it from the rail.

The following sections describe the mechanical design of the X20 system. The following topics are covered:

- Number of connection cycles
- Assembling an X20 system
- Top-hat rail installation
- Removal from the top-hat rail
- Expanding an X20 system
- Installing accessories
- Adding the terminal labels
- Application coding of terminal blocks

7.2 Number of connection cycles

The modules of the X20 system are divided into three parts. A module is made up of three basic elements:

- Bus module
- Electronic module
- Terminal block

The number of connection cycles between the respective basic elements is specified at 50.

Basic element	Number of connection cycles
Bus module ↔ Bus module	50
Bus module ↔ Electronic module	
Electronic module ↔ Terminal block	

Table 766: Number of connection cycles between the respective basic elements

7.3 Assembling an X20 system

There are several ways to assemble an X20 system. Two methods are described below:

Assembling an X20 system	Description
Variant 1	The X20 system is completely assembled and then installed on the top-hat rail.
Variant 2	The X20 system is installed and assembled directly on the top-hat rail.

Table 767: Two of the several methods for assembling an X20 system

Information:

- **Store X20 modules in the protective packaging until immediately before assembly.**
- **Only touch X20 modules on the housing.**
- **Take the necessary protective measures against electrostatic discharges (see also section 1.2.3 "Protection against electrostatic discharge").**

7.3.1 Variant 1

The X20 system is completely assembled and then installed on the top-hat rail.

1. Remove X20 modules from protective packaging. Check modules for obvious mechanical damages.
2. Insert electronic module in the guides on the bus module.

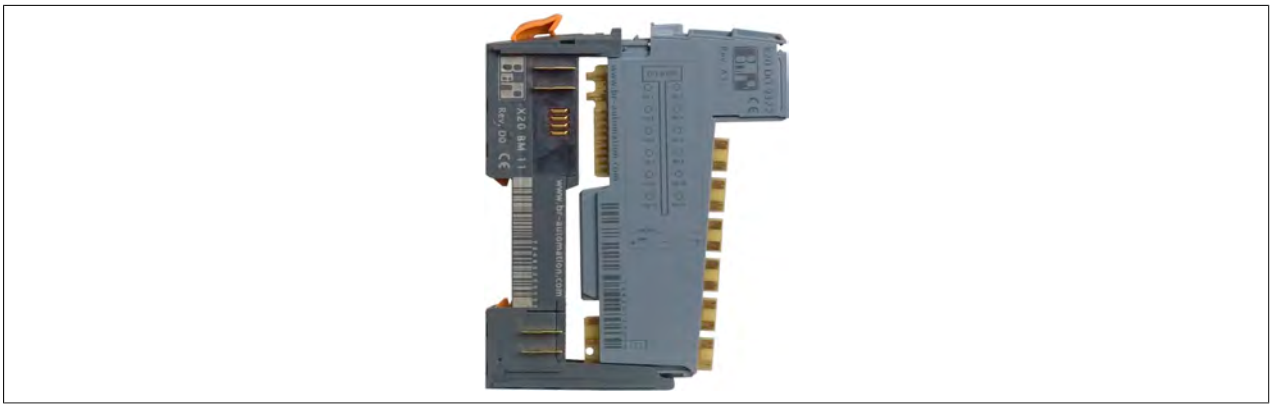

Figure 527: Insert electronic module in the guides on the bus module

3. Push the electronic module and the bus module flush together.

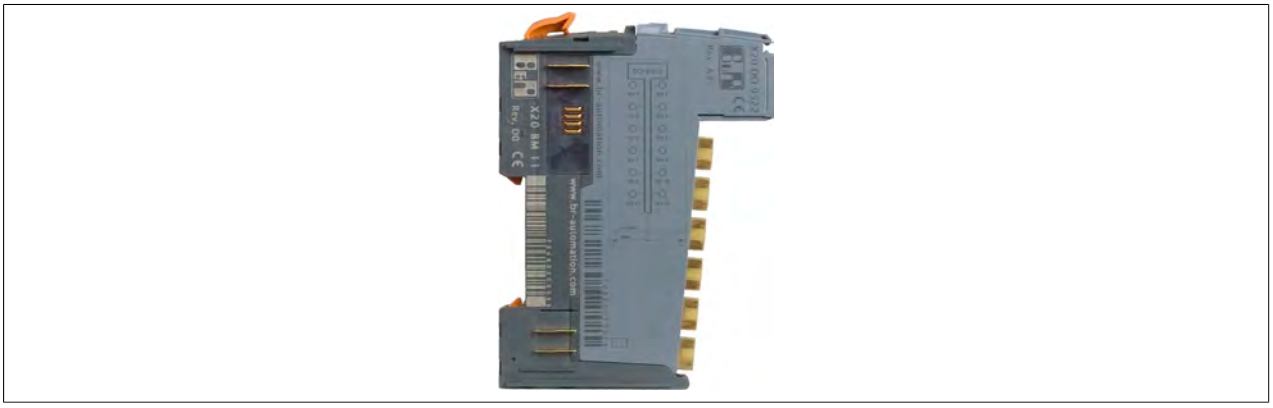

Figure 528: Push the electronic module and the bus module flush together

4. Hang the bottom edge of the terminal block in its place on the bus module.

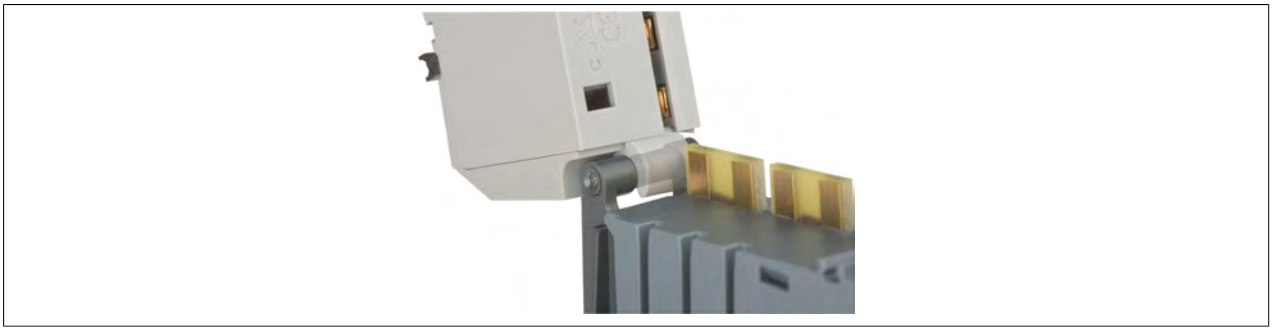

Figure 529: Hang the bottom edge of the terminal block in its place on the bus module

5. Rotate the terminal block up into place.

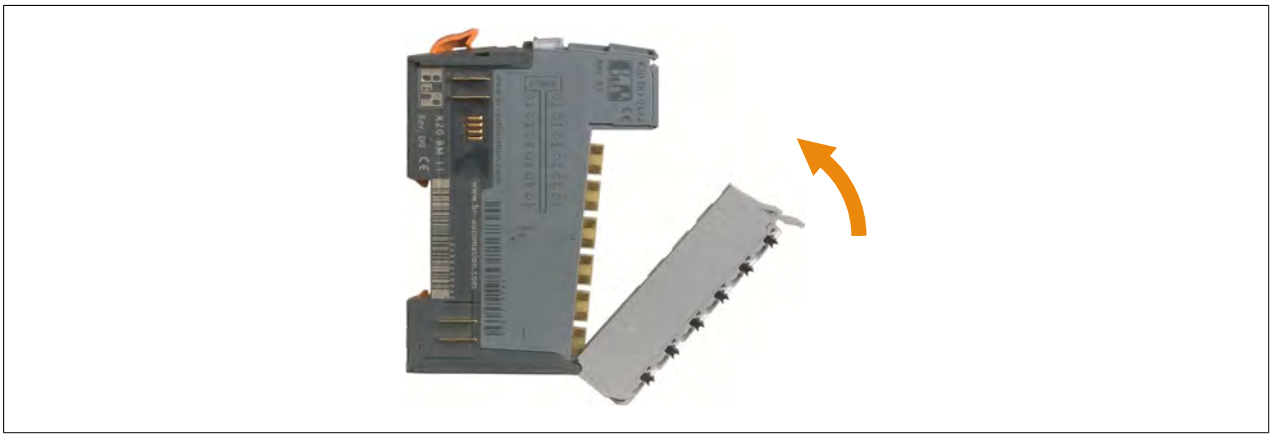

Figure 530: Rotate the terminal block up into place

6. The terminal block latch must close with an audible click. If the latch does not catch, the lever must be pushed up.

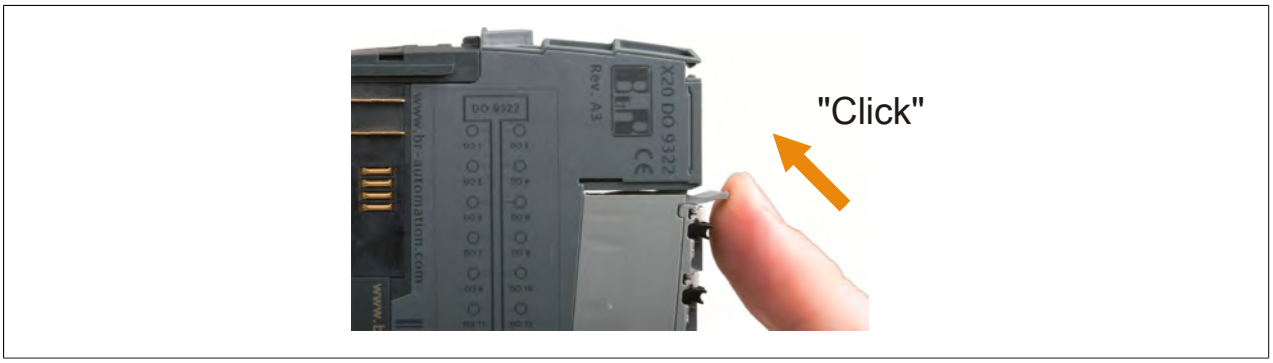

Figure 531: If the latch does not catch, the lever must be pushed up

7. Individual X20 modules should be assembled from left to right (viewed from front) to form the complete X20 system. To do this, connect the right module from behind to the guides for the left bus module.

Figure 532: Connect the right module from behind to the guides for the left bus module

8. Slide the right module forward until the two modules fit flush together.
9. Proceed like this until the second to last module.
10. For the last module, only insert the bus module in the guides of the left bus module.
11. Slide the right bus module forward until the two bus modules fit flush together.

12. Insert the right locking plate into the guides on the bus module from the front and push it all the way in.

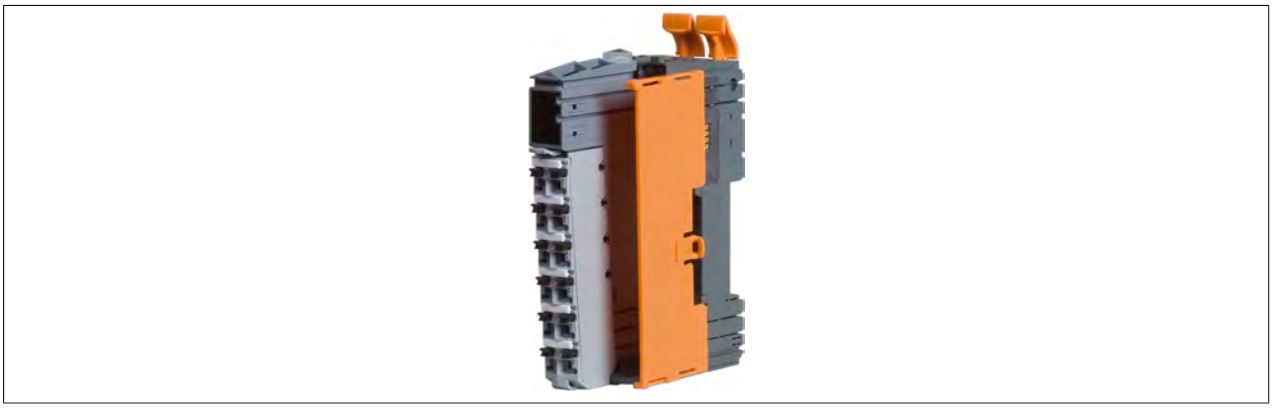

Figure 533: Insert the right locking plate into the guides on the bus module from the front

13. Insert the electronic module into the bus module and push firmly so that the two modules fit flush together.
14. Hang the bottom of the terminal block in its place on the bus module and push it up into place. The terminal block latch must close with an audible click.
15. Lay the left locking plate on the left module and insert it in the guides. Finally, slide the locking plate forward.

Figure 534: Lay the left locking plate on the left module and insert it in the guides

16. The procedure for hanging the X20 system on the top-hat rail is described in section 7.4 "Installing the X20 system on the top-hat rail".

7.3.2 Variant 2

The X20 system is installed and assembled directly on the top-hat rail.

1. Remove X20 modules from protective packaging. Check modules for obvious mechanical damages.
2. Push the locking lever all the way up on all of the bus modules. This opens the locking mechanism for top-hat rail installation.

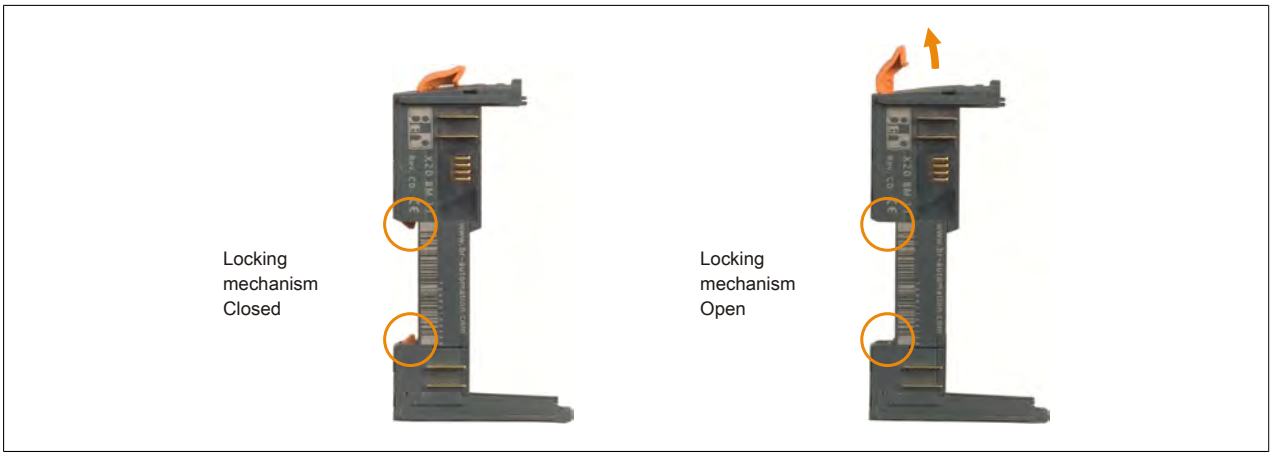

Figure 535: Push the locking lever all the way up to open the locking mechanism

3. Hang the first bus module in the desired position on the top-hat rail and close the locking mechanism by pushing the lever down.
4. Insert the next bus module in the guides of the previously mounted bus module.

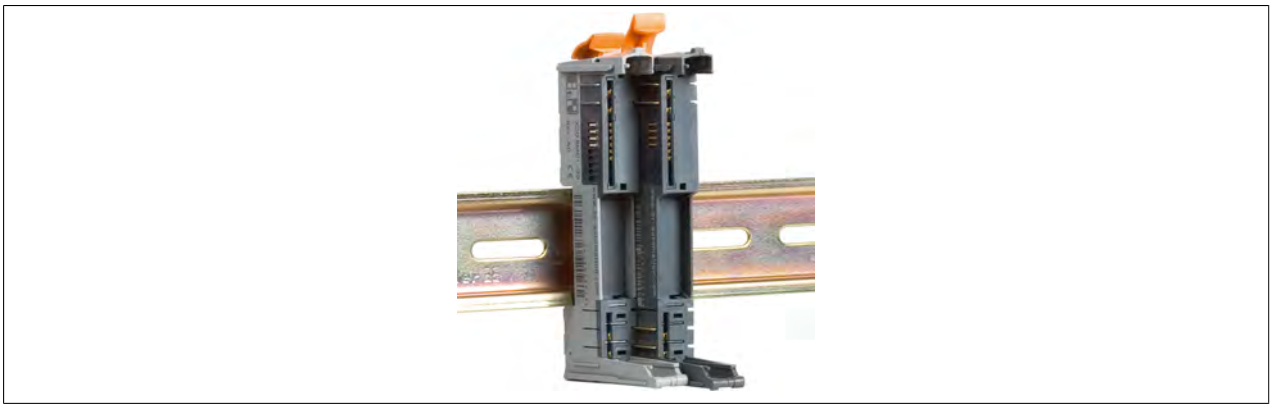

Figure 536: Insert the next bus module in the guides of the previously mounted bus module

5. Slide the bus module in against the top-hat rail and secure it by pushing down the locking lever.
6. Proceed like this with the rest of the bus modules.
7. Insert the corresponding electronic module in the guides on the leftmost bus module.

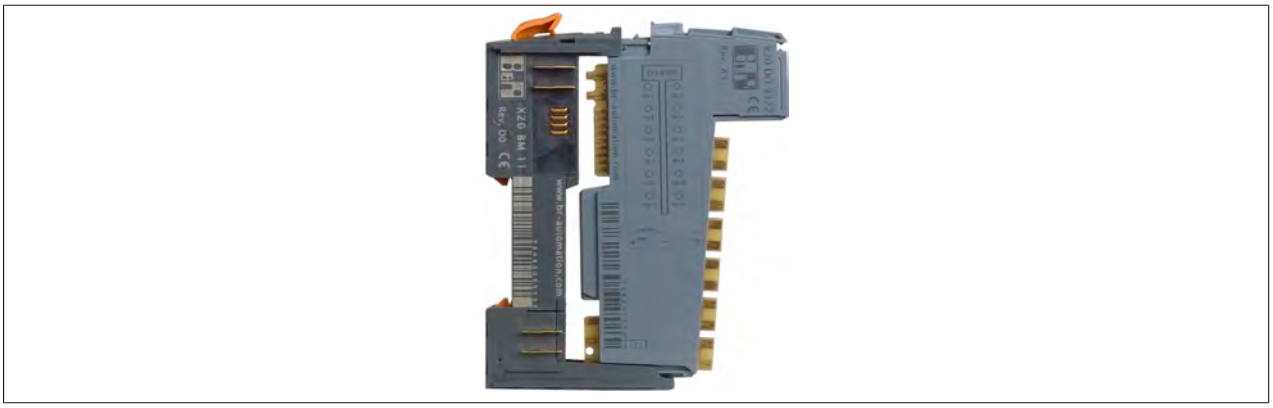

Figure 537: Insert electronic module in the guides on the bus module

8. Push the electronic module and the bus module flush together.

Figure 538: Push the electronic module and the bus module flush together

9. Proceed like this until the second to last electronic module.
10. Insert the right locking plate into the guides from the front and push it in all the way.

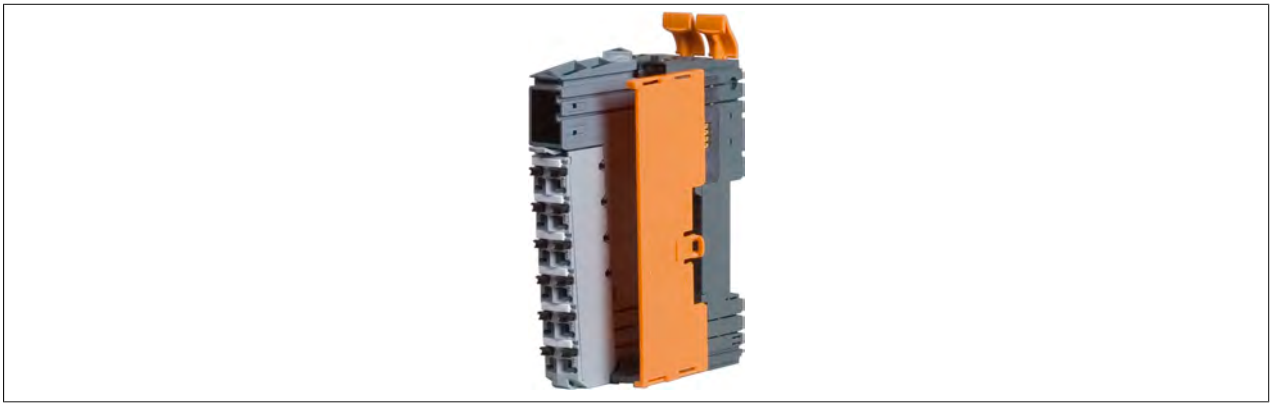

Figure 539: Insert the right locking plate into the guides on the bus module from the front

11. Insert the electronic module into the bus module and push firmly so that the two modules fit flush together.
12. Hang the terminal block in its place on the leftmost bus module.

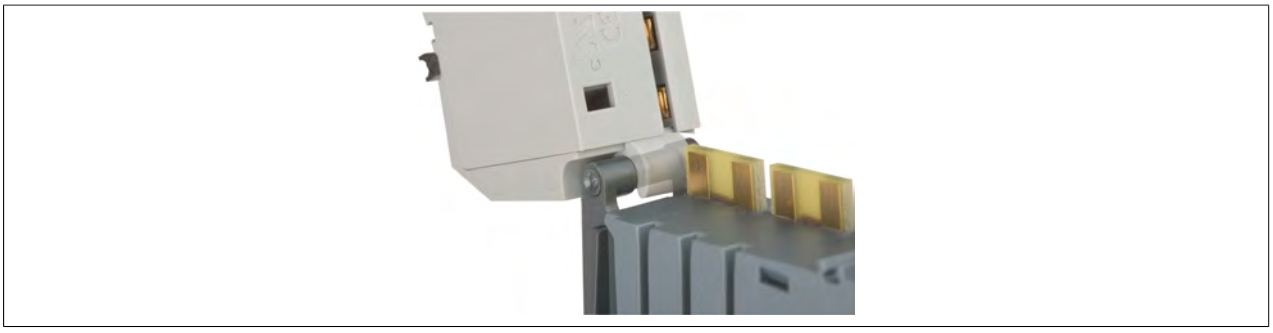

Figure 540: Hang the bottom edge of the terminal block in its place on the bus module

13. Rotate the terminal block up into place.

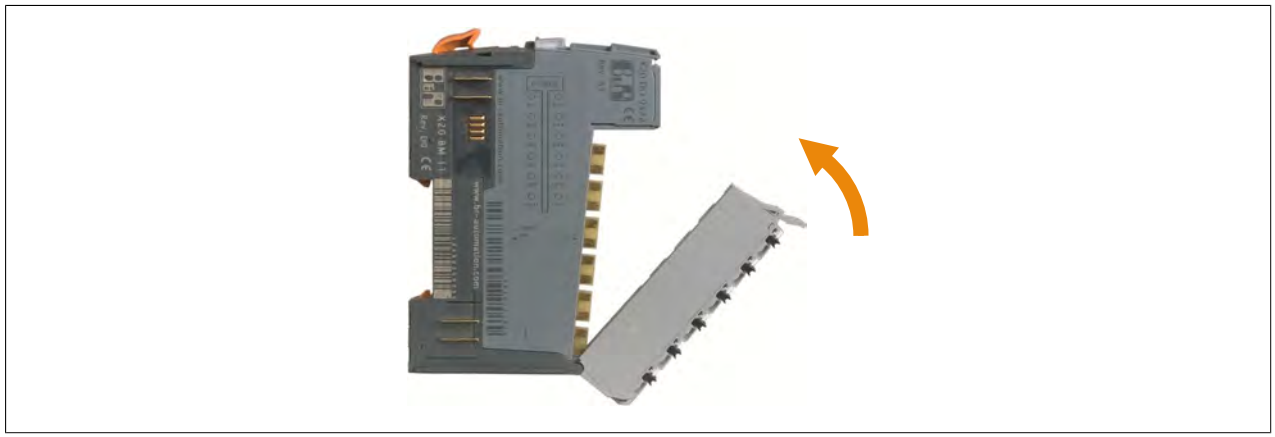

Figure 541: Rotate the terminal block up into place

14. The terminal block latch must close with an audible click. If the latch does not catch, the lever must be pushed up.

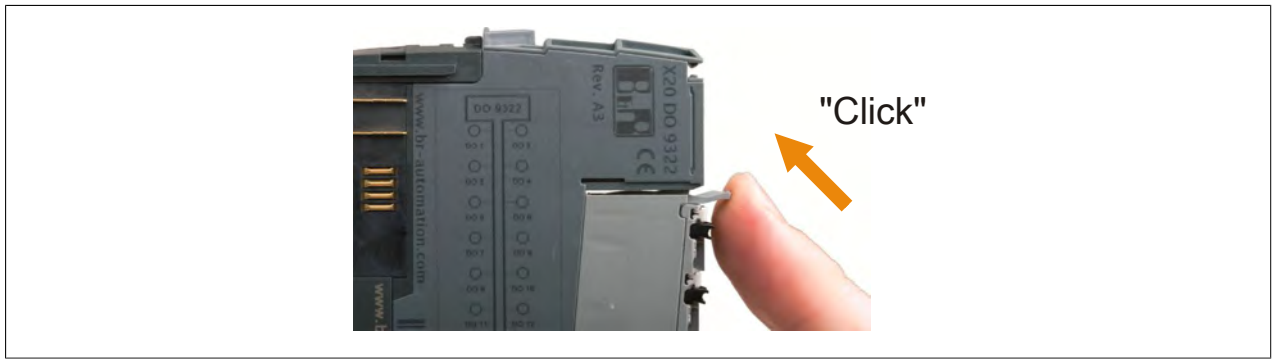

Figure 542: If the latch does not catch, the lever must be pushed up

15. Proceed like this with the rest of the terminal blocks.
16. Lay the left locking plate on the left module and insert it in the guides. Finally, slide the locking plate forward.

Figure 543: Lay the left locking plate on the left module and insert it in the guides

7.4 Installing the X20 system on the top-hat rail

Complete the following steps to install an assembled X20 system on the top-hat rail.

1. Push the locking lever all the way up on all of the bus modules. This opens the locking mechanism for top-hat rail installation.

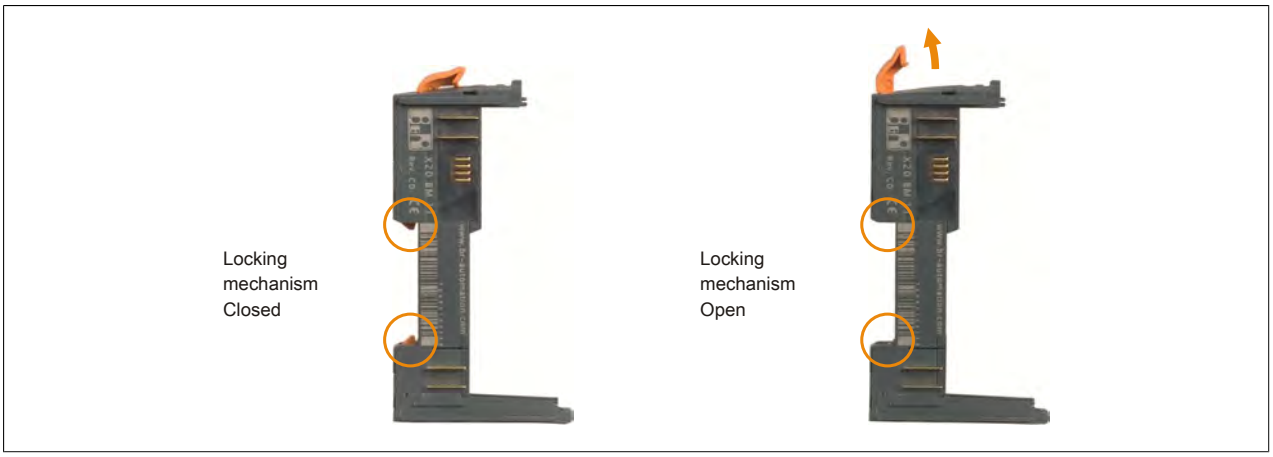

Figure 544: Push the locking lever all the way up to open the locking mechanism

2. Hang the X20 system in the desired position on the top-hat rail and close the locking mechanism by pushing the lever down.

7.5 Removing the X20 system from the top-hat rail

7.5.1 Remove the entire system from the top-hat rail

1. Push the locking lever all the way up on all of the bus modules. This opens the locking mechanism for top-hat rail installation.

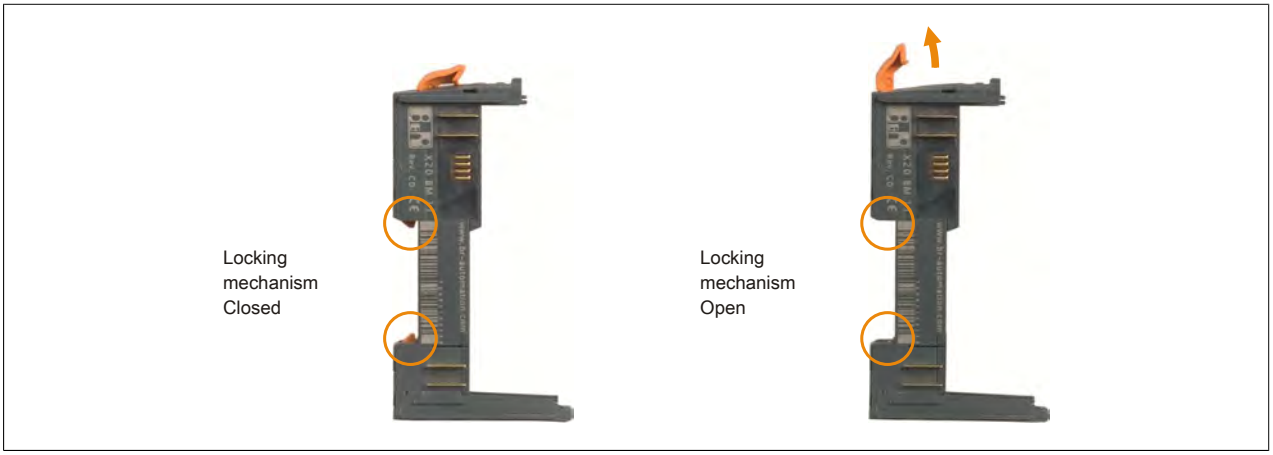

Figure 545: Push the locking lever all the way up to open the locking mechanism

2. Remove the X20 system from the top-hat rail.

7.5.2 Removing a block of modules from the top-hat rail

1. Push the locking lever all the way up on all of the modules that you wish to remove from the top-hat rail. This opens the locking mechanism for top-hat rail installation.

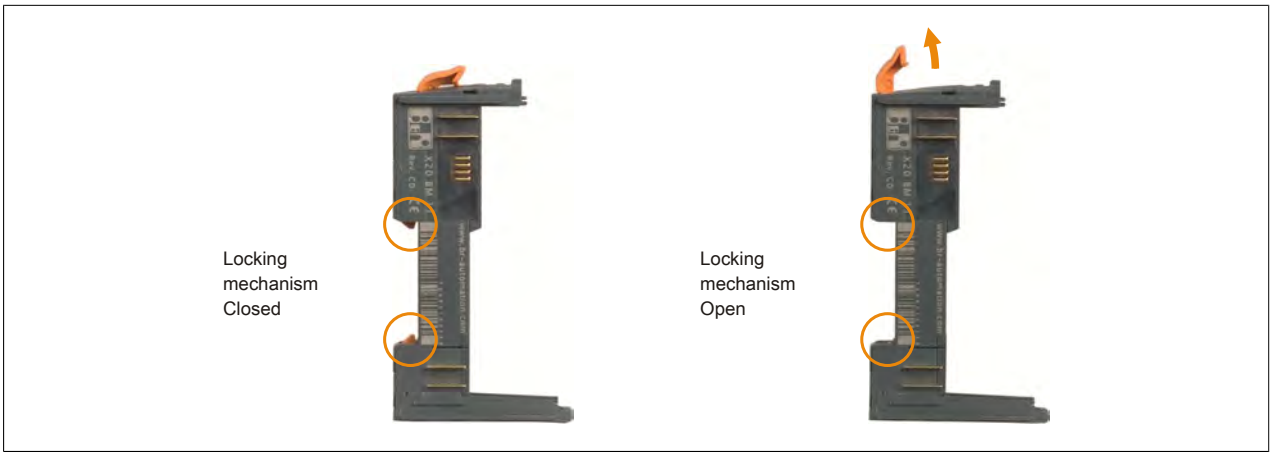

Figure 546: Push the locking lever all the way up to open the locking mechanism

2. The terminal block must be removed from the module to the left of the module block that is to be removed. To do this, push down on the locking lever on the terminal block ① and rotate the terminal block out and down ②.

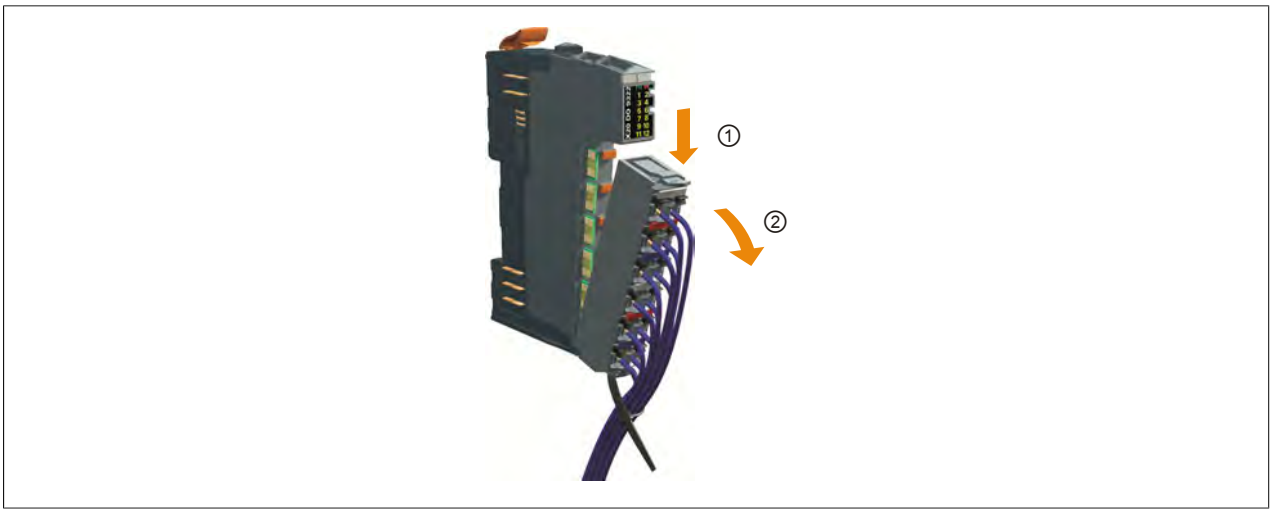

Figure 547: Remove the terminal block from the module to the left

3. Remove the module block from the top-hat rail.

Figure 548: Module block removed from the top-hat rail

4. Put the removed terminal block back on the module. To do this, hang the bottom in place in the bus module.

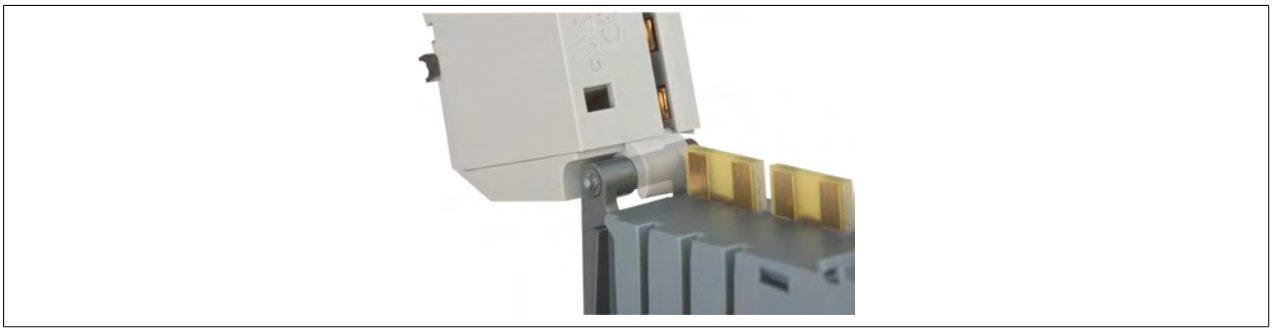

Figure 549: Hang the bottom edge of the terminal block in its place on the bus module

5. Rotate the terminal block up into place.

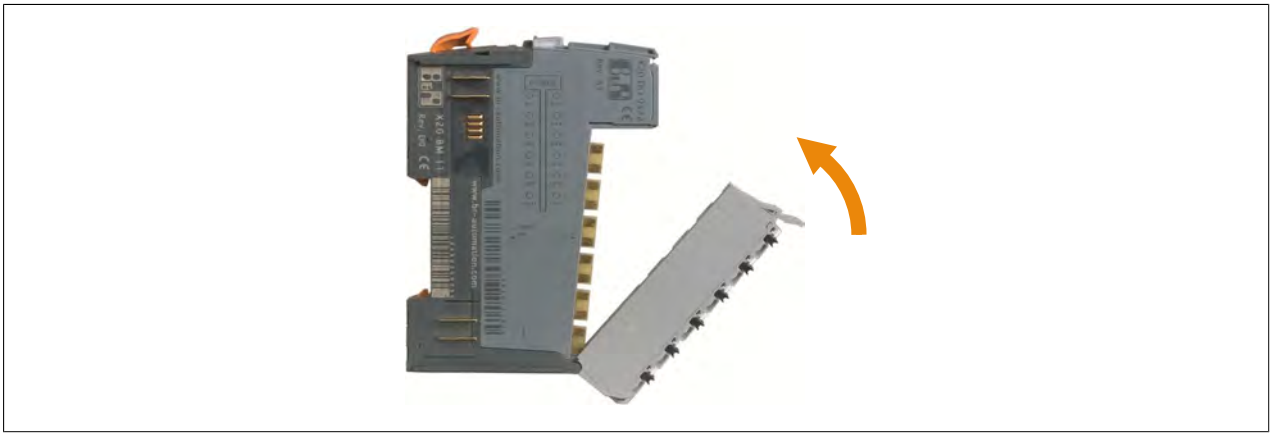

Figure 550: Rotate the terminal block up into place

6. The terminal block latch must close with an audible click. If the latch does not catch, the lever must be pushed up.

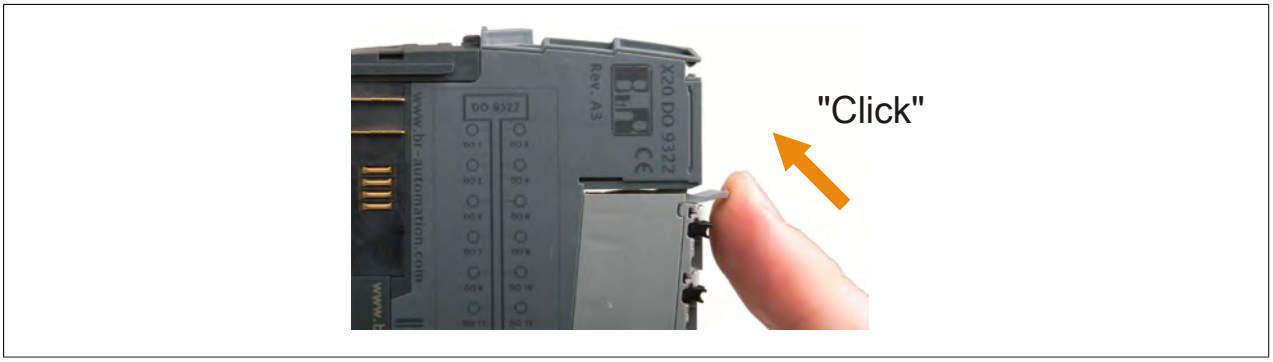

Figure 551: If the latch does not catch, the lever must be pushed up

7.6 Expanding an X20 system

If you want to expand an existing X20 system to the right, the right locking plate must be removed.

1. Remove the terminal block from the rightmost module. To do this, push down on the locking lever on the terminal block ① and rotate the terminal block out and down ②.

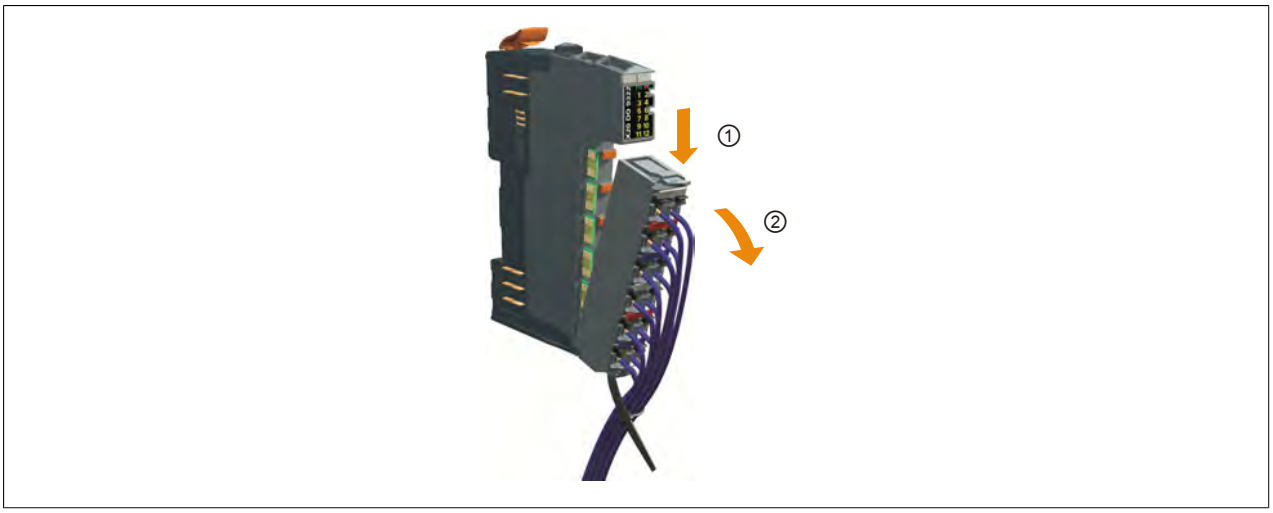

Figure 552: Remove the terminal block from the module to the left

2. Push down on the electronic module's locking lever ① and remove the electronic module ②.

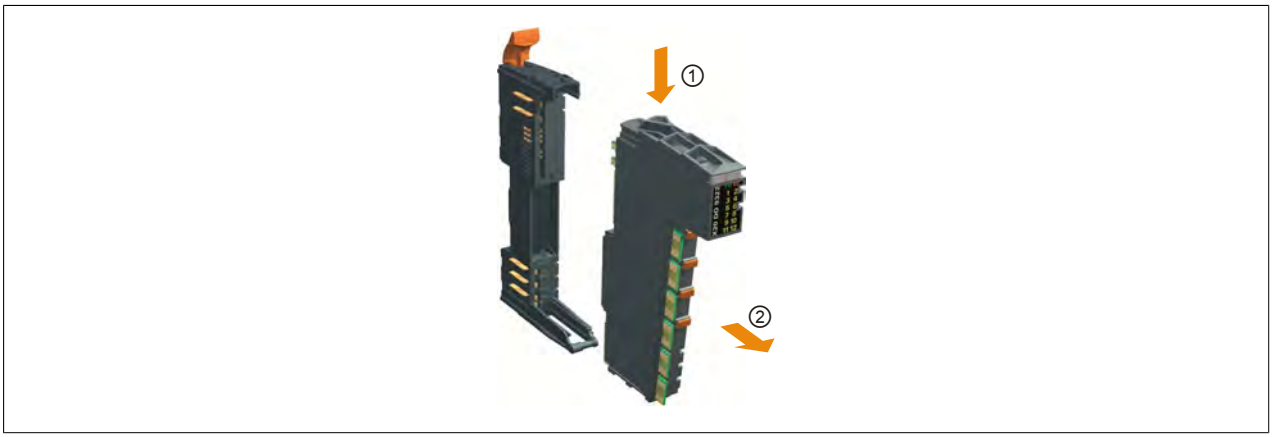

Figure 553: Remove the electronic module

3. Use a screwdriver to lift the locking lever of the right locking plate and pull the locking plate off of the bus module.

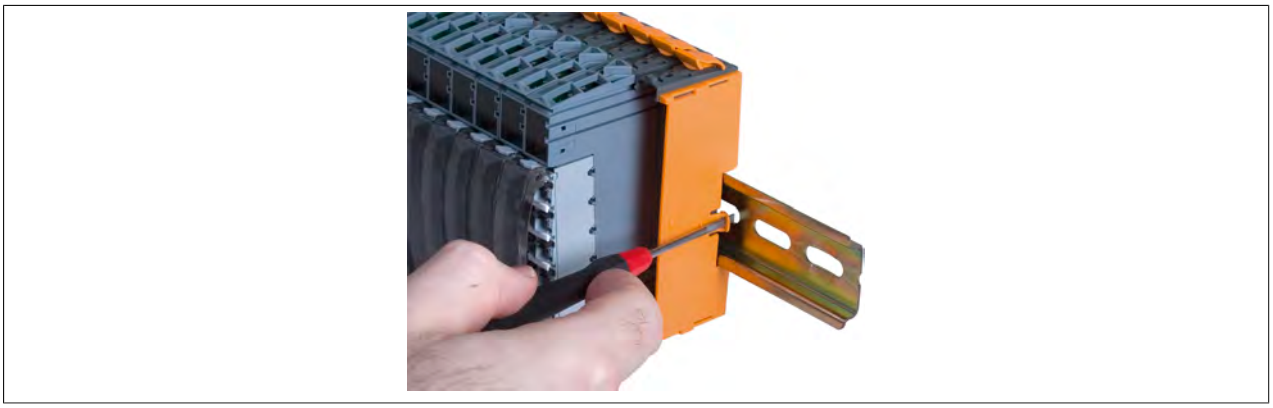

Figure 554: Unlock the right locking plate with a screwdriver

4. Now you can add more modules as described for assembly method 2 (see section 7.3.2 "Variant 2").

7.7 Installing accessories

7.7.1 Additional locking mechanisms

Some specific areas require additional locking mechanisms to prevent accidental release of the mechanical components.

7.7.1.1 Accessory locking clips

The accessory locking clip attaches the electronic module to the bus module. The locking clip is inserted in the appropriate opening on the module and pushed down.

Figure 555: Installing the accessory locking clip

7.7.1.2 Terminal locking clip

The terminal locking clip attaches the terminal block securely to the electronic module.

1. Set the terminal locking clip on the terminal block locking lever as shown.

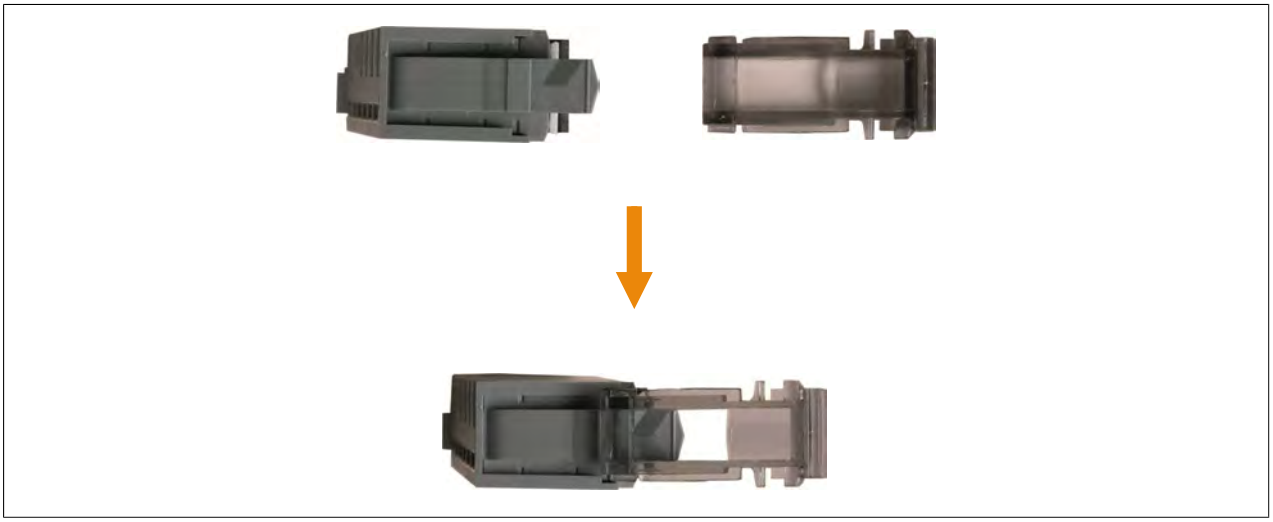

Figure 556: Set the terminal locking clip on the terminal block locking lever

2. Push down and hold the terminal locking clip and the locking lever with your index finger ①. Finally, slide the terminal locking clip forward with your thumb ②.

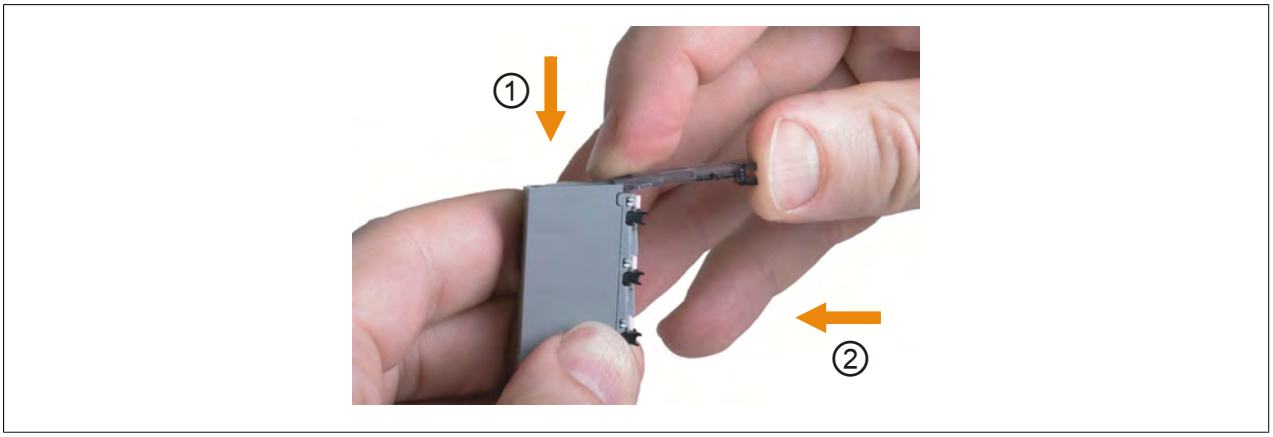

Figure 557: Install terminal locking clip on terminal block

3. Hang the bottom edge of the terminal block in its place on the bus module.

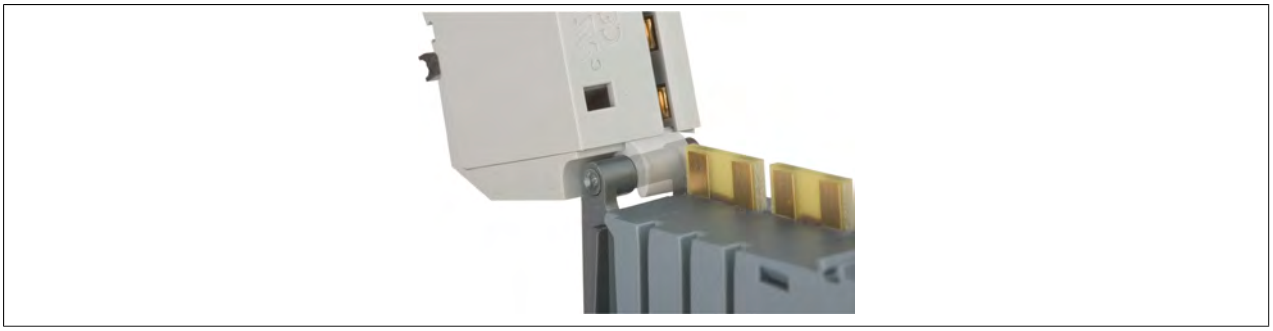

Figure 558: Hang the bottom edge of the terminal block in its place on the bus module

4. Rotate the terminal block up into place.

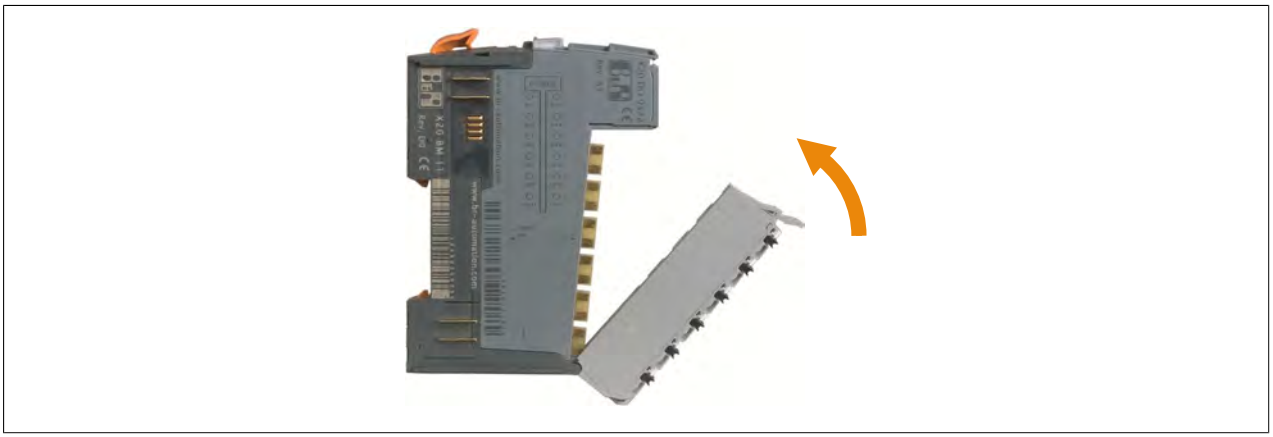

Figure 559: Rotate the terminal block up into place

5. Secure the terminal block in the electronic module by pushing in the terminal locking clip.

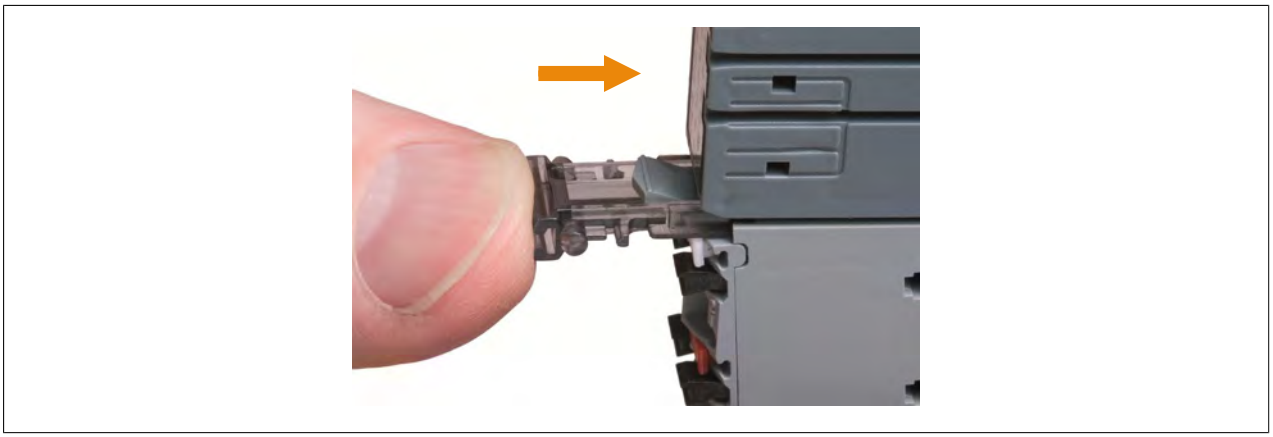

Figure 560: Secure the terminal block in the electronic module

6. Installed terminal locking clip.

Figure 561: Installed terminal locking clip

7. To remove the terminal block, pull the terminal locking clip out again.

7.7.2 Plain text tags

Tags are available for X20 modules into which plain text slide-in labels can be inserted. The tags are attached to the terminal locking clips.

1. Hold the plain text tag at a 90° angle to the terminal locking clip.
2. Push the plain text tag into the terminal locking clip's slot until it clicks into place.

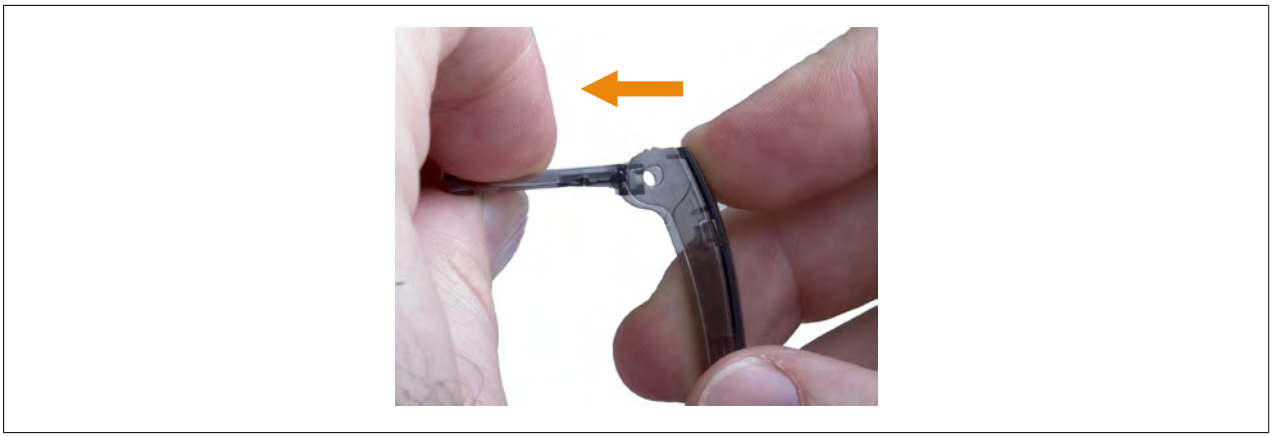

Figure 562: Attach plain text tag to terminal locking clip

7.8 Label tags

Label tags can serve the following purposes:

	Labeling the terminal connection		Labeling the module
	Labeling the terminal blocks		Labeling the terminals

The labeling tool is needed to attach the label tags.

Figure 563: Labeling tool

7.8.1 Labeling the terminal connection

This section explains how to label the terminal connection. The terminal connection, terminal blocks and modules are labeled in a similar manner.

Figure 564: Terminal block with label tags

1. Grip the desired label tags with the double-width cutters of the labeling tool.

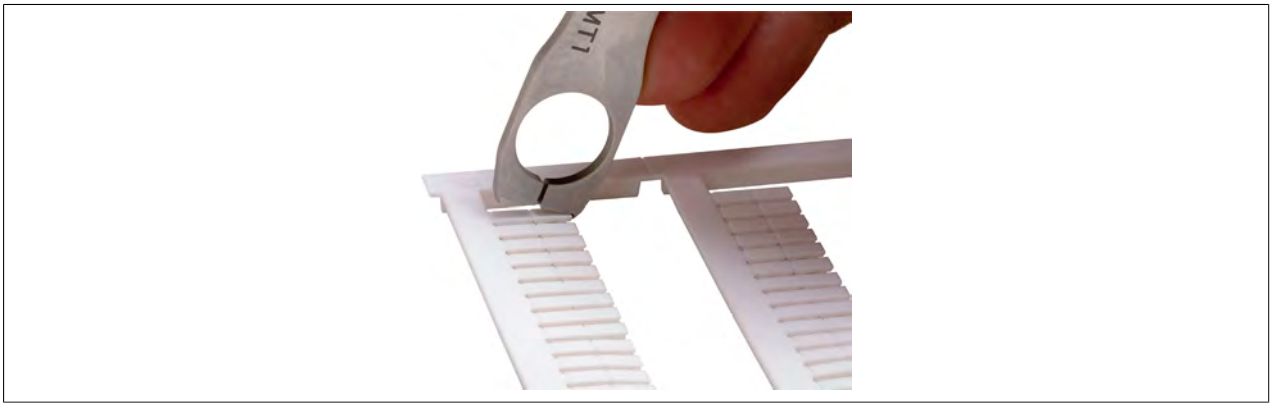

Figure 565: Grip desired label tags with labeling tool

2. Press with the labeling tool to separate the label tags.

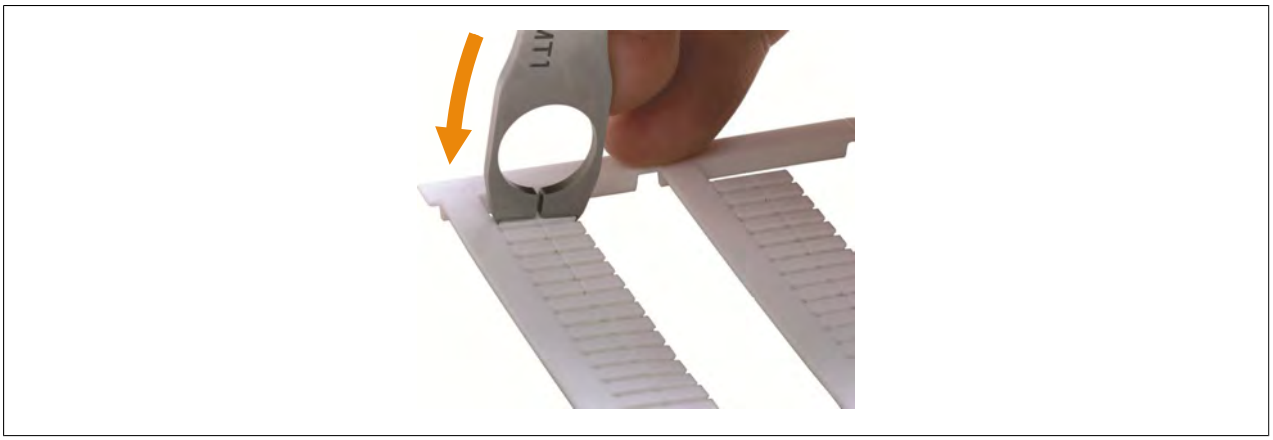

Figure 566: Separate the label tags with the labeling tool

3. Center the label tags over the slot on the terminal block.

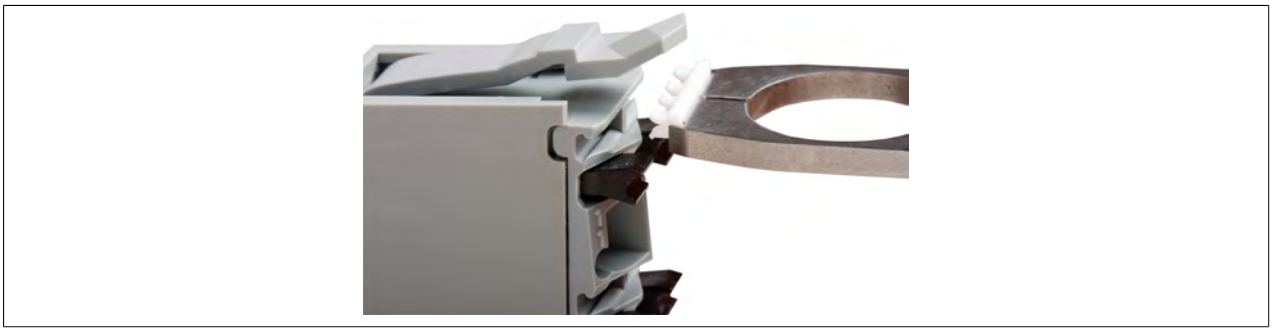

Figure 567: Center the label tags over the slot

4. Hold the labeling tool at approximately an 80° angle to the terminal block.

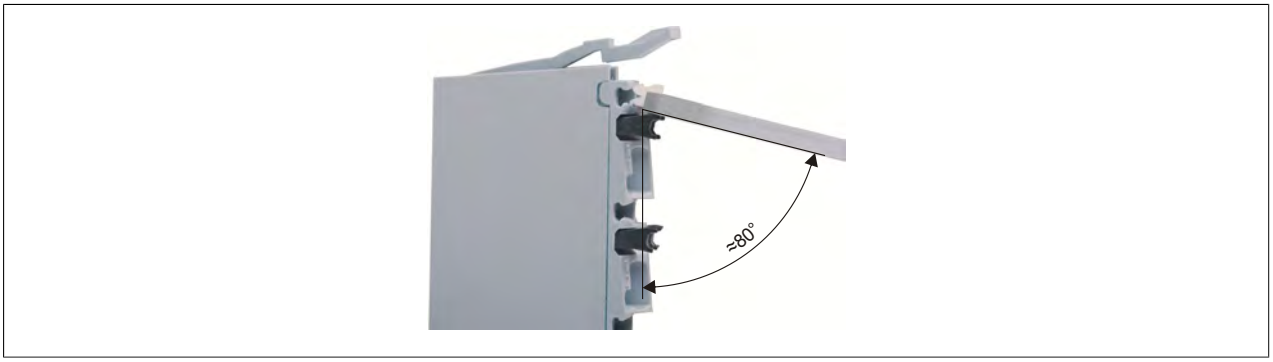

Figure 568: Hold the labeling tool at an approximately 80° angle to the terminal block

5. Press with the labeling tool to insert the feet of the label tags into the slot.
6. Inserted label tag.

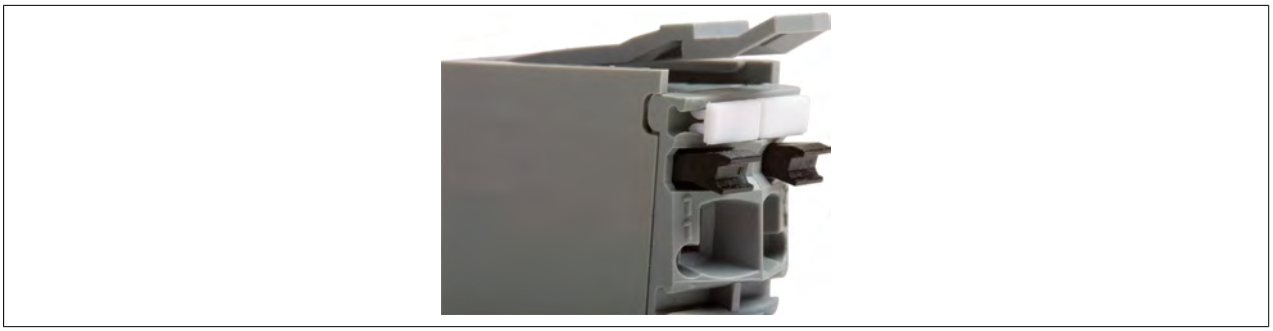

Figure 569: Inserted label tag

7.8.2 Labeling the terminals

To prevent errors, the X20 terminal blocks can be coded. This helps prevent terminal blocks from being inserted in the wrong electronic module.

Figure 570: Terminal coding helps prevent errors from the start.

1. Grip the desired label tag with the single-width cutters of the labeling tool (compare with section 7.8.1 "Labeling the terminal connection").
2. Center the label tag over the slot on the electronic module.

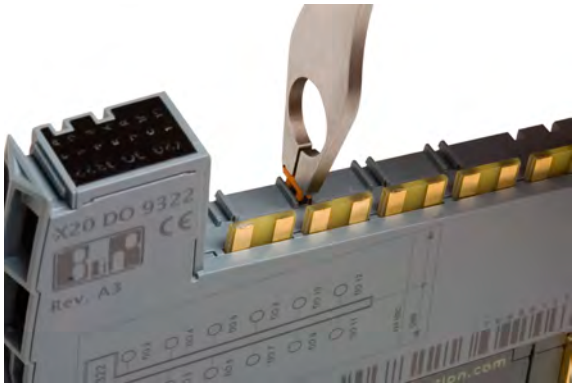

Figure 571: Center the label tag over the slot on the electronic module

3. Hold the labeling tool at a 90° angle to the electronic module and press to insert the label's feet into the slot.
4. Remove a label tag with the single-width cutter of the labeling tool.
5. Set the label tag in the slot on the back of the terminal block as shown.

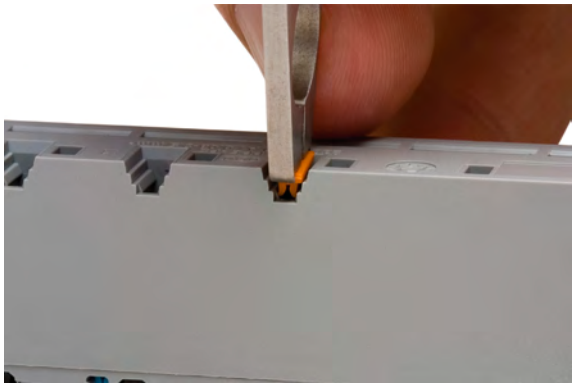

Figure 572: Set the label tag in the slot on the back of the terminal block

6. Use the labeling tool to push the left feet of the label into the slot.

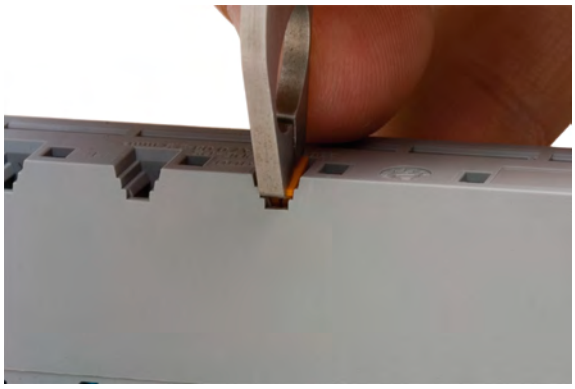

Figure 573: Press left feet of the label into the holes

7. With the labeling tool, press the right feet of the label into the slot.

Figure 574: Press right feet of the label into the slot

8. Inserted label for terminal coding.

Figure 575: Inserted label for terminal coding

8 Standards and certifications

8.1 Directives and explanations

CE mark

Product complies with all applicable directives and their harmonized EN standards.

EMC directive

These devices meet the requirements of EC directive "Electromagnetic compatibility 2004/108/EC" and are designed for industrial use:

EN 61131-2	Programmable logic controllers - Part 2: Equipment requirements and tests
EN 61000-6-2	Electromagnetic compatibility (EMC) - Part 6-2: Generic standards - Immunity for industrial environments
EN 61000-6-4	Electromagnetic compatibility (EMC) - Part 6-4: Generic standards - Emission standard for industrial environments

Low voltage directive

These devices satisfy the requirements of EC directive "Low voltage directive 2006/95/EC" and are designed for industrial use:

EN 61131-2	Programmable logic controllers - Part 2: Equipment requirements and tests

Machinery directive

The functional safety devices satisfy the requirements of the EC "Machinery directive 2006/42/EC". The products are certified by the recognized authorities (TÜV Rheinland, TÜV Süd, Underwriters Laboratories).

Information:

All standards refer to the currently valid year.

8.2 Certifications

Products and services from B&R comply with applicable standards. This includes international standards from organizations such as ISO, IEC and CENELEC, as well as national standards from organizations such as UL, CSA, GL, etc. We are committed to ensuring the reliability of our products in an industrial environment.

Information:

The certifications that apply to a particular module can be found in the following locations:

- **On the data sheet, in the "Technical data" table under "General information / Certification".**
- **At www.br-automation.com under "Products" in the "Certifications" area of the technical data**
- **On the side of the module housing**

UL certification

Products with this mark have been tested by Underwriters Laboratories and are listed as "Industrial Control Equipment". This mark is valid for the USA and Canada and simplifies the certification of your machines and systems in these areas.

Underwriters Laboratories (UL) in accordance with the UL508 standard - 17th Edition
Canadian (CSA) standard in accordance with C22.2 No. 142-M1987

CSA

Hazardous Locations

Products with this mark have been certified by the Canadian Standard Association and are suitable for use in potentially explosive environments. The X20 system is certified for Hazardous Locations Class I Division 2.
Each module is accompanied by an information sheet providing detailed installation and safety guidelines. This mark is valid for the USA and Canada and simplifies the certification of your machines and systems in these areas.

Functional safety

Products with this mark were designed, developed and manufactured for special applications for machine and personnel protection. The products are certified by the recognized authorities (TÜV Rheinland, TÜV Süd, Underwriters Laboratories), and satisfy the requirements of international safety standards ISO 13849, IEC 62061, IEC 61511 and IEC 61508.

DNV GL Maritime (Germanischer Lloyd)

Many B&R products are certified by Germanischer Lloyd and suitable for use in maritime environments. DNV GL Maritime certificates (type approval) are generally accepted by other classification societies during ship acceptance procedures.

Germanischer Lloyd (GL) in accordance with standard GL VI-7-2 (2012) (Categories B and D, each EMC1)

LR (Lloyd's Register Marine)

Products are suitable for use in maritime environments in accordance with the guidelines set forth by the Lloyd's Register classification society. Approval has been granted for marine, offshore and industrial applications for environmental categories ENV1, ENV2, and ENV3. These environmental categories are defined in the Lloyd's Register's Type Approval System, Test Specification Number 1-2013.

ATEX

Products with this mark have been tested by an accredited testing laboratory and are suitable for use in potentially explosive environments.
The X20 system is certified for use in environments with explosive gases with a normal level of safety in Zone 2.
Each module is accompanied by an information sheet providing detailed installation and safety guidelines.

GOST-R

Products with this mark have been tested by an accredited testing laboratory and approved for import to the Russian Federation (based on EU compliance).

EAC

Products with this mark have been tested by an accredited testing laboratory and approved for import (based on EU compliance) to the newly founded Eurasian Economic Union (Russia, Belarus, Kazakhstan).

KC

Products with this mark have been tested by an accredited testing laboratory and have been approved for import to the Korean market (based on EU compliance).

RCM

Products with this mark have been tested by an accredited testing laboratory and certified by the ACMA. This mark is valid in Australia/Oceania and simplifies the certification of your machines and systems in these areas (based on EU compliance).

Appendix A Abbreviations

A.1 General information

Abbreviations appear throughout this user's manual in technical data tables or descriptions of pinouts, for example.

A.2 Overview

Abbreviation	Stands for	Description
NC	Normally closed	A normally closed relay contact
	Not connected	Used in pinout descriptions if a terminal or pin is not connected to a module
ND	Not defined	In data tables, this stands for a value that has not been defined. This may be because a cable manufacturer does not provide certain technical data, for example.
NO	Normally open	A normally open relay contact
TBD	To be defined	Used in technical data tables when certain information is not yet available. The value will be provided later.

Table 768: Abbreviations used in this user's manual

Appendix B B&R ID codes

B.1 General information

This appendix contains two overviews of B&R ID codes:

- B&R ID codes sorted by ID code
- B&R ID codes sorted by model number

The B&R ID code is displayed in Automation Studio for error messages, for example. The tables in this appendix can be used to determine the corresponding module type and respective description.
