V<sub>+</sub> Supply voltage to the encoder. Before commissioning, note must be taken of the type label of the encoder.

GND Zero volt connection to the encoder, electrically isolated from the housing. The voltage referred to GND is V<sub>+</sub>.

V/R<sub>+</sub> Forward/reverse: This input programs the counting direction of the encoder. If not connected, this input is high. If the encoder starts, as viewed on the drive shaft, rotates in the clockwise direction, it counts in an increasing sequence. If it should count upwards when the shaft rotates in the anticlockwise direction, this connection must be connected permanently to low-level (zero volts).

Enable<sub>+</sub> This input activates the data output driver when a slow-level is applied. If not connected, this input is low. In the case of a high-level, the outputs are in the enable mode.

Strobe<sub>+</sub> This input stores the encoder data in Gray code when a slow-level is applied. This avoids a read error if the output data is requested in binary code. If this input is low, the data at the encoder output is stable, irrespective of whether the input shaft rotates. If not switched, this input is high.

Parity This output requires a high-level when the binary checksum of the data bits is even.

SET This input serves to set the zero electronically. If the SET line is connected to low for more than 100 ms, the mechanical position corresponds to the value 0.
